496 | Reproductive Planning in Kidney Disease: Survey of Patients with Chronic Kidney Disease and Preconception Counseling

Gwendolyn Lee[1]; Niloofar Nobakht[2]; Yaquelin A. Arevalo Iraheta[3]; Lorna Kwan[4]; Christina S. Han[4]
[1]UCSF, San Francisco, CA; [2]UCLA David Geffen School of Medicine, Los Angeles, CA; [3]University of California, Los Angeles, Los Angeles, CA; [4]UCLA, Los Angeles, CA

4:00 PM - 6:00 PM

Objective: Chronic kidney disease (CKD) is associated with greater rates of adverse maternal and fetal outcomes in pregnancy. Although preconception counseling (PCC) is recommended by the Centers for Disease Control and Prevention as primary prevention for pregnancy complications, the utilization and impact of PCC among patients with CKD is unknown.

Study Design: Patients assigned female sex at birth and aged 18-45 years with CKD who received care at a nephrology clinic in an urban academic setting received a survey between January and May 2024. In this cross-sectional analysis, data was analyzed using Chi-square test or Fisher's exact test. Uni- and multivariable logistic regressions were performed to identify characteristics associated with inadequate PCC.

Results: Of 122 surveys distributed, 108 (88%) were completed. Overall, 74% of respondents received PCC, including 17% who received PCC from a maternal-fetal medicine (MFM) provider. Respondents who received PCC from an MFM provider were significantly more likely to report discussing medication safety, maternal complications, and fetal complications, compared to those who received PCC without an MFM provider (Table 1). PCC recipients also reported greater concern about the effect of CKD on fertility and less knowledge about preconception and pregnancy with CKD. Respondents who reported a loss of libido were more likely to report PCC (OR 3.6, 95% CI 1.2-10.5).

Conclusion: PCC for patients with CKD remains suboptimal, with 26% of respondents reporting no receipt of PCC. Our finding that topics discussed varied between MFM and non-MFM providers suggest the opportunity for PCC standardization and equitable access to MFM providers. Furthermore, our finding that patients who did not receive PCC reported lower concern and greater knowledge than PCC recipients suggests false reassurance in the setting of lack of education and reaffirms the need for PCC.

Table 1. Components of preconception counseling with and without a MFM provider among those who received counseling

	Total (N=80)	Counseling without MFM Provider (N=62)	Counseling with MFM Provider (N=18)	P-value

497 | Predicting Early Onset Preeclampsia (EOPE): Leveraging Demographics, Biophysical, and Biochemical Markers for Effective Aspirin Intervention

Hameeda A. Naimi[1]; Siddharth Hariharan[2]; Eric K. BRONI[3]; Shifa Turan[4]; Ozhan M. Turan[5]
[1]Virginia Women's Center, Inc., Richmond, VA; [2]University of Rochester, Rochester, NY; [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [4]University of Maryland Medical System, Baltimore, MD; [5]University of Maryland Medical Center, Baltimore, MD

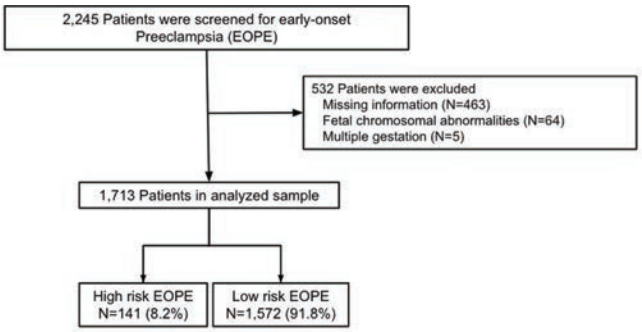
4:00 PM - 6:00 PM

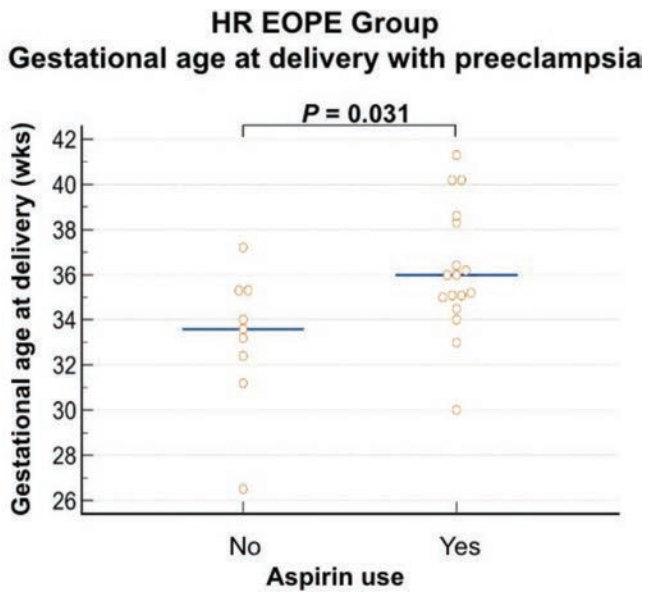
Objective: We hypothesized that combined screening using maternal demographics with biophysical and biochemical markers is a reliable method of predicting early onset preeclampsia (EOPE), requiring delivery prior to 34 weeks. Our secondary objective was to evaluate the effect of aspirin (ASA) on the performance of our prediction algorithm.

Study Design: This prospective cohort study assessed the risk of EOPE in pregnant patients between 11-13 weeks of gestation using the EOPE risk calculator (published by the Fetal Medicine Foundation). Risk assessment included maternal demographics, biophysical data (BMI, blood pressure, uterine artery pulsatility index), and biochemical markers (PAPP-A and PlGF). Patients were categorized as high risk (HR, ≥1:50) or low risk (LR, < 1:50). HR patients were advised to take 162mg of ASA, with compliance monitored via chart review. Logistic regression models considered factors such as history of preeclampsia, chronic hypertension, renal disease, and maternal age. The primary outcome was the development of EOPE, with secondary outcomes evaluating the impact of ASA on preventing preeclampsia.

Results: A total of 2,245 patients were screened, with 532 excluded (Figure 1). Among the remaining 1,713 patients, 141 (8.2%) were HR and 1,572 (91.8%) were LR. HR patients were more likely to be younger, Black, and have a history of hypertension and preeclampsia. HR individuals had a higher likelihood of developing EOPE (aOR: 4.38, 95% CI: 1.68-11.42, p< 0.001) despite ASA recommendations. Among HR patients, 9 (6%) did not use ASA, and all developed preeclampsia, with 6 cases being EOPE. ASA significantly reduced development of EOPE (OR: 0.08, 95% CI: 0.008-0.76, p = 0.03). Those using ASA had a higher median gestational age at delivery compared to non-users (36 weeks vs. 33.6 weeks, p = 0.03) (Figure 2).

Conclusion: Preeclampsia screening which combines maternal factors with biophysical and biochemical markers effectively identifies high risk individuals. ASA use in high risk individuals significantly reduces the risk of early-onset disease and delays gestational age at delivery.





498 | Antenatal Fetal Surveillance: Impact on Pregnancy Outcomes

Hannah S. Foster[1]; Jessica Wu[1]; Markolline Forkpa[2]; Jesse Chittams[3]; Nehemiah Weldeab[3]; Jennifer Mccoy[1]; Nadav Schwartz[4]
[1]Department of Obstetrics and Gynecology, University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA; [2]Pennsylvania Medicine Women's Health Clinical Research Center, Philadelphia, PA; [3]University of Pennsylvania School of Nursing, Philadelphia, PA; [4]University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA

4:00 PM - 6:00 PM

Objective: Serial antenatal testing is often recommended for high-risk pregnancies to reduce the stillbirth risk. However, the impact of testing recommendations on delivery outcomes is not well-studied. We explored how fetal testing impacts delivery outcomes to better inform patients.

Study Design: In this retrospective cohort, we identified all singleton pregnancies that delivered at 1 of 3 hospitals within an academic health system between 1/2022 and 5/2023. We then identified those that had undergone serial outpatient antenatal testing and collected testing indication and recommendations for the final testing visit prior to delivery. Primary outcomes included iatrogenic delivery < 39 weeks, iatrogenic preterm birth < 37 weeks (PTB), cesarean delivery (CS), and NICU admission. Stepwise regression models were used to assess the association

between demographic variables and testing indications and outcomes.

Results: A total of 3992 patients were included, with 480 (12.1%) recommended for delivery based on their final test. Overall, 370 (9.3%) were sent for delivery < 39 weeks and 161 (4.0%) patients were sent for iatrogenic PTB. Testing patients sent for delivery had a 50.4% CS rate, which was significantly higher than the CS rate amongst those not sent for delivery due to a testing visit (37.4%, P< 0.001). Overall NICU admission rate was 12.6% (N = 501). Nulliparity was only associated with increased likelihood of CS (aOR: 1.2; 1.0-1.4); whereas race was not associated with any of the outcomes. There were significant differences in NICU admission by hospital, likely related to NICU protocols. Several testing indications were significantly associated with each outcome (Table 1).

Conclusion: For patients undergoing antenatal testing, there is an overall low risk of iatrogenic preterm delivery or delivery prior to the 39-week elective induction window. Certain testing indications are associated with increased risk of adverse pregnancy outcomes. These data can be used to help high-risk patients understand their pregnancy risks when being recommended for serial fetal testing.

Table 1: Association of Fetal Testing Indication and Perinatal Outcomes

Testing indication	Frequency (n=3992)	Iatrogenic delivery <39 weeks	Iatrogenic delivery <37 weeks	Cesarean delivery	NICU admission
Advanced maternal age (AMA)	17.91% (n=715)	NS	NS	2.19 (1.84-2.62)	NS

499 | The Risk of ICP Recurrence in the Subsequent Pregnancy: a Retrospective Analysis

Henri M. Rosenberg[1]; Minhazur R. Sarker[2]; Daniel L. Kuhr[3]; Sara E. Edwards[3]; Allison Perelman[4]; Leslie J. Warren[4]; Gladys (Sandy) A. Ramos[2]; Angela T. Bianco[4]; Lauren A. Ferrara[4]; Chelsea A. DeBolt[4]

[1]Icahn School of Medicine at Mount Sinai, Division of Maternal-Fetal Medicine, Icahn School of Medicine at Mount Sinai, NY; [2]University of California, San Diego, San Diego, CA; [3]Division of Maternal-Fetal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [4]Icahn School of Medicine at Mount Sinai, New York, NY

4:00 PM - 6:00 PM

Objective: The recurrence risk of intrahepatic cholestasis of pregnancy (ICP) has been reported to be between 40-90% based on small studies with homogeneous populations. Our aim was to determine the recurrence risk of ICP and identify variables associated with recurrence in a larger, more diverse population.

Study Design: Retrospective cohort study of singleton, non-anomalous gestations complicated by ICP at a single academic center between 2015-2024. The EMR was used to identify patients with a first delivery complicated by ICP (initial) and a subsequent pregnancy with or without ICP (subsequent), both delivering at the same institution. The primary outcome was the recurrence of ICP in the subsequent pregnancy; secondary outcomes include identifying variables associated with ICP recurrence. Univariable and multivariable logistic regression were used to calculate the odds ratio and 95% confidence interval (OR [95% CI]) adjusting for advanced maternal age, history of hepatobiliary disease, and gestational diabetes.

Results: A total of 104 patients with ICP were identified, 46 (44%) of whom developed ICP in the subsequent pregnancy [Table 1]. In the group that had recurrent ICP, more patients self-identified as Hispanic (84.8% vs. 65.5%), but there were no differences in age or comorbidities in the initial pregnancy. The recurrent group had more patients with peak total bile acids (TBA) >40 (31. % vs. 7.6%, p = 0.01) and alkaline phosphatase (ALP) twice the upper limit of normal (37.0% vs. 19.0%, p = 0.04) in the initial pregnancy [Table 1]. In a multivariable regression, index pregnancy peak TBA >40 was associated with recurrence (aOR 6.03 Cl 1.81-20.07) and short-interval pregnancy was associated with decreased recurrence (aOR 0.40 Cl 0.17-0.96) [Table 2].

Conclusion: In this ICP cohort, the risk of recurrence in the subsequent pregnancy was 44%. Only peak TBA >40 in the initial pregnancy was associated with recurrence. Given the wide range of reported ICP recurrence rates in the literature, larger studies are warranted to improve pre-conception counseling.

500 | Predictors of Pregnancy Duration and Gestational Age at Delivery after Laser Photocoagulation for Twin-Twin-Transfusion Syndrome

Henry L. Galan[1]; Michael V. Zaretsky[2]; Stephen P. Emery[3]; Zhaoxing Pan[4]; Nicholas Behrendt[4]; Sarkis C. Derderian[2]; Anthony Johnson[5]; Greg Ryan[6]; William H. Goodnight[7]; On behalf of the NAFTNet

[1]University of Colorado, School of Medicine, Children's Hospital of Colorado, Aurora, CO; [2]University of Colorado, School of Medicine, Aurora, CO; [3]University of Pittsburgh, Pittsburgh, PA; [4]University of Colorado, Aurora, CO; [5]McGovern Medical School University of Texas Health Science Center at Houston (UThealth), Houston, TX; [6]University of Toronto, Toronto, ON; [7]University of North Carolina at Chapel Hill, Chapel Hill, NC

Objective: Limited data exist regarding the impact of peri-operative factors on pregnancy duration after fetoscopic laser photocoagulation (FLP) for twin-twin transfusion syndrome (TTTS). The objective of this study was to determine the best predictors of duration of pregnancy (latency) and gestational age (GA) at delivery following FLP for TTTS.

Study Design: TTTS cases treated with FLP between 2001-2023 were identified through the North American Fetal Therapy Network monochorionic twin registry containing perioperative variable and pregnancy outcomes. Higher order multiples, fetal anomalies and karyotypic abnormalities were excluded. Multiple perioperative variables were analyzed to determine the best predictors of latency and GA at delivery. Kaplan-Meier and COX regression were used in univariate analysis to identify significant factors that then had interplay evaluation with multiple Cox regression to determine the best predictors.

Results: Of 2317 TTTS cases treated with FLP, 1740 met inclusion criteria with sufficient information for analysis. Shown as Mean ± S.D, the GA at time of laser was 20.7±2.7 wks, the procedure time was 52.5±25.5 min, the latency period was 10.2±5.3 wks and GA at delivery was 30.8±4.9 wks. While univariate analysis found multiple factors significantly associated with both reduced latency (Table) and earlier delivery GA, Cox regression analysis (N = 865) showed the best predictors to be cervical length (CL) of < 25mm, amnioinfusion volume, laser time and earlier GA at time of FLP (Table). Early GA at time of surgery carried longer latency to delivery (Figure) but resulted in earlier delivery. The longer latency with early surgery persists regardless of whether CL is < or ≥ 25mm (Figure). The hazard to early delivery GA decreased by 4.3% if surgery occurs a week later as opposed to a week earlier.

Conclusion: From this large registry, the best predictors of both latency and GA at delivery after FLP for TTTS are the GA at time of the procedure, laser time, a short cervix and volume of amnioinfusion during FLP. These are factors to consider in the management of TTTS.

501 | Prevention of Preterm Birth in Twin Pregnancies: International Delphi Consensus

Hiba J. Mustafa[1]; Jameela Sheikh[2]; Vincenzo Berghella[3]; William A. Grobman[4]; Alireza A. Shamshirsaz[5]; Sanne J. Gordijn[6]; Wessel Ganzevoort[7]; Amanda Roman[8]; Asma Khalil[9]; On behalf of the PTB in the Twins Working Group

[1]Indiana University and Riley Children's Hospital, Indianapolis, IN; [2]Guy's and St Thomas' Hospital NHS Foundation Trust, London, England; [3]Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA; [4]The Ohio State University, Columbus, OH; [5]Fetal Surgeon Chief, Division of Fetal Medicine and Surgery Director of the Maternal Fetal Care Center Director of the Perinatal Surgery Fellowship Professor of Surgery, Boston Children's Hospital Harvard Medical School, Boston, MA; [6]University Medical Center Groningen, Groningen, Groningen; [7]Amsterdam University Medical Centers, Amsterdam, Groningen; [8]Department of Maternal-Fetal Medicine, Thomas Jefferson University Hospital, Philadelphia, PA; [9]Fetal Medicine Unit, St George's Hospital, St George's University of London, London, England

4:00 PM - 6:00 PM

Objective: To use a Delphi process to gain insight into approaches to the management of preterm birth (PTB) in twin pregnancies, including those with twin-to-twin transfusion (TTTS).

Study Design: A three-round Delphi procedure was conducted among an international panel of experts to assess their approach to PTB prevention, monitoring, and management strategies in twins. Experts were chosen based on expertise, relevant publications, or affiliations. Response options included multiple-choice answers or a 5-point Likert scale. A priori, a cut-off of ≥70% was used to define "consensus".

Results: 115 experts joined the first round and 94/115 (82%) completed the subsequent rounds. There was representation from 22 countries on five continents. At least 70% performed routine screening of cervical length (CL) via transvaginal (TV) scan between 18 and 23 weeks with CL≤25 mm to diagnose a short cervix in twin pregnancies. In twin pregnancies with short CL, most experts offered vaginal progesterone and not pessary or expectant management. There was significant agreement but no consensus to offer cerclage for CL≤10. In twin pregnancies with asymptomatic dilated cervix, consensus was reached for cerclage placement as well as adjunctive practices surrounding the cerclage placement procedure. Similarly, at least 70% of experts agreed that serial TV CL assessment was warranted in those who had a current singleton pregnancy with a previous twin pregnancy requiring physical exam-indicated cerclage. In those with TTTS, a laser procedure generally was offered by most regardless of whether the cervix was short or dilated. For those with TTTS and a short CL, most experts would recommend cerclage or progesterone but not pessary or expectant management. However, no consensus was reached on PTB prevention measures in TTTS with cervical dilation.

Conclusion: This Delphi shows the practice variations among obstetric providers worldwide in evaluations and management of PTB in twin pregnancies, which often differs from what is recommended by national and international societies.

502 | Elevated Levels of Circulating Endothelial Cells in Pregnancies Complicated by Preeclampsia And/OR Fetal Growth Restriction

C Helmicki[1]; J Ladd[1]; A Heck[1]; J Wu[2]; A Coffer[1]; M Hart[1]; H Gammill[1]; J Vanderhoeven[2]; S Peterson[2]; A Ramirez[1]; E Kaldjian[1]
[1]*RareCyte, Inc., Seattle, WA;* [2]*Swedish Medical Center, Seattle, WA*

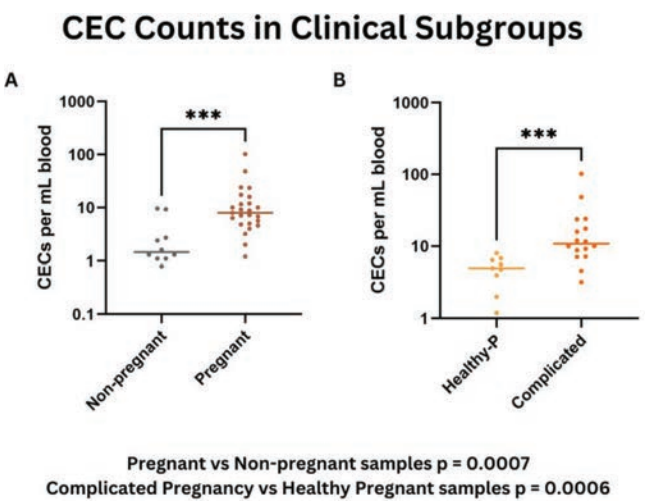
4:00 PM - 6:00 PM

Objective: To develop a circulating endothelial cell (CEC) assay to measure maternal blood CEC numbers in pregnancy and begin exploratory studies comparing pregnancies complicated by preeclampsia (PE) and fetal growth restriction (FGR).

Study Design: We used model human umbilical vein endothelial cells (HUVECs) to develop a 4-parameter immunofluorescence assay (IF) on the established RareCyte liquid biopsy platform with the following markers: Sytox (nucleus), VE-Cadherin (CD144, positive CEC marker #1), MCAM (CD146, positive CEC marker #2), and CD45 (white blood cell exclusionary marker). CECs were defined as nucleated cells, negative for CD45, and positive for either or both CD144 and CD146. Using the HUVEC spike-in model system, we analytically validated assay performance by evaluating specificity, sensitivity and limit of detection across clinically relevant CEC count ranges. In clinical studies, CEC numbers in healthy, non-pregnant female subjects of child-bearing age (20-40 years old; N = 10) were compared to third trimester pregnancy samples (N = 17 total, including N = 9 uncomplicated, N = 8 FGR, N = 5 PE, N = 3 FGR + PE). All pregnant subjects were enrolled after informed consented at Swedish Medical Center, Seattle, WA.

Results: Analytic validation studies demonstrated sensitivity and specificity of CD144 and CD146 of 99–100% and lower limit of detection of 1 cell in >1 million. CEC count was higher in pregnancy compared to non-pregnant reproductive age subjects and was higher in pregnancies with PE +/- FGR compared to those with uncomplicated outcomes. Results are shown in Figure 1A and B.

Conclusion: We have developed a robust assay for enumeration of CECs in pregnancy. Elevated levels of CECs in third trimester pregnant patients were observed in both PE and FGR relative to healthy third trimester pregnancies. These preliminary studies support further investigation of CEC enumeration as a predictive biomarker of pregnancy complications.



503 | Project PEN-FAST: Unmasking Allergies for Antibiotic Optimization

Hope Brandon[1]; Noelle Leung[2]
[1]*University of Kentucky College of Pharmacy, Lexington, KY;*
[2]*University of Kentucky HealthCare, Lexington, KY*

4:00 PM - 6:00 PM

Objective: Assess the clinical impact of the PEN-FAST scoring tool within the obstetric group at a single academic medical center.

Study Design: This was a single center, retrospective, observational analysis of pregnant patients with a documented penicillin or cephalosporin allergy admitted to the birthing center between January and June 2023 who also received an antibiotic and/or had a PEN-FAST assessment completed.

Results: Sixty-four patients were included in the final analysis. Within the analyzed cohort, 53 (83%) of patients had a PEN-FAST assessment completed, 17 (32%) of whom had their penicillin allergy successfully de-labeled. Among patients with a penicillin allergy that was not de-labeled, 11 (31%) had a score or assessment indicating that a cephalosporin could be safely utilized, nine (25%) had a score of three or greater, indicating a non-beta lactam antibiotic should be employed, and seven (19%) patients declined de-labeling despite a PEN-FAST assessment indicating a low-risk penicillin allergy, and the remaining nine (25%) were either referred for further workup or not de-labeled due to other reasons. Of the patients who had a PEN-FAST assessment completed, 38 (72%) received a penicillin or cephalosporin and 15 (28%) received alternate or no antibiotics. Comparatively, of the 11 patients who did not have a PEN-FAST assessment completed, two (18%) received a penicillin or cephalosporin and nine (82%) received an alternate antibiotic. Among all patients analyzed, there were no identified adverse reactions to penicillins or cephalosporins.

Conclusion: Within our cohort, 32% of patients had their penicillin allergy successfully de-labeled using the PEN-FAST assessment. Even without de-labeling due to factors such as patient preference, utilization of the PEN-FAST assessment resulted in a dramatic increase in the use of pencillins and cephalosporins as opposed to alternate antibiotics. Overall, the PEN-FAST assessment was an efficient and safe tool for stratifying risk of penicillin allergies within this cohort of patients and did impact antibiotic choice for the patients included.

504 | The Perinatal Effects of a Mindfulness Phone App - a Pilot Randomized Controlled Trial

Noa Gilad[1]; Swati Agrawal[2]; Klaudia Szczech[3]; Alexandra Berezowsky[1]; Amir Naeh[4]; Howard Berger[5]
[1]University of Toronto, Toronto, ON; [2]McMaster University, Hamilton, ON; [3]Saint Michael's Hospital, Toronto, ON; [4]Hillel Yaffe Medical Center, Hillel Yaffe Medical Center, HaMerkaz; [5]St. Michael's Hospital, University of Toronto, OR

4:00 PM - 6:00 PM

Objective: Sleep disturbances are commonly reported during pregnancy, are difficult to treat and are associated with adverse perinatal outcomes. We aimed to assess the feasibility of the use of a mobile mindfulness application (App) in pregnant people with self-reported sleep disturbance to improve sleep quality and perinatal outcomes.

Study Design: Pilot randomized controlled trial (RCT). Pregnant people with a singleton pregnancy, between 20-30 weeks gestation and self-reporting sleep disturbances were assessed for recruitment. Participants were randomized to either the use of a standard pregnancy sleep leaflet or to the addition of funded access to a commercially available mindfulness App. Both groups received and were instructed to use a sleep actigraph. The co-primary outcomes were: 1) recruitment rate and quantitative use of the mindfulness app. 2) Sleep quality actigraph measures and the change in PSQI score. Perinatal outcomes were collected and reported.

Results: Of 1576 potential participants,629 (39.9%) declined, 706 were not assessed and 113 were excluded leaving 128 randomized participants, 64 to each group. Baseline characteristics did not differ between groups. In the mindfulness group 35/64 (54.7%) used the App for an average of 9.9 (0.02–90) minutes per day and a mean of 8 (1-47) sessions per pregnancy. Actigraph use was similar with 30/64 (46.9%) and 32/64 (50%) providing data in the mindfulness and control groups respectively. No significant reduction was found in PSQI scores, actigraph measures or measures of stress, anxiety or depression (Table 1). Perinatal outcomes did not differ between groups except for the rate of post-partum hemorrhage which was increased in the intervention group (11.9% vs 1.6%, P = 0.03).

Conclusion: Performing a RCT using a mindfulness App is feasible, but recruitment and usage rates were lower than expected. Although exploratory, the use of a mindfulness App did not appear to improve sleep parameters when compared to routine sleep education.

Table 1: Sleep, stress anxiety and depression parameters during pregnancy

Parameter	Intervention (Mindfulness App)	Control	P value
Sleep latency (Mean (SD)	18.58 (4.6)	21.92 (0.1)	0.39
Wake episodes (Mean (SD)	3.88 (1.44)	3.64 (1.52)	0.46
Sleep quality (Mean (SD)	5.91 (1.74)	6.33 (1.61)	0.26
Poor sleep quality (<5)	29%	25%	0.95
PSQI score change	-0.97	-0.6	0.6*
PSS	-1.26	-3.12	0.08*
BAI	-1.44	-4.45	0.09*
EPDS	-1.65	-2.06	0.66*

PSQI = Pittsburgh Sleep Quality Index.

PSS= Perceived Stress Scale.

BAI - Beck Anxiety Inventory.

EPDS = Edinburgh Postnatal Depression Scale.

*P value is for score change by group interaction

505 | The Association Between Hepatitis C Virus Infection During Pregnancy and Risk of Infant Death

Ilish Gedestad[1]; Kriti N. Vedhanayagam[2]; Sergio Karageuzian[3]; Stephen Contag[4]; Synia Chunn[2]; Megan Marquez[5]; Rang Kim[5]; Ruofan Yao[2]
[1]Loma Linda University School of Medicine, Redlands, CA; [2]Loma Linda University School of Medicine, Loma Linda, CA; [3]Loma Linda University School of Medicine, Pasadena, CA; [4]University of Minnesota, Minneapolis, MN; [5]Loma Linda University School of Medicine, Loma Linda University, CA

4:00 PM - 6:00 PM

Objective: To investigate the association between Hepatitis C Virus (HCV) status and the likelihood of infant death.

Study Design: This retrospective cohort study used data from the National Center for Health Statistics Vital Statistics database. The cohort linked birth and infant death data files from 2015 to 2021 that were used for this study. The study included all births in the United States during the study period with known HCV status. The outcome of interest was infant death. Univariate analysis was performed to determine the association between HCV and infant death. Multivariate logistic regression was then performed to estimate the effect of HCV status on infant death adjusting for potential confounding variables. Interaction analysis was then performed to determine if the effect of HCV on infant death is modified by race and obesity.

Results: Of the 26,456,956 women, 122,485 (0.46%) were identified with HCV infection. HCV infection was associated with

high rate of infant mortality (1.0% vs 0.5%, p< 0.001; aOR 2.34 [2.21-2.47]). Compared to White, both Black and Asian race demonstrated a protective effect on infant mortality among individuals with HBV infection (aOR 0.55; 95% CI [0.39 - 0.77] and aOR 0.54 95% CI [0.37-0.78]). Compared to underweight group, individuals with class III obesity also had lower infant death (aOR 0.48; 95% CI [0.28-0.82]).

Conclusion: This study demonstrates that HCV infection is associated with a significant increase in the risk of infant death, which is modified by other risk factors.

Hepatitis C	Infant Death 0	Infant Death 1	Total
0	26,205,312 (99.51%)	129,159 (0.49%)	26,334,471 (100.00%)
1	121,231 (98.98%)	1,254 (1.02%)	122,485 (100.00%)
Total	26,326,543 (99.51%)	130,413 (0.49%)	26,456,956 (100.00%)

Variable	Odds Ratio	P value	[95% Conf. Interval]
HCV * Normal BMI	1.147641	0.362	0.8536816 - 1.542823
HCV * Overweight	1.044829	0.782	0.7661673 - 1.424841
HCV * Class I Obesity	0.8891428	0.502	0.6311943 - 1.252506
HCV * Class II Obesity	0.8022718	0.296	0.5309565 - 1.212227
HCV * Class III Obesity	0.4756539	0.008	0.2755505 - 0.8210714
HCV * Unknown BMI	0.791465	0.202	0.5525191 - 1.133747

506 | The Association Between Hepatitis B Virus Infection During Pregnancy and Risk of Infant Death

Ilish Gedestad[1]; Sergio Karageuzian[2]; Kriti N. Vedhanayagam[3]; Stephen Contag[4]; Synia Chunn[3]; Megan Marquez[5]; Rang Kim[5]; Ruofan Yao[3]

[1]Loma Linda University School of Medicine, Redlands, CA; [2]Loma Linda University School of Medicine, Pasadena, CA; [3]Loma Linda University School of Medicine, Loma Linda, CA; [4]University of Minnesota, Minneapolis, MN; [5]Loma Linda University School of Medicine, Loma Linda University, CA

4:00 PM - 6:00 PM

Objective: To investigate the association between Hepatitis B Virus (HBV) status and the likelihood of infant death.

Study Design: This retrospective cohort study used data from the National Center for Health Statistics Vital Statistics database. The cohort linked birth and infant death data files from 2015 to 2021 that were used for this study. The study included all births in the United States during the study period with known HBV status. The outcome of interest was infant death. Univariate analysis was performed to determine the association between HBV and infant death. Multivariate logistic regression was then performed to estimate the effect of HBV status on infant death adjusting for potential confounding variables. Interaction analysis was then performed to determine if the effect of HBV on infant death is modified by race and obesity.

Results: Of the 26,456,956 women, 56,299 (0.21%) were identified with HBV infection. HBV infection was associated with higher but not statically significant rate of infant mortality (0.52% vs 0.49%, p = 0.757; aOR 0.98 [0.87-1.10]). Compared to White, both Black and Asian races demonstrated a protective effect on infant mortality among individuals with HBV infection (aOR 0.55; 95% CI [0.39 - 0.77] and aOR 0.54; 95% CI [0.37 - 0.78]).

Conclusion: HBV infection is not significantly associated with an increased risk of infant death, however other risk factors may modify this outcome.

Hepatitis B	Infant Death 0	Infant Death 1	Total

507 | The Use of a Novel Point-Of-Care (POC) IgM Test for the Diagnosis of Congenital Syphilis

Irene A. Stafford[1]; Sabrina DaCosta[2]; Kaitlyn Stark[3]; Diana Villarreal[4]; Jeffrey K. Klausner[5]; Leandro Mena[6]; Gary Lehnus[7]; Sean C. Blackwell[1]

[1]McGovern Medical School at UTHealth Houston, Houston, TX; [2]Division of Maternal-Fetal Medicine, Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern Medical School at UTHealth Houston, Houston, TX; [3]University of Texas Health Science Center at Houston - McGovern Medical School, Houston, TX; [4]The University of Southern California, Los Angeles, CA; [5]University of Southern California, Los Angeles, CA; [6]All-In Health Solutions LLC, Atlanta, GA; [7]Lehnus & Associates Consulting, East Stroudsburg, PA

4:00 PM - 6:00 PM

Objective: The only hematologic test used for congenital syphilis (CS) diagnosis is the neonatal nontreponemal (NT) serologic combined antibody test directed towards *T. pallidum* antigens. This includes IgG antibodies which cross the placenta and may reflect maternal antibodies rather than neonatal infection. In contrast, any syphilis-specific IgM immunoglobulins detected in the neonate are fetal in origin and may reflect CS. This pilot study aims to determine the test performance of a POC IgM test for the diagnosis of CS.

Study Design:

After institutional review board approval, serum from 2 controls and 23 pregnant patients with syphilis and their newborns was collected between 05/24-06/24. Duplicate 20 µL aliquots were tested using the research-use only rapid lateral flow test developed by Diagnostics Direct, LLC for detection of syphilis IgM. This test uses a purified specific anti-IgM polyclonal antibody coupled with colloidal gold in the sample pad to form rose colored visually read test and control lines. A proprietary Protein is used to bind all IgG from reacting with the antigen test line, producing only IgM for visual results detection. Duplicate 50 µL aliquots from the samples were tested for IgM using two CE-marked Western Blot (WB) tests with different treponema targets as comparators (ViraBlot, Germany and Euroimun, Germany). Mother-baby dyads were staged for syphilis according to the Centers for Disease Control and Prevention guidelines and were also considered for test performance analytics.

Results: The positive and negative percent agreement (PPA, NPA) between the POC IgM test and the Virablot WB was 86% and 78% and for Euroimun, PPA and NPA were 80% and 86% respectively (Table 1). Clinical correlates were similar, demonstrating a

90% PPA and a 93.3% NPV between the POC IgM test and syphilis diagnosis for dyads (Table 2).

Conclusion: The syphilis POC IgM test demonstrated excellent test performance when compared to reference WB tests and clinical correlates. Given poor sensitivity of current lab tests for CS, further studies evaluating this POC IgM test for at-risk neonates are warranted.

Table 1. IgM Rapid POC test compared to reference IgM Virablot and Euroimun Western Blots tests.

		Virablot IgM						Euroimun IgM				
		+	-	Total	PPA	NPA		+	-	Total	PPA	NPA

NPA: negative predictive agreement

Table 2. IgM Rapid POC test compared to mother-baby dyads with syphilis

	Pregnant Patient and Neonatal Syphilis Infection Status			
		+	-	Total
IgM Rapid POC	+	9	1	10
	-	1	14	15
	Total	10	15	25
	PPA = 9/10 = 90% (C.I.= 55.5 - 99.7)			
	NPA = 14/15 = 93.3% (C.I. = 68.1 - 99.8)			

508 | Sibling Analysis of Long-Term Morbidities in Preterm Twins: Vaginal versus Cesarean Delivery

Itamar Ben Shitrit[1]; Eyal Sheiner[2]; Gali Pariente[2]; Ruslan Sergienko[3]; Tamar Wainstock[2]
[1]Soroka University Medical Center/ Ben Gurion University, Beer Sheva, HaDarom; [2]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom; [3]Ben-Gurion University of the Negev, Beer Sheva, HaDarom

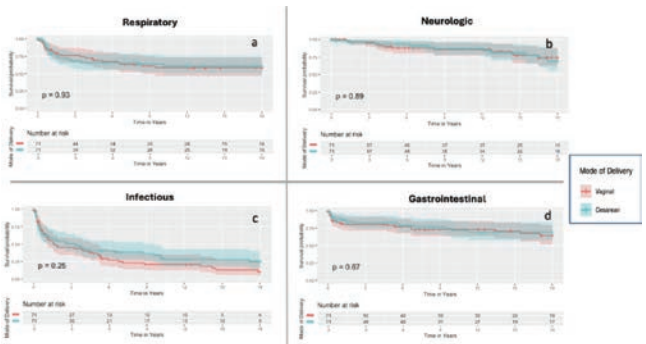
4:00 PM - 6:00 PM

Objective: Given the gap in knowledge regarding mode of delivery's impact on the premature twin population, we aimed to investigate the association between mode of delivery and long-term respiratory, neurologic, infectious, and gastrointestinal (GI) morbidities in preterm twin siblings, with the first delivered vaginally (VD) and the second by cesarean delivery (CD).

Study Design: A retrospective population-based cohort study was conducted at a tertiary medical center between 1991-2021. The study compared preterm twins where the first-born twin was vaginally delivered, and the second-born twin was delivered via CD, excluding cases with congenital malformations or perinatal deaths. Follow-up ended at the age of 18, end of the study period, or diagnoses of any morbidity from the studied outcomes. Kaplan-Meier survival curves were used to compare cumulative incidences, and Cox proportional hazards models were applied to adjust for potential confounders.

Results: The cohort included 71 offspring born via CD and 71 via VD, representing 3.5% of all preterm twin births at this center. No difference in the cumulative incidence of respiratory, neurologic, infectious, and gastrointestinal morbidity was noted between the groups (respiratory: 24% VD vs. 23% CD, p = 0.85; neurologic: 12% VD vs. 12% CD, p = 1.00; infectious: 52% VD vs. 45% CD, p = 0.20; GI: 20% VD vs. 17% CD, p = 0.56, Table, Figure). Similarly, the Cox model, adjusted for maternal age, ethnicity, gestational age group, repeated pregnancies, offspring's birth year, gestational diabetes mellitus, preeclampsia, weight group, and clustering within pregnancy, showed no association between delivery mode and long-term morbidity (respiratory: aHR 0.93, 95% CI 0.56–1.55; neurologic: aHR 1.16, 95% CI 0.47–2.27; infectious: aHR 0.81, 95% CI 0.59–1.12; GI: aHR 0.86, 95% CI 0.47–1.59, Table).

Conclusion: No significant differences in long-term respiratory, neurologic, infectious, and GI morbidities exist between preterm twin siblings when the first-born was delivered vaginally and the second-born by CD. Further research on larger cohorts is needed to confirm these findings.



Vaginal versus cesarean delivery and associated long term morbidities, incidence, hazard ratios and adjusted hazard ratios

	Disease Incidence			Crude HR (95%CI)	aHR* (95%CI)
	Vaginal[1] 71 (50%)	Cesarean[1] 71 (50%)	p[2]

509 | Elective Inductions of Labor at 39 Weeks versus Expectant Management in Multiparous Patients

James D. Doss[1]; Elise Requadt[2]; Claire Novack[2]; Anupama Balasubramanian[3]; Carly Duncan[4]; Dong Wang[5]; Antonina I. Frolova[6]; Jeannie C. Kelly[7]; Nandini Raghuraman[7]
[1]Washington University In St. Louis, St. Louis, MO; [2]Washington University at St. Louis, St. Louis, MO; [3]Larner College of Medicine at the University of Vermont, Larner College of Medicine at the University of Vermont, VT; [4]University of Alabama at Birmingham, Birmingham, AL; [5]Washington University at St. Louis, Department of Ob/Gyn, St. Louis, MO; [6]Washington University School of Medicine, St. Louis, MO; [7]Washington University School of Medicine in St. Louis, St. Louis, MO

4:00 PM - 6:00 PM

Objective: The ARRIVE trial demonstrated a reduction in cesarean section with similar perinatal outcomes in low risk nulliparas undergoing induction of labor (IOL) compared to

expectant management (EM). We compared outcomes in low-risk multiparous patients undergoing IOL vs EM.

Study Design: We performed a retrospective cohort study of multiparous patients with low-risk singleton pregnancies at 39 weeks gestation from 2020-2022. All multiparous patients who delivered after 39 weeks were included, and patients undergoing IOL for medical or fetal indications were excluded. The primary outcome was composite neonatal morbidity. The secondary outcomes were cesarean section, postpartum hemorrhage (defined as estimated blood loss ≥1000 ml), and chorioamnionitis. These outcomes were compared between patients undergoing scheduled IOL between 39w0d and 39w6d and those undergoing expectant management at 39 weeks. Multivariable Firth's penalized logistic regression was used to adjust for potential confounders.

Results: Of the 841 multiparous patients during the study period, 454 (54%) underwent IOL and 387 (46%) were EM. Among EM, 54 (14%) ultimately underwent an IOL. There were no significant differences in odds of having composite neonatal morbidity (aOR 1.04, 95% CI 0.63-1.71, p = 0.88), cesarean delivery (aOR 2.09, 95% CI 0.9-4.79, p = 0.09), or chorioamnionitis (aOR 0.58, 95% CI 0.13-2.57, p = 0.48) in IOL group as compared to EM group. The odds of having postpartum hemorrhage were 2.6 times higher in IOL as compared to EM patients (aOR 2.59, 95% CI 1.24-5.42, p = 0.011.)

Conclusion: Multiparous patients undergoing elective IOL have similar odds of cesarean section and neonatal morbidity as those undergoing EM. IOL is associated with an increased risk of hemorrhage compared to EM.

Table: Neonatal morbidity and cesarean section rates in multiparous patients undergoing elective IOL versus expectant management

510 | Dysglycemia Phenotypes in Pregnancy and the Risk of Fetal Shoulder Dystocia at Birth

Jasmine Hitt[1]; Eric K. BRONI[2]; Maria Som[3]; Cassandra Seifert[3]; May Blanchard[1]
[1]*University of Maryland Department of OBGYN, Baltimore, MD;* [2]*University of Pennsylvania Perelman School of Medicine, Philadelphia, PA;* [3]*University of Maryland School of Medicine, Baltimore, MD*

4:00 PM - 6:00 PM

Objective: Maternal diabetes is a well-established risk factor for fetal shoulder dystocia (ShD). However, data on the differential risk of ShD among women with dysglycemia subtypes in pregnancy are scarce. We evaluated whether the risk of fetal ShD differs by maternal dysglycemia subtype.

Study Design: We investigated 202 mothers who delivered infants with ShD and 747 randomly selected controls from a cohort of women who received antenatal care at an urban, tertiary medical center from 2012- 2023. Maternal dysglycemia phenotypes include [Type 1 diabetes (T1D), Type 2 diabetes (T2D), Gestational diabetes controlled by diet and exercise (GDMA1), Gestational diabetes requiring hypoglycemic agents (GDMA2)], Elevated 1-hour GCT without 3-hour GTT (E1GCT) and Elevated 1-hour GCT with normal 3-hour GTT (E1N3GTT). We used adjusted logistic regression models to estimate the risk of infant ShD among women in the different dysglycemia subgroups.

Results: Pregnant women who had infants with ShD were younger (27 vs 31 years, p< 0.001), more likely to be Black (72.8% vs 46.5%), delivered at later gestational age (39.3 vs 38.4 wks, p< 0.001), were more likely to have vaginal delivery (96% vs 53%, p< 0.001) and a history of smoking (17.3% vs 7.4%) **Table 1**. Compared to pregnant women with normoglycemia, those with E1GCT had a 4.4-fold [aOR, 4.35 (1.23–15.45)] higher risk of delivering an infant with ShD, even after controlling for maternal age, gestational age at delivery, race/ethnicity, parity, mode of delivery, prior delivery with ShD. Similarly, those with T2D had a 2.6-fold [aOR, 2.62 (1.19–5.75)] higher odds of delivering an infant with ShD. Additionally, women with E1N3GTT had a 3.4-fold [aOR, 3.36 (1.33-8.44)] higher odds of delivering an infant with ShD. **Table 2**.

Conclusion: Different dysglycemia phenotypes in pregnancy are independently associated with a higher risk of shoulder dystocia at birth. Continuous surveillance of pregnant women with dysglycemia, especially those with T2D and elevated 1-hour GCT (± 3-hour GTT), will reduce the risk of fetal shoulder dystocia and concomitant perinatal complications.

Table 1: Baseline Characteristics of Study Participants

Characteristic	Dystocia N=202	No dystocia N=747	P- value
Maternal age, years; median (IQR)	27(23-31)	31(27-36)	< 0.001

511 | Impact of Weight Discordance on Short-term Postnatal and Neurodevelopmental Outcomes in Triplet Pregnancies

Jeesun Lee[1]; Joon Hyung Lee[2]; JI HOI KIM[3]; Hee Young Cho[4]; Seung Mi Lee[1]; Chan-Wook Park[1]; Joong Shin Park[1]; Jong Kwan Jun[5]

4:00 PM - 6:00 PM

Objective: Weight discordance (WD) in multifetal pregnancies is a key concern due to its association with selective fetal growth restriction (sFGR). Although much research has focused on twins, studies on triplets are limited. This study evaluates the impact of WD on short-term postnatal and neurodevelopmental outcomes in triplets.

Study Design: We analyzed triplets delivered at Seoul National University Hospital from November 1997 to December 2022. WD was calculated as: ((birthweight of the largest fetus–birthweight of the smallest fetus) × 100) / birthweight of the largest fetus. Short-term outcomes included neonatal death, respiratory distress syndrome, bronchopulmonary dysplasia, persistent pulmonary hypertension, apnea of prematurity, intraventricular hemorrhage, periventricular leukomalacia, retinopathy of prematurity, necrotizing enterocolitis, and early-onset sepsis. Neurodevelopmental outcomes were assessed up to 60 months using the Korean Ages and Stages Questionnaires and the Bayley Scales of Infant and Toddler Development, 3rd Edition. ROC curves and Generalized Estimating Equations (GEE) were used to analyze the predictive value.

Results: A total of 436 triplets were analyzed. Short-term outcomes were linked to gestational age but not to WD or birthweight order. ROC curve analysis showed an AUC of 0.550 for short-term outcomes, indicating limited predictive value. GEE analysis found adjusted hazard ratios of 1.08 (95% CI 0.74-1.59) for the middle-sized fetus and 1.48 (95% CI 0.99-2.22) for the smallest fetus, suggesting minimal impact of birthweight order. Neurodevelopmental outcomes also showed no significant correlation with WD, with an AUC of 0.645. No differences in outcomes based on WD were seen when analyzed by chorionicity.

Conclusion: This study found no strong association between WD and short- or long-term complications in liveborn triplets. WD does not appear to be a significant predictor of adverse outcomes in triplet pregnancies, though further research is needed for a thorough understanding.

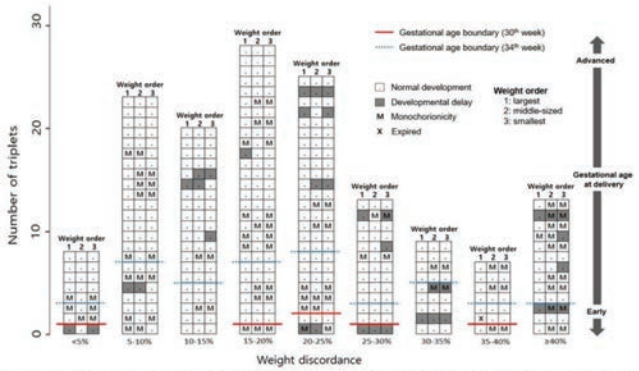

Figure 2. Occurrence of developmental delay in triplet children according to the weight discordance

512 | Azithromycin to Improve Latency in Exam-Indicated Cerclage: a Multicenter Randomized Control Trial (ALEC)

Jenani S. Jayakumaran[1]; Kavisha Khanuja[2]; Stephanie A. Fisher[3]; Emily S. Miller[4]; Emily B. Rosenfeld[5]; Justin S. Brandt[6]; Megan Piacquadio[7]; Adeeb Kalifeh[8]; Rupsa C. Boelig[9]
[1]Virtua Medical Group, Moorestown, NJ; [2]Sidney Kimmel Medical College at Thomas Jefferson University, Philadelphia, PA; [3]Northwestern University Feinberg School of Medicine, Chicago, IL; [4]Women & Infants Hospital of Rhode Island and Alpert Medical School of Brown University, Providence, RI; [5]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; [6]NYU Langone Health, New York, NY; [7]University of Miami, Miami, FL; [8]Jefferson Einstein Philadelphia, Philadelphia, PA; [9]Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA

4:00 PM - 6:00 PM

Objective: While prophylactic azithromycin has been shown to increase latency in the setting of cervical shortening, its use in physical exam-indicated cerclage (PEIC) has been understudied. Our objective is to determine whether adding azithromycin prior to PEIC increases gestational latency to usual care (cefazolin and indomethacin).

Study Design: This RCT included pregnant people with singleton gestations < 24 weeks gestational age (GA) planning a PEIC at one of four sites across the United States. Participants were randomized 1:1 to usual care (cefazolin 1-2 g IV and indomethacin 50 mg IV preoperatively, then 2 additional doses at 8 and 16 hours postoperatively) or usual care plus azithromycin (azithromycin 1g IV once perioperatively). Primary outcome was gestational latency (days) from cerclage placement to delivery. Secondary outcomes included preterm birth (< 37, < 34, < 32, < 28, and < 24 weeks), GA at birth, chorioamnionitis, birthweight, NICU admission, and composite neonatal morbidity and mortality. Fifty participants needed to be randomized to demonstrate a 20±25 days improvement in latency with 80% power. Assuming a 10% loss to follow-up, we aimed to recruit 55 individuals. Kaplan-Meier survival curve, Mann Whitney U test, and chi squared analyses were conducted. The study was registered at clinicaltrials.gov (NCT05132829).

Results: A total of 55 participants were randomized from December 2021 to September 2023; 27 to usual care, 27 to adjunctive azithromycin, and 1 excluded from analysis when found not to meet study criteria after randomization. Protocol adherence was 100% for each arm. The median gestational latency after PEIC did not differ between the usual care and azithromycin groups (median difference -1 day, 95% CI -20 to 26 days; Figure). Additional secondary obstetric and neonatal outcomes were similar between groups (Table).

Conclusion: A single perioperative dose of azithromycin in addition to usual care (cefazolin and indomethacin) does not improve latency to delivery or other obstetric or neonatal outcomes for individuals undergoing PEIC.

Figure

Composite adverse outcome[a]	12/26 (46.1)	12/27 (44.4)	0.901	

Data presented as n (percent), mean±standard deviation, or median [interquartile range].
RR: relative risk; MD: median difference.
[a]Composite adverse outcome includes: respiratory distress syndrome, bronchopulmonary dysplasia, retinopathy of prematurity, intraventricular hemorrhage grade 3 or 4, patent ductus arteriosus, culture-proven sepsis, necrotizing enterocolitis, and neonatal death.

513 | Characteristics Associated with Compliance Within a Postpartum Hypertension Remote Monitoring Program

Jenny Y. Mei[1]; Audra Fain[2]; Kate Corry-Saavedra[3]; Tina A. Nguyen[2]; Thalia Mok[2]; Aisling M. Murphy[2]
[1]Stanford University, Mountain View, CA; [2]University of California, Los Angeles, Los Angeles, CA; [3]University of California, Irvine, University of California, Irvine, CA

4:00 PM - 6:00 PM

Objective: Remote blood pressure (BP) monitoring has been shown to decrease postpartum Emergency Department (ED)

visits and readmissions. We evaluate characteristics associated with compliance within a remote BP monitoring program.

Study Design: A retrospective cohort study of birthing patients with peripartum hypertension (HTN) at a quaternary care center over 2 years. This study is part of an ongoing postpartum quality improvement project that entails lower BP targets and universal remote BP monitoring. Inclusion criteria were delivery at the study institution and diagnosis of HTN disorder of pregnancy at time of discharge. Primary outcome was compliance with utilizing remote BP monitoring, defined as logging at least one BP within the program. We compared maternal and hypertensive characteristics between groups.

Results: Out of 6410 deliveries between April 2022-April 2024, 2019 (31.5%) pregnancies met inclusion criteria, of which 1509 (74.7%) were compliant with utilizing remote BP monitoring. There were higher rates of compliance with higher maternal age (in years, 34.2±5.0 vs 33.0±6.3, p< 0.001), nulliparity (71.2% vs 56.5%, p< 0.001), lower BMI (in kg/m^2, 30.2±6.1 vs 31.6±7.0, p< 0.001), prenatal aspirin use (41.9% vs 33.1%, p< 0.001), IVF pregnancy (12.3% vs 7.8%, p = 0.006), and private insurance (84.9% vs 59.4%, p< 0.001). Patients discharged on anti-hypertensive medication were more likely to be compliant (36.0% vs 24.1%, p< 0.001) as were those with longer postpartum lengths of stay (in days, 2.4±1.3 vs 2.3±1.2, p = 0.027). Compliance was associated with lower rate of ED visit or readmission (1.8% vs 3.3%, p = 0.039).

Conclusion: Characteristics that are associated with higher rates of compliance with remote BP monitoring include nulliparous, older, and privately insured patients. Compliance was associated with lower rates of postpartum ED visit or readmission. Continued work is needed to identify barriers to remote BP monitoring and target these areas for improvement within programs to improve compliance and further decrease postpartum readmission rates.

Table 1. Baseline Characteristics by Remote Monitoring Compliance

Baseline Characteristic	Using Remote Monitoring (n=1509)	Not using Remote Monitoring (n=510)	P-value[a]
Maternal age in years (mean±SD)	34.2±5.0	33.0±6.3	**<0.001**

Vaginal delivery	1020 (67.6%)	335 (65.7%)	0.43
Cesarean delivery	489 (32.4%)	175 (34.3%)	
Postpartum hemorrhage	226 (15.0%)	79 (15.5%)	0.78
Composite maternal morbidity	21 (1.4%)	6 (1.2%)	0.72
Postpartum length of stay in days (mean±SD)	2.4±1.3	2.3±1.2	**0.027**

Abbreviations: SD, standard deviation; BMI, body mass index; IVF, in vitro fertilization

a. *P*-value significance was set at <0.05 and significant values are bolded.

b. Race and ethnicity were self-classified by the patient according to options defined by the study institution. They were assessed due to findings in previous studies of race and ethnicity being a risk factor for postpartum hypertension readmission.

Table 2. Hypertension Characteristics by Remote Monitoring Compliance

Hypertension Characteristics	Using Remote Monitoring (n=1509)	Not using Remote Monitoring (n=510)	P-value[a]
Hypertension diagnosis at discharge			
Gestational hypertension	791 (52.4%)	261 (51.2%)	**0.024**
Preeclampsia without severe features	269 (17.8%)	118 (23.1%)	
Preeclampsia with severe features or HELLP	268 (17.8%)	70 (13.7%)	
Chronic hypertension only	181 (12.0%)	61 (12.0%)	
Anti-hypertensives at discharge	543 (36.0%)	123 (24.1%)	**<0.001**
Postpartum ED visit or readmission[b]	27 (1.8%)	17 (3.3%)	**0.039**

Abbreviations: HELLP, hemolysis, elevated liver enzymes, low platelets; SD, standard deviation; ED, Emergency Department

a. *P*-value significance was set at <0.05 and significant values are bolded.

b. This indicates if patients had a postpartum ED visit or readmission prior to utilizing the remote monitoring program.

514 | Risk Factors for Discharge on Anti-Hypertensive Medication with Lower Blood Pressure Targets

Jenny Y. Mei[1]; Audra Fain[2]; Kate Corry-Saavedra[3]; Tina A. Nguyen[2]; Thalia Mok[2]; Aisling M. Murphy[2]
[1]Stanford University, Mountain View, CA; [2]University of California, Los Angeles, Los Angeles, CA; [3]University of California, Irvine, University of California, Irvine, CA

4:00 PM - 6:00 PM

Objective: With more institutions implementing lower blood pressure (BP) targets prior to postpartum discharge for patients with hypertensive disorders of pregnancy, a growing number of patients are discharged on anti-hypertensive (anti-HTN) medication. We aim to evaluate risk factors associated with being discharged on anti-HTN medication with lower BP goals.

Study Design: A retrospective cohort study of birthing patients with peripartum hypertension (HTN) at a quaternary care center over 2 years. This study is part of an ongoing postpartum quality improvement project that entails lower BP targets and universal remote BP monitoring. Goal blood pressure was under 140/90 leading up to discharge. Inclusion criteria were delivery at the study institution and diagnosis of HTN disorder of pregnancy. Primary outcome was prescription of anti-HTNs at time of discharge. Characteristics associated with discharge on anti-HTNs were compared between groups.

Results: Out of 6410 deliveries between April 2022-April 2024, 2019 (31.5%) pregnancies met inclusion criteria, of which 666 (33.0%) were discharged on anti-HTN medication. Baseline characteristics associated with discharge on anti-HTN included maternal age 40 and above (17.0% vs 11.8%, p = 0.001), non-Hispanic Black race (13.7% vs 9.5%, p = 0.005), chronic HTN (28.4% vs 12.3%, p< 0.001), prenatal aspirin use (52.1% vs 33.6%, p< 0.001), and having public or no insurance (25.2% vs 19.7%, p = 0.005). Other risk factors for discharge on anti-HTN medication include proteinuria (43.2% vs 23.6%, p< 0.001) and preeclampsia with severe features (40.4% vs 5.1%, p< 0.001). Patients discharged on anti-HTNs were more likely to be compliant with remote BP monitoring (97% vs 94.2%, p = 0.013) and undergo outpatient medication adjustments (24.6% vs 14.5%, p< 0.001).

Conclusion: At an institution implementing lower BP targets aiming for normotension, certain traditional high-risk patients remain at increased risk for discharge on anti-HTN medication. Continued research is needed to identify ways of mitigating long-term comorbidities for this high-risk cohort.

Table 1. Baseline Characteristics by Need for Anti-Hypertensive Medication on Discharge

Characteristic	Medication on Discharge (n=666)	No Medication (n=1353)	P-value[a]
Maternal age in years (mean±SD)	34.4±5.7	33.7±5.2	**0.02**

515 | Can the Supplementation of Ferric-Carboxymaltose Improve Postpartum Depression After Birth? a Randomized, Controlled Clinical Trial

Jeong-won Oh[1]; Eun Sil Lee[2]; Kyu Yeon Choi[2]; Subeen Hong[3]; Hyun Sun Ko[4]; Geun Joon Cho[5]; Jeong Jae Lee[2]

[1]Department of Obstetrics and Gynecology, Soonchunhyang University Seoul Hospital, Soonchunhyang University College of Medicine, Soonchunhyang University Seoul Hospital, Soonchunhyang University College of Medicine/Seoul, Seoul-t'ukpyolsi; [2]Department of Obstetrics and Gynecology, Soonchunhyang University Seoul Hospital, Soonchunhyang University College of Medicine, Seoul, Soonchunhyang University Seoul Hospital, Soonchunhyang University College of Medicine, Seoul, Seoul-t'ukpyolsi; [3]Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Seoul-t'ukpyolsi; [4]Department of Obstetrics and Gynecology, Catholic University College of Medicine/ Seoul, Catholic University College of Medicine/ Seoul, Seoul-t'ukpyolsi; [5]Department of Obstetrics and Gynecology, Korea University College of Medicine/ Seoul, Seoul-t'ukpyolsi

4:00 PM - 6:00 PM

Objective: This study aims to compare the efficacy of intravenous(IV) ferric-carboxymaltose(FCM) administration versus conventional oral iron supplementation in improving postpartum depression(PPD) in postpartum women with iron-deficiency anemia(IDA).

Study Design: A randomized, open-label, controlled clinical trial was conducted at three centers in South Korea between 2021 and 2023. Postpartum women with (i)moderate IDA, diagnosed with hemoglobin(Hb) levels of 8≤ Hb< 11g/dL and ferritin< 30ng/mL or transferrin saturation(TSAT) < 20%, and with (ii)a high risk of PPD based on the Edinburgh Postnatal Depression Scale(EPDS) score of ≥ 8 within the first three days after delivery, were enrolled. Following randomization, participants received either IV FCM(500-1000 mg) or oral iron(20-400 mg). The primary endpoint was the change in EPDS score from baseline to 8 weeks postpartum. Hematologic parameters, presence of PPD (EPDS score > 11), and maternal fatigue were evaluated at ten days, 4, 6, and 8 weeks.

Results: Among 96 patients, 90 were analyzed, with 45 in each group. The aggregated change in EPDS scores over 8 weeks postpartum did not differ between the groups, while the mean EPDS score(±SD) for the entire study population significantly decreased from 11.5 ± 3.2 initially to 8.6±5.0 at 8 weeks(p-value for trend < 0.001). The prevalence of PPD at 8 weeks was 22.2 %(10/45) in each group, with no significant difference. Variables such as Hb changes and type of iron therapy did not affect the risk of PPD, except for fatigue at 8 weeks (adjusted odds ratio 1.05, 95% confidence interval 1.01–1.09; P = 0.016). Hb levels increased well in both groups, but changes in Hb, ferritin, and TSAT levels at 8 weeks (p < 0.001) and fatigue scores at 6 weeks(p = 0.03) were significantly improved in the IV iron group compared to the conventional group.

Conclusion: While the administration of FCM did not show significant benefits over placebo in improving EPDS scores, the study's findings demonstrated that IV iron was more effective than conventional oral iron in correcting postpartum IDA, iron stores and reducing fatigue.

4:00 PM - 6:00 PM

Objective: Individuals with diabetes (gestational or pregestational) are at increased risk of adverse outcomes, particularly in the setting of chronic hypertension (HTN) or new-onset HTN in pregnancy. Though remote self-measured blood pressure (SMBP) monitoring programs may reduce rates of HTN-related hospital readmission, emergency department (ED) presentations, or severe maternal morbidity (SMM), it is unclear whether the extent of this reduction differs between those with and without diabetes. We aimed to compare outcomes between postpartum patients in our remote SMBP program with versus without diabetes.

Study Design: Postpartum patients with HTN at our tertiary care hospital are offered enrollment in our remote SMBP program, which includes BP monitoring for 6 weeks postpartum. For this analysis, participants were stratified by presence or absence of diabetes (pregestational or gestational). Those with unknown diabetes status were excluded. The primary outcome was a composite of postpartum readmission or ED presentation for HTN within 30 days of delivery hospitalization. Secondary outcomes included HTN-related SMM. A generalized linear model was used to estimate relative risks (RR) after adjustment for differences in demographic, obstetric, and medical conditions from table 1.

Results: Of 2003 participants in the SMBP program, 17.2% had diabetes. Compared to those without, those with diabetes were older, less likely to identify as White, less likely to have gestational but more likely to have chronic hypertension, more likely to be delivered via cesarean, and had a lower median gestational age at delivery (**Table 1**). After adjusting for these factors, there was no difference in the risk of the composite outcome of HTN-related postpartum readmission or ED presentation between those with and without diabetes [15.9% versus 16.6%; adjusted RR 0.9 (0.7, 1.2)]. Similarly, there were no differences in secondary outcomes (**Table 2**).

Conclusion: In our remote SMBP program for postpartum patients with HTN, both unplanned HTN-related healthcare utilization and SMM were similar between those with and without diabetes.

Table 1: Demographics

Variable	With diabetes (n=337; 17.15%)	Without diabetes (N= 1,628; 82.85%)	P value

4:00 PM - 6:00 PM

Objective: Adverse pregnancy outcomes (APO) have been reported to increase the risk of long-term atherosclerotic cardiovascular disease (ASCVD) later in life. Additionally, socioeconomic status (SES) is known to be associated with ASCVD risk. In the current analysis, we determined the interaction between SES and APO, specifically, if low SES further aggravates the ASCVD risk after APO.

Study Design: We conducted the current analysis using data from the UK Biobank, which is a large prospective cohort. This data includes participants in age 40 to 69 years recruited between

2006 and 2010, with ongoing follow-up. APO included hypertensive disease during pregnancy (HDP), gestational diabetes mellitus (GDM), and low birth weight (< 2.5kg). SES was analyzed using the following indicators; household income, education, employment and Townsend Deprived Score. The study population were categorized into four main groups according to APO and SES: no APO/high SES, APO/high SES, no APO/low SES and APO/low SES groups. The incidence of long-term ASCVD events and the cumulative hazard risk (HR) for ASCVD was analyzed according to the APO and SES categories.

Results: In total, 219,147 female participants were analyzed. The results indicated that the APO group had relatively lower SES in all indicators and higher incidence of ASCVD, hypertension, hyperlipidemia, diabetes mellitus, compared to the no APO group. After adjusting for the confounding factors, the risk of ASCVD was highest in the group with APO and low SES group. Specifically, the HR was 2.029 (95 % CI, 1.762-2.338, $p < 0.001$) in those with APO and unemployment.

Conclusion: We found that the CVD risk varied according to SES and APO. This study suggests the importance for support policies tailored to individuals' SES to prevent APO and improve long-term cardiovascular disease.

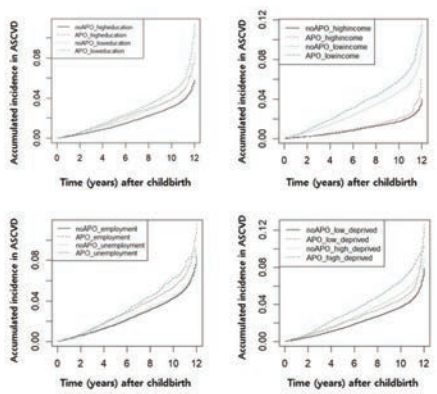

Figure 1. Kaplan-Meier curve for long-term outcome of ASCVD according to SES and APO

518 | The Risk of Long-Term Cardiovascular Disease after Adolescent Pregnancies

JI HOI KIM[1]; Haemin Kim[2]; Manu Shivakumar[3]; Dokyoon Kim[3]; Kue Hyun Kang[4]; Minyoung Park[1]; Chan-Wook Park[5]; Joong Shin Park[5]; Juwon Lim[1]; Jeehoon kang[1]; Seung Mi Lee[5]
[1]Seoul National University Hospital College of Medicine, Seoul, Seoul-t'ukpyolsi; [2]Kyungpook National University Chilgok Hospital, Kyungpook National University, School of Medicine, Daegu, Ch'ungch'ong-bukto; [3]University of Pennsylvania, Philadelphia, PA; [4]Ain Hospital, Incheon, Inch'on-jikhalsi; [5]Seoul National University College of Medicine, Seoul, Seoul-t'ukpyolsi

4:00 PM - 6:00 PM

Objective: Previous studies have reported that adolescent pregnancy is associated with higher risks of adverse pregnancy outcomes (APO) compared to pregnancies after the age of 20. Although there have been accumulating evidence regarding age at reproductive event, such as menarche or menopause, and long-term cardiovascular (CVD) risk, there aren't enough research on the effect of adolescent pregnancy on long-term outcome. This study aimed to evaluate the risk of long-term CVD after adolescent pregnancy using large cohort data.

Study Design: This study was based on the UK biobank database. Participants aged 40 to 69 years, who were recruited between 2006 and 2010, were analyzed. Clinical events were collected from the time of enrollment. The study population was divided into groups of first delivery before and after the age of 20. The risk of atherosclerotic cardiovascular disease (ASCVD) was evaluated according to adolescent pregnancy (< 20 years) and adult pregnancy (≥ 20 years).

Results: Among 182,843 women in the UK biobank, 28,090 women had their first delivery at adolescence with an average age at childbirth of 18.69 years. The adolescent pregnancy group had lower rates of hypertensive disease during pregnancy (HDP) compared to the adult pregnancy group. However, the incidence of ASCVD was 8.4 % (2269/28,090) in the adolescent pregnancy group, compared to the adult pregnancy group. Even after adjusting for confounding variables, the risk of ASCVD remained higher in adolescent pregnancy group (HR 1.320; 95 % CI 1.245 to 1.398, $p < 0.001$).

Conclusion: Adolescent pregnancy increases the risk of long-term ASCVD. Healthcare providers should focus on both prenatal care and long-term postpartum management for adolescent pregnancies. To improve potential risks and outcomes, appropriate care and comprehensive support are necessary throughout pregnancy and the postpartum period.

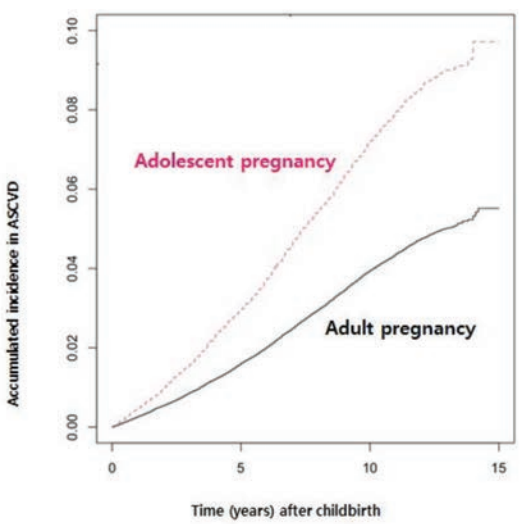

Figure 1. Kaplan-Meier curve for long-term outcome of ASCVD in adolescent pregnancies (<age of 20)

519 | Risk Factors Associated with Unexpected Neonatal Resuscitation Among Term Neonates in Uncomplicated Pregnancies

Nari Kim[1]; Eun Hee Ahn[1]; Sang Hee Jung[1]; Hyun Mee Ryu[1]; Ji Yeon Lee[2]
[1]Department of Obstetrics and Gynecology, CHA Bundang Medical Center, CHA University School of Medicine, CHA Bundang Medical Center, CHA University School of Medicine / Seongnam, Kyonggi-do; [2]Department of Obstetrics and Gynecology, CHA Bundang Medical Center, CHA University School of Medicine, Seongnam, Kyonggi-do

4:00 PM - 6:00 PM

Objective: Unexpected neonatal resuscitation (NR) in anticipated smooth deliveries is troubling without available neonatologists. This study evaluated risk factors for unexpected NR in singleton pregnancies with planned cesarean deliveries after 36 weeks gestation and no fetal abnormalities.

Study Design: This retrospective cohort study included singleton pregnant women at our hospital who received prenatal care from the first trimester, had no fetal abnormalities, and delivered via planned cesarean section after 36 weeks of gestation, between 2013 and 2023. Only cases with stable vital signs and no significant blood loss from anesthesia to delivery were included. Women with medical conditions requiring hospitalization were excluded. Cases were divided into the NR group (5-minute Apgar score < 7) and the control group. Maternal characteristics, medical history, and laboratory tests from the first trimester and the last visit before delivery were reviewed. We formulated a scoring model after performing multivariable analysis using adjusted odds ratios (aOR).

Results: A total of 5,324 cases were included, with the NR group comprising 78 cases (1.5%). Five variables were associated with unexpected NR: prior preterm birth (aOR 5.6, 95%CI 1.9-16.2, P = 0.002), psychiatric medication during pregnancy (aOR 10.3, 95%CI 1.8-59.2, P = 0.009), leukocytosis (WBC count ≥15,000/mm^3) in the first trimester (aOR 4.1, 95%CI 1.5-11.2, P = 0.007), leukocytosis just before delivery (aOR 3.1, 95%CI 1.3-7.5, P = 0.010), and increased HbA1c (≥6.0%) just before delivery (aOR 2.7, 95%CI 1.1-7.0, P = 0.048). We formulated a scoring model, assigning each factor a score of 1 to 4 based on the aOR. A score of 4 out of 13 had a sensitivity of 72% and a specificity of 82% for predicting unexpected NR. The AUC was 0.817 (P< 0.001).

Conclusion: Prior PTB, psychiatric medication, leukocytosis in the first trimester, leukocytosis just before delivery, and increased HbA1c just before delivery were identified as risk factors for unexpected NR in uncomplicated pregnancies. This scoring model may provide useful information for predicting unexpected NR.

520 | Association of Isolated Leukocytosis in Early Pregnancy with Adverse Pregnancy Outcomes

Ji Yeon Lee[1]; Nari Kim[2]; Yeomin E. Kang[3]
[1]Department of Obstetrics and Gynecology, CHA Bundang Medical Center, CHA University School of Medicine, Seongnam, Kyonggi-do; [2]Department of Obstetrics and Gynecology, CHA Bundang Medical Center, CHA University School of Medicine, CHA Bundang Medical Center, CHA University School of Medicine / Seongnam, Kyonggi-do; [3]University of Maryland, Baltimore, MD

4:00 PM - 6:00 PM

Objective: Animal studies suggest that maternal systemic inflammation in early pregnancy can affect adverse outcomes. There is no clear standard for maternal leukocytosis, and there is limited research on how high white blood cell(WBC) counts affect outcomes. This study aims to investigate how high WBC counts in the first trimester relate to adverse pregnancy outcomes and identify the WBC count level linked to poor prognosis.

Study Design: This retrospective cohort study included healthy, singleton pregnant women who delivered between 2014 and 2023. Cases included only those without fetal anomalies and no fever at the time of the first trimester laboratory test. Women showing signs of infection/inflammation or with autoimmune diseases were excluded. Women with a WBC count of 13,000-14,000 in the first trimester were classified as group I (n = 382), those with a WBC count of 14,000-15,000 as group II (n = 151), and those with a WBC count of ≥15,000 as group III (n = 70). Meanwhile, those with a WBC count of 7,500-8,500 were designated as the control group (n = 1,524). Multivariate analysis was performed considering maternal characteristics.

Results: Groups I/II did not show statistical differences in adverse outcomes compared to the control group. However, group III had significantly higher risks compared to the control group, including the risk of preterm birth(PTB) before 32 weeks (aOR 5.5, 95% CI 1.5-20.6, P = 0.012), before 34 weeks (aOR 8.2, 95%CI 3.4-20.3, P< 0.001), and before 36 weeks (aOR 2.9, 95%CI 1.4-6.1, P = 0.006). Additionally, the risks of gestational diabetes(GDM) (aOR 2.1, 95%CI 1.2-3.7, P = 0.013), cesarean delivery(CD) (aOR 1.8, 95%CI 1.1-3.1, P = 0.029), transient tachypnea(TTN) (aOR 2.6, 95%CI 1.1-6.3, P = 0.036), and neonatal jaundice (aOR 1.7, 95%CI 1.1-2.8, P = 0.039) were also elevated in group III compared to the control group.

Conclusion: Associations between high WBC counts (≥15,000) in early pregnancy and increased risks of PTB, GDM, CD, TTN, and neonatal jaundice have been observed. High first-trimester WBC counts may help predict adverse pregnancy outcomes.

521 | Opt-Out and Rapid Syphilis Testing in Pregnant Patients Presenting to the Ed: a Pre-Post Study

Joe Haydamous[1]; Ana Davie[1]; Jose C. Noriega Valdez[1]; Cassandra Igbe[1]; Aidan Blackwell[1]; Carrie Bakunas[2]; Jeffrey K. Klausner[3]; Leandro Mena[4]; Irene A. Stafford[5]
[1]Division of Maternal-Fetal Medicine, Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern Medical School at UTHealth Houston, Houston, TX; [2]Department of Emergency Medicine, McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, Texas, Houston, TX; [3]University of Southern California, Los Angeles, CA; [4]All-In Health Solutions LLC, Atlanta, GA; [5]McGovern Medical School at UTHealth Houston, Houston, TX

4:00 PM - 6:00 PM

Objective: According to regional pilot data, 35% of pregnant patients with newborns diagnosed with congenital syphilis (CS) visited the emergency department (ED) during pregnancy but were not tested for syphilis. This represents a critical missed opportunity to identify and treat syphilis in pregnant patients and reduce the incidence of CS. This pre- and post-implementation study aims to determine if implementing an opt-out laboratory-based and rapid syphilis testing program improves the detection and treatment of syphilis during pregnancy in the ED.

Study Design: This pre-post implementation study was conducted at the University of Texas Health Science Center, Houston, TX after institutional approval. During the pre-implementation phase (11/01/2023 - 02/29/2024), eligible pregnant patients presenting to the ED underwent standard lab-based syphilis testing only when clinically indicated. In the post-implementation phase (03/01/2024 - 06/25/2024), pregnant patients without a documented syphilis result or prenatal care received lab-based

opt-out syphilis testing with or without the Syphilis Health Check (SHC) point-of-care test, with coordinators facilitating linkage to prenatal care for all patients.

Results: During the pre-implementation period, 302 pregnant patients presented to the ED for care, with only 6 (2%) undergoing syphilis testing, yielding no positive results. In the post-implementation period, 322 pregnant patients presented to the ED. Of these, 79 (24.5%) were tested for syphilis, representing a 12.5-fold increase in screening ($p < 0.001$). Three patients tested positive for syphilis, indicating a 3.8% prevalence rate. Moreover, 70% of those who tested positive were scheduled for prenatal care by research coordinators dedicated to the project.

Conclusion: The implementation of an opt-out and rapid syphilis testing program for underserved pregnant patients in the ED led to a significant increase in syphilis testing and referral for treatment. The public health impact of this program for adults and neonates is likely to demonstrate further substantial benefits, particularly in high-prevalence regions.

Periods	Pre (11/01/2023 - 02/28/2024)	Post (03/04/2024 - 06/25/2024)
Pregnant patients coming to ED, n	302	322
Patients tested, n(%)	6 (2%)	79 (24.53%)
Newly reactive (positive), n	0	3

522 | The Texas Experience: The Impact of Levels of Care on Severe Maternal Morbidity

John J. Byrne[1]; Sangeeta Jain[2]; Kirsten Robinson[3]; David B. Nelson[4]; Carlos Anaya[5]; Mattie Mason[6]; Sadhana Chheda[7]; Patrick S. Ramsey[8]

[1]University of Texas Health San Antonio, San Antonio, TX; [2]University of Texas Medical Branch, Galveston, TX; [3]Texas Tech University Health Sciences Center School of Medicine, Lubbock, TX; [4]University of Texas Southwestern Medical Center, Dallas, TX; [5]University of Texas Rio Grande Valley School of Medicine, Edinburg, TX; [6]New Life Perinatal Health Care Services, Inc, Houston, TX; [7]TTUHSC-El Paso, El Paso, TX; [8]University of Texas Health Science Center San Antonio, San Antonio, TX

4:00 PM - 6:00 PM

Objective: The State of Texas instituted Levels of Maternal Care (LoMC) Designation in 2018, with all hospitals that provide maternity services receiving a formal LoMC designation by August 31, 2021. We sought to assess the impact of instituting LoMC in Texas on the rates of severe maternal morbidity (SMM) across levels of care.

Study Design: We conducted a retrospective, cross-sectional study for years 2018 and 2022 using Texas Medicaid Data, prior to- and after- LoMC designation occurred. Data extracted included total SMM rate, hysterectomy rate, and hospital level of care. Data related to total SMM (without transfusion), hysterectomy rate, and eclampsia rates were compared pre- and post-implementation.

Results: There are 219 facilities that have achieved maternal designation (55–level I, 88–level II, 44–level III, 32–level IV) by 2021. The number of Medicaid births increased significantly from 2018 to 2022 in level I, II, III facilities ($p< 0.001$), and was not statistically different in the level IV facilities ($p = 0.33$). Of the 260,986 deliveries included in 2018 and 258,674 deliveries included in 2022, there were 4675 (1.79%) and 4533 (1.75%) SMM events, respectively ($p = 0.29$). There was a decrease of 0.5% in SMM rates in level I centers from 2018-2022 ($p = 0.001$, Table). There were no statistically significant differences between SMM events in level II, III, IV centers. SMM among hemorrhage cases was noted to be reduced from 2018 to 2022, and was statistically decreased in level I ($p = 0.002$) and level IV centers ($p = 0.04$). SMM among cases of patients with preeclampsia was significantly reduced in Level I-IV centers ($P< 0.01$). There was a non-statistically significant decrease in hysterectomies in Level I/II facilities from 2018 (64/204, 31.4) to 2022 (92/319, 28.8%), ($p = 0.54$).

Conclusion: Using Texas Medicaid data, which includes approximately 50% of births in Texas, there was a statistically significant decrease in SMM rates in Level 1 centers after implementation of LoMC. Additionally, there was a reduction in both hemorrhage- and preeclampsia-related SMM during this timeframe.

Table: Severe Maternal Morbidity Across Levels of Maternal Care

	Level	2018	2022	p-value
Severe Maternal Morbidity (Excluding Transfusion Only) Among All Deliveries	Level I	245/13823 (1.78%)	196/15072 (1.3%)	**0.001**
	Level II	1324/83546 (1.58%)	1419/84196 (1.69%)	0.104
	Level III	1218/65352 (1.86%)	1232/69585 (1.77%)	0.200
	Level IV	1707/88366 (1.93%)	1645/87250 (1.89%)	0.478
	Total	*4675/260986 (1.79%)*	*4533/258674 (1.75%)*	*0.288*
Severe Maternal Morbidity (Excluding Transfusion Only) Among Hemorrhage Cases	Level I	69/941 (7.3%)	53/1261 (4.2%)	**0.002**
	Level II	248/5130 (4.8%)	301/6509 (4.6%)	0.60
	Level III	231/4163 (5.6%)	279/5719 (4.9%)	0.14

523 | Tranexamic Acid Prevents Postpartum Hemorrhage During Cesarean Delivery: A Meta-Analysis

Jordan A. McKinney[1]; Gustavo Vilchez[2]; Luis Sanchez-Ramos[3]

[1]University of Florida College of Medicine, Gainesville, FL; [2]UTHealth Houston, Houston, TX; [3]University of Florida College of Medicine, Jacksonville, FL

4:00 PM - 6:00 PM

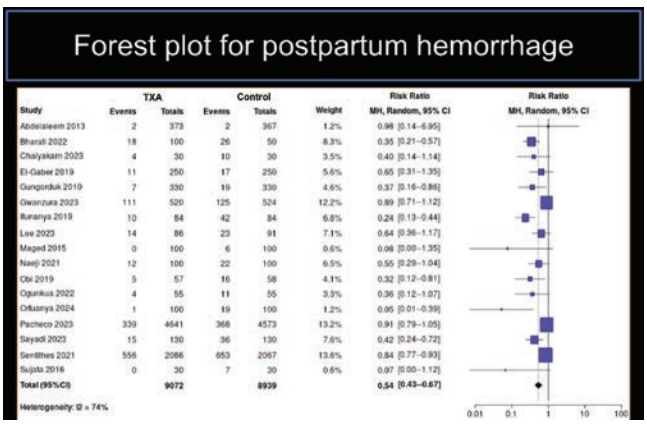
Objective: Postpartum hemorrhage remains a leading cause of maternal morbidity and mortality worldwide, particularly following cesarean delivery. Effective prophylactic interventions are critical to mitigate this risk and improve maternal outcomes. Tranexamic acid (TXA), an antifibrinolytic agent, has shown promise in reducing blood loss in various surgical contexts. This updated systematic review and meta-analysis aimed to assess the impact of prophylactic tranexamic acid on preventing postpartum hemorrhage and the need for blood transfusion in patients undergoing cesarean delivery.

Study Design: We systematically searched multiple electronic databases and grey literature from their inception up to May 24, 2024, to identify randomized controlled trials (RCTs) that compared prophylactic TXA with placebo or no treatment in patients undergoing cesarean delivery. The primary outcome was postpartum hemorrhage. The need for a blood transfusion was the secondary outcome. We performed a meta-analysis using random-effects models to calculate odds ratios (OR) along with 95% confidence intervals (CI). We also performed an extensive literature review to investigate the cost-effectiveness for the prophylactic TXA at the time of cesarean.

Results: Data from 29 RCTs involving 22,003 participants was collected. The meta-analysis showed that prophylactic TXA in cesarean delivery reduces the risk of postpartum hemorrhage (RR

0.54; 95% CI 0.43-0.67; FI 84) and the need for blood transfusion (RR 0.45; 95% CI 0.34-0.60; FI 63) compared to placebo/no treatment.

Conclusion: Our findings indicate that the use of prophylactic TXA in cesarean delivery reduces the risk of postpartum hemorrhage and the need for blood transfusion. These results support the routine use of prophylactic TXA in cesarean deliveries for individuals at high risk of postpartum hemorrhage.



524 | Antenatal Corticosteroids Show Limited Benefit in Improving Neonatal Outcomes in Late-Preterm Fetuses: A Meta-Analysis

Jordan A. McKinney[1]; Gustavo Vilchez[2]; Lifeng Lin[3]; Luis Sanchez-Ramos[4]

[1]University of Florida College of Medicine, Gainesville, FL; [2]UTHealth Houston, Houston, TX; [3]University of Arizona, Tucson, AZ; [4]University of Florida College of Medicine, Jacksonville, FL

4:00 PM - 6:00 PM

Objective: Recent large-scale trials highlight the evolving landscape of antenatal corticosteroid (ACS) use in late preterm gestations (34–36 weeks), emphasizing the need for reassessment of current practices due to limited data on long-term psychiatric and neurodevelopmental outcomes. This systematic review and meta-analysis synthesize current evidence on the benefits and risks of ACS administration during this period.

Study Design: We conducted a search of electronic databases and gray literature from inception to February 1, 2024. We included randomized trials (RCTs) that assessed neonatal outcomes in newborns whose mothers received ACS during the late preterm period, compared to those whose mothers received a placebo or no treatment. Pooled unadjusted odds ratios (OR) with 95% confidence intervals (CI) were calculated using a random-effects model. Primary outcomes included the need for respiratory support and neonatal hypoglycemia, with other adverse neonatal outcomes as secondary. We also calculated fragility indices, 95% prediction intervals, and performed subgroup analyses to evaluate the robustness of the results.

Results: Data from 12 RCTs were included in the meta-analysis. ACS administration did not significantly reduce the likelihood of neonates requiring any form of respiratory support compared to placebo or no treatment (OR, 0.74; 95% CI, 0.54-1.02). Neonates exposed to ACS did not have a significantly increased chances of hypoglycemia (OR, 1.37; 95% CI, 0.99-1.90). However, ACS exposure was associated with reduced odds of requiring resuscitation at birth (OR, 0.54; 95% CI, 0.35-0.83) and a lower probability of developing respiratory distress syndrome (OR, 0.63; 95% CI, 0.40-0.99).

Conclusion: The findings of this meta-analysis suggest that late preterm ACS administration may offer limited benefits in preventing neonatal respiratory morbidity and improving other neonatal outcomes. Current evidence highlights the importance of shared decision-making in providing patient-centered care and underscores the need for further research into the efficacy and safety of late preterm ACS.

Pooled odds ratios and fragility indices of neonatal outcomes

Outcome	ACS Group, n/N (%)	Control Group, n/N (%)	OR (95% CI)	P-value	FI/rFI	Heterogeneity, I²
Need for any respiratory support	353/3,014 (11.7)	445/2,983 (14.9)	0.74 (0.54-1.02)	0.06	2	82.9%

525 | Maternal Immune Microenvironment in Fetal Congenital Heart Disease

Jordan R. Lowe[1]; Rajeev Aurora[1]; Dana Alshekhlee[1]; Megan Krupp[1]; Amanda Criebaum[2]; Niraj R. Chavan[3]

[1]Saint Louis University, St. Louis, MO; [2]Saint Louis University, St. Louis, MT; [3]Saint Louis University School of Medicine, St. Louis, MO

4:00 PM - 6:00 PM

Objective: This study was undertaken to evaluate the relationship between maternal immunological milieu (cytokines and chemokines) and complex fetal congenital heart disease (CHD).

Study Design: We performed a prospective, non-interventional, case-control study of pregnancies with complex fetal CHD (cases) at a single tertiary academic fetal care center matched to those with normal fetal cardiac anatomy (controls). Maternal serum was collected after CHD diagnosis based on fetal echocardiogram evaluation. Serum cytokine and chemokine levels were assessed using multiplex enzyme-linked immunosorbent assay (ELISA) and compared across groups. Demographic (age, race, parity, insurance) and clinical characteristics (obesity, diabetes, hypertension, connective tissue / thyroid disorder, In-vitro fertilization and history of CHD) were abstracted from electronic medical records and compared using student's t test and chi squared / Fisher's exact test for continuous and categorical data respectively. Statistical significance was set at $p < 0.05$.

Results: ELISA was performed for 23 cases with fetal CHD and 25 matched controls. The predominant CHD phenotypes were hypoplastic (left/right) heart syndrome (9/23, 39%), tetralogy of Fallot (4/23, 17%), and coarctation (3/23, 13%). Demographic and clinical characteristics were similar across both groups except gestational age at specimen collection [cases: 30.1±4.4 vs controls 27.5±2.8 weeks (mean ± SD), $p = 0.02$]. Multiplex analysis of

38 pro- and anti-inflammatory cytokines and chemokines was performed. Of those assayed, IL-2 was significantly overexpressed in cases vs control (positive fold change 1.58, p = 0.03). Other analytes–including IL-8 (p = 0.03) fractalkine (p = 0.02), GM-CSF (p = 0.01), IFNα2 (p = 0.04), IL-17A (p = 0.01), and MCP-1(p = 0.03) were significantly under expressed in cases compared to controls.

Conclusion: Significant differences were noted in immunoregulatory cytokine and chemokine expression among pregnancies with and without fetal CHD. Our findings suggest a predominant involvement of the Th1 cell line in fetal CHD pathogenesis.

Table 1: Cytokine/chemokine expression between cases and controls

	Case		Control			
Cytokine/Chemokine	Mean (±SD) (pg/mL)	Range (pg/mL)	Mean (±SD) (pg/mL)	Range (pg/mL)	Fold-change	p-value
Fractalkine	73.0 (6.9)	71.8 - 82.0	91.4 (18.3)	74.3 - 132.8	0.80	0.02
GM-CSF	59.4 (5.1)	52.7 - 65.8	68.1 (7.65)	58.0 - 73.5	0.87	0.01
IFNα2	61.7 (4.7)	55.0 - 68.8	69.0 (8.50)	62.8 - 81.3	0.89	0.04
IL-2	486.3 (193.3)	253.3 - 717.8	308.7 (112.7)	167.5 - 490.5	1.58	0.03
IL-8	2689.4 (1430.4)	1050.2-5681.8	4068.6 (1063.9)	1949.7 - 5522.7	0.66	0.03
IL-17A	63.7 (4.76)	57.3 - 71.8	71.2 (5.9)	63.7 - 80.2	0.90	0.01
MCP-1	66.7 (4.3)	59.8 - 72.7	73.0 (6.4)	63.0 - 80.33	0.91	0.03

526 | Association Between Antibiotic Regimen and Adverse Outcomes in Pregnancies Complicated by Chorioamnionitis

Jordan R. Lowe[1]; Niraj R. Chavan[2]; Audrey Brechter[1]; Tracy M. Tomlinson[1]

[1]Saint Louis University, St. Louis, MO; [2]Saint Louis University School of Medicine, St. Louis, MO

4:00 PM - 6:00 PM

Objective: We aimed to assess the association between antibiotic regimen choice subsequent to a change in institutional treatment guidelines for management of chorioamnionitis and adverse maternal and neonatal outcomes.

Study Design: Passive prospective, single center, cohort study of pregnancies complicated by chorioamnionitis treated with either intravenous ampicillin, gentamicin, ± clindamycin (AGC, 2010-2017) or piperacillin/tazobactam with clindamycin (PTC, 2017-2021). Acute chorioamnionitis was defined based on accepted clinical and histopathological criteria. We assessed the univariate associations between pregnancy characteristics and antibiotic regimen administered in addition to our composite adverse outcome: maternal sepsis, atonic postpartum hemorrhage, and/or neonatal sepsis with antibiotic administration prior to delivery, readmission for endometritis, wound infection, and/or maternal temperature of 99.5 for >24 hours after administration of first antibiotic dose. Factors with P < 0.2 on one or both univariate analyses were considered for incorporation into a multivariable model predictive of the primary outcome.

Results: Of 403 pregnancies, 211 were treated with AGC vs 192 with PTC regimens. Most characteristics were similar between antibiotic regimen groups, however women receiving AGC were younger and fewer had a public payor source. The 88 (22%) pregnancies with the primary outcome had a longer median duration of rupture of membranes prior to delivery (20.6 vs 14.3 hours, $P < 0.01$), more underwent cesarean delivery (CD) (36% vs 11%, $P < 0.0001$), and more received the AGC regimen (27 % vs 16%, P 0.01). Factors associated with the primary outcome on multivariable analysis include BMI >30, substance use, delivery < 37 weeks, CD, and treatment with AGC regimen (aOR 2.15, 95% CI 1.08-3.46). The 5-covariate model had an optimism-corrected bootstrapped (1000 replicates) AUROC of 0.76 (95% CI 0.69-0.80).

Conclusion: Treatment of intrapartum acute chorioamnionitis with the PTC regimen has the potential to lead to improved maternal and neonatal outcomes.

4:00 PM - 6:00 PM

Objective: To explore how various outpatient clinic types providing obstetric services manage care for birthing people with opioid and other substance use disorder (OUD/SUD) in pregnancy.

Study Design: Prenatal care providers from across the state of Michigan were identified through systematic web searches and snowball sampling. We conducted semi-structured surveys supported by Blue Cross Blue Shield of Michigan on routine prenatal care practices including management of high-risk conditions such as OUD/SUD. Specifically, we queried if clinics manage OUD/SUD in pregnancy, co-manage with another provider, or refer patients to other providers. We assessed practices across clinic attributes using chi-square tests.

Results: Of the 18 clinics across 8 out of 10 designated prosperity regions in Michigan who completed the survey, 7 clinics self-managed OUD/SUD, 6 clinics utilized co-management, and 5 clinics utilized referrals for specialized care. Federally Qualified Health Centers and outpatient clinics associated with hospitals were more likely to self-manage patients with OUD/SUD than private practices (p = 0.01). All respondents from private practices reported referring as their primary management strategy. Clinics with Epic or Cerner electronic health record (EHR) systems were more likely to manage or co-manage OUD/SUD than clinics with local EHR systems (p = 0.01). Management strategy did not differ by the clinic population size, state designated prosperity regions, or insurance limitations.

Conclusion: OUD/SUD is the leading cause of pregnancy associated mortality in the state of Michigan. Different practice patterns for managing birthing people with OUD/SUD warrant further exploration to define the most effective, efficient, and patient-centered models of care to improve outcomes for this population.

4:00 PM - 6:00 PM

Objective: To evaluate the association of prolonged induction of labor (IOL) on severe maternal morbidity (SMM) and severe neonatal morbidity (SNM) among nulliparous, term, singleton, vertex (NTSV) births.

Study Design: Retrospective cohort study across 70 hospitals using clinically abstracted data from the Obstetrics Initiative, a quality improvement initiative supported by Blue Cross Blue Shield of Michigan and Blue Care Network. We included NTSV IOL from 01/2022 to 12/2023. Prolonged IOL was defined as duration > 75th percentile for the cohort. Primary outcomes were SMM (Centers for Disease Control criteria) and SNM (unexpected

complications in term newborns, PC-06). Secondary outcomes were postpartum hemorrhage (PPH, blood loss > 1000 mL) and obstetric infection (chorioamnionitis or endometritis). A 1-to-1 propensity score-matched analysis was performed between those with and without prolonged IOL within a hospital using greedy nearest neighbor matching. Adjusted odds ratios (aOR) were calculated adjusting for hospital characteristics (teaching status, higher level neonatal care) to account for hospital-level clustering. Results were stratified by mode of delivery.

Results: Among 29,340 NTSV inductions, the 75th percentile for IOL length was 31 h 47 min. In unadjusted analyses, prolonged IOL was associated with SMM (4.5% vs. 3.0%, $p < 0.001$), SNM (6.1% vs. 4.0%, $p < 0.001$), cesarean (50% vs. 28%, $p < 0.001$), PPH (19% vs. 10%, $p < 0.001$), and obstetric infection (10% vs. 5.2%, $p < 0.001$). After propensity score matching (**Table**), prolonged IOL was associated with SMM (aOR 1.43, 95% CI 1.06-1.92) and SNM (aOR 1.37, 95% CI 1.07-1.75) among vaginal, but not cesarean births (**Figure**). Prolonged IOL was associated with increased risk of PPH for vaginal (aOR 1.70, 95% CI 1.40-2.07) and cesarean births (aOR 1.30, 95% CI 1.13-1.50). Similarly, prolonged IOL was associated with obstetric infection for vaginal (aOR 2.07, 95% CI 1.68-2.54) and cesarean births (aOR 1.48, 95% CI 1.20-1.81).

Conclusion: Prolonged IOL is associated with maternal and neonatal morbidity, particularly for vaginal births.

Figure. Forest plot of maternal and neonatal morbidity outcomes, stratified by delivery mode

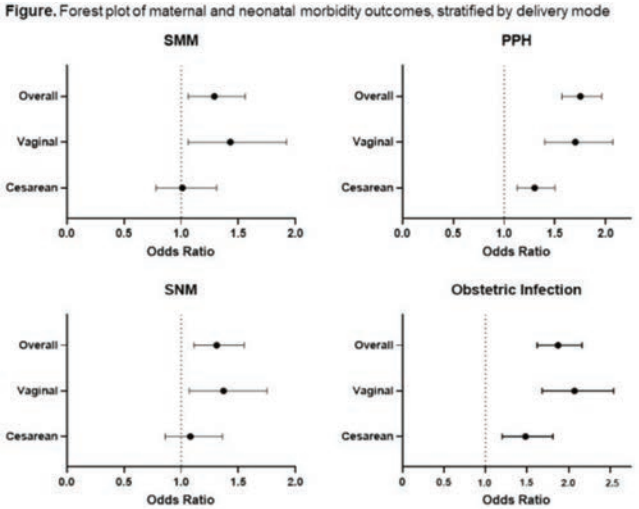

Table. Obstetric and demographic characteristics after propensity score match

Characteristic	Control (n = 5492)[1]	Prolonged IOL (n=5492)[1]	Difference[2]
Maternal age	28.0 (24.0, 32.0)	28.0 (24.0, 32.0)	-0.05
Admission BMI, kg/m2	35 (30, 40)	36 (31, 42)	-0.16
Admission cervical dilation, cm	1.0 (0.0-1.0)	0.5 (0.0-1.0)	0.16
Gestational diabetes	671 (12%)	765 (14%)	-0.05
Pregestational diabetes	101 (1.8%)	147 (2.7%)	-0.06

529 | Is There a Role for Maternal Oxygen for Fetal Resuscitation in High Risk Gestations?

Julia Burd[1]; Brianna Bradley[1]; Lori Atwood[1]; Nicole McCandless[1]; Paige Wilder[1]; Cookie Van[1]; Jeannie C. Kelly[2]; Antonina I. Frolova[3]; Alison G. Cahill[4]; Nandini Raghuraman[2]

4:00 PM - 6:00 PM

Objective: Level 1 evidence indicates that maternal oxygen (O2) administration is ineffective for fetal resuscitation in low-risk patient populations. We investigated whether intrapartum maternal O2 administration benefits patients at high risk of placental insufficiency in labor.

Study Design: This is a secondary analysis of two randomized controlled trials at a single center comparing O2 at 10L/min to room air (RA) in term patients with Category II fetal heart tracings in active labor. For this analysis, patients were categorized into high- and low- risk cohorts, with high-risk defined as those with fetal growth restriction, chronic hypertension, hypertensive disorders of pregnancy, tobacco use, and/or gestational diabetes requiring medications. The primary outcome was umbilical artery (UA) pH < 7.20. Multivariable logistic regression was used to account for potential confounders. Interaction testing was performed to assess effect modification.

Results: 320 patients were recruited across both trials, among which 265 had validated UA pH values and were included. There were no statistically significant demographic or delivery differences between those receiving O2 versus RA in the total cohort or among high-risk gestations (Table 1). There was no difference in rate of pH < 7.2 between O2 and RA groups in the entire cohort (28.9% vs 23.9%, aOR 1.27 (95% confidence interval 0.73, 2.21). In a stratified analysis assessing pH < 7.2 in high- and low-risk groups, O2 was not associated with a significant reduction in pH < 7.2 in either group, with no evidence of effect modification (p for interaction = 0.97)

Conclusion: This secondary analysis suggests that there is no differential benefit for intrapartum maternal O2 supplementation among high risk gestations. This supports ACOG's recommendation to deimplement this practice.

Table 1: Selected demographic characteristics and delivery outcomes in high risk cohort

	Oxygen *n=35*	Room air *n=29*	p

Wood Jr. Center for Fetal Diagnosis and Treatment at CHOP, Philadelphia, PA; [3]Richard D. Wood, Jr Center for Fetal Diagnosis and Treatment, The Children's Hospital of Philadelphia, Philadelphia, PA

4:00 PM - 6:00 PM

Objective: To determine whether recipient or donor velamentous cord insertion (VCI) is associated with perioperative complications and worse outcomes after laser for Twin-Twin Transfusion Syndrome (TTTS).

Study Design: Retrospective analysis of prospectively collected data from a monochorionic (MC) pregnancy registry at a Level III fetal care center. The records of patients with MC twins that underwent laser for TTTS between 1/2013-1/2024 were reviewed. Pregnancy characteristics and outcomes were then compared between patients that had recipient VCI versus recipient non-VCI as well as donor VCI versus donor non-VCI. Statistical analysis included Mann-Whitney U, chi-square, and Fisher's exact tests, as appropriate.

Results: 373 patients underwent laser over the study period including 77 (20.6%) with recipient VCI, 92 (24.7%) with donor VCI, and 18 (4.9%) with both recipient and donor VCI. Although postoperative outcomes were similar between groups (Tables 1-2), patients with recipient VCI had a lower estimated fetal weight (EFW) discordance (13 vs 18, p< 0.001), larger recipient deepest vertical pocket (10.4 vs 9.5, p = 0.004), later gestational age at laser (20.6 vs 19.6, p< 0.001) and lower need for amnioexchange (6.5 vs 17.9%, p = 0.014) compared to those with recipient non-VCI. On the contrary, patients with donor VCI had higher EFW discordance (23 vs 16, p< 0.001) and earlier gestational age at laser (19.3 vs 20.2, p = 0.001) compared to those with donor non-VCI.

Conclusion: In our cohort, although recipient and donor VCIs were associated with differences in baseline characteristics at laser, they were not associated with worse pregnancy outcomes.

531 | Impact of Second Trimester Vaginal Bleeding on Outcomes in Patients Undergoing Laser for TTTS

Juliana S. Gebb[1]; Alekhya Jampa[2]; Violetta Bakunina[1]; Desiree Fiorentino[2]; Christina Paidas Teefey[2]; Shelly Soni[2]; Edward R. Oliver[1]; Julie S. Moldenhauer[2]; Nahla Khalek[2]
[1]Richard D. Wood, Jr Center for Fetal Diagnosis and Treatment, Children's Hospital of Philadelphia, Philadelphia, PA; [2]Richard D. Wood Jr. Center for Fetal Diagnosis and Treatment at CHOP, Philadelphia, PA

4:00 PM - 6:00 PM

Objective: To determine whether second trimester vaginal bleeding is associated with perioperative complications and worse outcomes after laser for Twin-Twin Transfusion Syndrome (TTTS).

Study Design: Retrospective analysis of prospectively collected data from a monochorionic (MC) pregnancy registry at a Level III fetal care center. The records of patients with MC twins that underwent laser for TTTS between 1/2013-1/2024 were reviewed to determine the incidence of second trimester vaginal bleeding prior to the laser procedure. Those without clear documentation of bleeding were excluded. Pregnancy characteristics and outcomes were then compared between patients that had second trimester bleeding versus those that did not using Mann-Whitney U, chi-square, and Fisher's exact tests, as appropriate.

Results: Of 373 patients that underwent laser over the study period, 359 (96.2%) had clear documentation of whether they had second trimester vaginal bleeding including 30 (8.4%) that did and 329 (91.6%) that did not, respectively. Although demographic characteristics and survival outcomes were similar between groups, patients with second trimester vaginal bleeding had longer median operating room times (61 vs 50 minutes, p = 0.032), higher need for amnioexchange (33.3 vs 14.3%, p = 0.006), and higher incidence of preterm premature rupture of membranes within 1 week after the laser procedure (16.7 vs 3.3%, p = 0.001).

Conclusion: In our cohort, second trimester vaginal bleeding was associated with a higher incidence of perioperative complications surrounding laser for TTTS. This information can be utilized to guide future studies and in counseling patients prior to the laser procedure.

532 | Validation of the Delivery Trauma Scale for Evaluation of Emotional Burden Secondary to Birth

Katherine Lambert[1]; Irene A. Stafford[2]; Rafael Bravo Santos[3]; Alicia Lore[4]; Jennifer Tang[4]; Grace Ge[4]; Charles Green[4]
[1]University of Texas Medical Branch Galveston, Galveston, TX; [2]McGovern Medical School at UTHealth Houston, Houston, TX; [3]The University of Texas Health Science Center at Houston (UTHealth), Houston, TX; [4]University of Texas Health Science Center at Houston, Houston, TX

4:00 PM - 6:00 PM

Objective: The purpose of this study is to assess the validity of the Delivery Trauma Scale (revised City Birth Trauma Scale) in a U.S. population. The aim is to determine if this questionnaire is appropriate for use in assessing emotional burden secondary to birth (previously referred to as postpartum post-traumatic stress disorder) in the target population and to propose a new name for the questionnaire that better suits the birth and postpartum stress response.

Study Design: The study conducted is a methodological non-interventional study aimed at establishing the validity and reliability of a scale to assess delivery-related trauma. In the first stage of the study, face validity and content validity were established via expert review of the individual items on the questionnaire and subsequent content validity index analysis. The questionnaire was then administered to women in the postpartum period at

least 18 years of age who has delivered an infant within the past 12 months. The construct validity and reliability of the questionnaire was evaluated via statistical analysis using Cronbach's alpha coefficient and confirmatory factor analysis.

Results: The initial review of the questionnaire by experts resulted in a content validity index of 1. This can be interpreted as every question being appropriate for and relevant to the evaluation of emotional burden secondary to birth. The Cronbach's alpha coefficient for the questionnaire was calculated to be 0.898 (Bootstrap 95% CI 0.82-0.93) indicating a very high degree of internal consistency within the questionnaire. Confirmatory factor analysis showed statistical significance of all symptom categories ($p < 0.001$) with the exception of the category of negative symptoms (Table 1).

Conclusion: The Delivery Trauma Scale is validated for use in assessment of emotional burden secondary to birth in a U.S. population, though it should be used cautiously in evaluation for negative symptoms. Overall, the DTS is a promising tool that can be used in the postpartum period to identify patients who may benefit from additional mental health resources and support.

533 | Comparison of Fetal Abdominal Circumference References for the Prediction of Sga

Katherine Pressman[1]; Madeline Erwich[2]; Gustavo Vilchez[3]; Anthony O. Odibo[4]; Jose R. Duncan[5]

[1]Department of Obstetrics and Gynecology, University of South Florida, Tampa, FL; [2]University of South Florida, University of South Florida, FL; [3]UTHealth Houston, Houston, TX; [4]University of Missouri - Kansas City, Leawood, KS; [5]Department of Obstetrics and Gynecology, University of South Florida, Morsani College of Medicine, Tampa, FL

4:00 PM - 6:00 PM

Objective: Small for gestational age (SGA) infants are at increased risk for adverse neonatal outcomes. Fetal growth restriction (FGR) is defined as estimated fetal weight (EFW) < 10% or abdominal circumference (AC) < 10%. In the United States, the Hadlock reference is the most widely used method for estimating the fetal AC, however, several other methods exist including the INTERGROWTH-21st standard and the Chitty standard. We sought to compare the ability of three antenatal AC standards to predict SGA and adverse neonatal outcomes.

Study Design: In this secondary analysis of a cohort of singleton gestations that underwent fetal growth assessment between 26 and 36 weeks of gestation, fetuses with chromosomal or congenital malformations and those without delivery information were excluded. The Hadlock, Chitty, and INTERGROWTH-21st fetal AC methods' ability to detect SGA and adverse neonatal outcomes were compared by calculating the area under the receiver operating curve of clinical characteristics, sensitivity, specificity, positive predictive value, and negative predictive value.

Results: Of 1054 patients, 122 had an AC < 10% by Hadlock, 31 by Chitty, and 50 by INTERGROWTH-21st (Table 1). The Hadlock definition for AC < 10th was a better identifier for SGA. AUC and 95% CI for SGA for Hadlock, Chitty, and INTERGROWTH-21st were 0.73 [0.69 -0.77] vs 0.59 [0.55 -0.61] vs 0.62 [0.59-0.66]) ($p < 0.001$), respectively (Figure 1). All AC standards had suboptimal performance for the prediction of adverse neonatal outcomes.

Conclusion: The Hadlock AC < 10% was a better predictor than Chitty or INTERGROWTH-21st for SGA. All references

had a suboptimal ability to predict composite adverse neonatal outcomes. The Hadlock reference chart should be utilize in obstetrical practice.

Table 1

Test characteristic	Sensitivity	Specificity	PPV	NPV	AUC (95% CI)
Hadlock AC < 10 (122)					
Neonatal SGA (n=139)	0.50	0.94	0.57	0.93	0.73 (0.69 – 0.77)
Composite adverse neonatal outcome (n=221)	0.16	0.90	0.30	0.80	0.53 (0.50-0.56)
Chitty AC < 10 (31)					
Neonatal SGA	0.17	0.99	0.74	0.89	0.59 (0.55-0.61)
Composite adverse neonatal outcome	0.06	0.98	0.42	0.80	0.52 (0.50-0.54)
INTERGROWTH-21st AC < 10 (50)					
Neonatal SGA	0.26	0.99	0.72	0.90	0.62 (0.59-0.66)
Composite adverse neonatal outcome	0.08	0.96	0.34	0.80	0.52 (0.50-0.54)

534 | Screening Analysis for Autism Spectrum Disorders in FNAIT-Affected Children with and without Intra-Cranial Hemorrhage

Katherine A. Knightly[1]; Margaret H. McKelvy[2]; Eleanore A. McFarland[1]; Stephanie V. Volpe[3]; Thea D. Palmer[3]; Stacy Corke[3]; James B. Bussel[1]; Emilie L. Vander Haar[1]

[1]Weill Cornell Medicine, New York, NY; [2]Renaissance School of Medicine at Stony Brook University, New York, NY; [3]NAITbabies, Penzance, England

4:00 PM - 6:00 PM

Objective: Fetal/neonatal alloimmune thrombocytopenia (FNAIT) results from parental platelet antigen incompatibility. De Vos et al. identified increased neurodevelopmental issues in FNAIT-affected children without ICH. Members of NAITbabies suggested increased autism in FNAIT-affected children. Our survey evaluated neurodevelopmental issues (autism) in FNAIT-affected children, with and without ICH.

Study Design: A de-identified survey was distributed via Qualtrics to mothers in NAITbabies and assessed neurodevelopment using 4 age-specific autism screening scales to identify FNAIT-affected children at high risk: Q-CHAT-10 for 18-24 months; M-CHAT 2–4 yrs; AQ10-Child 4 -11; and AQ10-Adolescent for $\geq$12 with 20, 61, 173, and 70 children. Mothers reported if autism diagnosis was known prior to screening and responses were scored using algorithms.

Results: There were 324 children across the 4 age groups, 55 with ICH and 269 without. Autism diagnoses were more prevalent in the ICH groups across all ages, except the 18–24-mo group (no reported autism) see Table 1. Most notably, for 2-4yr olds, none of 49 children without ICH reported a diagnosis or screened at risk. Among 4-11yr-olds, screening showed 33% with ICH and 13% without ICH. The highest levels were in the 12+ age group, reporting 36.4% with ICH and 11.8% without ICH, with screening identifying autism risk in 45% with ICH and 37% without ICH. Overall, while the ICH group showed more high-risk screening compared to pre-reported diagnoses across the 3 older ages, screening totals never exceeded 45% of ICH cases. In the non-ICH groups, at-risk screening was seen in > 1/3 of the 12+ age group.

Conclusion: Autism and other neurodevelopmental issues become more apparent with age in ICH and non-ICH groups. The screening tool is NOT a specific diagnostic test for autism and identifies non-specific neurologic damage. Children affected by FNAIT, especially adolescents, are at risk for "autism" even without ICH. These results indicate the need for periodic screening for autism and neurologic damage in general in children affected by FNAIT, regardless of ICH occurrence.

Table 1. Summary of reported autism diagnosis, autism screening results and ICH status across 4 Age Groups

Age Group	ICH Status	Number of Children	Reported Autism Dx	Screened at Risk
18 – 24 months	ICH	5	0 (0%)	3 (60%)
	NO ICH	15	0 (0%)	0 (0%)
24 months – 4 years	ICH	12	1 (8%)	2 (16.6%)
	NO ICH	49	0 (0%)	0 (0%)
4 – 11 Years	ICH	27	2 (7.4%)	9 (33%)
	NO ICH	146	10 (6.8%)	23 (13%)
12+ Years	ICH	11	4 (36%)	5 (45%)
	NO ICH	59	7 (11.8%)	22 (37%)

535 | Racial Disparities in Severe Maternal Morbidity: Identifying Predictors for Designing Interventions and Risk Reduction

Katherine L. Chen[1]; Mary McLennan[2]; Jennifer A. Bickhaus[2]; Andrew Storm[1]; Samantha Levine[1]; Rachel Hsu[3]; Jason Doherty[1]; Niraj R. Chavan[1]

[1]Saint Louis University School of Medicine, St. Louis, MO; [2]Saint Louis University School of Medicine, Department of Obstetrics and Gynecology, St. Louis, MO; [3]Saint Louis University School of Medicine, St Louis, MO

4:00 PM - 6:00 PM

Objective: To evaluate differences in severe maternal morbidity (SMM) and identify key predictors of SMM among Non-Hispanic Black (NHB) versus Non-Hispanic White (NHW) pregnancies

Study Design: We undertook a retrospective cohort study of all patients receiving prenatal care and delivering at a single academic tertiary medical center from 2017–2013. The cohort was divided based on self-identified race into 2 subgroups - i.e. NHB vs NHW. Our primary outcome was SMM as defined by the Centers for Disease Control (CDC). Demographic and clinical characteristics were abstracted from electronic records and compared across study groups using Student's T test and chi2/Fischer's exact test for continuous and categorical data, respectively. The Kruskal Wallis test was used to compare nonparametric data. Multivariable regression analyses were used to identify the key predictors of SMM in each cohort.

Results: Of the 6403 patients, 4200 (66%) identified as NHB, while 2203 (34%) identified as NHW. NHB patients were significantly younger (p< .01), had governmental insurance (p< .01) with a higher BMI (p< .01), and presented at later gestational

age at prenatal care initiation (p< .01). Overall, 417/6403 (7%) of the cohort had a SMM event with a higher incidence of SMM among NHB patients as compared to their NHW counterparts [307/4200 (7%) vs 110/2203 (5%), p< .05]. Rates of individual SMM events were similar across both groups except for higher rates of sickle cell disease with crisis (p = .02) and hemorrhage (p< .01) in NHB Patients. Among NHB patients–gestational hypertension [aOR: 1.61 (1.10–2.330], cesarean delivery [aOR: 2.82 (2.17–3.67)] and gestational age at delivery [aOR:1.87 (1.13–2.99)] were identified as key predictors of SMM. In NHW patients–gestational hypertension [aOR: 3.73 (1.88–7.16) and cesarean delivery [aOR: 3.71 (2.36–5.94)] had the highest impact on SMM risk.

Conclusion: Key clinical predictors of SMM were identified in our study with a differential risk impact among NHB and NHW patients as an opportunity for risk reduction and maternal mortality prevention.

536 | Epidural Placement Early in Cervical Ripening: is There a Negative Impact?

Katie Brow[1]; Nandini Raghuraman[2]; Alison G. Cahill[3]; Candice Woolfolk[4]; Sydney M. Thayer[5]; Jeannie C. Kelly[2]; Antonina I. Frolova[1]; Julia Burd[5]

[1]Washington University School of Medicine, St. Louis, MO; [2]Washington University School of Medicine in St. Louis, St. Louis, MO; [3]Dell Medical School Health Transformation Research Institute, Dell Medical School, The University of Texas at Austin, Austin, TX; [4]Washington University School of Medicine in Saint Louis, St. Louis, MO; [5]Washington University in St. Louis, St. Louis, MO

4:00 PM - 6:00 PM

Objective: National guidelines recommend epidural anesthesia be offered at any point in labor. At our institution, patients undergoing induction of labor (IOL) often request "early" epidurals during cervical ripening or prior to mechanical ripening. Our objective was to evaluate if early epidural placement during IOL impacts labor duration.

Study Design: This is a secondary analysis of a prospective cohort study of term patients from a single institution. We included all patients who presented for IOL and received either a prostaglandin or mechanical cervical ripening. Patients with history of cesarean and those without an epidural were excluded. Patients were divided into two groups based on the exam prior to epidural placement: early epidural (EE) if < 2 cm and late epidural (LE) if ≥ 2 cm. Analysis was stratified by parity. The primary outcome was length of IOL, defined as interval between first cervical exam and delivery. Secondary outcomes were mode of delivery, intraamniotic infection, 3rd/4th degree lacerations, and neonatal outcomes. Time to event analysis was performed and the log-rank test was used to compare the primary outcome between groups. Cox proportional hazards modeling was used to adjust for potential confounders.

Results: 1704 patients were included with 816 (48%) in the EE group and 888 (52%) in the LE group. Median Bishop score on admission was 1 for both groups. IOL duration was significantly longer in patients with EE (22.7 hours vs 19.9 hours in nulliparous and 15.9 hours vs 14.8 hours in multiparous, both P< 0.001) (Figure). There was no difference in second stage duration between groups. After adjusting for confounders, there was no association between timing of epidural and rates of cesarean delivery, operative vaginal delivery, intraamniotic infection, 3rd/4th degree lacerations, or neonatal outcomes (Table).

Conclusion: Early epidural placement < 2 cm is associated with a statistically longer total duration of IOL with an absolute difference of no more than 2-3 hours. Early epidural is not associated with adverse maternal or neonatal outcomes or a longer second stage of labor.

Figure: Labor duration in nulliparous and multiparous patients in those with early epidural placement vs late epidural placement

537 | Maternal Covid-19 and Placental Expression of Senescence-Associated Secretory Phenotype Genes

Kimen S. Balhotra[1]; Katherine B. Le[2]; Rachel Keuls[3]; Natalie N. Lanners[2]; Tina Findley[2]; Ron Parchem[3]; Jacqueline G. Parchem[2]

[1]McGovern Medical School at UTHealth, Houston, TX; [2]McGovern Medical School at UTHealth Houston, Houston, TX; [3]Baylor College of Medicine, Houston, TX

4:00 PM - 6:00 PM

Objective: Maternal COVID-19 increases the risk for adverse pregnancy outcomes related to placental dysfunction, including preeclampsia and stillbirth, however, the biologic basis remains underexplored. Based on recent work showing the association between placental senescence and preeclampsia, we hypothesized that senescence-associated secretory phenotype (SASP) genes are dysregulated in COVID-19 placentas.

Study Design: We analyzed a single-nucleus RNA sequencing dataset of placentas from symptomatic COVID-19 patients at birth (n = 4) and gestational age-matched controls (n = 4) to characterize the response of different trophoblast populations to COVID-induced stress. Differentially expressed gene (DEGs) in COVID-19 v. controls were identified for villous syncytiotrophoblasts (STB), membrane extravillous trophoblasts (EVT-M), and membrane

cytotrophoblasts (CTB-M) using the Seurat (v4.3.0) in R given that these populations are likely sources of circulating placental proteins. Our analysis focused on DEGs belonging to a previously defined set of SASP genes.

Results: The baseline characteristics for COVID-19 patients and control groups were similar for maternal age (26 vs 28 years-old), gestational age (36 vs 38 weeks) and BMI (37 vs 34 kg/ m2). DEG analysis showed upregulation of distinct SASP pathway genes in STB, EVT-M, and CTB-M populations. Follistatin-like 3 (FSTL3) was significantly upregulated in COVID-19 samples across all cell populations, but predominantly expressed in EVT-M and CTB-M($P \leq 0.0001$)(Figure 1). In contrast, activin A (INHBA) was only upregulated in the STB and EVT-M populations, but predominantly expressed in STBs ($P \leq 0.0001$)(Figure 2).

Conclusion: Compared with control placentas, trophoblast populations from COVID-19 positive patients showed an increased expression of senescence genes. Our data reveals cell type-specific expression of senescence genes, suggesting that SASP proteins in the maternal circulation have different sources. This increased expression of senescence genes among COVID-19 positive patients may provide potential insight into the link between COVID-19 and preeclampsia.

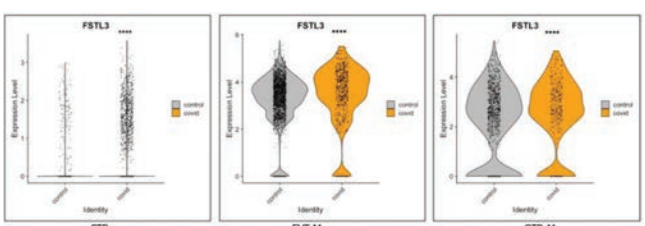

Figure 2: Violin plot of the composite fold change in relative gene expression of the significant expressed SASP proteins FSTL3 in different trophoblast populations from COVID-19 patients and controls. **** P ≤ 0.0001

538 | The Association Between Hepatitis B Virus Infection During Pregnancy and Risk of Primary Cesarean Delivery

Kriti N. Vedhanayagam[1]; Stephen Contag[2]; Ilish Gedestad[3]; Sergio Karageuzian[4]; Rang Kim[5]; Synia Chunn[1]; Megan Marquez[5]; Ruofan Yao[1]

[1]Loma Linda University School of Medicine, Loma Linda, CA; [2]University of Minnesota, Minneapolis, MN; [3]Loma Linda University School of Medicine, Redlands, CA; [4]Loma Linda University School of Medicine, Pasadena, CA; [5]Loma Linda University School of Medicine, Loma Linda University, CA

4:00 PM - 6:00 PM

Objective: To investigate the association between hepatitis B virus (HBV) status and the likelihood of primary cesarean section (C-section) delivery compared to vaginal delivery.

Study Design: This retrospective cohort study used data from the National Center for Health Statistics Vital Statistics database. The cohort linked birth and infant death data files from 2015 to 2021 was used for this study. The study included all births in the United States during the study period, with known HBV status and without prior Cesarean Delivery (CD). The outcome of interest was mode of delivery. Univariate analysis was performed to determine the association between HBV and CD rate. Multivariate logistic regression was then performed to estimate the effect of HBV status on CD adjusting for potential confounding variables. Interaction analysis was then performed to determine if the effect of HBV on CD is modified by race and obesity.

Results: The rate of CD was higher in pregnancies complicated by HBV infection compared to uninfected individuals (22.4% vs 21.9%, $p = 0.004$).The effect of HBV on CD is modified by both race and obesity. Specifically, HBV infection increases risk of primary CD (aOR 1.39; 95% CI [1.25-1.54]). Compared to White, both Black and Asian race demonstrated a protective effect on primary CS among individuals with HBV infection (aOR 0.93; 95% CI [0.87 - 0.99] and (aOR 0.74; 95% CI [0.85-0.79]). Compared to underweight group, individuals in the higher weight groups complicated by HBV infection also demonstrated a protective effect on primary CD.

Conclusion: This study demonstrated that HBV infection increased the risk of primary CD in otherwise uncomplicated pregnancies. However, in pregnancies complicated by racial categories and high BMI groups with already increased risk of primary CD, HBV infection demonstrated a protective effect.

HBV	C-section rate	Vaginal Delivery
Positive	4,880,527 (21.86%)	17,442,141 (78.14%)
Negative	10,296 (22.43%)	35,616 (77.57%)

539 | How Much is Enough? Incomplete Treatment Course of Intravenous Iron to Prevent Postpartum Blood Transfusions

Lama R. Noureddine[1]; Miranda Hawthorne[1]; Chavi Eve Karkowsky[2]; Jessica Greenberg[3]; Lisa N. Gittens-Williams[1]; Joseph J. Apuzzio[1]; Shauna F. Williams[1]

[1]Rutgers New Jersey Medical School, Newark, NJ; [2]Rutgers New Jersey Medical School, Rutgers NJMS, NJ; [3]Rutgers New Jersey Medical School, South Orange, NJ

4:00 PM - 6:00 PM

Objective: To compare the benefit of partial and full doses of IV iron treatment in reducing postpartum blood transfusions.

Study Design: This was a retrospective cohort study of patients with Iron Deficiency Anemia (IDA) who presented for prenatal care at a tertiary urban academic center from June 2020 to June 2024. Women were included if they received IV iron antepartum and excluded if they had contraindications to blood transfusion. The primary outcome was postpartum blood transfusion. Secondary outcomes included hemoglobin (Hg) levels at admission and percent change in Hg (pre-treatment to admission). Fisher's exact, chi square, parametric and non-parametric tests were used. Median (interquartile range) and mean +/- standard deviation shown.

Results: Among 224 patients with IDA, 116(52%) completed the calculated IV iron dose based on the iron deficit (Full dose, Group 1) and 108(48%) initiated, but did not complete the prescribed treatment (Partial dose, Group 2). The median dose of IV iron was 900 mg (400-1800) in Group 1 and 400 mg (200-1200) in Group 2 ($p< 0.0001$). Pre-treatment Hg was similar between Groups 1 and 2 (8.7 +/- 0.89 vs 8.6 g/dL +/- 0.92 respectively, $p = 0.71$). However, Group 2 had more short interval pregnancies [8(7%) vs 24(22%) in Groups 1 and 2, $p = 0.001$], later gestational age at treatment initiation [median 34(20-38) vs 36 weeks (24-40), $p< 0.0001$] and a higher median delivery blood loss [285(200-543) vs 361 mL(200-612), $p = 0.04$]. There was no difference in postpartum transfusions between Groups 1 and 2 [8(7%) vs 11(10%), $p = 0.33$]. However, Group 1 had a higher mean admission Hg than Group 2 (10.8 +/- 0.92 vs 9.7 g/dL +/- 0.98, $p< 0.0001$), a higher median percent increase in Hg [25% (12-36) vs 11% (4-21), $p< 0.0001$], and a higher mean postpartum day 1 Hg (9.8 +/- 1.18 vs 8.3 +/- 1.19 g/dL, $p< 0.0001$).

Conclusion: A full course of IV iron improved Hg response and admission Hg compared to partial course but did not significantly decrease postpartum blood transfusions. Partial treatment still benefits pregnant patients with anemia, even when optimal treatment cannot be completed.

540 | Creating Optimal Pain Management FOR Tailoring (COMFORT) Guidelines for Pain Management: Postpartum Recommendations

Alex Peahl[1]; Laura Peyton Ellis[2]; Courtney Townsel[3]; Lisa Kane Low[4]; Jennifer Waljee[4]; Mark Bicket[4]; Dana Feldman[5]; Bryan L. Aaron[4]; Michelle Moniz[4]

[1]Michigan Medicine, Ann Arbor, MI; [2]UConn Health Obstetrics and Gynecology, Farmington, CT; [3]University of Maryland Department of Obstetrics, Gynecology and Reproductive Sciences, Baltimore, MD; [4]University of Michigan, Ann Arbor, MI; [5]Wake Forest University, Winston-Salem, NC

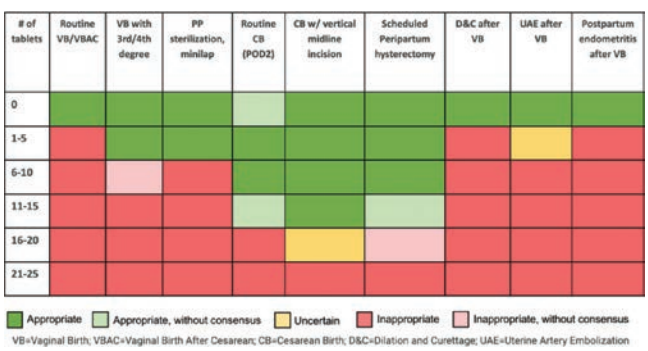
4:00 PM - 6:00 PM

Objective: To develop a new clinical practice guideline for postpartum pain management that promotes opioid stewardship, patient-centeredness, and health equity.

Study Design: We developed the COMFORT (Creating Optimal Pain Management FOR Tailoring pain management after surgery in pregnancy and childbirth) guideline using a rigorous, evidence-based, eDelphi process, the RAND-UCLA Appropriateness Method. After a systematic review, we identified 19 procedures, 6 populations, and 5 postpartum pain management strategies. Interprofessional panelists (n = 17) and public members (n = 3) rated the appropriateness of pain management strategies in 3 eDelphi rounds. Two consensus conferences were held between rounds with panelists and public members to resolve discrepancies and ensure public contributions. Quantitative ratings were assessed using basic statistics and the RAM definitions for consensus. Key findings from the panel discussion were summarized using a qualitative content analysis and matched to quantitative findings.

Results: Key panel recommendations for postpartum patients include: 1) provide robust patient education on postpartum pain management and opioid risk-reduction; 2) use scheduled non-opioid medications (e.g., acetaminophen, Non-steroidal Anti-Inflammatory Drugs); 3) utilize non-pharmacologic strategies as additive pain management; 4) utilize alternative inpatient strategies for individuals with complex pain; 5a) use judicious opioid prescribing as needed; 5b) utilize tailored prescription benchmarks to determine appropriate opioid prescription sizes for shared decision making (Table 1).

Conclusion: New guidelines for pain management after surgery in pregnancy and after childbirth may standardize care, reduce risks of opioid prescribing, and improve patient-centeredness and equity.



541 | Preconception and First Trimester Blood Pressure: Risks of Hypertensive Disorders in Pregnancy Using AHA Guidelines

4:00 PM - 6:00 PM

Objective: Hypertensive disorders during pregnancy (HDP) significantly contribute to maternal morbidity. We aimed to assess the risk of HDP according to the 2017 American Heart Association AHA criteria based on preconception and early pregnancy blood pressure (BP) measurements.

Study Design: This retrospective study utilized the Clalit Health Services database, and included all singleton pregnancies from 2010 to 2023 with at least one BP measurement within one year before conception until 13 weeks of gestation. Participants were classified into three groups according to the AHA guidelines:normotensive, elevated BP (systolic BP [SBP] of 120-129

mm Hg with diastolic BP [DBP] < 80 mm Hg), and stage 1 hypertension (SBP of 130-139 mm Hg or DBP of 80-89 mm Hg). Patients with chronic hypertension were excluded. Maternal, neonatal, and composite hypertensive outcomes were compared between the groups. Subgroup analyses were conducted for patients with obesity (BMI ≥ 30) and those with pre-gestational diabetes mellitus (PGDM). A logistic regression model adjusted for maternal age, aspirin use, BMI, and PGDM was utilized.

Results: The study included 57,524 women. Of these, 46,924 (81.6%) were normotensive, 6,636 (11.5%) had elevated BP, and 3,964 (6.9%) had stage 1 hypertension. The incidence of composite hypertensive adverse outcome increased in a dose-response manner: 2.8% in the normotensive group, 6.4% in the elevated BP group, and 8.2% in the stage 1 hypertension group (p< 0.001). Neonatal NICU admissions were more common in the elevated BP and stage 1 hypertension groups compared to the normotensive group (p< 0.001). Logistic regression revealed that elevated BP, stage 1 hypertension, maternal age ≥35 years, and PGDM were independently associated with increased odds of composite hypertensive outcome: OR 2.22 (95% CI 1.94-2.55), OR 2.75 (95% CI 2.34-3.24), OR 1.88 (95% CI 1.57-2.27), and OR 1.55 (95% CI 1.29-1.86), respectively (p< 0.001 for all).

Conclusion: Preconceptional and first-trimester elevated BP and stage 1 hypertension, as defined by the AHA guidelines, are associated with an increased risk of maternal HDP.

542 | Standardized Clinical Assessment and Management Plan Improves Neonatal Outcomes in prenatally suspected Congenital Heart Disease

Lior Kashani Ligumsky; Angela Desmond; Guadalupe Martinez; Joanne Newens; Deborah Krakow; Gary Satou; Yalda Afshar
University of California, Los Angeles, Los Angeles, CA

4:00 PM - 6:00 PM

Objective: Prenatal diagnosis of congenital heart disease (CHD) has been associated with early-term and cesarean births. We implemented a standardized clinical assessment and management plan (SCAMP) aimed at reducing early-term and cesarean births. We aimed to evaluate the SCAMP's impact on neonatal outcomes focusing on survival at discharge rate and birthweight in pregnancies complicated by fetal CHD.

Study Design: Neonatal data from historical and intervention cohorts before and after SCAMP implementation were analyzed. Neonates with complete data on birth mode, birthweight, and survival at discharge were included. The primary outcome was survival at discharge. Secondary outcomes included birthweight and survival differences based on birth mode (vaginal birth, IOL, and cesarean birth). Statistical comparisons used t-tests for continuous and chi-square tests for categorical variables.

Results: A total of 424 pregnancies were included in the study, comprising 177 historical pregnancies and 247 intervention cohort pregnancies. Mean birthweight increased from 2808g in the historical cohort to 2967g in the post-SCAMP intervention cohort ($p = 0.02$). The overall survival rate to discharge was higher in the intervention cohort (91.1%) compared to the historical cohort (83.1%) ($p = 0.012$). In the cesarean birth group, survival rates were higher in the intervention cohort (89.1%) compared to the historical cohort (76.1%) ($p = 0.02$). There were no significant differences in survival rates for induction of labor and spontaneous births between the historical and intervention cohorts ($p = 0.8$ and $p = 0.1$, respectively).

Conclusion: The implementation of a SCAMP focused on reducing early-term and cesarean birth significantly improved neonatal

outcomes, notably increasing neonates with CHD survival rates at discharge. This improvement was most pronounced in cesarean births. Clinical pathways focused on the prenatal course of pregnancies affected by CHD improve neonatal outcomes.

	Historical (n=177)	Intervention (n=247)	P value
Neonatal birth wight (g)	2808	2967	0.02
Survival at discharge n(%)	147(83.1)	225(91.1)	0.01

Survival at discharge -Induction of labor n,total(%)	37/42(88.1)	54/56(96.4)	0.11
Survival at discharge -Caesarean Birth n,total(%)	51/67(76.1)	90/101(89.1)	0.02

543 | Predictive Modeling for Antenatal Shoulder Dystocia Risk

Lior Heresco[1]; Noa Levy[2]; Omer Todress[2]; Tal Biron-Shental[3]; Omer Weitzner[1]
[1]Meir Medical Center, Kfar Saba, HaMerkaz; [2]Department of Biomedical Engineering, Faculty of Engineering, Tel Aviv University, Israel, Tel Aviv, Tel Aviv; [3]Meir Medical Center, Meir Medical Center, HaMerkaz

4:00 PM - 6:00 PM

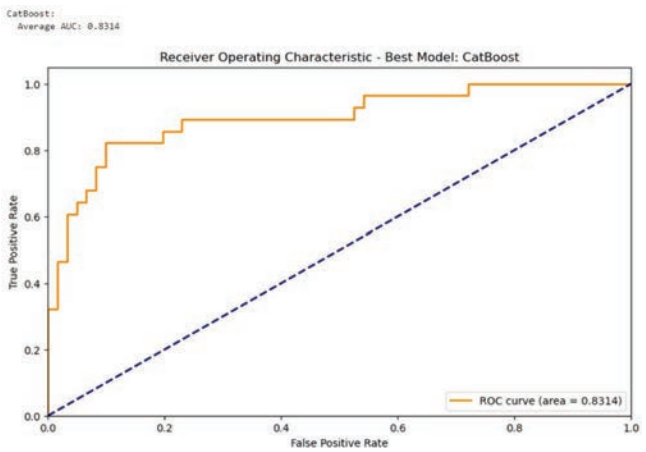
Objective: Shoulder dystocia (SD) represents a significant complication during delivery, posing substantial risks. Despite its challenging predictability, assessing individual risk is crucial for informed counseling on optimal delivery methods. The objective of this study was to develop and validate a model prediction system for SD using fetal ultrasound and maternal data.

Study Design: Data was retrospectively obtained from deliveries in Meir Hospital between 2014 and 2023.The inclusion criteria were singleton pregnancies and vaginal deliveries. The features included in the tested models were those that had a small percentage of null values in the SD cases. In cases of null values in normally distributed features, we completed the data with mean values. The final model parameters included maternal age, BMI, obstetric history, maternal height, gestational or pre-gestational diabetes, gestational age at delivery, clinical and sonographic estimated fetal weight, fetal gender, and mode of delivery (vaginal or operative vaginal). To address imbalanced data, we used repeated random sampling of the negative cases. The training and test sets were split in a 70:30 ratio and standardized.

Several classifiers, including logistic regression, decision tree, random forest, support vector machine, XGBoost, and CatBoost, were evaluated using cross-validation and area under the ROC Curve (AUC). We chose the model based on the highest mean AUC. The analysis was conducted in Python using Pandas, Scikit-learn, Numpy, and visualization libraries.

Results: A total of 51,628 deliveries were analyzed, including 94 SD cases. SD patients had higher rates of diabetes (13% vs. 4.8%) and obesity (23% vs. 5%) compared to non-SD patients, and higher mean neonatal birthweight (3751 g vs. 3287 g). The highest mean AUC was achieved using the CatBoost model, which demonstrated high discriminatory ability in predicting SD (AUC = 0.83).

Conclusion: The SD prediction model presented in this study serves as a valuable adjunct for clinical decision-making regarding the appropriate mode of delivery.



544 | Do Maternal Attributes Including Clinical Risk and Antenatal Services Predict Postpartum Care by 6 Months?

Lisbet S. Lundsberg; Caitlin Partridge; Olivia Paoletti; Jennifer F. Culhane
Yale School of Medicine, New Haven, CT

4:00 PM - 6:00 PM

Objective: Adequate postpartum care (PPC) is critical to overall maternal health, however rates of PPC utilization in the United States are suboptimal. To better understand factors related PPC engagement, we sought to broadly examine maternal attributes including clinical risk, antenatal services, labor and delivery outcomes, and their association with 6-month PPC.

Study Design: Retrospective cohort analysis of patients delivering in a hospital system 2013-2022 with at least 1 documented prenatal care (PNC) visit. We identified PPC visits by examining electronic medical record (EMR) data for ICD codes for any PPC engagement within 6 months across all specialty departments, and traditional PPC defined by ICD codes Z39 and V24. Patient socio-demographics, antenatal clinical diagnoses, measures of PNC service utilization, and maternal/neonatal outcomes were examined by PPC engagement using chi-square or ANOVA. Multivariable logistic regression was performed including all variables $p < 0.05$ in bivariate tests. Adjusted odds ratios (aOR) and 95% CI are presented in Table 1.

Results: Among 60,933 deliveries, 90.3% and 78.3% had any PPC and traditional PPC, respectively. PPC engagement at 6 months varied by many patient attributes. Following multivariable adjustment, significantly reduced odds of any PPC and traditional PPC were observed among patients with the following attributes: multiparous, smoking, single relationship status, public insurance, gestational diabetes (GDM), and substance use disorder (SUD). In contrast, significantly increased likelihood of PPC was demonstrated among patients with planned or intrapartum cesarean, preterm birth, chronic hypertension (cHTN), depres-

sion or anxiety, influenza vaccination, and higher number of PNC visits.

Conclusion: Although the overall rate of PPC is high in this diverse cohort, patients with disparity-related risk demonstrate significantly lower rates of PPC. These data can inform targeted antenatal and delivery admission encounter interventions to optimize PPC with the goal of improving maternal health.

545 | Patient-Reported Unmet Health-Related Social Needs in Patients with and Without Gestational Diabetes

Logan Mauney[1]; Jonathan Y. Siden[2]; Kaitlyn E. James[1]; Chengbo Zeng[3]; Camille E. Powe[1]; Sarah N. Bernstein[4]

[1]Massachusetts General Hospital, Boston, MA; [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA; [3]Brigham & Women's Hospital, Boston, MA; [4]Massachusetts General Hospital, Division of Maternal Fetal Medicine, Boston, MA

4:00 PM - 6:00 PM

Objective: Gestational diabetes (GDM) is a common pregnancy complication associated with social determinants of health (SDOH) including economic stability, social and community context and neighborhood environment. Little is known regarding the impact of patient-level manifestations of SDOH, termed unmet health-related social needs (HRSNs), on GDM. We sought to characterize the impact of patient-reported HRSNs on GDM.

Study Design: Retrospective cohort study of pregnant patients that completed a validated electronic screening tool at least one time for HRSNs during pregnancy in a regional health-care system from 5/2020 to 3/2024. Patients with pre-existing diabetes or multiple gestation were excluded. HRSNs were compared between patients with and without GDM by ICD-10 codes at delivery. Generalized estimating equations were generated to determine adjusted odds ratios (aOR) for the association between HRSNs and GDM, adjusting for patient characteristics known to be associated with GDM.

Results: 2,024 patients met inclusion criteria, of whom 174 (8.6%) had GDM. The GDM cohort was more likely to be older, Black or Asian, multiparous, and to have obesity. Compared to patients without GDM, patients with GDM were more likely to have food insecurity (8.6% vs. 3%) and transportation barriers (13.8% vs. 8.1). 77 patients with GDM (44.3%, p = 0.03) had ≥ 1 HRSN in any domain. In logistic regression models controlling for patient characteristics, transportation barriers (aOR 4.3, 95% CI 2.18-8.50), food insecurity (aOR 1.95, 95% CI 1.14-3.34), and ≥ 3 HRSN domains (aOR 1.93, 95% CI 1.19-3.13) were significantly associated with GDM (Table 1). Other HRSNs represented in the cohort (Figure 1) were not significantly associated with risk of GDM (Table 1).

Conclusion: Multiple HRSNs are risk factors for GDM, and the effect size of transportation barriers was on par with that of obesity. Further research is needed to understand the impact of these HRSNs on the development of GDM so appropriate primary prevention tools on a patient- and community-level can be developed to optimize birth outcomes.

Table 1 - Patient characteristics and odds of gestational diabetes among those with health-related social needs

546 | Influence of Preconception and Pregnancy Exposure to Marijuana on Adverse Perinatal Outcomes

Madison Blount[1]; Neil B. Patel[2]; Emily A. DeFranco[3]

[1]The University of Kentucky College of Medicine, Lexington, KY; [2]Ascension Sacred Heart - Pensacola, Pensacola, FL; [3]Department of Obstetrics and Gynecology, University of Kentucky, Lexington, KY

4:00 PM - 6:00 PM

Objective: Marijuana consumption during pregnancy has been associated with adverse perinatal outcomes. However, whether exposure during the preconception period also poses a risk is unknown.

Study Design: Retrospective cohort utilizing data from PRAMS Phase 8 Core Questionnaire and the Marijuana & Prescription Drug Supplement from 2017-2021. The association between marijuana use 3 months prior to pregnancy, during pregnancy, and during both periods and pregnancy outcomes were observed. The primary outcome was fetal growth restriction (FGR) < 10%ile. Other outcomes examined were severe FGR, preterm birth <37 weeks, low birth weight, infant mortality, and NICU admission. Generalized linear modeling estimated the associations while adjusting for coexisting risks of maternal race, tobacco use, education status, obesity, and parity.

Results: Of 17,882 postpartum individuals surveyed, 88.7% reported no marijuana consumption, 5.4% reported use prior to pregnancy only, 0.1% during pregnancy only, and 5.9% preconception and during pregnancy. Marijuana consumption prior to and during pregnancy was associated with a 30% increased risk of FGR and severe FGR, even after accounting for tobacco use and other risk factors (Table 2). The rate of infant mortality also increased but was not statistically significant. Cessation of marijuana use after the preconception period was not associated with an increased risk of adverse perinatal outcomes.

Conclusion: Marijuana use before and during pregnancy is associated with increased risk of adverse perinatal outcomes, even after adjusting for confounding risks. However, exposure during only the pregestational period was not. This highlights the importance of counseling patients regarding the risks of marijuana use during pregnancy and the importance of cessation

547 | Temporal Trends in Gonorrhea and Chlamydia Infections During Pregnancy: 2013-2023

Marcia Des Jardin[1]; Christina T. Blanchard[2]; Victoria C. Jauk[1]; Lynda Ugwu[1]; Jodie A. Dionne[1]; Akila Subramaniam[2]
[1]University of Alabama at Birmingham, Birmingham, AL; [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL

4:00 PM - 6:00 PM

Objective: Gonorrhea (GC) and chlamydia (CT) infection during pregnancy is increasing nationally. We evaluated the incidence of GC and/or CT infection in pregnancy as well as risk factors for infection over the past 11 years at single center.

Study Design: Retrospective study of all pregnant patients who delivered between 2013-2023 at large urban tertiary care center in Alabama. The primary outcome was the incidence of infection with GC, CT, or both (GC/CT co-infection) identified during pregnancy by nucleic acid amplification testing; secondary outcomes included rates of treatment, time to treatment, and reinfection rates. Outcomes were compared across the study period with linear regression to assess trends. We secondarily compared baseline characteristics between individuals with and without GC and/or CT infection using multivariable logistic regression. Tests of heterogeneity (interaction p-values) were conducted by year to assess different effects in these risk factors over the study period.

Results: Over the study period, 40,139 patients were analyzed (no exclusions) - 1.8% had GC, 6.6% CT, and 0.8% both. Rates of infection (GC, CT, and both) significantly decreased over time (Figure, all $p < 0.001$). Rates of treatment were high (range 58.4%-71.7%), reinfection low (6.2%-12.9%), and did not demonstrate trends across the study period ($p > 0.05$). Of note, time to treatment significantly decreased over the study period from a median of 5 days (IQR 0-10) to 2 days (0-4) ($p < 0.001$). Multiple risk factors were associated with infection in multivariable analyses (Table). However, over time, there were only increasing risks of infection based on non-White/Black/Hispanic race/ethnicity (p-interaction = 0.02) and government insurance (p-interaction = 0.003).

Conclusion: Contrary to national reports in pregnant individuals, at our urban institution, we describe decreasing rates of GC and/or CT infection. Risk factors in our population are consistent with the literature. Further larger studies to confirm or refute our findings, and identify risk factors in populations with rising infection rates should be performed.

Figure: Rates of Gonorrhea (yellow), Chlamydia (blue), and co-infection with both GC/CT (purple) annually in pregnant individuals from 2013-2023 in a single center in Alabama

548 | Association of Perinatal Inflammation and Breastfeeding Intensity

Margaret S. Butler[1]; Lauren S. Keenan-Devlin[2]; Ann EB Borders[3]; Britney P. Smart[4]; Janedelie Romero[5]
[1]Center of Excellence in Maternal and Child Health, Chicago, IL; [2]Endeavor Health/ University of Chicago Pritzker School of Medicine, Endeavor Health, IL; [3]Endeavor Health, Evanston Hospital, Evanston, IL; [4]Sinai Chicago, Chicago, IL; [5]Endeavor Health, Evanston, IL

4:00 PM - 6:00 PM

Objective: Higher systemic inflammation has been associated with lower rates of breastfeeding, but this has not been measured across multiple perinatal timepoints. We aimed to identify whether elevated inflammatory cytokines in blood during pregnancy and postpartum were associated with lower breastfeeding intensity.

Study Design: The Stress, Pregnancy, and Health (SPAH) observational study included 605 participants enrolled mid-gestation with singleton pregnancies. Participants completed surveys and antecubital blood draws between 20-27 and after 32 weeks gestation. Clinical outcomes were abstracted from the medical record. A sub-group of SPAH participants additionally completed surveys at 1 week, 6 weeks, 3 months, and 6 months postpartum as well as an additional blood draw at 6 weeks. Breastfeeding intensity was self-reported at all 4 surveys, and cytokines IL-1RA, IL-6, IL-10, and TNF-α, and C-reactive protein were measured in serum. Inflammation markers were log-transformed for normality and z-scored, and z-scores were summed into composites. Stepwise regression identified key covariates, which were retained in multiple regression models.

Results: 155 individuals were included in the analysis. As indicated by the stepwise regression, we retained marital status, SES, and any diabetes in prenatal models and gestational weeks at delivery, any diabetes, and hypertensive disorders of pregnancy, last BMI measured during pregnancy, and resource composite score in postpartum models. Adjusted models indicated that lower circulating inflammatory markers during pregnancy were associated with higher breastfeeding intensity across week 6, month 3, and month 6 time points. The postpartum inflammatory composite was associated with breastfeeding intensity at point of blood draw (6 weeks).

Conclusion: Lower prenatal inflammatory markers were associated with higher rates of breastfeeding in the postpartum period, but postpartum inflammatory markers were not. Inflammation in pregnancy may influence lactogenesis and breastfeeding initiation, differentiating breastfeeding outcomes in the postpartum period.

Table 1. Participant characteristics (n=155)

	M (SD) / N (%)
Age	34.4 (5.04)
Married	132 (85.2%)
Resource Composite	0.03 (0.73)
Pre-pregnancy BMI	32.5 (6.79)
Any diabetes (Yes)	24 (15.6%)
Hypertensive disorders of pregnancy (Yes)	21 (13.6%)
Gestational age (weeks)	
<37 weeks	13 (8.4%)
>37 weeks	139 (89.7%)
41 weeks	3 (1.9%)

Resource composite is the mean of z-scores of IPR, total savings, and how long they could maintain current cost of living if they lost income. Hypertensive disorders of pregnancy includes those with pre-eclampsia, gestational hypertension, and chronic hypertension. N=1 missing for any diabetes and hypertensive disorders of pregnancy.

Table 2. Unadjusted and adjusted relationships between prenatal and postpartum composite measures of inflammation and breastfeeding intensity at all timepoints.

Adjusted for marital status, resource composite score, and any diabetes in prenatal models and for gestational age at delivery (weeks), any diabetes, last BMI measured during pregnancy, hypertensive disorders of pregnancy, and resource composite score in postpartum models.

549 | Physiologic Treatment of Mild Chronic Hypertension and Pregnancy Outcomes

Mariam Ayyash[1]; Ayodeji Sanusi[2]; On behalf of The CHAP Study Consortium
[1]*Columbia University Irving Medical Center, New York, NY;* [2]*Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL*

4:00 PM - 6:00 PM

Objective: Among patients with hypertension (HTN) in pregnancy, emerging research suggests that improved blood pressure (BP) control can be achieved if the antihypertensive drug used accounts for the underlying maternal hemodynamic physiology. We evaluated whether physiologic treatment of mild chronic HTN is associated with a reduction in adverse pregnancy outcomes.

Study Design: We conducted a secondary analysis of CHAP, an open-label, multicenter, randomized trial of antihypertensive treatment (vs. none) for pregnant patients with mild chronic HTN. Patients with BPs≥160/105 were excluded from CHAP trial. Eligible participants for this analysis had either hyperdynamic– a pulse pressure (PP)≥65, or vasoconstrictive– diastolic BP≥100 physiology. Three groups were compared based on treatment of BP at randomization: 1) Physiologic- hyperdynamic receiving Labetalol or vasoconstrictive receiving Nifedipine; 2) Non-physiologic- hyperdynamic receiving Nifedipine or vasoconstrictive receiving Labetalol, and 3) control- not on medications. The primary outcome was a composite of superimposed preeclampsia with severe features, preterm birth before 35 weeks' gestation, placental abruption, or fetal or neonatal death. Adjusted odds ratios (aORs) and 95% CIs were estimated with logistic regression.

Results: Of 2408 in CHAP, 542 (23.3%) participants met physiologic classification criteria and were analyzed: 136 (25.1%) had physiologic treatment, 125 (23.0%) had non-physiologic treatment, with 281 (51.8%) untreated controls. The primary outcome did not differ among those who received physiologic treatment (44.9%), non-physiologic (45.6%), or control (48.4%) with aOR (CIs) for physiologic vs control 0.85 (0.56-1.30), non-physiologic vs control 0.90 (0.59-1.39), and physiologic vs non-physiologic 0.95 (0.58-1.56).

Conclusion: Physiologic treatment of mild chronic HTN was not associated with a significant reduction in primary composite adverse outcome. Most patients did not meet criteria for physiologic classification. Further research using different thresholds to account for dynamic physiology over a greater BP range is needed.

550 | Are Maternal Fever Height and Duration During Labor Associated with the Risk of Hypoxic-Ischemic Encephalopathy?

Marie Cornet[1]; Michael W. Kuzniewicz[2]; Aditi Lahiri[2]; Yvonne Wu[3]
[1]*University of California San Francisco, San Francisco, CA;* [2]*Kaiser Permanente Northern California, Kaiser Permanente Northern California, CA;* [3]*University of California, San Francisco, San Francisco, CA*

4:00 PM - 6:00 PM

Objective: To examine if the height of fever and/or duration between maternal fever onset and delivery modifies the risk of hypoxic-ischemic encephalopathy (HIE).

Study Design: Population-based cohort study of singleton neonates without congenital anomalies born ≥ 35 weeks at 15 Kaiser Permanente Northern California hospitals between January 2012 and July 2019. Maternal fever was defined as at least one temperature ≥38°C before delivery. Maximal maternal temperature and timing of the first maternal fever were extracted from medical records. HIE was defined as the presence of both neonatal encephalopathy and perinatal acidosis (cord pH< 7 or base deficit >10 on any gas within 2 hours after birth). We evaluated the associations between maximal maternal temperature and duration between fever onset to delivery and neonatal outcomes, using Poisson regression adjusting for duration of labor as a spline.

Results: Among 280,347 neonates, exposure to maternal fever occurred in 27,317 (9.8%) and HIE occurred in 490 (0.17%). The incidence of HIE was higher among infants of febrile compared to afebrile mothers (Relative risk - RR 4.4 [95% CI 3.6-5.3]). Both the height (Figure 1) and duration (Figure 2) of fever were associated with an increased risk of HIE. After adjusting for duration of labor, the incidence of HIE increased with each 0.1°C increase in maximal maternal temperature (Incidence rate ratio- IRR 1.09; 95% CI 1.08-1.11) and for each hour between fever onset and delivery (IRR 1.06 95%CI 1.05-1.07).

Conclusion: The higher the maternal fever and the longer the duration between fever onset and delivery, the higher the risk of developing HIE. Novel strategies designed to predict the risk of adverse neonatal outcomes during labor and delivery should account for these factors.

Figure 1. Height of maximal maternal temperature in labor and incidence of hypoxic-ischemic encephalopathy (95% CI).

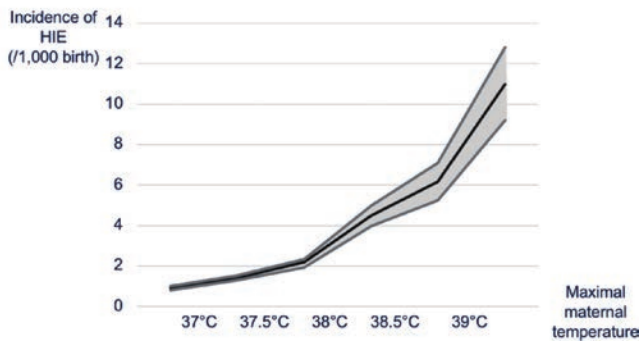

Figure 2. Duration between fever onset and delivery and incidence of hypoxic-ischemic encephalopathy (95% CI).

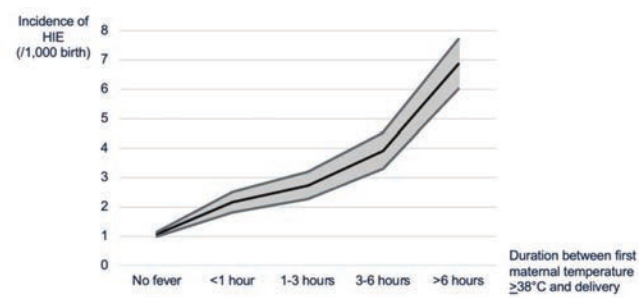

551 | Obstetric, Maternal and Neonatal Outcomes Associated with Attempted Trial of Labor after Cesarean Delivery

Marlee Hirsch[1]; Erez Lenchner[2]; Ashley Zimmermann[3]; Moti Gulersen[4]; Eran Bornstein[5]

[1]Northwell Lenox Hill Hospital, Lenox Hill Hospital, NY; [2]New York University Rory Meyers College of Nursing, New York, NY; [3]Northwell Lenox Hill Hospital, New York, NY; [4]Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA; [5]Northwell Lenox Hill Hospital, New Hyde Park, NY

4:00 PM - 6:00 PM

Objective: To examine the obstetric, maternal, and neonatal outcomes associated with attempted trial of labor after cesarean delivery (TOLAC) in the United States (US).

Study Design: A retrospective analysis of the Centers for Disease Control and Prevention's Natality live birth database (2016-2022). The inclusion criteria consisted of term (37 0/7 - 40 6/7 weeks), singleton pregnancies with a history of cesarean delivery. The study group comprised of individuals who attempted TOLAC, while the comparison group consisted of those undergoing repeat cesarean section without TOLAC. Obstetric, maternal, and neonatal outcomes were compared between the two groups using Pearson's chi-square test. Results were presented as odds ratios (OR) with 95% confidence intervals (CI). Statistical significance was defined as p-value < 0.05.

Results: Of the 7,250,494 live births with previous cesarean sections analyzed, 2,313,494 (31.9%) individuals attempted TOLAC. The prevalence of attempted TOLAC and the ORs based on different maternal and neonatal outcomes are presented in Tables 1 and 2, respectively.

Conclusion: Based on this large contemporary US database, we provide an update on obstetric, maternal, and neonatal outcomes associated with attempted TOLAC. Attempted TOLAC was associated with a higher risk of maternal intensive care unit (ICU) admission, maternal antibiotic use, uterine rupture, immediate neonatal assisted ventilation, and 5-minute APGAR scores < 7. However, attempted TOLAC was associated with lower odds of assisted neonatal ventilation after six hours and neonatal ICU admissions, suggesting that attempted TOLAC has a transient impact on the neonatal status. These findings can be used to help counsel patients on risks of attempting TOLAC.

Table 1. Maternal Outcomes Associated with Attempted TOLAC.

	Elective Cesarean	Attempted TOLAC	OR (95% CI)
Maternal ICU	15,911/4,932,996 (0.3%)	6,440/1,842,731 (0.4%)	1.08 (1.05-1.12)
Maternal Antibiotics	97,308/4,935,096 (2.0%)	59,892/1,843,673 (3.3%)	1.67 (1.65-1.69)
Uterine Rupture	2,702/4,932,996 (0.1%)	2,777/1,842,731 (0.2%)	2.75 (2.61-2.90)

Table 2. Neonatal Outcomes Associated with Attempted TOLAC.

	Elective Cesarean	Attempted TOLAC	OR (95% CI)
Infant Weight < 2500g	326,717/4,170,713 (7.8%)	88,163/1,527,799 (5.8%)	0.72 (0.71-0.73)
Assisted Ventilation (Immediate)	331,244/4,935,096 (6.7%)	152,144/1,843,673 (8.3%)	1.25 (1.24-1.26)
Assisted Ventilation (6 hours)	128,976/4,935,096 (2.6%)	36,455/1,843,673 (2.0%)	0.75 (0.74-0.76)
Neonatal ICU	562,234/4,935,096 (11.4%)	206366/1,843,673 (11.2%)	0.98 (0.97-0.99)
5-Minute APGAR < 7	125,627/4,937,000 (2.5%)	64,719/1,844,474 (3.5%)	1.39 (1.38-1.41)

552 | Does Day of Delivery Matter? Obstetric, Maternal and Neonatal Outcomes in Term, Singleton Weekend Births

Marlee Hirsch[1]; Erez Lenchner[2]; Ashley Zimmermann[3]; Moti Gulersen[4]; Eran Bornstein[5]

[1]Northwell Lenox Hill Hospital, Lenox Hill Hospital, NY; [2]New York University Rory Meyers College of Nursing, New York, NY; [3]Northwell Lenox Hill Hospital, New York, NY; [4]Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA; [5]Northwell Lenox Hill Hospital, New Hyde Park, NY

4:00 PM - 6:00 PM

Objective: To determine whether obstetric, maternal, and neonatal outcomes differ between weekend and weekday deliveries in the contemporary United States (US).

Study Design: A retrospective analysis of the Centers for Disease Control and Prevention's Natality live birth database (2016-2022). The inclusion criteria consisted of term (37 0/7 - 40 6/7 weeks), singleton pregnancies. The study group comprised of births occurring on the weekend (Saturday or Sunday) while

the comparison group consisted of those occurring during the weekdays (Monday through Friday). Obstetric, maternal, and neonatal outcomes were compared between the two groups using Pearson's chi-square test. Results were presented as odds ratios (OR) with 95% confidence intervals (CI). Statistical significance was defined as p-value < 0.05.

Results: Of the 22,355,756 live births analyzed, 4,598,349 (20.6%) births occurred on weekends. The prevalence of weekend births and the ORs based on different maternal and neonatal outcomes are presented in Tables 1 and 2, respectively.

Conclusion: Based on this large contemporary US database, weekend births are associated with higher rates of maternal intensive care unit (ICU) admission, 3rd and 4th degree perineal lacerations, maternal antibiotic use, uterine rupture, neonate less than 2500g, assisted ventilation, 5-minute APGAR score < 7, and neonatal ICU admission. However, there was a lower risk of primary cesarean section on weekends than weekdays. This information can be used to guide providers into stratifying higher risk deliveries on weekdays when planning is possible.

Table 1. Maternal Outcomes Associated with Weekend Deliveries.

	Weekday	Weekend	OR (95% CI)
Maternal ICU Admission	24,056/17,741,286 (0.14%)	6,793/4,593,943 (0.15%)	1.09 (1.06 – 1.12)
3rd/4th Degree Perineal Lacerations	132,406/17,741,286 (0.7%)	42,698/4,593,943 (0.9%)	1.25 (1.23 – 1.26)
Maternal Antibiotic Use	255,239/17,748,909 (1.4%)	85156/4,596,094 (1.9%)	1.29 (1.28 – 1.30)
Mode of Delivery			
Vaginal Delivery	11,544,953 (65.0%)	3,475,124 (75.6%)	REF
VBAC	355,853 (2.0%)	113,167 (2.5%)	
Primary Cesarean	3,059,764 (17.2%)	693,358 (15.1%)	0.75 (0.75 - 0.75)
Repeat Cesarean	2,778,281 (15.6%)	311,210 (6.8%)	
Uterine Rupture	5,240/17,741,286 (0.03%)	1,670/4,593,943 (0.04%)	1.23 (1.16 – 1.30)

Table 2. Neonatal Outcomes Associated with Weekend Deliveries.

	Weekday	Weekend	OR (95% CI)
Neonate < 2500g	687,430/14,959,271 (4.6%)	209,463/3,838,123 (5.5%)	1.198 (1.192 - 1.204)
Assisted Ventilation (Immediate)	691,944/17,748,909 (3.9%)	196,558/4,596,094 (4.3%)	1.101 (1.097 – 1.106)
Assisted Ventilation (6 hours)	209,849/17,748,909 (1.2%)	63,939/4,596,094 (1.4%)	1.179 (1.169 – 1.190)
5-Minute APGAR < 7	290,756/17,757,407 (1.6%)	88,190/4,598,349 (1.9%)	1.175 (1.166 – 1.184)
Neonatal ICU	1,139,074/17,748,909 (6.4%)	340,390/4,596,094 (7.4%)	1.166 (1.162 – 1.171)

553 | Burdened by Prevention? Factors Associated with High Burden of Attending Antenatal Fetal Surveillance

Marta J. Perez[1]; Miriam Alvarez[1]; Sarah Lasater[1]; Lorie M. Harper[1]; Alison G. Cahill[2]
[1]Dell Medical School, Austin, TX; [2]Dell Medical School Health Transformation Research Institute, Dell Medical School, The University of Texas at Austin, Austin, TX

4:00 PM - 6:00 PM

Objective: Antenatal fetal surveillance (AFS) is recommended to screen for acidemia and prevent stillbirth in pregnancies with a maternal or fetal condition that increase these risks. AFS visits are in addition to prenatal care and factors associated with patient's experience of burdens of attending this care is lacking.

Study Design: We performed a cross-sectional survey of patients attending AFS in a maternal fetal medicine ultrasound unit, querying patients regarding their burdens in cost, childcare, employment, and time-related domains. Patients eligible for inclusion were those undergoing any type or frequency of AFS and were English or Spanish speaking. The primary aim was to describe factors associated with experiencing a high burden of AFS visits. Patients were categorized as "high burden" if they agreed with experiencing burden in any domain and "low burden" if they universally disagreed with experiencing burden. Chi square and t-test as appropriate were used to determine associations between demographic and patient characteristics.

Results: Of 186 patients, 82 (44.1%) experienced high burden and 104 (55.9%) were low burden. The high burden group was older (32.4 years vs 28.6 years, p< 0.01) and more likely to attend twice weekly testing (31.7% vs 15.4%, p< 0.01). There was no difference between high and low burden experience groups in gestational age at start of AFS, number of visits scheduled, having children at home, or work outside the home. The high burden group were more likely to have gestational diabetes as the indication for AFS (24.4% vs 9.6%, p< 0.01) though other indications for AFS were similar between high and low burden groups.

Conclusion: Almost half of patients experienced a high burden of recommended AFS, which was associated with a slightly older patient age, twice-weekly frequency of AFS, and a diagnosis of gestational diabetes, which requires daily intensive blood glucose monitoring. Providers should attempt to query patients about burdens to develop a regimen of AFS that balances burden and stillbirth prevention.

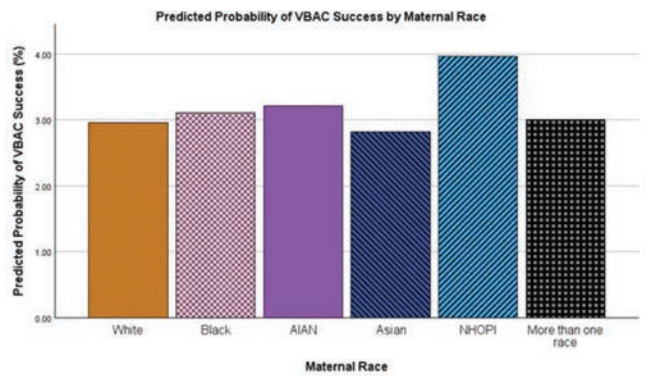
554 | Predictors of VBAC Success After Two Previous Cesarean Sections

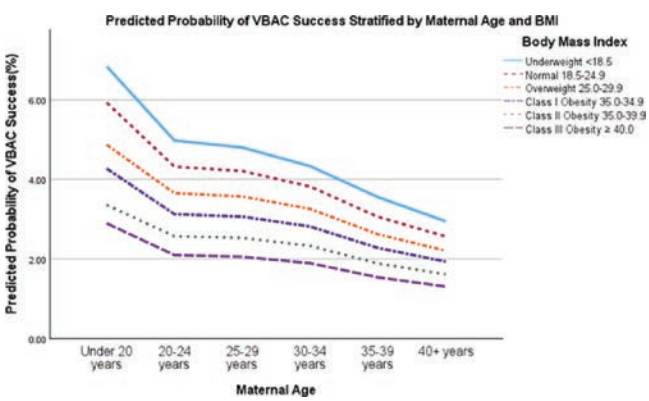
Mary C. Gallo; Shaun R. Wesley; Siddharth Hariharan; Sarah Crimmins
University of Rochester, Rochester, NY

4:00 PM - 6:00 PM

Objective: This study aimed to identify key predictors of a successful vaginal birth after cesarean (VBAC) among women with two previous cesarean sections and no prior spontaneous vaginal deliveries (SVD) using US vital statistics natality birth data, and to determine the uterine rupture rate in this population.

Study Design: A retrospective cohort study used data from the US Vital Statistics natality birth dataset. The analysis included women with two previous cesarean sections and no prior SVD. Descriptive statistics were performed on all variables. Logistic regression was used to identify predictors of VBAC success. Adjusted odds ratios (aOR) and 95% confidence intervals (CI) were calculated, and the uterine rupture rate was determined.
Results: The study included 537,852 women, with an overall VBAC success rate of 3.0%. Native Hawaiian or Other Pacific Islander (NHOPI) women had higher odds of VBAC success compared to White women (aOR = 1.38, CI: 1.09-1.75). Women with Class II (aOR = 0.53, 95% CI: 0.46-0.60) and Class III (aOR = 0.43, 95% CI: 0.38-0.49) obesity had significantly lower odds of VBAC success. Women aged 40+ years exhibited lower odds of VBAC compared to women aged under 20 years (aOR = 0.41, 95% CI: 0.31-0.55). Privately insured had higher odds of VBAC success than those with public insurance (aOR = 1.97, 95% CI: 1.84-2.12). There were 536 cases of uterine rupture identified, corresponding to a rate of 0.10%.
Conclusion: This study highlights predictors associated with VBAC success. The overall VBAC success rate was low at 3.0%, a result potentially limited by using a retrospective dataset with many covariates. The finding that privately insured women had better outcomes than those with public insurance may reflect disparities in access to healthcare resources. The finding of increased risk of failure in the highest BMI and age categories continues to support these variables as independent risk factors for cesarean delivery. The reported uterine rupture rate of 0.10% is lower than previous studies, supporting VBAC as a viable option for delivery mode as part of shared decision making.





555 | Influence of French Labor-management Guidelines on Incidence of Severe Postpartum Hemorrhage: A National Population-Based Study

Mathilde Lepelletier[1]; Camille Le Ray[1]; Aude Girault[2]
[1]INSERM UMR 1153, Obstetrical, Perinatal and Pediatric Epidemiology Research Team (Epopé), Center for Epidemiology and Statistics, FHU PREMA, Université de Paris, Paris, Ile-de-France; [2]FHU PREMA, Paris, France. FHU PREMA, Paris, France; Université Paris Cité, Inserm, Centre for Research in Epidemiology and StatisticS (CRESS), Obstetrical Perinatal and Pediatric Epidemiology Research Team (EPOPé), Paris, France., Paris, Ile-de-France

4:00 PM - 6:00 PM
Objective: The 2021 French National Perinatal Survey (FNPS) revealed an increased rate of severe postpartum hemorrhage (PPH) since the previous survey in 2016. This rise might be attributed not only to the evolution of maternal risk factors but also to the publication of the 2017 guidelines that aimed at restricting labor interventions, such as oxytocin administration, for women in spontaneous labor. Our aim was to explore the association between changes in medical practice between 2016 and 2021 and incidence of severe PPH.
Study Design: Women who participated to the 2016 and 2021 FNPS and delivered of a term live-born cephalic singleton after a spontaneous labor were included. We described the evolution of severe PPH rate, oxytocin use, and labor duration. We then assessed the determinants of severe PPH using univariate and multivariable analyses adjusting on maternal characteristics. Finally, we investigated the potential mediation effect of oxytocin use and prolonged labor on the relationship between the year of delivery and the occurrence of severe PPH.
Results: A total of 14,168 women were included, 7,529 in 2016 and 6,639 in 2021. The incidence of severe PPH increased from 1.2% in 2016 to 2.0% in 2021, p< 0.01. The use of oxytocin during labor decreased from 45.0% in 2016 to 30.2% in 2021, p< 0.01. Labor duration were significantly longer in 2021, regardless of parity (p < 0.01) After adjusting for maternal, obstetrical and maternity unit characteristics, giving birth in 2021 (versus 2016) remained associated with an increased risk of severe PPH (OR 1.7 [1.3-2.2]). While oxytocin use did not appear as a mediating factor, prolonged labor mediated only 9% of the observed association between the year of delivery and the risk of severe PPH.
Conclusion: While the French Labor management Guidelines could partially explain the increase in severe PPH rates observed between 2016 and 2021, the decrease in the use of oxytocin does not appear to be associated with this increase.

556 | Trajectory Analysis of Prenatal Urinary Tract Dilation and Risk of Postnatal Surgery

Matthew K. Janssen[1]; Markolline Forkpa[2]; Dana Weiss[3]; Nadav Schwartz[4]

[1]University of Pennsylvania, Pittsburgh, PA; [2]Pennsylvania Medicine Women's Health Clinical Research Center, Philadelphia, PA; [3]Children's Hospital of Philadelphia, Philadelphia, PA; [4]University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA

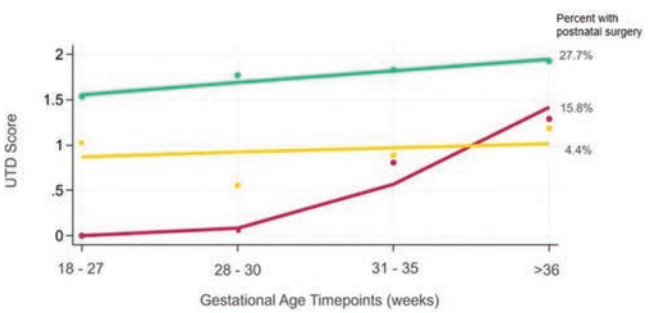
4:00 PM - 6:00 PM

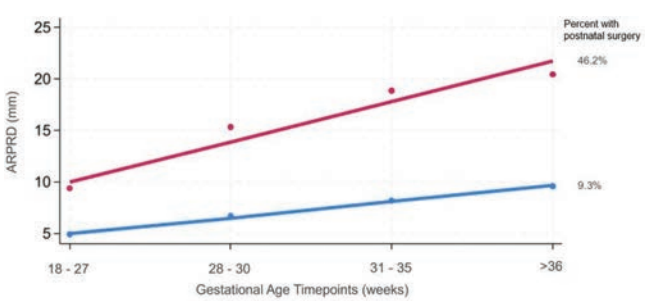
Objective: A prenatal urinary tract dilation (UTD) classification system is associated with postnatal urologic outcomes and assigns a score (UTDA1 or UTDA2-3) depending on anterior-posterior renal pelvis diameter (APRPD) and other markers of renal dysfunction. Postnatal management is dictated by a maximum peri-delivery UTD score and there is limited data assessing the trajectory of UTD across gestation with postnatal outcomes. We aimed to identify trajectories of UTD and describe the association with postnatal surgery.

Study Design: We conducted a retrospective cohort study of infants with congenital UTD, via ICD-10 codes, in visits with pediatric urology at an academic health system and born between 2015-2020 with at least 2 years of follow up. We matched infants to maternal charts and delivery records in the health system. We obtained demographic, obstetric, prenatal ultrasounds, and infant surgical outcomes. We excluded patients without sonographic evidence of UTD prior to delivery as this would not have prompted postnatal follow up, or if there was only a single prenatal ultrasound. Postnatal management followed a standardized algorithm. We performed a trajectory analysis with UTD score and APRPD at multiple gestational ages and assessed their association with postnatal surgery.

Results: There were n = 243 matched dyads and n = 54 were excluded for missing prenatal ultrasound data, leaving n = 189 dyads for analysis. There were no demographic differences between infants with or without postnatal surgery. Three trajectories of UTD score (Figure 1) were identified: stable-high, stable-medium, and escalating groups with postnatal surgery in 27.7% (n = 23/83), 4.4% (n = 3/68), and 15.8% (n = 6/38), respectively, (p< 0.001). Two trajectories for APRPD (Figure 2) were identified with postnatal surgery in 46.2% (n = 18/39) vs 9.3% (n = 14/150, p< 0.001).

Conclusion: UTD score trajectories demonstrated an increased risk of postnatal surgery in stable-high and escalating groups, while a stable-medium risk UTD group conferred a low risk of surgery. ARPRD measures had two trajectories with differing risks of postnatal surgery.





557 | Accuracy of ICD-10 Codes for Placenta Accreta Spectrum: Frequency and Reasons for Miscoding

Matthew Givens[1]; Savvy Benipal[2]; Amanda A. Allshouse[2]; Ibrahim Hammad[3]; Robert M. Silver[2]; Jason D. Wright[4]; Koji Matsuo[5]; Bret D. Einerson[6]

[1]Intermountain Health, Salt Lake City, UT; [2]University of Utah, Salt Lake City, UT; [3]Intermountain Health, Intermountain Health, UT; [4]Columbia University Irving Medical Center, New York, NY; [5]University of Southern California/Los Angeles General Medical Center, Los Angeles, CA; [6]University of Utah Health, Salt Lake City, UT

4:00 PM - 6:00 PM

Objective: The ICD-10 codes for placenta accreta spectrum (PAS) were introduced in 2015, facilitating improved research and quality tracking of this important source of maternal morbidity. However, the validity of these codes has not been thoroughly evaluated. We aimed to identify the frequency and reasons for PAS miscoding.

Study Design: We conducted a case series analysis of all deliveries associated with an ICD-10 code for PAS in the two large healthcare systems (17 hospitals, including 2 PAS referral centers) in our state between September 2015 and December 2023. Medical records were reviewed by three reviewers to determine whether PAS was present using the FIGO clinical and/or histopathologic criteria. If PAS was excluded, the reason for misapplication of the code was assigned.

Results: There were 394 deliveries associated with ICD-10 codes for PAS during the study period, with most (n = 156, 68%) occurring at a PAS referral center; 40% (95% CI 35-45%) were false positive PAS. Many demographic and delivery factors were associated with a false PAS diagnosis including younger maternal age at delivery, a lower number of prior cesarean deliveries, absence of placenta previa, and delivery without hysterectomy, and later gestational age at delivery (Table). The most common cause (42.9%) for a false positive was hemorrhage due to another etiology not meeting clinical or histopathologic criteria for PAS (Figure). In 22.4% of false positives, there was antenatal suspicion of PAS, but PAS was not seen at delivery. In 22.4% of false positives, the code was erroneously applied.

Conclusion: In this study, 40% of cases with an ICD-10 code for PAS did not meet clinical and/or histopathologic criteria for PAS. This underscores the need for improved clinician understanding of the clinical PAS criteria and improved coding practices for PAS. Additionally, studies using ICD-10 to identify cases of PAS should consider the possibility of bias introduced by a significant false positive rate.

Table. Demographic and delivery attributes associated with accuracy of diagnostic code application

Characteristic	Value	False positive (N=156)	True PAS (N=238)	P
Age at delivery (mean ± SD)		32.06 ± 5.8	34.00 ± 4.8	<.001
Gravidity	1	12 (7.7)	6 (2.5)	<.001
	2	44 (28.2)	18 (7.6)	
	3	32 (20.5)	44 (18.5)

Reasons for false positive coding for PAS are mutually exclusive and exhaustive of all identified false positives (n=156)
PAS - Placental Accreta Spectrum

558 | Cardiovascular Disease and Hypertensive Disorders of Pregnancy Increase Severe Maternal Morbidity Risk

Maura Jones Pullins[1]; Johanna Quist-Nelson[1]; Jerome J. Federspiel[2]; Kim Boggess[3]; Matthew Fuller[4]; Marie-Louise Meng[2]

[1]University of North Carolina, Chapel Hill, NC; [2]Duke University School of Medicine, Durham, NC; [3]University of North Carolina at Chapel HIll, Chapel Hill, NC; [4]Duke University, Durham, NC

4:00 PM - 6:00 PM

Objective: Cardiovascular disease (CVD) and hypertensive disorder of pregnancy (HDP) both confer risk of severe maternal morbidity (SMM). Our objective was to examine rates of SMM by CVD and HDP type during delivery hospitalization and 90 days postpartum compared to births without CVD.

Study Design: Retrospective cohort study of pregnant patients $\geq$ 18 years of age delivering between 2015 and 2020 in the Premier Database. Patients without CVD were compared to patients with six categories of CVD: congenital, ischemic, aortic, pulmonary hypertension (pHTN), cardiomyopathy, and valvular. Patients with multiple types of CVD were included in the analyses for each

category. The exposure of interest was any SMM during delivery hospitalization and < 90 days postpartum. Patients were stratified by HDP type: gestational hypertension (GHTN), preeclampsia (PEC), and preeclampsia with severe features (sPEC). Adjusted predicted SMM rate (%) was calculated during delivery and within 90 days postpartum by CVD type stratified by HDP type, adjusted for age, payor status, race, ethnicity, hospital characteristics, and OB comorbidities.

Results: Of 4,606,247 deliveries, 22,366 (0.5%) had CVD. The prevalence of HDP in this population was 11.9%. Patients with PEC had higher adjusted predicted SMM rates, independent of CVD. Those with CVD had significantly higher SMM rates across all HDP types. Patients with cardiomyopathy and pHTN who developed sPEC had the highest rates of SMM (26% and 33%) during delivery hospitalization (Figure 1). Acute respiratory distress syndrome (ARDS) and mechanical ventilation were the most common types of SMM during delivery hospitalization, while heart failure/pulmonary edema were the most common < 90 days postpartum (Figure 2).

Conclusion: Patients with CVD and PEC have a substantial increase in risk of SMM. The indications for the high rates of mechanical ventilation and etiologies of ARDS during delivery should be explored further. Heart failure is the most common postpartum morbidity and care should be targeted to improve surveillance and prevention postpartum.

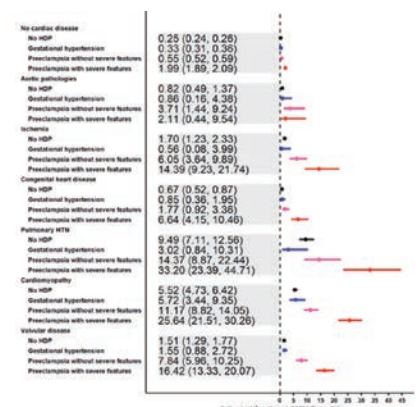

Figure 1. Adjusted predicted severe maternal morbidity rate (%) during delivery hospitalization by cardiovascular disease subtype stratified by hypertensive disorders of pregnancy subtype

Abbreviations: HDP, hypertensive disorders of pregnancy

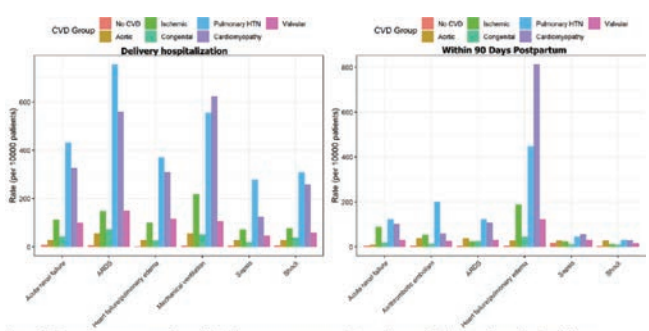

Figure 2. Rates of severe maternal mortality (six most common types) by cardiovascular disease subtype during delivery hospitalization (left) and within 90 days postpartum (right)

Abbreviations: ARDS, acute respiratory distress syndrome

559 | Risk of Hemorrhage and Severe Maternal Morbidity (SMM) with Low-lying Placenta: A Nationwide Analysis

4:00 PM - 6:00 PM

Objective: To evaluate and compare rates of hemorrhage and the CDC-defined severe maternal morbidity (SMM) associated with persistent low-lying placenta (LLP) and placenta previa (PP) using a national database.

Study Design: We conducted a retrospective analysis using the Nationwide Readmissions Database (NRD) from 2017 through 2019, reflecting the initial 3 years of coding for LLP. Patients with multifetal gestation, ectopic/molar pregnancies, and other placental abnormalities were excluded. Hemorrhage was defined as ante-, intra-, and post-partum hemorrhage. Baseline characteristics and maternal outcomes were compared using chi-square tests for categorical variables and Kruskal-Wallis tests for continuous variables. Multivariable regression analysis was used to evaluate the risk ratios (RR) of adverse outcomes across these groups.

Results: Among 5,644,185 singleton deliveries, 11,755 were diagnosed with LLP & 23,817 with PP. Compared to normal placentation, LLP was associated with a higher prevalence of hemorrhage (21.1% vs. 4.1%, $p < 0.001$), and increased RR of hemorrhage (RR: 5.19; 95% CI: 5.01-5.38), SMM (RR: 2.55, 95% CI: 2.35-2.78), blood transfusion (RR: 3.08; 95% CI: 2.79-3.40), and hysterectomy (RR: 4.69; 95% CI: 2.95-7.45). Additionally, delivery admission with LLP was found to have a longer inpatient stay (3 vs. 2 days, $p < 0.001$) and a higher cost ($21,451 vs. $17,025; $p < 0.001$). Patients with PP had significantly worse outcomes than those with normal placentation as well, with a 5.28-fold RR of SMM, 7.11-fold RR of blood transfusion, and 10.49-fold RR of hemorrhage.

Conclusion: With the institution of distinct coding for LLP in 2017, we were able to distinguish between patients with LLP and PP. While patients with PP are known to have poor maternal outcomes, patients with LLP also have an increased risk of hemorrhage, SMM, and prolonged inpatient care relative to

normal placentation. These findings should be considered during the prenatal counseling and management of patients with LLP.

Table 1. Maternal outcomes in patients with low-lying placenta and placenta previa at delivery

	Normal Placentation N=5,604,372	Low-Lying Placenta N=11,601	p-value (normal vs LLP)	Placenta Previa N=21,601	p-value (normal vs PP)	p-value (LLP vs PP)

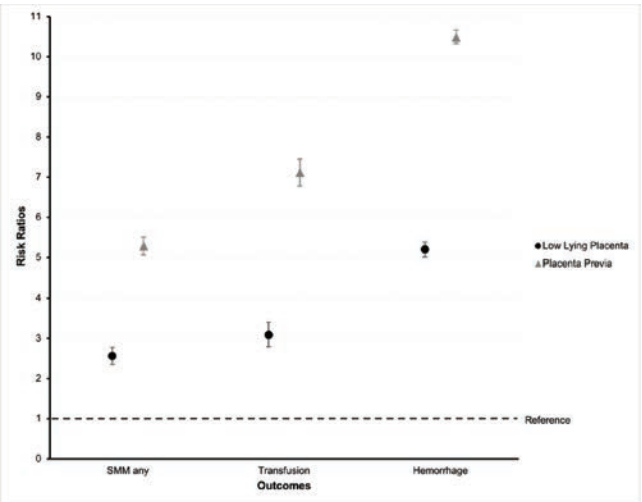
LLP: Low-lying placenta; PP: Placenta previa; SMM: Severe maternal morbidity (CDC-defined); DIC: Disseminated intravascular coagulation; VTE: Venous thromboembolism; PE: Pulmonary embolism.



560 | Association between a Healthy Plant-Based Diet and Adverse Pregnancy Outcomes

McKenzie K. Jancsura[1]; William A. Grobman[2]; Jiqiang Wu[2]; Michael Wirth[3]; David M. Haas[4]; Robert M. Silver[5]; George R. Saade[6]; Judith H. Chung[7]; Lynn M. Yee[8]; Kartik K. Venkatesh[2]
[1]The Ohio State University College of Nursing, Columbus, OH; [2]The Ohio State University, Columbus, OH; [3]University of South Carolina, Columbia, SC; [4]Indiana University School of Medicine, Indianapolis, IN; [5]University of Utah, Salt Lake City, UT; [6]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [7]University of California- Irvine, Irvine, CA; [8]Northwestern University Feinberg School of Medicine, Chicago, IL

4:00 PM - 6:00 PM

Objective: We determined whether a healthy plant-based diet in early pregnancy was associated with adverse pregnancy outcomes (APOs).

Study Design: This is a secondary analysis of data from the prospective Nulliparous Pregnancy Outcomes Study-Monitoring Mothers-to-Be (nuMoM2b) cohort. We calculated Healthy Plant-Based Diet Index (hPDI) scores from a validated food-frequency questionnaire in the first trimester. Healthy plant-based foods (e.g., whole grains, seed oils, vegetables) were assigned positive scores and unhealthy plant foods (e.g., refined grains, sugar sweetened beverages) and animal foods (e.g., meat, dairy) received negative scores. The hPDI was categorized in quartiles from quartile 1 (Q1, least plant-based) to Q4 (most plant-based). The outcomes were: small-for-gestational-age [< 10th percentile, SGA], large-for-gestational-age [≥ 90th percentile, LGA]), hypertensive disorder of pregnancy (HDP), gestational diabetes (GDM), and preterm birth (PTB) < 37 weeks. APOs were evaluated individually. Modified Poisson regression models adjusted for age, income, education, and health insurance. Secondarily, we assessed whether the above associations varied by adequate neighborhood food access, determined using the USDA *Food Atlas)*.

Results: Among 7,981 nulliparous individuals with dietary and outcome data, those who were in the highest quartile of a healthy plant-based diet were at a lower risk of developing HDP (11.0% vs 15.1%; aRR 0.76; 95% CI 0.62 to 0.94) and GDM (3.4% vs 4.1%; aRR 0.64; 95% CI 0.44 to 0.92) compared with those in the lowest quartile. The above associations did not vary by neighborhood food access (interaction p-value = 0.31 for HDP and 0.52 for GDM in adjusted models). A healthy plant-based diet was not associated with SGA, LGA, or PTB (TABLE).

Conclusion: A healthy plant-based diet in early pregnancy was associated with a lower risk of developing HDP and GDM in nulliparous individuals, after accounting for potential socioeconomic confounders. Findings suggest the potential benefits of a plant-based diet in early pregnancy and warrant further study.

TABLE. Association between plant-based diet and adverse pregnancy outcomes

	Frequency (row percentage)		Unadjusted and adjusted analysis

561 | Effect of Oxytocin Rest on Labor Outcomes and Uterine Contractility During Induction of Labor

McKenzie Barber[1]; Nandini Raghuraman[2]; Katherine H. Bligard[2]; Jeannie C. Kelly[2]; Antonina I. Frolova[3]
[1]Washington University in Saint Louis, St. Louis, MO; [2]Washington University School of Medicine in St. Louis, St. Louis, MO; [3]Washington University School of Medicine, St. Louis, MO

4:00 PM - 6:00 PM

Objective: For patients with inadequate contractions despite high-dose continuous oxytocin (OT), a period of OT rest is often trialed to resensitize uterine smooth muscle to OT; however, the utility of this is unknown. Our aim was to determine the effect of OT rest on labor outcomes and uterine contractility compared to continuous OT during induction of labor (IOL).

Study Design: A secondary analysis of a prospective cohort study of singleton, term pregnancies admitted in labor or for IOL from

January 2020 to July 2022 was performed. Inclusion criteria were nulliparity, IOL, and OT use. All patients had an intrauterine pressure catheter placed within 30 minutes of membrane rupture, regardless of labor progress. OT rest was compared to continuous OT. Primary outcomes were completion of first stage, length of active phase, and length of second stage. We used multivariable logistic regression to adjust for potential confounders. Secondary outcomes were Cesarean delivery and Montevideo units (MVUs) at three time points: active labor (cervix ≥ 6cm), max OT dose, and first stage completion. Subgroup analysis was performed to exclude OT rest for non-reassuring fetal status (NRFS).

Results: Of the 120 patients included, 55 (45.8%) had OT rest and 65 (54.1%) had continuous OT. Indications for OT rest were NRFS (73.7%), protracted labor (12.3%), and other (14.0%). Those with OT rest had significantly lower risk of completing the first stage (aRR 0.81, 95% CI 0.52-0.97). This association persisted when OT rest for NRFS was excluded (aRR 0.52, 95% CI 0.15-0.90). There were no differences in max OT dose (19.1 vs 16.7, p = 0.24), length of active phase, or length of second stage (Table 1). Those with OT rest were more likely to deliver via Cesarean (Table 2). MVUs did not differ between groups at any time (Table 2).

Conclusion: Nulliparous patients who had OT rest for protracted labor were 48% less likely to complete the first stage of labor compared to those who had continuous OT; a higher proportion also delivered via Cesarean. Further research is needed to determine the utility of OT rest after diagnosis of protracted labor.

Table 1. Delivery outcomes between OT rest compared to continuous OT during IOL

	Continuous OT (n=65)	OT rest, all indications (n=55)	p value	RR (95%CI)	aRR‡ (95%CI)
Completion of first stage	61 (93.6%)	41 (74.6%)	0.003	0.79 (0.05-0.96)	0.81 (0.52-0.97)
Length of active phase (hrs)	2.9 (1.1-5.2)	2.8 (0.7-4.8)	0.78	-	-
Length of second stage (hrs)	1.2 (0.5-1.8)	1.0 (0.5-1.9)	0.49	-	-

562 | Baby Got #Vbac: A Content Analysis of Trending Videos on Tiktok

Megan N. Happ[1]; Allison Chu[2]; Anissa Cervantes[3]; Jenny Wu[4]; Jonas J. Swartz[4]
[1]Duke University, Durham, NC; [2]Duke University School of Medicine, Durham, NC; [3]Howard University, Washington DC, DC; [4]Duke University Medical Center, Durham, NC

4:00 PM - 6:00 PM

Objective: Obstetric providers may be able to combat disinformation and strengthen patient-provider trust by understanding health information many of their patients consume on social media. We aimed to characterize and evaluate vaginal birth after Cesarean (VBAC) video content presented on TikTok.

Study Design: We used the web-scraping tool Apify to compile the 100 top "#vbac" videos. Unrelated, unavailable, or non-English videos were excluded. Two independent reviewers collected twenty-six descriptive data points for each video; a third arbitrated differences. Medical facts were appraised using VBAC guidelines from American College of Obstetricians and Gynecologists and Society of Maternal Fetal Medicine. Two validated measures were used: a modified 5-point DISCERN scale assessed information quality and Patient Education Materials Assessment Tool (PEMAT) assessed understandability and actionability.

Results: The top 100 videos had approximately 156 million views, 12 million likes, and 317,000 shares. A majority (81.0%) were made by non-healthcare professionals. The most common primary video theme was a personal experience or opinion (36.0%); of these, 13 (36.0%) mentioned distrust of or dismissal by providers. Twenty percent of all videos addressed home birth after Cesarean (HBAC), including 16 promoting HBAC by a single creator. Twenty-four videos presented medical facts; of these, videos by healthcare providers (n = 11) and non-healthcare providers (n = 13) included evidence-based facts 64.0% (n = 7) and 46.0%(n = 5) of the time, respectively. Overall videos exhibited high understandability (PEMAT median 85.5%, SD 15.7%), but low information quality (DISCERN mean 1.5, SD 0.9).

Conclusion: Videos with #vbac had low information quality, a finding consistent with previous work evaluating videos on contraception and abortion. Our study shows that top #vbac videos often lack health information. Of videos that include medical facts, many are incomplete or inaccurate. Obstetric providers can use the findings of this study to engage with patients they know are using TikTok for health education.

Table 1. Select characteristics of top #vbac videos.

A. Video content characteristics	N = 100 (%)
Primary video type	
Personal experience or opinion	36 (36.0%)
Reaction video or response	20 (20.0%)
Vlog	17 (17.0%)
Humor	15 (15.0%)
Educational	12 (12.0%)
Define VBAC or TOLAC	
Yes	3 (3.0%)
No	97 (97.0%)
Provide tips for VBAC	
Yes	13 (13.0%)
No	87 (87.0%)

563 | Second Stage of Labor Duration Among Patients with Obesity: How Likely is Vaginal Delivery?

Xiang Yu Feng[1]; Christina Frasik[1]; Megan C. Oakes[2]
[1]University of California, Irvine Division of Maternal-Fetal Medicine, University of California, Irvine, CA; [2]MemorialCare Miller Children's and Women's Hospital Long Beach, Miller Children's and Women's Hospital, Long Beach, CA

4:00 PM - 6:00 PM

Objective: ACOG recently revised guidelines defining an abnormally prolonged second stage labor as ≥ 3 hours. We sought to evaluate the difference in vaginal delivery rate for nulliparous patients with obesity and a singleton, term, vertex fetus (NTSV) with a normal (< 3 hour) versus prolonged (≥ 3 hour) second stage of labor.

Study Design: A retrospective cohort study of NTSV patients with obesity who achieved the second stage of labor, delivered at a tertiary care center hospital from 6/1/2023-12/31/2023. Obesity was defined as BMI ≥ 30 kg/m^2 on admission. The primary outcome was vaginal delivery. Secondary outcomes included select maternal and neonatal morbidities. Categorical variables were compared using Chi square and Fisher's exact. Normally distributed continuous variables were assessed using Student's T-test. Multivariable logistic regression was used to adjust for confounders.

Results: Of 348 included patients, 274 (78.7%) had a second stage < 3 hours and 74 (21.3%) had a second stage ≥ 3 hours. Those with a prolonged second stage were older (p = 0.04), more

likely to be admitted for induction of labor (p< 0.01) and utilize oxytocin in the second stage (p = 0.02). After adjusting for confounders, a prolonged second stage was associated with a 22% lower likelihood of vaginal delivery (aRR 0.78, CI 0.41-0.95). Patients with a prolonged second stage were more than 4 times as likely to have an operative vaginal delivery (aRR 4.54, 95% CI 2.97-6.29). 3rd degree lacerations were more likely in a prolonged second stage (aRR 10.25, 95% CI 2.02-41.55); however, the overall frequency was low. There were no other differences in maternal or neonatal morbidities between the groups.

Conclusion: While NTSV patients with obesity and a prolonged second stage of labor had a lower likelihood for vaginal delivery compared to those with a normal second stage duration, both groups had high rates of success. In patients with a prolonged second stage, 40% had an operative vaginal delivery, highlighting the importance of this obstetric skill in preventing the first cesarean section in patients with a protracted labor course.

Table 1: Baseline demographics between NTSV patients with obesity and a normal (<3 hour) or prolonged (≥3 hour) second stage of labor

	Second stage <3h (n=274)	Second stage ≥3h (n=74)	P-value

564 | Prolonged Second Stage: What is the Likelihood of a Safe, Vaginal Delivery?

Christina Frasik[1]; Xiang Y. Feng[1]; Megan C. Oakes[2]
[1]University of California, Irvine Division of Maternal-Fetal Medicine, University of California, Irvine, CA; [2]MemorialCare Miller Children's and Women's Hospital Long Beach, Miller Children's and Women's Hospital, Long Beach, CA

4:00 PM - 6:00 PM

Objective: ACOG has recently revised a clinical practice guideline defining a prolonged second stage labor as ≥3 hours, citing increased risk for adverse maternal and neonatal outcomes and lower likelihood of vaginal delivery at longer second stage durations. We aimed to measure how second stage duration is associated with vaginal delivery rate and adverse maternal and neonatal outcomes.

Study Design: This was a retrospective cohort study of nulliparous, term patients with a singleton, vertex fetus (NTSV) delivered at a tertiary care center hospital from 6/1/2023-12/31/2023. Patients who did not achieve the second stage of labor were excluded. Patients were stratified into three groups based on second stage duration: < 3 hours, ≥3 hours but < 4 hours, or ≥ 4 hours. The association between second stage duration and all outcomes was tested using the Cochran-Armitage test of trend.

Results: 700 patients were included. There was a significant decrease in vaginal delivery rate with increasing duration of the second stage (P-trend < 0.01). In contrast, there was a significant increase in operative vaginal delivery rate with increasing second stage duration (P-trend < 0.01). The rate of neonatal 5-minute Apgar < 7 increased with increasing second stage duration (P-trend 0.04); however, no other significant trends were noted for other markers of maternal morbidity or neonatal ICU admission.

Conclusion: Patients who reached the second stage of labor were significantly less likely to achieve a vaginal delivery as the second stage duration increased. However, the overall vaginal delivery rate remained high, with a significant proportion of operative vaginal deliveries among those with a prolonged second stage.

Table 1: Primary and secondary outcomes by duration of second stage of labor

	2nd stage<3h (n=527)	2nd stage>3h (n=68)	2nd stage >4h (n=105)	P-trend
Vaginal delivery	525 (99.6)	64 (94.1)	92 (87.6)	<0.01
Operative vaginal delivery	69 (13.1)	18 (26.5)	49 (46.6)	<0.01
Maternal Morbidity				
3rd degree laceration	16 (3.0)	1 (1.5)	8 (7.6)	0.09
4th degree laceration	0	1 (1.5)	1 (0.9)	0.10

565 | Longitudinal Trends in Symptom and Mood During Pregnancy: a Retrospective Study from Digital Health App

Mia Charifson[1]; Timothy Wen[2]; Bonnie Zell[1]; Isabel Fulcher[1]
[1]Delfina Care Inc, Delfina Care Inc, CA; [2]University of California, San Diego, Irvine, CA

4:00 PM - 6:00 PM

Objective: Pregnancy symptomatology and mood are routinely captured during prenatal care, however, little data exists on how their trajectories vary throughout pregnancy. The use of mobile pregnancy trackers presents new opportunities to study symptom and mood trajectories throughout pregnancy.

Study Design: Pregnant patients from three clinics enrolled in a pregnancy mobile application between January 2023 and July 2024 and were instructed by their care team to track weekly pregnancy symptoms (100 unique symptoms available to select)

and daily mood rating (1 to 5) in the application. We plot the trajectories of the top five symptom groups and average mood throughout pregnancy using cubic splines. We perform statistical tests for linear and quadratic terms in regression models to describe trends by gestational week.

Results: By July 2024, there were n = 1445 patients using the application. 1073 users reported a total of 24,273 symptoms (average 22.62 symptoms per user) and 1100 reported a total of 29,148 mood measures (average 26.5 moods per user). The top five symptom groups ever reported in our cohort were constitutional, musculoskeletal, gastrointestinal, obstetric, and genitourinary symptoms (Table 1). Each symptom group had a unique trajectory throughout pregnancy (Figure 1). Musculoskeletal symptoms increased linearly ($p < 0.01$) and gastrointestinal symptoms decreased linearly ($p < 0.01$). Constitutional ($p < 0.01$), obstetric ($p < 0.01$), and genitourinary ($p < 0.01$) all had U-shaped curves throughout pregnancy. Average mood also exhibited a slight inverted U-shaped curve ($p < 0.01$), although variation throughout pregnancy was low overall (SD = 0.15).

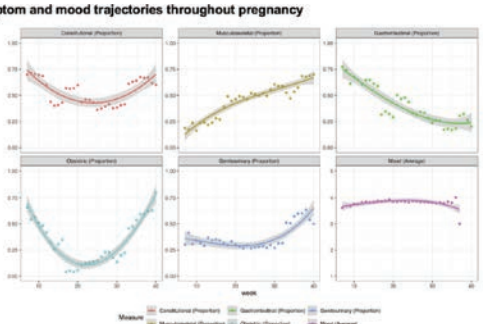
Conclusion: We observed distinct trajectories of symptoms and mood throughout pregnancy. Such information could improve personalized pregnancy care, use evidence-based knowledge to normalize pregnancy experiences, and may be potentially informative for early detection of adverse outcomes.

Table 1: Symptom groups definitions

Group	Number of unique symptoms	Example symptoms*
Constitutional	7	Trouble sleeping, fatigue, sudden weight gain, hot flashes, uncomfortable sleeping positions
Musculoskeletal	14	Lower back pain, leg cramps, leg swelling and pain, aches and pains, numbness of legs and feet
Gastrointestinal	22	Nausea or vomiting, appetite loss or food aversion, abdominal pain, severe nausea or vomiting, constipation
Obstetric	27	Braxton Hicks contractions, pelvic pain, vaginal bleeding, contractions that happen in regular pattern and get closer together over time, change in vaginal discharge
Genitourinary	3	Frequent urination, urinary problems including urinary tract infections (UTI), symptoms of UTI

*Only a selection of the top 5 unique symptoms for each group are shown due to space limitations

Figure 1: Symptom and mood trajectories throughout pregnancy



The proportion of users who experienced that symptom in each week of gestation is presented for the top five symptom groups (y-axis is from 0 to 1). The average weekly mood across users is presented for each week of gestation (y-axis is from 1 to 5, where 1 = Terrible and 5 = Great).

566 | Oral Presentation Conversion to Manuscript Publication Among Obstetrics and Gynecology Subspecialty Meetings

Minhazur R. Sarker[1]; Maha Pasha[2]; Dana R. Canfield[3]; Blair Thompson[4]; Dylan Hutson[4]; Megan King[4]; Harriet Rothschild[4]; Rachel L. Wiley[1]; Gladys (Sandy) A. Ramos[1]; Cynthia Gyamfi-Bannerman[1]

[1]University of California, San Diego, San Diego, CA; [2]N/A, San Diego, CA; [3]UC San Diego Health, San Diego, CA; [4]University of California San Diego, San Diego, CA

4:00 PM - 6:00 PM

Objective: We aimed to evaluate the oral presentation to full manuscript conversion rate of Obstetrics and Gynecology subspecialty meetings.

Study Design: We evaluated the 2019 meeting supplements from four subspecialty societies: 1) Society for Maternal-Fetal Medicine (SMFM), 2) Society of Gynecologic Oncology (SGO), 3) American Urogynecologic Society (AUGS), and 4) American Society for Reproductive Medicine (ASRM). Abstracts awarded an oral presentation were included and queried on PubMed using a multimodal method incorporating abstract keywords and first and last author's names to determine publication status. An abstract was classified as a published manuscript if the first author of the meeting abstract was credited in the final publication. The primary outcome was publication status. Secondary outcomes included first author consistency, manuscript journal impact factor, and time to publication. All analyses were performed on STATA IC 15.1 with Chi-square, ANOVA, and Kruskal-Wallis to determine statistical significance at a p-value < 0.05.

Results: There were differences in the proportion of abstracts presented as oral presentations with SMFM 109/1059 (10.3%), SGO 42/629 (6.7%), AUGS 153/704 (21.4%), and ASRM 276/1099 (25.1) (p-value < 0.01, Table 1). SMFM and SGO had a greater proportion of randomized controlled trials and SMFM had the greatest proportion of basic science studies. Among oral presentations, the publication rate was greatest for SGO (78.6%) and SMFM (74.3%), lower in AUGS (66.7%), and lowest in ASRM (51.1%) (p-value < 0.01, Figure 1). Among published manuscripts, SMFM had the highest median impact factor and quickest median time to publication (p-value < 0.01, Table 1). There were no differences noted in first author consistency (Table 1).

Conclusion: We found that the societies with the lowest proportion of oral presentations had the highest publication rate. More importantly, 21-49% of all oral presentations at subspecialty meetings are unpublished suggesting the need to improve the mechanism for or access by which highly regarded research translates to publication.

Table 1. Characteristics of Abstracts from 2019 National Meetings

567 | Practice Patterns in the Administration of Antenatal Corticosteroids in Patients at Risk of Preterm Birth

Moti Gulersen[1]; Frank I. Jackson[2]; Ashley N. Battarbee[3]; Vincenzo Berghella[1]; Matthew J. Blitz[2]
[1]Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA; [2]Northwell, New Hyde Park, NY; [3]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL

4:00 PM - 6:00 PM

Objective: Although suboptimal timing of antenatal corticosteroid (ACS) administration in patients at risk of preterm birth (PTB) is well known, studies stratifying timing by GA at administration are limited. We aimed to evaluate whether ACS timing differs by gestational age (GA) of administration in patients at risk of PTB.

Study Design: Multicenter retrospective cohort of all singleton pregnancies exposed to ACS between 22 0/7-36 6/7 weeks of gestation and delivered from 2019-2023. Patients who had neonates that were not actively resuscitated at birth and intrauterine fetal demise were excluded. The primary outcome of time interval from ACS administration to delivery, stratified by < 2, 2-7, and >7 days, was compared among 4 gestational age groups: 22 0/7-25 6/7, 26 0/7-29 6/7, 30 0/7-33 6/7, and 34 0/7-36 6/7 weeks of gestation. The secondary outcome was delivery at term (37 0/7 weeks of gestation or later). Statistical analysis included use of Chi-squared test. Statistical significance was set $P < 0.05$.

Results: Of the 116,803 patients who delivered during the study period, 5,003 (4.3%) received ACS prior to delivery. Primary and secondary outcomes are displayed in the Table.

Conclusion: Data from this large cohort suggest that optimal timing of ACS in patients at risk of PTB is low, regardless of gestational age of ACS administration. The likelihood of optimal timing is significantly decreased in the late preterm period compared to early preterm periods. A significant proportion of patients exposed to ACS in the periviable period deliver at term. These data highlight the importance of developing PTB prediction tools to aid practitioners in optimizing the timing of ACS.

Table. Primary and secondary outcomes compared among the 4 groups.

	ACS administered 22 0/6-25 6/7 weeks (n=246)	ACS administered 26 0/7-29 6/7 weeks (n=676)	ACS administered 30 0/7-33 6/7 weeks (n=1,932)	ACS administered 34 0/7-36 6/7 weeks (n=2,149)	P value
Delivery < 2 days after ACS administration	45 (18.3)	112 (16.6)	525 (27.2)	1,501 (69.8)	<0.001
Delivery 2-7 days after ACS administration	51 (20.7)	140 (20.7)	432 (22.4)	190 (8.8)	
Delivery > 7 days after ACS administration	150 (61.0)	424 (62.7)	975 (50.5)	458 (21.3)	
Delivered ≥ 37 weeks of gestation	57 (23.2)	207 (30.6)	472 (24.4)	422 (19.6)	<0.001

Data are presented as number (percentage)

568 | Should Antenatal Corticosteroids Be Considered in Singletons Undergoing Cerclage at 22 0/7-23 6/7 Weeks' Gestation?

Moti Gulersen[1]; Frank I. Jackson[2]; Rupsa C. Boelig[3]; Eran Bornstein[4]; Vincenzo Berghella[1]; Matthew J. Blitz[2]
[1]Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA; [2]Northwell, New Hyde Park, NY; [3]Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA; [4]Northwell Lenox Hill Hospital, New Hyde Park, NY

4:00 PM - 6:00 PM

Objective: The American College of Obstetricians and Gynecologists (ACOG) suggests that antenatal corticosteroids (ACS) can be considered as early as 22 0/7 weeks' gestation in patients at increased risk of preterm (PTB) within 7 days of presentation. We aimed to evaluate the likelihood of delivery within 7 days of cerclage placement to determine whether ACS should be considered in this high-risk population.

Study Design: Multicenter retrospective cohort of all singletons undergoing an ultrasound-indicated cerclage (UIC) or physical exam-indicated cerclage (PEIC) between 22 0/7-23 6/7 weeks' gestation and delivered from 01/2018-06/2023. The primary

outcome was delivery < 7 days after cerclage placement. Secondary outcomes included delivery < 14 days after cerclage placement and PTB. We planned to compare baseline characteristics at the time of cerclage placement between those who delivered < 7 days versus 7 days or later after cerclage. Statistical analysis included use of Pearson's chi-square for categorical variables and Wilcoxon rank sum test for continuous variables. Statistical significance was set $P < 0.05$.

Results: Of the 83 patients included, 61 (73.5%) underwent an UIC and 22 (26.5%) underwent a PEIC. There were no patients who delivered < 7 days after cerclage placement; thus, we primarily compared those who delivered < 14 days versus 14 days or later. Three (3.6%) of patients delivered < 14 days after cerclage placement (12, 13, and 13 days). The prevalence of PTB < 37 weeks was 70.0%. Baseline characteristics compared between the two groups are displayed in the Table. Patients who delivered < 14 days after cerclage more commonly had a BMI > 40 kg/m^2 compared to those who delivered later (Table).

Conclusion: Although patients undergoing cerclage at 22 0/7-23 6/7 weeks' gestation are at high risk of PTB, none of the patients in this cohort delivered < 7 day after placement. These data suggest that ACS administration may be deferred in this patient population unless additional indications are present.

Table. Characteristics compared between those who delivered <14 days versus ≥ 14 days after cerclage placement.

	Delivered < 14 days after cerclage placement (n=3)	Delivered ≥ 14 after cerclage placement (n=80)	*P* value
Maternal age (years)	31.3 (2.1)	32.4 (5.3)	0.7
Body mass index (kg/m²)

569 | The Impact of Peripartum Fever on Long-Term Neurological Morbidity in Offspring

Narkis Hermon[1]; Omri Zamstein[2]; Tamar Wainstock[3]; Eyal Sheiner[3]

[1]Soroka Medical Hospital, Soroka Medical Center, HaDarom; [2]Soroka University Medical Center, Soroka University Medical Center, HaDarom; [3]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom

4:00 PM - 6:00 PM

Objective: Peripartum fever, resulting from various infectious and non-infectious causes, can lead to adverse maternal and neonatal outcomes. This study explores the potential long-term neurological effects of peripartum fever on the offspring.

Study Design: A population-based cohort analysis was conducted at a tertiary referral hospital to assess the incidence of neurological conditions in the offspring—encompassing both hospital and community-based diagnoses—based on the presence of peripartum fever. Kaplan-Meier survival curves evaluated the cumulative incidence of morbidity, while Cox proportional hazards models adjusted for confounding factors.

Results: In this study involving 232,476 deliveries, 1,728 (0.7%) were associated with peripartum fever. Compared to the group without fever, those with peripartum fever exhibited significantly higher incidences of hypertensive disorders (9.5% vs. 4.6%), preterm births (15.7% vs. 7.0%), non-reassuring fetal heart rate patterns (17.7% vs. 5.4%), and cesarean deliveries (47.0% vs. 13.8%; Table). Although overall neurological morbidity in the offspring was somewhat higher in the fever group (19.6% vs. 17.4%, p = 0.018), there was no notable difference in the occurrence of autism spectrum disorders (0.3% vs. 0.5%, p = 0.62). Additionally, the Kaplan-Meier analysis revealed no significant difference in the overall neurological morbidity (Log-rank p-value = 0.899; Figure). Following adjustments for maternal age and gestational age at birth, there was no significant association between peripartum fever and long-term neurological outcomes in the offspring (adjusted HR = 0.95, 95% CI 0.85–1.06, p = 0.35; Table).

Conclusion: Peripartum fever is linked to increased rates of obstetric complications; however, it does not significantly impact long-term neurological outcomes in offspring.

Figure. Cumulative Incidence of Total Neurological Morbidity in Offspring Based on Maternal Peripartum Fever Status (Log-Rank p-value = 0.89).

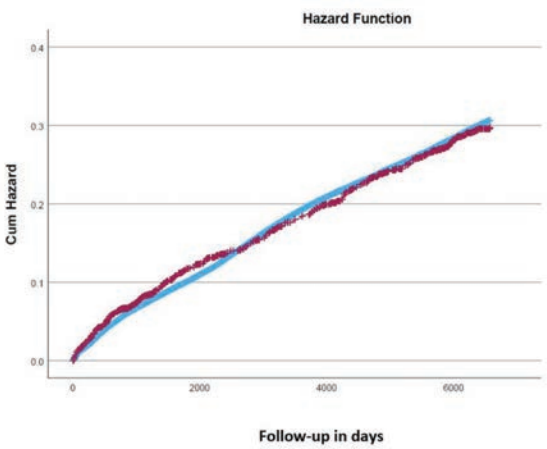

Table. Obstetrical Characteristics and Long-Term Neurological Morbidity in Offspring by Peripartum Fever Status.

	Peripartum fever (n=1,728)	No peripartum fever (n=230,748)	*P*-value

570 | Maternal and Neonatal Outcomes: Ampicillin Plus Gentamicin vs. Ampicillin Alone for Intrapartum Fever

Natav Hendin; Yarin Mash; Or Bercovich; Yossi Geron; Mor Ginat Shaked; Eran Hadar; Ohad Houri
Rabin Medical Center, Petach Tikva, HaMerkaz

4:00 PM - 6:00 PM

Objective: To evaluate the effectiveness of ampicillin plus gentamycin versus ampicillin alone in treating women with intrapartum fever.

Study Design: 10-year retrospective study at a single tertiary hospital, including term singleton vaginal deliveries who developed isolated intrapartum fever (≥38°C) without any concurrent evidence of infection. The department's treatment protocol changed in 2016 from ampicillin alone to ampicillin plus gentamicin. Primary outcome was puerperal endometritis. Secondary outcomes included microbiological studies, such as maternal urine or blood cultures, and neonatal outcomes.

Results: A total of 389 women met inclusion criteria and were treated with either ampicillin alone (n = 128, 33%) or ampicillin plus gentamycin (n = 261, 67%). The incidence of endometritis was higher in the ampicillin group compared to the ampicillin plus gentamycin group, although not statistically significant (6.25% vs. 2.30%, P = 0.08). Blood and urine culture positivity rates were similar (6.25% vs. 4.60%, p = 0.47, 2.34% vs. 5.36%, p = 0.20 respectively). Maternal hospitalization was longer for the ampicillin group (3.36 ± 1.1 days vs. 3.03 ± 1.04 days, P< 0.01).

Neonatal intensive care unit (NICU) admission rates were significantly higher in the ampicillin group (36.7% vs. 11.9%, P< 0.01). Conversely, among the neonates admitted to the NICU, the incidence of respiratory pathologies, such as respiratory distress syndrome or transient tachypnea of the newborn, and the need for ventilation were significantly higher in the ampicillin plus gentamycin group (2.1% vs. 25.8%, P< 0.01, 4.3% vs. 38.7 %, p< 0.01 respectively) (Table 1).

Conclusion: Women treated with ampicillin alone for intrapartum fever had higher rates of adverse maternal outcomes compared to those treated with ampicillin plus gentamycin. Although NICU admission rates were higher in the ampicillin group, respiratory diseases were more prevalent in the ampicillin plus gentamycin group.

Figure 1. Flowchart of the study population

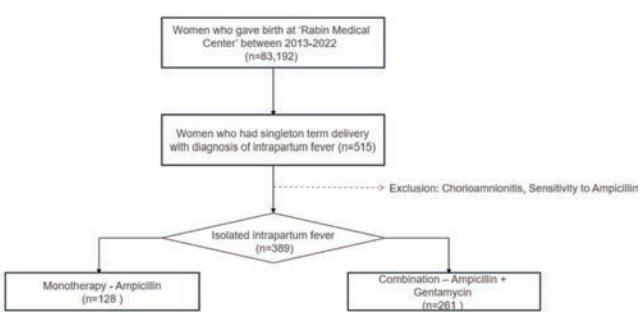

Table 2. Maternal and neonatal outcomes of women included in the study

	Ampicillin (N=128)	Ampicillin + Gentamycin (N=261)	P Value
Maternal Outcomes			
Endometritis	8 (6.25%)	6 (2.30%)	0.08
Blood culture growth	8 (6.25%)	12 (4.60%)	0.47
Urine culture growth	3 (2.34%)	14 (5.36%)	0.20
Hospitalization duration (Days)	3.36 ± 1.1	3.03 ± 1.04	<0.01
Neonatal Outcomes			
NICU	47 (36.7%)	31 (11.9%)	<0.01
RDS/TTN	1/47 (2.1%)	8/31 (25.8%)	<0.01
Need for ventilation	2/47 (4.3%)	12/31 (38.7%)	<0.01
Early sepsis	4/47 (8.5%)	8/31 (25.8%)	1.00
Positive Blood Culture	1/47 (2.1%)	2/31 (6.5 %)	0.56

571 | Neonatal Outcomes After Expedited Delivery Versus Expectant Management for Preeclampsia with Severe Features

Frank I. Jackson; Nathan A. Keller; Sarah H. Abelman; Luis A. Bracero; Matthew J. Blitz
Northwell, New Hyde Park, NY

4:00 PM - 6:00 PM

Objective: To determine if expectant management versus expedited delivery for preeclampsia with severe features (sPEC) improves neonatal outcomes.

Study Design: Retrospective cohort study of pregnancies complicated by sPEC within a large health care system in New York between 2019 and 2023. Patients who delivered < 24 hours after diagnosis (immediate delivery), without receiving two doses of betamethasone were excluded. Deliveries were classified as expectant management (EM) if they occurred > 72 hours after diagnosis and as expedited delivery (ED) if they occurred within 24-72 hours after diagnosis. The primary outcome was severe neonatal morbidity (SNM), a composite neonatal adverse outcome indicator which includes diagnoses and procedures. Secondary outcomes included respiratory distress syndrome (RDS), bronchopulmonary dysplasia (BPD), interventricular hemorrhage (IVH), and sepsis. Analysis was performed separately for deliveries at 28-34 weeks and < 28 weeks due to presumed variation in clinical management strategies. A logistic regression was performed. All statistical analyses were performed in R 4.3.1.

Results: In total, 218 patients were included for analysis: 178 (81.7) delivered between 28 and 34 weeks and 40 (18.3) delivered at < 28 weeks. Overall, the time interval from diagnosis to delivery had a median of 4.0 days [IQR: 2.4-8.0]. There were no significant differences in SNM, RDS, BPD, IVH, or sepsis between the ED and EM groups in either gestational age grouping (Table 1).

Conclusion: Pregnancies complicated by sPEC did not show improvement in SNM, RDS, BPD, IVH, or sepsis whether the delivery was expedited or occurred after expectant management. Significant maternal risks without clear neonatal benefit of expectant management may favor expedited delivery.

Table 1 – Expedited delivery vs. expectant management and neonatal outcomes by gestational age group

	Delivery < 28 weeks (n=40)			Delivery 28-34 weeks (n=178)		
Outcome	Expedited Delivery (n=14)	Expectant Management (n=26)	Odds Ratio (95% CI)	Expedited Delivery (n=60)	Expectant Management (n=118)	Odds Ratio (95% CI)
SNM	8 (57.1)	17 (65.4)	1.42 (0.37-5.42)	39 (65)	78 (66.1)	1.05 (0.54-2.01)

572 | Racial and Ethnic Disparities in Severe Maternal Morbidity and Icu Admission by Bariatric Surgery Status

Nathan A. Keller; Frank I. Jackson; Sarah H. Abelman; Luke Pierce; Sarika Arora; Alexis Palmer; Luis A. Bracero; Matthew J. Blitz
Northwell, New Hyde Park, NY

4:00 PM - 6:00 PM

Objective: To assess racial and ethnic disparities in severe maternal morbidity (SMM) and ICU admission in patients with and without a history of bariatric surgery.

Study Design: Retrospective cohort study of pregnancies within a large health care system in New York from 2019-2023. The primary exposure was bariatric surgery, which included: gastric sleeve, gastric band, Roux-en-Y gastric bypass, and biliopancreatic diversion with duodenal switch. Race and ethnicity were self-identified from pre-specified categories. The primary outcome was SMM during delivery hospitalization. SMM was defined using the Centers for Disease Control and Prevention (CDC) criteria which includes 21 indicators. A multivariable logistic regression was used to estimate the strength of association between prior bariatric surgery and SMM and ICU admission, adjusting for Obstetric Comorbidity Index (OBCMI) and race and ethnicity group. All statistical analyses were performed in R 4.3.1.

Results: In total, 127,959 pregnancies with delivery outcomes were identified with 493 (0.4%) with and 127,466 (99.6%) without a history of bariatric surgery. SMM occurred in 43 (8.7%) of pregnancies with a history of bariatric surgery and in 5,333 (4.2%) of pregnancies without such a history [unadjusted OR: 2.19, 95% CI 1.58-2.96]. After adjustment for OBCMI and race and ethnicity groups, no significant differences among SMM in patients with a history of bariatric surgery was observed [aOR: 1.37, 95% CI 0.98-1.88]. ICU admission occurred in 12 (2.4%) pregnancies with a history of bariatric surgery and in 797 (0.6%) pregnancies without such a history [aOR: 2.13, 95% CI 1.11-3.71]. All other race and ethnicity groups were at increased risk for SMM compared to Non-Hispanic White patients (Table 1).

Conclusion: A history of bariatric surgery was associated with increased risks of SMM before, but not after, adjustments for OBCMI and race and ethnicity group. ICU admission was significantly increased even after adjustments. Significant differences in SMM were seen by race and ethnicity group.

Table 1 – Incidence of severe maternal morbidity and ICU admission with and without bariatric surgery by race and ethnicity

573 | Ultrasonographic Fetal Lung Echotexture Analysis in the Prediction of Neonatal Respiratory Distress Syndrome

Nathan A. Keller[1]; Luis A. Bracero[1]; Frank I. Jackson[1]; Insaf Kouba[2]; Christina Karras[1]; Sarah H. Abelman[1]; Wassil Kouba[1]; Matthew J. Blitz[1]; Sleiman R. Ghorayeb[1]
[1]Northwell, New Hyde Park, NY; [2]Northwell, St. Petersburg, FL

4:00 PM - 6:00 PM

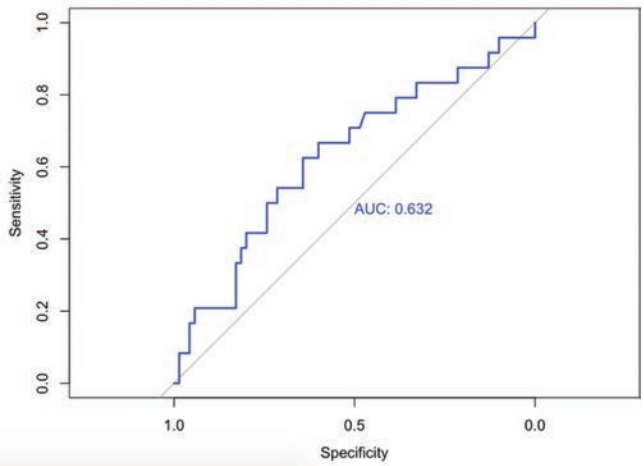
Objective: To determine if ultrasonographic fetal lung echotexture analysis is predictive of neonatal respiratory distress syndrome (RDS).

Study Design: Prospective cohort study of singleton gestations with medically-indicated ultrasound examinations from October 2017 through September 2021. Grayscale transverse fetal lung images were obtained at the level of the four-chamber heart view with GE Voluson E8 and E10 ultrasound machines with convex array transducers. A region of interest was selected in each fetal lung image. Fetal lung heterogeneity index (HI) was determined with MATLAB software using a dithering technique with ultrasound image pixels transformed into a binary map from which a dynamic range value was determined. The fetal lung HI ultrasound occurred $\leq$ 7 days prior to delivery. Pregnancies were categorized by delivery timing: late preterm (34+0 to 36+6 WGA), early term (37+0 to 38+6 WGA), and full-term (39+0 to 40+6 WGA). Pregnancies with delivery occurring > 7 days from HI measurement were excluded from the analysis.

Results: In total, 468 singletons were delivered $\leq$ 7 days from the HI ultrasound examination. Of these, 94 (20.1%), 276 (59.0%), and 98 (20.9%) delivered preterm, early term, and full term, respectively. RDS occurred in 20 (21.3%) of late preterm, 3 (1.0%) of early term, and 1 (1.0%) of full term deliveries. Figure 1 shows the receiver operating characteristic (ROC) curve for fetal lung HI as a predictor of RDS in the preterm delivery cohort. HI was modestly predictive of RDS in the late preterm cohort (AUC: 0.632), but not in the early or full term cohort, potentially from low incidences of RDS in these time frames.

Conclusion: Fetal lung HI had a modest association with RDS in the late preterm time period which is the time of greatest fetal lung HI change and greatest risk of RDS. While fetal lung HI alone may not be a great predictor of RDS, it may be a useful adjunct when combined with other pregnancy risk factors.

Figure 1 – ROC Curve for HI Predicting RDS in Late Preterm Newborns



574 | Risk Factors for Maternal Abruption after the Fetoscopic Laser Surgery for Twin Twin Transfusion Syndrome

Neha Agarwal[1]; Ramesha Papanna[2]; Dejian Lai[3]; Anthony Johnson[4]; Sami Backley[5]; Eric P. Bergh[6]; Edgar A. Hernandez-Andrade[2]; Gustavo Vilchez[7]; Felicia V. LeMoine[5]; Alexandra Garcia[5]; Tania clarete[5]; Elisa Garcia[5]; Ashley Salazar[8]; Jimmy Espinoza[5]

[1]Division of Fetal Intervention, Department of Obstetrics, Gynecology and Reproductive Sciences, UTHealth McGovern Medical School, Houston, TX, USA, Houston, TX; [2]McGovern Medical School at UTHealth Houston, Houston, TX; [3]UT School of Public Health, Houston, TX; [4]McGovern Medical School University of Texas Health Science Center at Houston (UThealth), Houston, TX; [5]Division of Fetal Intervention, Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern Medical School at UTHealth Houston, Houston, TX; [6]UT Health, Houston, TX; [7]UTHealth Houston, Houston, TX; [8]Division of Fetal Intervention, Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern Medical School at UT Health Houston, Houston, TX

4:00 PM - 6:00 PM

Objective: To evaluate the risk factors associated with maternal abruption in twin-twin transfusion syndrome (TTTS) after fetoscopic laser surgery (FLS).

Study Design: This retrospective study included TTTS cases that underwent FLS between 2011 and 2024 at a single institution. Maternal demographics and preoperative, intraoperative and postoperative outcomes were collected. Patients were subsequently grouped by abruption status. Placental abruption was diagnosed based on documentation in the medical record. Multiple logistic regression analysis was performed to identify risk factors, adjusted for maternal ethnicity, placental location, gestational age at FLS, amnioinfusion, amnioreduction, number of uterine entries, Solomonization, laser time and kilojoules, chorioamnion separation (CAS) observed on the first postoperative day, and preterm prelabor rupture of membrane (PPROM).

Results: 749 patients were enrolled in the study. Among them, 88 (11.7%) were complicated by maternal abruption. Patients with abruption delivered earlier than those without abruption (29.2 [26.3, 31.5] wks. vs 32 [28.5, 34.2] wks., $p < 0.001$). There were no significant statistical differences in maternal age, race, BMI, smoking status or other demographics or intraoperative variables between groups (Table 1). Rates of CAS (18.1% [16/88] vs. 9.6% [64/661], $p = 0.04$) and PPROM (61.3% [54/93] vs 37% [245/655], $p = 0.001$) were statistically significantly higher among the abruption group than the no abruption group. Multiple logistical regression demonstrated that CAS and PPROM are significant risk factors for placental abruption ([aOR, 2.04; 95% CI 1.01–4.11, $p = 0.04$] and [aOR, 2.16; 95% CI 1.29-3.61, $p = 0.003$], respectively).

Conclusion: CAS and PPROM are significant risk factors for placental abruption. After FLS, patients with CAS and PPROM should be advised of the increased risk for placental abruption.

Table 1. Demographics and intraoperative findings of patients with and without abruption.

575 | Evaluation Of Severity Determination Using Transvaginal Ultrasound In Placenta Accreta Spectrum Scoring (TUPAS)

Neha Agarwal[1]; Sarah T. Mehl[2]; Edgar A. Hernandez-Andrade[2]; Dejian Lai[3]; Gustavo Vilchez[4]; Eleazar E. Soto[2]; Farah H. Amro[2];

Rosa Guerra[5]; Sen Zhu[6]; Baha M. Sibai[2]; Sean C. Blackwell[2]; Ramesha Papanna[2]
[1]Division of Fetal Intervention, Department of Obstetrics, Gynecology and Reproductive Sciences, UTHealth McGovern Medical School, Houston, TX, USA, Houston, TX; [2]McGovern Medical School at UTHealth Houston, Houston, TX; [3]UT School of Public Health, Houston, TX; [4]UTHealth Houston, Houston, TX; [5]Division of Gynecologic Oncology, Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern Medical School at UTHealth Houston, Houston, TX; [6]McGovern Medical School at the University of Texas, Houston, TX

4:00 PM - 6:00 PM

Objective: We showed that TUPAS, based on loss of uterine wall interface (LUS), arterial vascularity, and cervical involvement, can determine PAS severity based on blood loss during surgery. This study aims to validate the TUPAS in an external cohort and associate it with surgical outcomes.

Study Design: This is a retrospective cohort study of consecutive patients referred to our center for suspected PAS from 2023-2024. Transvaginal ultrasound evaluated the LUS and cervix per pre-defined protocol (evaluating the placental-uterine/cervical and bladder interface with bladder half full). Patients were managed per usual clinical approach, not based on TUPAS, including c-section with placenta removal, c-hysterectomy, and conservative management. An examiner blinded to patient history and clinical outcomes retrospectively scored images/clips. Cumulative scores of 0-9 were converted to 4 categories as previously published (0: score 0; 1: score 1-3; 2: score 4-6; 3: score 7-9). The primary outcome was calculated estimated blood loss (cEBL) during the primary surgery. Secondary outcomes were surgery type, blood product transfusion, ICU admission and length of hospital stay.

Results: 86 patients were referred: 78 were included in the analysis, 6 had incomplete or no images, 2 had placenta in the upper uterine segment. Maternal demographics and number of c-section deliveries did not differ by category. Surgical management differed by category: all Cat-0 patients and 82% in Cat-1 had c-section with placenta removal (Tab 1). Cystotomy occurred only in Cat-3. From multiple linear regression analysis in log scale, Cat-3($\beta = 0.94$, $p = 0.002$) was associated with greater blood loss than other categories, irrespective of surgery type, on multiple linear regression. C-hysterectomy in Cat-3 was associated with higher cEBL (Fig1.), requiring massive transfusion, and more severe pathology than Cat-2.

Conclusion: Our scoring strongly associated with severity of PAS with blood loss regardless of management approach. Cat 3 represents the most severe cases; referral to a tertiary care center specializing in PAS management should be considered.

Table 1. Selected variables of significant differences among the categories.

576 | Dietary Risk Factors for Excess Weight Gain in Pregnancy

Ngantu Le[1]; Megan L. Lawlor[1]; Jeannie C. Kelly[2]; Sarah K. England[3]; Antonina I. Frolova[4]; Nandini Raghuraman[2]; Peinan Zhao[3]
[1]Washington University in St. Louis, St. Louis, MO; [2]Washington University School of Medicine in St. Louis, St. Louis, MO; [3]Washington University, St. Louis, MO; [4]Washington University School of Medicine, St. Louis, MO

4:00 PM - 6:00 PM

Objective: Excess gestational weight gain (GWG) is associated with adverse pregnancy and metabolic outcomes. Patients are motivated to improve their health during pregnancy but

describe a lack of knowledge on dietary recommendations. We investigated dietary components that are most associated with GWG.

Study Design: This is a nested case control study in a cohort of singleton pregnancies who completed the NIH Dietary Health Questionnaire II (DHQ-II) in the third trimester or within 3 months of delivery. Cases were patients with excess GWG greater than the Institute of Medicine (IOM) recommended guidelines. Controls were patients with GWG within the IOM guidelines. Those with GWG below guidelines were excluded. Exposures of interest were Healthy Eating Index-2015 (HEI-2015) score components and other DHQ-II dietary components. These components were compared between cases and controls. Multivariable logistic regression was used to adjust for BMI at first prenatal visit.

Results: 531 patients completed the DHQ-II, among which 312 (58.8%) had excess GWG and 219 (41.2%) had appropriate GWG. There were no significant socioeconomic differences between those with excess and adequate GWG. The average BMI was 29.60±8.07 kg/m^2 among patients with excess GWG and 27.20±7.49 kg/m^2 among patients with appropriate GWG (P = 0.001). Overall HEI-2015 scores were not significantly different between cases and controls. However, a diet composed of low whole grains (aOR 1.75, 95% CI 1.18- 2.60) or high dairy intake (aOR 1.84, 95% CI 1.18- 2.81) was associated with excess GWG.

Conclusion: A diet low in whole grains or high in dairy is associated with excess GWG. Obstetric providers should address specific dietary components when counseling patients about GWG.

577 | Predicting Live Birth with the PRC2 Age Index, a Novel Epigenetic Biomarker

Nicola C. Perlman[1]; Andrea Cipriano[2]; Daniel J. Simpson[3]; Xixi D. Plummer[1]; Samantha L. Kruger[1]; Arian Korshid[2]; Janet Hurtado[1]; Ruth B. Lathi[1]; Danielle M. Panelli[1]; Vittorio Sebastiano[2]; Katherine Bianco[1]
[1]Stanford University, Palo Alto, CA; [2]Stanford University, Stanford, CA; [3]Mayo Clinic, Rochester, MN

4:00 PM - 6:00 PM

Objective: Polycomb Repressive Complex 2 (PRC2) is a novel epigenetic biomarker of advanced cellular aging that has not yet been evaluated in pregnancy. PRC2 regions, present in all somatic cells, are associated with CpGs which gain DNA methylation with age. We evaluated whether PRC2 related methylation changes, as a marker of cellular aging, were associated with live birth in a preconception population.

Study Design: This pilot study utilized biobanked samples from patients desiring pregnancy at an academic center. Peripheral blood mononuclear cell DNA was extracted from buffy coat. Using the Illumina Infinium MethylationEPIC BeadChip array, we evaluated CpG methylation at PRC2 sites to generate the "PRC2 Age Index." Mean PRC2 site methylation was reported for each patient. Patients were then grouped by chronologic age (age by birthdate) decade. The primary outcome was successful live birth, defined as pregnancy and delivery of live infant after 24 weeks. Using the PRC2 Age Index, mean methylation was compared between live birth and no live birth within chronologic age decades.

Results: 64 patient samples were analyzed. In the population, 57.2% had a live birth, of which 80% utilized assisted reproductive therapy. Demographics were overall similar between those with and without live birth. As expected, when the PRC2 Age Index was applied, patients in each chronologic age decade gained methylation. There were trends towards increased methylation of the PRC2 Age Index in people with no live birth across all chronologic age decades (Figure 1). Mean methylation was plotted for the live birth versus the no live birth groups (Figure 2).

Conclusion: The PRC2 Age Index correlated increased methylation at PRC2 sites with aging in a preconception population. Although insignificant, the PRC2 age index exhibited trends in increasing mean methylation for people without live birth, suggesting accelerated cellular aging compared to live birth counterparts. Larger studies evaluating the PRC2 Age-Index may contribute to understanding of biological age and outcomes in a reproductive age population.

Figure 1: Relationship between PRC2 region methylation and decade of chronologic age grouped by live birth or no live birth.

578 | The Association of Race and Ethnicity with Postpartum Hemorrhage Care Escalation

Nigel Madden; On behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network
Beth Israel Deaconess Medical Center, Boston, MA

4:00 PM - 6:00 PM

Objective: We aimed to evaluate whether there were racial and ethnic disparities in postpartum hemorrhage (PPH) care escalation after cesarean birth in a large, diverse cohort of birthing people.

Study Design: Secondary analysis of a multicenter placebo-controlled randomized trial of prophylactic use of tranexamic acid during cesarean birth. We included participants who self-reported as non-Hispanic White (NHW), non-Hispanic Black (NHB), or Hispanic and who had a PPH (estimated blood loss [EBL] > 1L). Based on a published algorithm for classifying PPH management, the primary outcome was level of PPH care intervention during the delivery admission: Level 0 (no intervention beyond standard third stage oxytocin), Level 1 (uterotonics only), Level 2 (performance of a procedure), and Level 3 (hysterectomy). We created multivariable ordinal regression models to evaluate the independent association between race/ethnicity and receipt of higher levels of anti-hemorrhagic intervention. A secondary analysis stratified these results by PPH severity.

Results: Of 656 individuals who met inclusion criteria, 37% identified as NHW, 27% as NHB, and 36% as Hispanic. A majority received no interventions, with 360 (55%) Level 0, 154 (23%) Level 1, 118 (18%) Level 2, and 24 (4%) Level 3. NHB patients had a lower pre-delivery hemoglobin (10.9 mg/dL NHB vs. 11.7 NHW vs. 11.8 Hispanic, p< 0.01). In adjusted analyses, NHB patients had lower odds of receiving higher levels of PPH care compared to NHW patients (aOR 0.48, 95% CI 0.31-0.75, Table 1). As a proportion of Level 1 interventions, NHB patients received methylergonovine less often (9.0% NHB vs. 29.6% NHW vs. 30.3% Hispanic, p < 0.01). When stratified by severity of PPH, NHB patients had significantly lower odds of receiving higher levels of PPH care at an EBL between 1500-1999mL (aOR 0.32, 95% CI 0.14-0.78, Table 2).

Conclusion: NHB patients with PPH after cesarean birth had 50% lower odds of receiving higher levels of anti-hemorrhagic intervention and this finding persisted at higher EBL. Racial differences in PPH care escalation may underlie disparities in PPH outcomes.

Table 1: Multivariable ordinal regression models for relationship of race and ethnicity with receipt of higher levels[1] of anti-hemorrhagic intervention[2]

	Level 0 (none)	Level 1 (uterotonics)	Level 2 (procedural)	Level 3 (hysterectomy)	aOR (95% CI)[3]

579 | Obesity and Weight Gain: How are the SMFM Annual Meetings Weighing in?

Nkechinyelum Ogu; Jacqueline C. Hairston
Northwestern University Feinberg School of Medicine, Chicago, IL

4:00 PM - 6:00 PM

Objective: Obesity and weight gain are commonly understood risk factors for adverse pregnancy outcomes and the Society for Maternal-Fetal Medicine (SMFM) Annual Meeting is one of the primary venues for high impact research on this topic. We sought to determine whether scientific presentations regarding obesity were focused on interventions to improve maternal and neonatal outcomes versus identification of risk factors.

Study Design: This is a descriptive study of abstract submissions related to obesity from the 2020 to 2024 SMFM Annual Meetings. Two independent researchers searched abstract titles with the following terms: “obesity”, “obese”, “weight gain”, “habitus”, “overweight”, “body mass index”, and “BMI”. The abstracts were then reviewed to determine if obesity was studied as a risk factor or if a clinical intervention was evaluated for the management of patients with obesity. Abstracts with multiple search terms in the title were only analyzed once and redundancies were eliminated. Only human studies were eligible for inclusion. The categorization of each abstract was compared and if a discrepancy arose a third-party independent researcher provided final designation.

Results: Of the 6,023 abstracts presented at SMFM from 2020 to 2024, 254 (4.2%) were regarding obesity and weight gain and

met criteria for inclusion. There were no abstracts with "habitus" or "overweight" in the title. 38 (15%) abstracts focused on interventions related to obesity and weight gain. 216 (85%) abstracts concentrated on obesity as a risk factor. 16 (6.3%) abstracts were oral presentations, of which eight featured interventions. Abstract categorization by year was assessed (Table 1).

Conclusion: Obesity is a well-studied risk factor in perinatal outcomes, yet studies of interventions that aim to mitigate obesity-related morbidity represent a minority of presented science on this topic. Further studies directed towards interventions and protocols to improve care surrounding obesity and weight gain are needed.

Table 1: Abstract Categorization from 2020-2024

	Year										
	2020 n = 59		2021 n = 52		2022 n = 51		2023 n = 50		2024 n = 42

Intervention	1	10			1	4	2	4	3	3	28
Risk Factor	2	46			1	45	0	44	3	33	174
Total	3	56	0	0	2	49	2	48	6	36	202

580 | The Association Between Group B Streptococcus Colonization and Long Term Infectious Morbidity of the Offspring

Noa Leybovitz Haleluya[1]; Tamar Wainstock[2]; Eyal Sheiner[2]
[1]Soroka Medical Center, Meitar, HaDarom; [2]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom

4:00 PM - 6:00 PM

Objective: Group B *Streptococcus* (GBS) colonizes the gastrointestinal and genital tracts of pregnant women. Determining colonization state near delivery time is an important determinant of infections in infants. Positive GBS carrier state is associated with short-term infant morbidity and mortality. However, long-term effects were not thoroughly studied. We aimed to study the association between positive test for GBS colonization near delivery and long-term infectious morbidity of offspring.

Study Design: A population based cohort analysis was performed comparing infectious related pediatric morbidity among offspring to mothers with positive GBS status and negative or unknown GBS status. The analysis included all singletons born between the years 2002- 2021 at a single tertiary regional medical center. Infants with congenital malformations, multiple gestations, and cesarean deliveries were excluded from the analysis. Infectious related morbidities included hospitalizations or medical visits involving a pre-defined set of ICD-9 codes, as recorded in computerized files. A Kaplan-Meier survival curve was constructed to compare the cumulative infectious morbidity, and a Cox proportional hazards model was used to adjust for confounders.

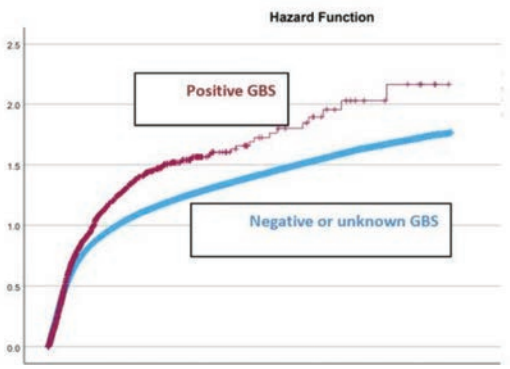
Results: The study population included 146103 singletons. Positive GBS carrier state was recorded in 2225 (1.5%) patients. The cumulative incidence of long-term infectious morbidity was higher among the offspring in the group of positive GBS (Figure; Log-rank $p < 0.001$). The association remained significant and independent while adjusting for gestational age, maternal age, maternal hypertension and diabetes and ethnicity (Table, Adjusted HR = 1.15, 95%CI 1.09-1.22, $p < 0.001$).

Conclusion: GBS colonization in genital tract near delivery is independently associated with an increased risk for long-term pediatric infectious morbidity of the offspring. Our results highlight the importance of GBS screening in pregnancy. In addition, we suggest using GBS status as a possible predictor for long-term pediatric morbidities which may require special surveillance in this group of children.

Table – Cox proportional hazards model for the association between GBS status and total infectious morbidity in the offspring.

Cox variable controlled for	Adjusted HR (95% CI)	P value
GBS status	1.15 (1.09-1.22)	<0.001
Maternal age	0.99 (0.99-1.00)	<0.001
Hypertension	1.06 (1.03-1.10)	<0.001
Gestational age in weeks	1.00 (1.00-1.01)	0.046
Maternal diabetes	1.13 (1.09-1.17)	<0.001
Ethnicity	0.99 (0.96-1.00)	0.071

Figure- A Kaplan-Meier cumulative hazard function of infectious morbidity in both groups



581 | Group B Streptococcus Vaginal Colonization and Long Term Respiratory Morbidity of the Offspring

Noa Leybovitz Haleluya[1]; Tamar Wainstock[2]; Eyal Sheiner[2]
[1]Soroka Medical Center, Meitar, HaDarom; [2]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom

4:00 PM - 6:00 PM

Objective: Group B *Streptococcus* (GBS) colonize the gastrointestinal and the genital tract. Vertical transmission primarily occurs following rupture of membranes or during passage through the birth canal. Early-onset neonatal GBS infection manifests as sepsis, pneumonia, or meningitis, while late-onset GBS disease most often presents as bacteremia. Both are associated with short-term morbidity and mortality. However, the long-term effects are not well established. We aimed to study the association between GBS colonization near and long-term childhood respiratory morbidity of offspring.

Study Design: A retrospective population based cohort analysis was performed, in which respiratory pediatric morbidity was compared between offspring to mothers with positive GBS and offspring to mothers with negative or unknown GBS status. The analysis included all singletons born between the years 2002-2021 at a tertiary medical center. Infants with congenital malformations, multiple gestations and cesarean deliveries were excluded from the analysis. Data for the diagnosis of respiratory morbidity was extracted from community-based clinics and hospitalization records. A Kaplan-Meier survival curve was

constructed to compare the long- term cumulative respiratory morbidity, and a Cox proportional hazards model was used to adjust for confounders

Results: The study population included 146103 singletons. Positive GBS carrier state was recorded in 2225 (1.5%) patients. The cumulative incidence of long-term respiratory morbidity was comparable between both groups (Figure, Log-rank p = 0.540). Selected respiratory morbidities groups are presented in the Table. Using a Cox proportional hazard model, no significant association was noted between GBS colonizationand the risk for long-term pediatric respiratory morbidity, while adjusting for gestational age, maternal age, ethnicity, maternal hypertension and diabetes (Adjusted HR = 1.00, 95%CI 0.93-1.08, $p = 0.920$).

Conclusion: GBS colonization in maternal genital tract is not independently associated with a risk for long-term pediatric respiratory morbidity of the offspring

Table - Respiratory morbidity in the offspring in positive GBS and negative or unknown GBS groups

respiratory Disease	Positive GBS (n=2225)	No GBS (n=143878)	OR (95% CI)	P value
Asthma	31.7% (706)	36.2% (52140)	0.82 (0.75-0.89)	<0.001
Fibrosis	0% (0)	0.1% (103)	0.99 (0.98-0.99)	0.207
Pneumonitis	0 % (1)	0.1% (134)	0.99 (0.98-0.99)	0.150

582 | Basal Insulin Type and Neonatal Outcomes: a Secondary Analysis of the Mompod Trial

Noelia Zork[1]; Qi Yan[1]; Gladys (Sandy) A. Ramos[2]; Celeste Durnwald[3]; Mark B. Landon[4]; On behalf of the MOMPOD consortium

[1]Columbia University Irving Medical Center, New York, NY; [2]University of California, San Diego, San Diego, CA; [3]Hospital of University of Pennsylvania, Philadelphia, PA; [4]The Ohio State University, Columbus, OH

4:00 PM - 6:00 PM

Objective: A variety of basal insulin types (e.g. intermediate vs long-acting) are available for managing diabetes in pregnancy, however, the optimal choice of basal insulin remains uncertain in those with Type 2 diabetes (T2D) and diabetes diagnosed in early pregnancy (eDM). We aimed to compare neonatal outcomes according to basal insulin type.

Study Design: A secondary analysis of a randomized trial comparing the addition of metformin versus placebo in insulin treated pre-existing T2D or eDM at < 23 weeks. Included were those using either intermediate or long-acting insulin at randomization, though specific insulin types were not recorded. The primary outcome was a composite of newborn complications (Table 2). Categorical variables were compared between those on intermediate versus long-acting insulin using Chi-square or Fisher's exact test, and continuous variables using t-test or Wilcoxon rank sum test. Logistic regression estimated the association between the basal insulin type and the composite outcome. Adjustments were made for confounding.

Results: A total of 812 participants were included in the analysis, 485 (59.7%) treated with intermediate and 327 (40.2%) with long-acting insulin. There were several demographic differences between the groups (Table 1). The primary neonatal composite outcome was less common among participants treated with intermediate insulin (65.8% vs 72.8%, p = 0.035); however, after adjusting for confounders, there was no significant association (Table 2). There were no associations between basal insulin type and the individual components of the composite outcome. A post hoc power analysis confirmed that the study had sufficient power to detect a 10% difference in the primary outcome.

Conclusion: In participants with T2DM and eDM, while basal insulin choice varied by maternal characteristics there was no significant difference in neonatal outcomes. Consistent with a shared decision making model, providers and patients can be reassured that their choice of basal insulin can be based on preference and/or insurance coverage without concerns for adverse nor varying neonatal outcomes.

583 | The Triple Threat of Socioeconomic Insecurity: Housing, Financial, and Food Insecurity Association with Postpartum Depression

Noor Ali; Emily A. DeFranco
Department of Obstetrics and Gynecology, University of Kentucky, Lexington, KY

4:00 PM - 6:00 PM

Objective: Examine the influence of housing, financial, and food insecurity on postpartum depression.

Study Design: Using data from the Pregnancy Risk Assessment Monitoring System (PRAMS) Core and Standard Questionnaire from 2016 to 2021 linked to US birth certificate data, a retrospective cohort study was performed to quantify the relative risk of the exposures of housing, financial, and/or food insecurity on the outcome of postpartum depression. Pre-pregnancy depression was determined by anyone who reported depression in the three months before pregnancy. Postpartum depression was quantified by a previously created variable by PRAMS titled "Postpartum Depression Indicator." Participant surveys occurred at 2-6 months postpartum. Generalized linear modeling (GLM) estimated adjusted relative risk (adjRR) and 95% CIs while accounting for the confounding influences of maternal race, marital status, education, and WIC utilization.

Results: 221,381 Postpartum patients completed the Pregnancy Risk Assessment Monitoring System (PRAMS) Core and Standard Questionnaire. Of those surveyed, 11,482 (5.2%), 373 (3.2%), and 4,302 (3.0%) reported financial, food, and housing insecurity, respectively, and 15,768 (7.1%) had any of the three. The prevalence of reported depression was 15.8% before pregnancy and 14.4% postpartum. Each exposure was associated with a significantly higher risk of pre-pregnancy and postpartum depression, even after adjusting for race, marital status, education, and WIC usage (see table). The highest individual risks for depression were observed with food insecurity, with greater than 2-fold increased risk for depression before pregnancy and postpartum.

Conclusion: The physical and social environments of birthing people can impact their psychological state. Postpartum depression can influence the bond between the mother-infant dyad, potentially contributing to adverse psychosocial outcomes. Public health initiatives should focus on improving access to financial, food, and housing resources for reproductive-age people to mitigate postpartum depression effects.

Table 1: Demographic characteristics of the study population

	No Housing, Food, or Financial Insecurity n= 205,613 (92.9%)	Housing Insecurity n= 4,302 (3.0%)	Food Insecurity n= 373 (3.7%)	Financial Insecurity n= 11,482 (5.2%)	Housing, Food, or Financial Insecurity n= 15,768 (7.12%)

4:00 PM - 6:00 PM

Objective: Participants in postpartum self-measured blood pressure (SMBP) programs can have antihypertension medications initiated remotely, thereby preventing severe hypertension (HTN) and reducing HTN-related readmissions, emergency department (ED) presentations, and severe maternal morbidity (SMM). Nifedipine and labetalol are commonly prescribed first-line HTN medications, although outcomes related to their use may differ. We aimed to compare outcomes between participants in a postpartum remote SMBP program who were prescribed nifedipine versus labetalol after hospital discharge.

Study Design: Postpartum patients with HTN at our tertiary care hospital are offered enrollment in our remote 6-week SMBP program, during which antihypertensives are prescribed for BP >140/90 mmHg. For this analysis, participants were stratified by antihypertensive prescribed (nifedipine versus labetalol). Patients who were prescribed a different medication or who were prescribed both medications were excluded. The primary outcome

was a composite of postpartum readmission or ED presentation for HTN within 30 days of delivery hospitalization. Secondary outcomes included HTN-related SMM. A generalized linear model was used to estimate relative risks (RR) after adjustment for differences in medical conditions.

Results: Among 2003 remote SMBP participants, 446 (22.3%) were prescribed either labetalol alone (n = 104; 23%) or nifedipine alone (n = 342; 77%) after hospital discharge. Differences between groups were identified in type of HTN diagnosis (Table 1). After controlling for these differences, the rate of the composite outcome of HTN-related postpartum readmission or ED presentation was similar between those who received labetalol (n = 23 (22.1%)) or nifedipine (n = 65 (19.1%); adjusted relative risk = 1.26 (0.81, 1.94) (Table 2). There were no differences between groups for secondary outcomes.

Conclusion: In our remote SMBP program for postpartum patients with HTN, there was no difference in risk of HTN-related healthcare utilization between those prescribed labetalol alone or nifedipine alone for persistent HTN after hospital discharge.

Table 1: Demographics

Data presented at n (%)
*adjusted for diagnosis of chronic hypertension with superimposed preeclampsia and chronic hypertension alone
**Includes any of the following HTN-related condition: stroke, seizure/eclampsia, acute fatty liver of pregnancy, posterior reversible encephalopathy syndrome, pulmonary edema, heart failure, HELLP syndrome, placental abruption, postpartum hemorrhage, acute kidney injury, transaminitis

585 | Association Between Treatment Modalities for Gestational Diabetes Mellitus and Risk of Attention-Deficit/Hyperactivity Disorder in Offspring

Ofer Fischer[1]; Shaked Yarza[2]; Eran Hadar[3]; Asnat Walfisch[4]; Keren Tzadikevitch Geffen[3]
[1]Helen Schneider Hospital for Women, Rabin Medical Center, Kfar Hess, HaMerkaz; [2]Meir medical center, Kfar Saba, HaMerkaz; [3]Rabin Medical Center, Petach Tikva, HaMerkaz; [4]Helen Schneider Hospital for Women, Rabin Medical Center,, Petah Tikva, HaMerkaz

4:00 PM - 6:00 PM

Objective: The association between gestational diabetes mellitus (GDM) and long-term neurodevelopmental disorders (NDD), particularly attention-deficit/hyperactivity disorder (ADHD), remains a topic of debate. We aimed to explore the association between GDM, either dietary controlled (GDMA1) or pharmacologic treated (GDMA2) and the risk of ADHD in the offspring.

Study Design: Retrospective population-based study included all deliveries in "Clalit" HMO hospitals from 2012 to 2020. Women with unknown diabetic status during pregnancy or with pregestational diabetes were excluded from the study. Offspring were followed through electronic medical records starting at age 4 years.

Results: Among 15,074 children exposed to maternal GDM (13,566 GDMA1, 1,508 GDMA2) and 187,112 children born to mothers with normal glycemic index (control group), 13,446 were diagnosed with ADHD, median age was 6.5 years with interquartile range (IQR) 2.15 years. The incidence of ADHD was significantly higher in the GDM groups compared to 6.6% in the control group; 7.4% (pV< 0.001) in the GDMA1 group, and 8.5% (pV< 0.001) in the GDMA2 group. The adjusted odds ratios (aOR) for ADHD were 1.30 (95% CI: 1.06-1.57, p = 0.008) for children exposed to GDMA2 and 1.09 (95% CI: 1.01-1.16, p = 0.02) for those exposed to GDMA1, compared to unexposed children. Additionally, gestational hypertension during pregnancy was identified as a significant risk factor for ADHD, with an aOR of 1.19 (95% CI: 1.003-1.39, p = 0.04).

Conclusion: Maternal GDM significantly increases the risk of ADHD in exposed offspring. The need for pharmacologic intervention to control gestational diabetes further amplifies this risk.

586 | False Positive Prenatal Diagnosis of Placenta Accreta Spectrum: Factors Associated with Overdiagnosis and Perinatal Outcomes

Olga Grechukhina[1]; Colleen Sinnott[2]; Khadija Alshowaikh[1]; Jennifer F. Culhane[1]; Lisbet S. Lundsberg[1]; Caitlin Partridge[1]; Mert Ozan Bahtiyar[2]; Sonya Abdel-Razeq[1]
[1]Yale School of Medicine, New Haven, CT; [2]Yale University, New Haven, CT

4:00 PM - 6:00 PM

Objective: Accurate prenatal prediction of placenta accreta spectrum (PAS) is known to improve maternal and neonatal outcomes. However, when striving to increase sensitivity of prenatal sonographic identification of PAS, the risk of overdiagnosis also

increases. We aim to identify factors associated with false positive prenatal diagnosis of PAS and the impact on perinatal outcomes.
Study Design: All delivery encounters at a single academic institution from 2013-2023 were queried for ICD-10 codes for PAS. Cases (n = 775) were then manually reviewed and those with any degree of prenatal suspicion for PAS but no evidence of PAS at the time of delivery were included (n = 181). For each case, two variables were created by a consensus of 4 clinical experts: prenatal suspicion (low - true negative; or high - false positive diagnosis), determined by prenatal ultrasound reports and documentation of delivery planning, and *a priori* risk for PAS (low or high) based on clinical risk factors (i.e prior uterine surgeries and placenta previa). Other patient attributes and perinatal outcomes were identified through the EMR. Bivariate analyses comparing low *vs* high prenatal suspicion and patient attributes were conducted. Multivariate logistic regression was performed on significantly different outcome measure - preterm birth (PTB) - adjusting for covariates significant at $p< 0.05$.
Results: Of the 181cases, 73 (40.3%) were coded as high prenatal suspicion. Advanced maternal age, race, multiparity, higher gestational age at initial prenatal visit and ultrasound, high *a priori* risk and placenta previa were associated with high prenatal suspicion for PAS. High prenatal suspicion was an independent risk factor for PTB after adjusting for *a priori* risk and placenta previa (aOR 4.6, 95% 2.1-10.2, $p< 0.0001$).
Conclusion: False positive PAS diagnosis (prenatal high suspicion) results in 4.6 times increased risk of iatrogenic preterm birth compared to those with low suspicion. New tools are urgently needed to accurately prenatally rule out PAS to decrease the risk of iatrogenic adverse neonatal outcomes.

587 | Can B-type Natriuretic Peptide (BNP) help Differentiate Gestational Hypertension and Preeclampsia from Chronic Hypertension?

Olivia Grubman[1]; Mackenzie MItchell[2]; Christina Cary[2]; Mia A. Heiligenstein[3]; Thomas Owens[4]; Guillaume Stoffels[5]; Zainab Al-Ibraheemi[4]; Desmond M. Sutton[6]; Lois Brustman[4]
[1]Westchester Medical Center, Westchester, NY; [2]Icahn School of Medicine, New York, NY; [3]Mount Sinai West, Astoria, NY; [4]Icahn School of Medicine at Mount Sinai West, New York, NY; [5]Icahn School of Medicine at Mount Sinai, New York, NY; [6]Mount Sinai West Hospital, New York, NY

4:00 PM - 6:00 PM
Objective: B-type natriuretic peptide (BNP) is a cardiac biomarker that is synthesized and secreted from the cardiac ventricles in response to volume expansion and pressure overload. The primary objective was to determine if BNP value could help differentiate gestational hypertension, preeclampsia without severe features and preeclampsia with severe features from chronic hypertension (CHTN). Given the acuity of gestational hypertension (GHTN) and preeclampsia (PEC) versus the chronic nature of preexisting CHTN, we hypothesized that a higher BNP value will be associated with GHTN and PEC compared to CHTN.
Study Design: This was a retrospective cross-sectional study involving 391 patients evaluated for hypertension in pregnancy from January 2022 to February 2023 in an urban teaching hospital. CHTN, GHTN and PEC were defined according to ACOG. Those patients with superimposed preeclampsia were excluded. Demographic characteristics, BNP value, hypertension diagnosis and delivery information were collected for all patients. BNP value was collected on the labor and delivery unit at the time of initial evaluation for hypertensive disease.

Results: The study population consisted of 391 patients. There were 326 patients in the GHTN/PEC group (149 with GHTN, 54 with PEC w/oSF & 123 with PEC w/SF) and 65 in the CHTN group. There was no significant difference in patient demographics between the two groups. The mean BNP level for the GHTN/PEC group was 22.0 pg/mL, whereas the mean BNP level for the CHTN group was 11.2 pg/mL, which was significantly different (p = 0.0004) (Figure 1 & Table 1).

Conclusion: This study demonstrates that BNP levels are significantly higher in patients with GHTN/PEC compared to those with CHTN. Therefore, BNP may be a useful test in helping to differentiate between CHTN and GHTN/PEC at the time of initial diagnosis.This is important given the differences in management and delivery implications for each disease.

Figure 1. BNP level and hypertensive groups

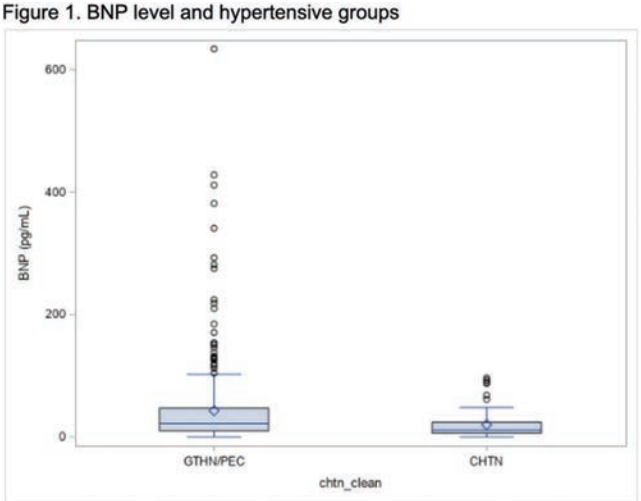

Table 1. BNP level and hypertensive groups

Characteristic	ALL (n=391)	CHTN (n=65)	GHTN/PEC (n=326)	P value
BNP level (pg/mL) – median (IQR)	19.3 (10.0, 40.9)	11.2 (9.9, 24.0)	22.0 (10.0, 47.3)	0.0004
BNP level (pg/mL) – range	(0.0, 633.8)	(0.0, 96.2)	(0.0, 633.8)	

588 | Evaluating the Impact of Labor Induction on Autism Spectrum Disorder Risk

Omri Zamstein[1]; Tamar Wainstock[2]; Eyal Sheiner[2]
[1]Soroka University Medical Center, Soroka University Medical Center, HaDarom; [2]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom

4:00 PM - 6:00 PM

Objective: Significant effort has been dedicated in recent years to uncovering the environmental factors, particularly perinatal exposures, that contribute to the development of autism spectrum disorder (ASD). However, the overall picture remains incomplete, with many suggested associations lacking consistency. Given the frequent use of labor inductions for medical reasons as well as patient preference, we aimed to investigate their relationship with ASD development, considering synergistic factors that may influence ASD onset.

Study Design: A population-based cohort study was conducted, focusing on singleton births. The study aimed to compare the occurrence of ASD in children, considering both hospital and community-based diagnoses, in relation to whether labor was induced (using mechanical cervical ripening or prostaglandins, with or without oxytocin) or began spontaneously. A Kaplan-Meier survival curve was employed to assess the cumulative ASD incidence, and a Cox proportional hazards model was used to account for confounders.

Results: Among 115,081 births, 13,071 (11.4%) were labor induced, with the remainder beginning spontaneously. Pregnancy complications, such as gestational diabetes mellitus, preeclampsia or eclampsia, and non-reassuring fetal heart rate patterns, were significantly more common in the labor induction group (p< 0.001 for all). Conversely, preterm births were more prevalent in the spontaneous labor onset group (7.1% vs. 5.3%, p< 0.001; Table). During follow-up, 767 children were diagnosed with ASD: 1.0% in the labor induction group and 0.6% in the spontaneous labor onset group (p< 0.001). The Kaplan-Meier analysis showed a significantly higher cumulative hazard for ASD diagnosis in the labor induction group (log-rank p-value < 0.001; Figure). However, after adjusting for maternal, delivery, and fetal factors such as age, cesarean delivery, ethnicity, and gestational conditions, no significant association was found between labor induction and ASD risk (adjusted HR = 1.21, 95% CI 0.99–1.47, p = 0.063).

Conclusion: Labor induction does not appear to be associated with an increased risk of ASD.

Table. Comparison of Obstetrical Characteristics and ASD Risk Based on Labor Induction vs. Spontaneous Labor Onset.

	Labor induction (*n*=13,071, 11.4%)	Spontaneous labor onset (*n*=102,010, 88.6%)	*P*-value
	Obstetrical characteristics		
Maternal age (mean ± SD)	28.1 ± 5.7	28.2 ± 5.7	0.006
Gestational diabetes mellitus (%)	9.0	3.4	<0.001
Preeclampsia or eclampsia (%)	8.1	2.7	<0.001
Preterm birth (<37 weeks, %)	5.3	7.1	<0.001
Non-reassuring fetal heart rate patterns (%)	10.3	5.8	<0.001
Cesarean delivery (%)	13.4	15.4	<0.001
	Autism spectrum disorder		
ASD (cases, %)	125 (1.0)	642 (0.6)	<0.001
Adjusted HR [a],	1.21 (95% CI 0.99-1.47)	1 (*reference*)	0.063

589 | Gender as a Determinant of Neurological Sequelae in Twin Gestations

Omri Zamstein[1]; Tamar Wainstock[2]; Eyal Sheiner[2]

[1]Soroka University Medical Center, Soroka University Medical Center, HaDarom; [2]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom

4:00 PM - 6:00 PM

Objective: Evidence suggests that biological and genetic differences between genders may influence the prevalence and severity of various perinatal and chronic health outcomes. To further investigate these discrepancies, we conducted a detailed evaluation of the long-term neurological outcomes in male and female offspring from twin gestations.

Study Design: A population-based sibling analysis was conducted at a tertiary referral center, focusing on twin births of male-female dyads. The study aimed to compare the occurrence of neurological-related morbidity throughout childhood, considering both community and hospital-based diagnoses, in relation to offspring gender. A Kaplan-Meier survival curve was utilized to evaluate the cumulative incidence of neurological morbidity, while a Cox proportional hazards model was applied to control for confounding variables.

Results: The analysis of 1,471 twin pairs revealed gender differences in neurological and psychiatric conditions (Table). Males exhibited higher rates of ADHD (8.3% vs. 3.5%, p< 0.001) and total neurological-related morbidity (21.5% vs. 17.4%, p = 0.006). Notably, sleep disorders were only reported in males (0.3%, p = 0.02), and developmental disorders were also more prevalent among males compared to females (4.3% vs. 2.5%, p = 0.008). The Kaplan-Meier analysis demonstrated an increased cumulative neurological morbidity among male offspring (log-rank p-value = 0.004; Figure). In a Cox regression hazards model, which accounted for mode of delivery and small-for-gestational-age neonates, male gender remained independently associated with long-term neurological sequelae (aHR = 1.28, 95% CI 1.08-1.51, p = 0.004).

Conclusion: Male offspring from twin gestations are notably more prone to experiencing long-term neurological morbidity.

Table. Long-term neurological morbidity, by offspring gender, among twin gestation.

	Males (n=1,438)	Females (n=1,471)	*p*-value
Autism Spectrum Disorder (%)	13 (0.9)	7 (0.5)	0.183
Muscular Dystrophy (%)	3 (0.2)	3 (0.2)	0.98
Eating Disorders (%)	8 (0.6)	13 (0.9)	0.38
Sleep Disorders (%)	5 (0.3)	0 (0)	0.02
Movement Disorders (%)	46 (3.2)	51 (3.5)	0.76
Cerebral Palsy (%)	7 (0.5)	6 (0.4)	0.79

590 | Labor Progression in Women with or without Premature Rupture of Membranes

Or Bercovich[1]; Daniela Chen[2]; Natav Hendin[1]; Shay Sukenik[3]; Eran Hadar[1]; Ohad Houri[1]

[1]Rabin Medical Center, Petach Tikva, HaMerkaz; [2]Helen Schneider Hospital for Women, Rabin Medical Center, Petach-Tikva, Tel Aviv, HaMerkaz; [3]Beilinson, Tel Aviv, HaMerkaz

4:00 PM - 6:00 PM

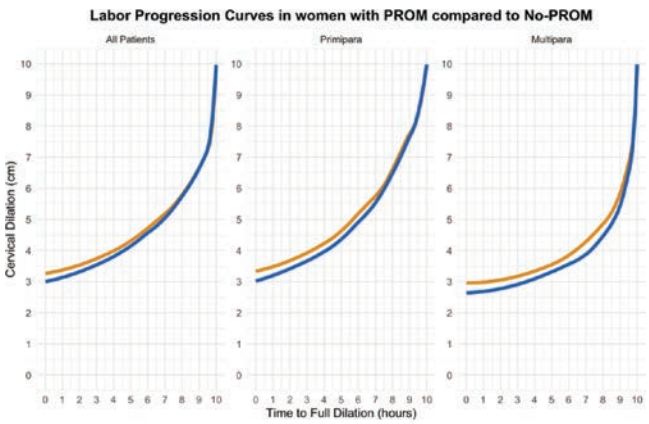
Objective: To compare labor progression in women with premature rupture of membranes (PROM) versus those without PROM.

Study Design: Retrospective study conducted at a tertiary university medical center between July 2012 and September 2020. Women carrying singleton pregnancies who underwent vaginal delivery at or beyond 37 weeks of gestation were included. Exclusion criteria included multiple gestations, non-vertex presentations, and cesarean deliveries. The cohort was divided into two groups: PROM and No-PROM. Interval-censored regression estimated median labor duration at each centimeter of

cervical dilatation. Multivariate analyses adjusted for maternal age, chronic hypertension, thrombophilia, and gestational age were conducted.

Results: 26,438 women were included, with 6,626 (25.1%) in the PROM group and 19,812 (74.9%) in the No-PROM group. In primiparous women, first stage of labor (3-10cm) was significantly shorter in the PROM compared to the No PROM group, with medians of 5.00 (95th percentile 12.79) versus 5.48 hours (95th percentile 13.91; P< 0.001). Similarly, in multiparous women, the median times were 2.70 (95th percentile 8.68) versus 3.16 hours (95th percentile 10.06; P< 0.001). The active phase (6-10 cm) did not significantly differ in primiparous women with medians of 2.76 (95th percentile 8.53) versus 2.84 hours (95th percentile 9.01; P = 0.394). However, multiparous women with PROM had a shorter active phase with medians of 1.02 (95th percentile 4.16) versus 1.16 hours (95th percentile 4.82; P = 0.002).

Conclusion: Labor progression from 3 cm to full dilatation was significantly shorter in women with PROM compared to those without PROM, regardless of parity. Active phase duration was statistically significantly shorter in multiparous women with PROM, albeit the median difference of 8 minutes is not clinically significant.



Labor duration in women with PROM compared to No-PROM

Comparison*	PROM	No-PROM	Adjusted_P_Value**
3cm to 10cm – Primipara	5.00 (12.79)	5.48 (13.91)	<0.001
3cm to 10cm – Multipara	2.70 (8.68)	3.16 (10.06)	<0.001
3cm to 10cm – All	3.94 (12.39)	4.27 (13.26)	<0.001
6cm to 10cm – Primipara	2.76 (8.53)	2.84 (9.01)	0.394
6cm to 10cm – Multipara	1.02 (4.16)	1.16 (4.82)	0.002

591 | Labor Progression in Women with SGA versus AGA Newborns

Or Bercovich[1]; Daniela Chen[2]; Natav Hendin[1]; Shay Sukenik[3]; Eran Hadar[1]; Ohad Houri[1]
[1]Rabin Medical Center, Petach Tikva, HaMerkaz; [2]Helen Schneider Hospital for Women, Rabin Medical Center, Petach-Tikva, Tel Aviv, HaMerkaz; [3]Beilinson, Tel Aviv, HaMerkaz

4:00 PM - 6:00 PM

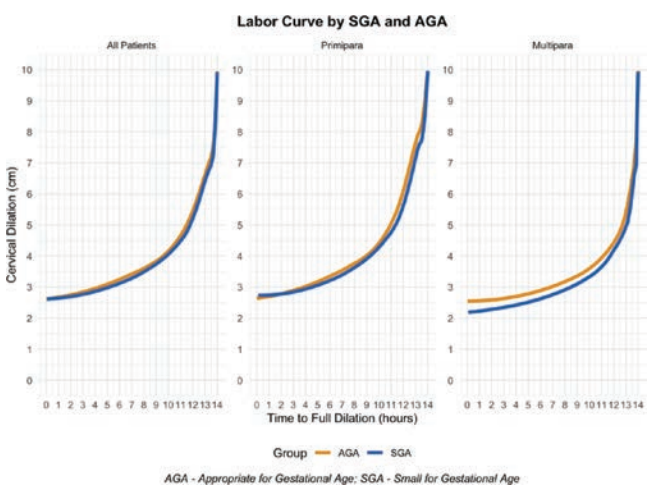
Objective: To compare labor progression in women with small for gestational age (SGA) newborns versus those with appropriate for gestational age (AGA) newborns.

Study Design: Retrospective study at a tertiary university medical center from July 2012 to September 2020. Women with singleton pregnancies at or beyond 37 weeks of gestation were included. Exclusion criteria were multiple gestations, non-vertex presentations, previous multiple cesarean deliveries, and neonates with congenital anomalies, 5-minute Apgar < 7, or admission to the intensive care unit. The cohort was divided into SGA (birth weight < 10th percentile) and AGA (birth weight 10-90th percentile) newborns.

Interval-censored regression estimated median labor durations at each centimeter of cervical dilatation. Multivariate analyses adjusted for maternal age, BMI, and gestational age.

Results: 23,629 women were included, with 2,283 (9.66%) in the SGA group and 21,346 (90.33%) in the AGA group. In both primiparous and multiparous women, the duration of the first stage of labor (3-10cm dilatation) was not significantly different between the SGA and AGA groups, with medians of 4.45 (95th percentile 13.31) vs. 4.65 hours (95th percentile 12.27; P = 0.54) in primiparous women and 2.49 (95th percentile 9.73) vs. 2.72 hours (95th percentile 9.34; P = 0.88) in multiparous women, respectively. The active phase of labor (6-10cm dilatation) was shorter in primiparous women with SGA compared to AGA, with a median of 1.92 (95th percentile 7.61) vs. 2.22 hours (95th percentile 7.58; P< 0.01). However, no significant difference was observed in multiparous women, with medians of 0.64 hours (95th percentile 4.08) vs. 0.84 hours (95th percentile 4.45; P = 0.95) in the SGA and AGA groups, respectively.

Conclusion: Women with SGA and AGA newborns have a similar duration of labor overall. Although active phase of labor was statistically significantly shorter in primiparous women with SGA, the difference of 18 minutes is of limited clinical significance.



Labor Progression Curves in women with SGA compared to SGA newborns

Comparison*	SGA	AGA	Adjusted_P_Value*
3cm to 10cm – Primipara	4.45 (13.31)	4.65 (12.27)	0.550
3cm to 10cm – Multipara	2.49 (9.73)	2.72 (9.34)	0.881
3cm to 10cm – All	4.16 (14.08)	4.19 (12.94)	0.600
6cm to 10cm – Primipara	1.92 (7.61)	2.22 (7.58)	0.005
6cm to 10cm – Multipara	0.64 (4.08)	0.84 (4.45)	0.954

592 | Fetal Head Circumference Underestimation of Neonatal Head Circumference: Results from a Prospective Multicenter Study

Patrick Dicker[1]; Naomi Burke[1]; Fergal D. Malone[2]
[1]Royal College of Surgeons in Ireland, Dublin, Dublin; [2]Royal College of Surgeons in Ireland, Dubiln, Dublin

4:00 PM - 6:00 PM

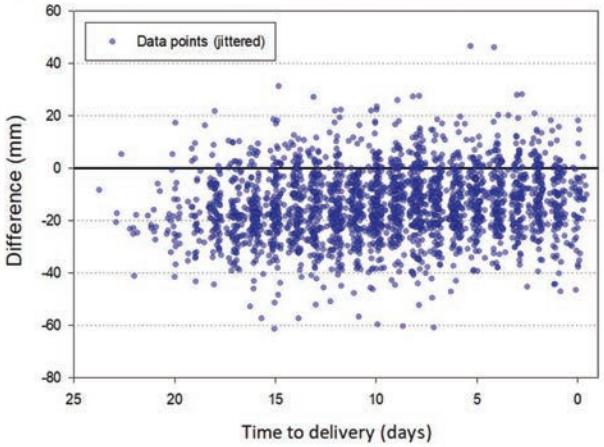
Objective: Being able to prospectively predict difficult labor, and the need for operative vaginal delivery or cesarean delivery, is of great value in contemporary obstetric practice, in particular for nulliparous patients. Increasing fetal head circumference (FHC) has been the focus of predictors in this regard, but this assumes that prenatal ultrasound assessment of FHC is an accurate surrogate marker for neonatal head circumference (NHC).

Study Design: We evaluated the accuracy of prenatal FHC measurement for predicting NHC in a secondary analysis of a prospective multicenter study of nulliparous term labor. 2,336 pregnancies with an ultrasound examination at 39 weeks' gestation were included, in which FHC was measured in triplicate and averaged. NHC was measured at birth by a standard Holtain measuring tape, placed 2cm above the ears around the occipitofrontal circumference. Linear regression was used to compare differences in FHC and NHC, adjusting for time to delivery (TTD) in days. An alternative approach without adjustment for TTD, FHC and NHC were compared using the 90th centiles from the INTERGROWTH-21st study for FHC and NHC.

Results: The median [IQR] gestational age at ultrasound examination was 39.3 weeks [39.0 - 39.6], and FHC was 337mm [329-345]. The median [IQR] gestational age at delivery was 40.7 weeks [40.3–41.3], and NHC was 350mm [340-360]. Regression analysis indicated that FHC underestimated NHC by 10.5mm on average (difference = -10.5–0.37 * TTD, see Figure 1). Centile-based comparisons found that 17% of FHC measurements were above the 90th centile, compared to 30% of NHC values above the 90th centile.

Conclusion: Late pregnancy ultrasound measurement of FHC underestimates neonatal head circumference by approximately 1cm at term, and a centile-based comparison did not compensate for this difference. This systematic error may have important implications and should be taken into account in the interpretation of fetal head circumference.

Figure 1. Difference between FHC and NHC according to Time to Delivery (days)



593 | Suboptimal Fetal Lung Growth After Fetal Endoluminal Tracheal Occlusion in Congenital Diaphragmatic Hernia: Clinical Characteristics

4:00 PM - 6:00 PM

Objective: Suboptimal fetal lung growth (SFLG) affects cases that undergo Fetoscopic endoluminal tracheal occlusion(FETO) in severe left-sided congenital diaphragmatic hernia (L-CDH).We describe the demographic and clinical characteristics of SFLG and optimal fetal lung growth (OFLG) after FETO

Study Design: Singleton pregnancies with isolated L-CDH, defined as observed-to-expected lung-to-head ratio (O/E LHR) < 25% and normal chromosomes, underwent FETO under an IRB- and FDA-approved clinical trial protocol (NCT02596802) at the UTHealth Houston Fetal Center from 2015-2024. The FETO balloon insertion was scheduled at 27-30 weeks' gestation (wGA), and balloon removal at 34-35-wGA.Observed-to-expected total fetal lung volume (O/E TFLV) was measured by MRI before and 3 weeks after FETO, and percent changes from pre- to post-FETO MRIs were calculated.Descriptive, analytical statistics and (ROC)

curve analysis associating metrics with neonatal survival and the need for extracorporeal life support (ECLS) were performed via R interface(jamovi.org).

Results: 19 pregnant women were enrolled, 4 children died, 2 cases did not undergo the post-FETO-MRI, 2 cases died before surgical repair.Area under the ROC curve(AUC) of O/E TFLV for the prediction of survival and not need for ECLS were 0.974, and 0.729, respectively.The best cut-off for identification of SFLG was an increase of < 12.8% of O/E TFLV 21 days post-FETO with a sensitivity of 92.3% and specificity of 100% to predict childhood mortality at hospital discharge.An increase of ≥ 12.8 % of TFLV(OFLG) had a sensitivity of 90% and specificity of 57.1% to predict children that do not require ECLS. Demographic and maternal characteristics were not different between SFLG and OFLG(Table 1). SFLG had lower O/E TFLV and O/E LHR three weeks post-FETO, and was associated with a lower frequency of surviving hospital discharge than OFLG(Table 2).

Conclusion: SFLG, characterized by decreased lung volume, is associated with a lower survival than optimal fetal lung growth.

Table 1. Demographic and clinical characteristics according to the percent increase in observed-to-expected total lung volume(O/E TLFV) after fetoscopic endoluminal tracheal occlusion (FETO)

Demographic and Clinical Characteristics	Optimal Fetal Lung Growth (≥ 12.8% O/E TFLV) (n=12)	Suboptimal Fetal Lung Growth (>12.8% O/E TFLV) (n-5)	P value
Maternal age, years	25 (21–43)	32 (22–41)	0.43

4:00 PM - 6:00 PM

Objective: Sleep disorders in pregnancy have been associated with adverse perinatal outcomes (APO) including hypertensive disorders of pregnancy (HDP), preterm birth (PTB), and gestational diabetes mellitus (GDM), yet prospective studies that use validated tools to assess sleepiness in pregnancy are limited. We aimed to assess the association of sleepiness in pregnancy with APOs.

Study Design: In this secondary analysis of data from a large, diverse observational cohort of nulliparous individuals conducted at eight US medical centers, those with self-reported sleep data were included. Sleepiness was evaluated in early (6-13 weeks) and mid pregnancy (22-29 weeks) via the Epworth Sleepiness Scale, a validated tool to assess daytime sleep propensity, the ability to fall or stay asleep. Those with scores ≤10 were categorized as having no sleepiness (referent), 11-15 moderate sleepiness, and 16-24 severe sleepiness. The outcomes were HDP, GDM, PTB, and small-for-gestational-age birth < 10%ile (SGA). Multivariable logistic regression analysis was performed to evaluate the associations of moderate and severe sleepiness with each APO. A sensitivity analysis that included "high risk for sleep disordered

breathing (SDB)," measured by an adapted Berlin Questionnaire for Sleep Apnea, as a covariate in the multivariable model was performed.

Results: Of 6,806 eligible participants who completed sleep questionnaires at both time points, the average sleepiness score in early and mid pregnancy was 7.8 (SD 4.1) and 6.5 (SD 4.0) respectively. In early pregnancy, 20.0% and 4.3% of people experienced moderate and severe sleepiness, respectively; in mid pregnancy 14.4% and 2.5% experienced moderate and severe sleepiness. Severe sleepiness in mid-pregnancy was associated with GDM (aOR 1.78, 95% CI 1.01-3.12) and SGA (aOR 1.35, 95% CI 1.06-1.71) (Table). Findings were similar when accounting for SDB.

Conclusion: Severe sleepiness during pregnancy, a symptom reflective of sleep quality, length, and often SDB, is associated with GDM and SGA suggesting a potential relationship with maternal glucose metabolism and placental function.

Table. Association of sleepiness and adverse perinatal outcomes

	Total	Moderate Sleepiness	Severe Sleepiness
		Early pregnancy (6-13 weeks)	
	N=6, 806	N= 1,361 (20.0%)	N= 293 (4.3%)
HDP		0.92 (0.75, 1.13)	0.94 (0.55, 1.61)
GDM		1.16 (0.74,1.82)	1.24 (0.70, 2.21)
PTB		0.80 (0.68, 0.94)	1.17 (0.77, 1.78)
SGA		0.99 (0.84, 1.18)	0.79 (0.57, 1.11)
		Mid pregnancy (22-29 weeks)	
		N= 980 (14.4%)	N= 170 (2.5%)
HDP		0.80 (0.68, 0.95)	0.95 (0.69, 1.33)
GDM		1.18 (0.80, 1.73)	**1.78 (1.01, 3.12)**
PTB		0.92 (0.73, 1.15)	1.30 (0.76, 2.20)
SGA		0.92 (0.73, 1.16)	**1.35 (1.06, 1.71)**

Data presented as % and adjusted odds ratio (95% confidence interval)

HDP- Hypertensive disorders of pregnancy, GDM- Gestational diabetes, PTB-preterm birth (<37w), SGA- Small for gestational age status (<10%ile), aOR- adjusted odds ratio, CI- confidence interval

1. Moderate sleepiness scores were defined as a score of 11-15; Severe sleepiness score were defined as 16-24.
2. Multivariable models were adjusted for early pregnancy maternal age, race/ethnicity as a social construct, insurance, body mass index, and current smoking within the prior 3 months.
3. The 95% confidence intervals are based on robust standard errors, which are clustered at the study sites.
4. The sample exlcuded those with chronic hypertension and pregestational diabtes.

595 | Association of Sleepiness in Pregnancy with Cardiovascular Health 2-7 years after first birth

Rachel L. Friedlander[1]; Xiaoning Huang[2]; Sadiya S. Khan[3]; Phyllis Zee[3]; Philip Greenland[4]; Natalie A. Bello[5]; Janet Catov[6]; Bethany B. Gibbs[7]; William A. Grobman[8]; David M. Haas[9]; Lisa D. Levine[10]; C. Noel Bairey Merz[11]; Eliza C. Miller[12]; Uma M. Reddy[13]; Lynn M. Yee[3]

[1]Northwestern Feinberg School of Medicine, Chicago, IL; [2]Northwestern University, Chicago, IL; [3]Northwestern University Feinberg School of Medicine, Chicago, IL; [4]Northwestern, Northwestern/Chicago, IL; [5]Cedars Sinai Medical Center, Los Angeles, CA; [6]Magee-Womens Hospital, Pittsburgh, PA; [7]West Virginia University, Morgantown, WV; [8]The Ohio State University, Columbus, OH; [9]Indiana University School of Medicine, Indianapolis, IN; [10]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [11]Cedars-Sinai Medical Center, Los Angeles, CA; [12]Columbia University Medical Center, New York, NY; [13]Columbia University, New York, NY

4:00 PM - 6:00 PM

Objective: Excessive daytime sleepiness has been associated with cardiovascular disease in non-pregnant populations. This study examined the association of sleepiness during pregnancy and cardiovascular health (CVH) scores 2-7 years after first birth.

Study Design: In this secondary analysis of longitudinal data from a large, diverse cohort of nulliparas conducted at eight US medical centers, individuals were followed 2-7 years after their first birth. The Epworth Sleepiness Scale, a validated tool to assess daytime sleep propensity (i.e. the likelihood of falling or staying asleep), was used to evaluate sleepiness in early (6-13 weeks) and mid- pregnancy (22-29 weeks). Individuals with scores ≤10 were categorized as having no sleepiness (referent), 11-15 as moderate sleepiness, and 16-24 severe sleepiness. The primary outcome was CVH quantified by the American Heart Association's Life's Essential 8 (LE8) score, which is a validated surrogate of cardiovascular disease risk, with lower scores representing worse CVH. The LE8 score includes diet, physical activity, nicotine exposure, sleep, body mass index, blood pressure, blood glucose, and lipids, and ranges from 0 (worst) to 100 (best). Separate multivariable linear regression models were performed for early and mid-pregnancy adjusting for maternal age, insurance type, smoking status, and study site.

Results: Of 2,193 participants, moderate and severe sleepiness was reported in 20.3% and 4.1%, respectively, in early pregnancy and in 14.2% and 2.2%, respectively, in mid-pregnancy. Severe sleepiness in mid-pregnancy was associated with lower mean LE8 score (76.9 [SD 13.8] vs. 80.4 [SD 12.9]) 2-7 years after first birth (aβ -3.63 95% CI [-6.90, -0.36]). In contrast, moderate and severe sleepiness in early pregnancy were not associated with LE8 score.

Conclusion: Severe sleepiness in mid-pregnancy may be a previously unidentified risk factor for poorer CVH indices 2-7 years after first birth.

Table. Association of sleepiness during pregnancy and cardiovascular health 2-7 years after birth

LE8 score[1]	No Sleepiness	Moderate Sleepiness[2]	Severe Sleepiness[2]
		Early pregnancy (6-13 weeks)	
	N=1,658	N=445 (20.3%)	N=90 (4.1%)
LE8 score	80.5 (12.9)	80.1 (13.1)	79.3 (12.7)
aβ (95% CI)[3]		-0.44 (-1.64, 0.76)	-1.05 (-3.51, 1.41)
		Mid pregnancy (22-29 weeks)	
		N=311 (14.2%)	N=48 (2.2%)
LE8 score	80.4 (12.9)	80.7 (12.4)	76.9 (13.8)
aβ (95% CI)[3]		-0.28 (-1.66, 1.10)	**-3.63 (-6.90, -0.36)**

Data presented as mean LE8 scores (standard deviation), beta coefficients (95% confidence interval); LE8, American Heart Association Life's Essential 8 score

1. Mean and standard deviation American Heart Association Life's Essential 8 score for cardiovascular health, which includes diet, physical activity, nicotine exposure, sleep, body mass index, blood pressure, blood glucose, and lipids.
2. Moderate sleepiness scores were defined as a score of 11-15; Severe sleepiness score were defined as 16-24.
3. Multivariable linear regression models were adjusted for baseline maternal age, insurance status, smoking status, and study site.

596 | Time to Treatment Initiation of Piperacillin-Tazobactam Compared to Ampicillin-Gentamicin for the Treatment of Intraamniotic Infection

Rachel P. Gerber; Lizmari Pena-Perez; Hannah Sturm; Patricia Saunders-Hao; Matthew J. Blitz; Burton Rochelson; Alpna Aggarwal; Melissa T. Chu Lam
Northwell, New Hyde Park, NY

4:00 PM - 6:00 PM

Objective: Both the traditional regimen of ampicillin-gentamicin and the new regimen of piperacillin-tazobactam, have been proven to successfully treat intraamniotic infection (IAI). We sought to evaluate the time from diagnosis to initiation of antibiotics in the setting of IAI when comparing the recommended traditional regimen of ampicillin (2g IV q6h) and gentamicin (5mg/kg IV q24h), to the alternative regimen of piperacillin-tazobactam (4.5 g IV q8h).

Study Design: Retrospective cohort study of women with suspected IAI as defined by the ACOG at [3] 34 weeks of gestation, with singleton gestation, who received either regimen at a university hospital from November 2022 to May 2024. The primary outcome was time to treatment initiation (TTI). This was defined by an analysis of both provider and nursing input into an electronic medical record system, from time of medication order placement to administration initiation. Mann-Whitney analysis was used to study the difference in time to treatment.

Results: We included 394 patients of which 199 received piperacillin-tazobactam, and 195 received ampicillin-gentamicin. Most patients (57.8%) were diagnosed with suspected IAI based on maternal fever and fetal tachycardia. Median TTI was 21 minutes (interquartile-range 28 minutes) for the piperacillin-tazobactam group, and 68 minutes (interquartile-range 51.2) for the ampicillin-gentamicin group (p-value < 0.01). There was no significant difference in the rate of postpartum fever, ICU admission, or postpartum readmissions (Table 1). Regarding neonatal outcomes, there were no clinically significant differences in early onset sepsis (EOS) score, rate of NICU admission or cord gas pH (Table 2).

Conclusion: Interestingly, the TTI of the complete antibiotic regimen from time of diagnosis is over twice as long with ampicillin-gentamicin than piperacillin-tazobactam, likely due to the weight-based dosing rather than fixed dosing regimen and ease of medication availability for administration to nursing staff.

Table 1. Maternal Outcomes

	Ampicillin/ Gentamicin (n=195)	Piperacillin-Tazobactam (n=199)	p-value
Postpartum Fever – n (%)			
No Fever	176 (90.2%)	176 (88.4%)	0.20
Within 1 Hour of Delivery	5 (2.6%)	13 (6.5%)	
More than 1 Hour After Delivery	14 (7.2%)	10 (5.0%)	
ICU Admission – n (%)	0 (0%)	1 (0.5%)	1
Postpartum Readmission – n (%)	16 (8.2%)	13 (6.5%)	1
Reason for Readmission – n (%)			
Wound Infection	3 (1.5%)	2 (1.0%)	0.21
Endometritis	1 (<0.1%)	1 (<0.1%)	
Other (Non-Infectious)	12 (6.2%)	9 (0.05%)	

Table 2. Neonatal Outcomes

	Ampicillin/ Gentamicin (n=195)	Piperacillin-Tazobactam (n=199)	p-value
Early Onset Sepsis Score – median (IQR)	1.1 (1.3)	0.9 (1.2)	0.19
Cord Gas pH – median (IQR)	7.27 (0.11)	7.24 (0.11)	0.01
NICU Admission – n (%)	59 (30.3%)	59 (29.6%)	1
Neonate requiring antibiotics – n (%)	41 (21.0%)	40 (20.1%)	1
Length of NICU Stay (days) – median (IQR)	2 (1)	2 (1)	0.10
Neonate Readmission within 7 days – n (%)	11 (5.6%)	11 (5.5%)	0.96
Reason for Readmission – n (%)			
Fever	5 (2.6%)	6 (3.0%)	0.19
Other (Non-Infectious)	6 (3.1%)	5 (2.5%)	

597 | A Comparison of Newborn Birthweights Between Opioid Use Disorders Treated with Methadone vs Buprenorphine

Rachel Lee[1]; Cassandra Heiselman[2]; Emily H. Stetler[3]; Zenobia Gonsalves[2]; Kimberly Herrera[3]; David Garry[2]
[1]Stony Brook University Hospital, Lake Grove, NY; [2]Stony Brook University Hospital, Stony Brook, NY; [3]Stony Brook University, Stony Brook, NY

4:00 PM - 6:00 PM

Objective: To determine effects of in-utero exposure to medications for opioid use disorder (MOUD) on birthweight (BW) and birthweight classification comparing methadone to buprenorphine.

Study Design: This is a retrospective study of patients (N = 362) on MOUD who delivered at a single institution between

Jan 2017 and Dec 2023. Patients were divided into comparison groups based on type of MOUD: buprenorphine or methadone. Demographics and clinical outcomes including gestational age at delivery and BW were extracted from medical records. BW was categorized using Fenton 2013 Growth Charts with small for gestational age (SGA) newborns defined as a BW less than 10%ile for gestational age. Univariate and multivariable statistical analyses were done across groups with a statistical significance considered at $p < 0.05$.

Results: During the study period there were 362 patients, 105 (29%) utilizing methadone and 257 (71%) utilizing buprenorphine. Groups were similar when comparing parity, maternal age, ethnicity, preterm delivery rate, mode of delivery, and concurrent psychiatric diagnosis. BW was greater in the buprenorphine group (3020±615 g) compared to methadone group (2810±586 g; $p = 0.003$); however, there was a similar incidence of SGA newborns, 14.5% for buprenorphine vs 12.5% for methadone ($p = 0.61$). Dosing did not affect incidence of SGA infants [Table 1]. In regression modeling, there were no independent predictors of a SGA newborn, although chronic hypertension approached significance (OR 4.30: 95% CI 0.903 to 20.485; $p = 0.066$) [Table 2].

Conclusion: When using buprenorphine or methadone for MOUD, reassurance can be provided to patients that the incidence of SGA newborns is similar, even when accounting for medical comorbidities.

Table 1. Buprenorphine and Methadone Dosing and its Effect on Small for Gestational Size Infants

	Mean	Median	Range	Dosing Mean Rank	Dosing Mean Rank	P
Dosing at Beginning of Pregnancy				161.09	160.99	
Methadone (mg)	72	70	0 - 170	SGA (n=46)	Non-SGA (n=275)	0.99
Buprenorphine (mg)	10.8	8	0 - 48			
Dosing at Delivery				165.57	178.23	
Methadone (mg)	105.8	100	0 - 270	SGA (n=48)	Non-SGA (n=304)	0.42
Buprenorphine (mg)	11.6	11	0 - 30			

Table 2. Logistic Regression in Prediction of a SGA Newborn

Variable	Odds Ratio	95% CI	P
AMA (>35y)	1.18	0.537 to 2.618	0.673
Buprenorphine MOUD	1.09	0.494 to 2.416	0.827
White Race	4.25	0.498 to 36.176	0.185
BMI >30	0.87	0.388 to 1.976	0.750
Chronic Hypertension	4.30	0.903 to 20.485	0.066
Gestational Diabetes	0.36	0.045 to 2.861	0.335
Psychiatric Diagnosis	0.75	0.354 to 1.625	0.477

598 | Patient Outcomes: Preterm Prelabor Rupture of Membranes Before 34 weeks with Late Preterm Delivery

Rachelle Abdelnour; Christopher Ennen; Noora Batrash
University of Virginia School of Medicine, Charlottesville, VA

4:00 PM - 6:00 PM

Objective: Preterm prelabor rupture of membranes (PPROM) affects 3% of births in the United States and is a significant cause neonatal morbidity and mortality. Guidelines recommend offering expectant management of delivery when appropriate. The objective of this study was to evaluate neonatal and maternal outcomes by gestational week of delivery for patients with PPROM before 34 weeks and delivery at 34 weeks or greater.

Study Design: This was a historical cohort study of patients delivered for PPROM at a single institution between January 2015 and October 2023. The study group included patients who had PPROM with a singleton gestation and non-anomalous fetus. Maternal and neonatal outcomes were compared by gestational week of delivery.

Results: In the cohort, 72 patients had PPROM before 34 weeks with delivery at 34 weeks or greater. Maternal and neonatal outcomes are outlined in the table. Those who delivered at 34 weeks were more likely to have a vaginal delivery after spontaneous preterm labor, compared to those that delivered at 35 weeks, who were more likely to have a vaginal delivery after induction of labor ($p = 0.039$). Neonates delivered at 35 weeks were less likely to have hyperbilirubinemia ($p = 0.019$) and less likely to be admitted to the neonatal intensive care unit ($p < 0.001$) than those delivered at 34 weeks. Outcomes of cesarean delivery, chorioamnionitis, postpartum endometritis, postpartum hemorrhage, 5-minute APGAR < 7, neonatal hypoglycemia, neonatal sepsis, respiratory distress or tachypnea, and neonatal resuscitation were not significantly different between groups. There were no differences in maternal death, neonatal death, necrotizing enterocolitis, intraventricular hemorrhage, and fetal demise.

Conclusion: For those with PPROM before 34 weeks and delivery at 34 weeks or greater, those that delivered at 34 weeks were more likely to have spontaneous preterm labor, neonatal intensive care unit admission, and neonatal hyperbilirubinemia than those delivered at 35 weeks. This data supports counseling patients for expectant management to 35 weeks or more when appropriate.

Table. Maternal and Neonatal Outcomes

Gestational Week of Delivery	34 Weeks n=43	35 Weeks n=28	36 Weeks n=1	P value
Maternal Outcomes				
Most Likely Outcome of Delivery	Spontaneous labor → vaginal delivery 18 (41.9%)	Induction of labor → vaginal delivery 17 (60.7%)		0.039*
Cesarean Delivery	13 (30.2%)	11 (39.3%)	1 (100%)	0.284
Chorioamnionitis	4 (9.3%)	1 (3.6%)	0	0.626
Postpartum Endometritis	1 (2.3%)	2 (7.1%)	0	0.576
Postpartum Hemorrhage	3 (7.0%)	0	0	0.304
Neonatal Outcomes				
5-Minute APGAR <7	6 (14.0%)	0	0	0.152
Neonatal Hypoglycemia	3 (7.0%)	7 (25.0%)	0	0.092
Neonatal Sepsis	6 (14.0%)	1 (3.6%)	0	0.334
Respiratory Distress Syndrome/Transient Tachypnea of the Newborn	12 (27.9%)	5 (17.9%)	0	0.476
Neonatal Hyperbilirubinemia	33 (76.7%)	12 (42.9%)	0	0.019*
Neonatal Resuscitation	18 (41.9%)	9 (32.1%)	0	0.524
Neonatal Intensive Care Unit Admission	42 (97.7%)	9 (32.1%)	0	<0.001*

599 | Inpatient versus Outpatient Management of Preterm Prelabor Rupture of Membranes: A Systematic Review and Meta-Analysis

Rafaela Germano Toledo[1]; Nadiha Noor Chelsea[1]; Tina Yi Jin Hsieh[1]; Carol Mita[2]; Anna M. Modest[1]; Cassandra R. Duffy[1]
[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Countway Library, Harvard Medical School, Boston, MA

4:00 PM - 6:00 PM

Objective: The management of preterm prelabor rupture of membranes (PPROM) varies across healthcare settings with limited data on the safety of outpatient management. The aim of this study was to compare neonatal sepsis and other maternal and perinatal outcomes by outpatient vs inpatient management of PPROM.

Study Design: We performed a systematic review in October 2023 of Cochrane Central, Embase, PubMed and Web of Science databases for studies comparing outpatient and inpatient management of PPROM. We included studies of pregnancies complicated by PPROM < 37 weeks' gestational age (GA) published in full text English. Primary outcome was neonatal sepsis; secondary outcomes included neonatal intensive care unit (NICU) admission, NICU length of stay (LOS), intrauterine fetal demise (IUFD), neonatal death, pregnancy latency, chorioamnionitis, and maternal LOS. A random-effects model was used to calculate pooled odds ratios (OR) or mean differences (MD) and 95% confidence intervals (CI) for all outcomes.

Results: Out of the 485 studies identified, 10 were included. These studies comprised a total of 2,286 patients, with 1,040 undergoing outpatient and 1,246 inpatient management. Included studies involved pregnancies from 20 to 35 weeks' GA. Neonatal sepsis was assessed in all studies, and no significant statistical differences were found between the groups (pooled OR 0.92, 95% CI 0.63-1.35, Figure 1). The latency period was longer (pooled MD 7.73; 95% CI 0.56-14.90; Figure 2) and there was less chorioamnionitis (pooled OR 0.54; 95% CI 0.41-0.72) in the outpatient setting. Regarding neonatal outcomes, the outpatient group had lower odds of NICU admission (pooled OR 0.57; 95% CI 0.36-0.90) and a shorter NICU LOS (pooled MD -9.43 days; 95% CI -13.02 to -5.84). There were no significant differences in maternal LOS, IUFD, and neonatal death.

Conclusion: Outpatient management of PPROM was associated with a longer latency period, lower odds of chorioamnionitis, NICU admission, and shorter NICU length of stay, without an increase in rates of neonatal sepsis.

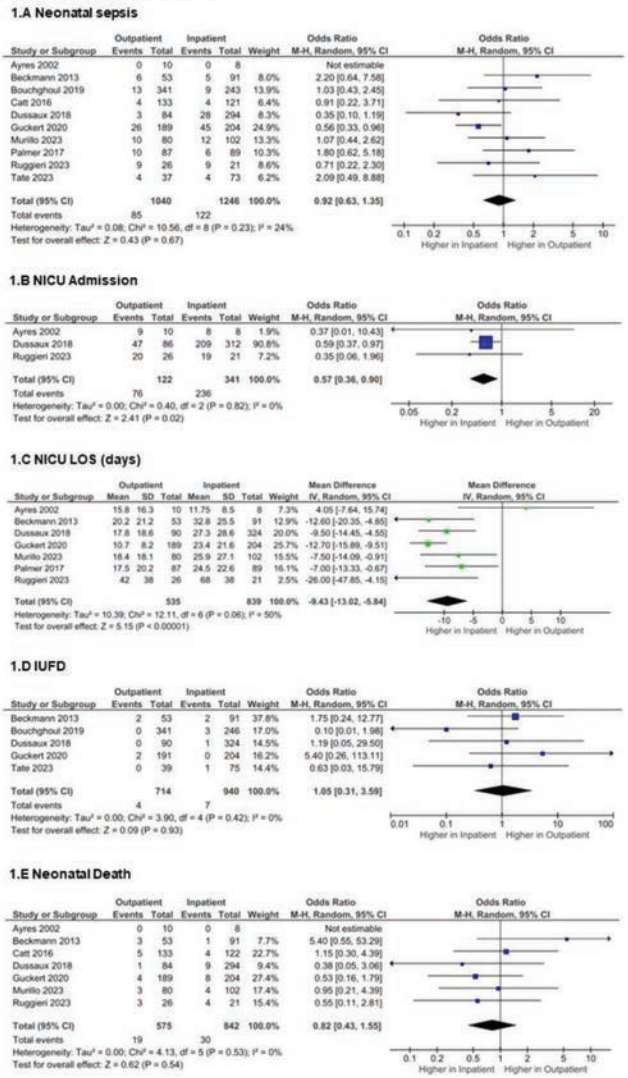

Figure 2. Maternal Outcomes

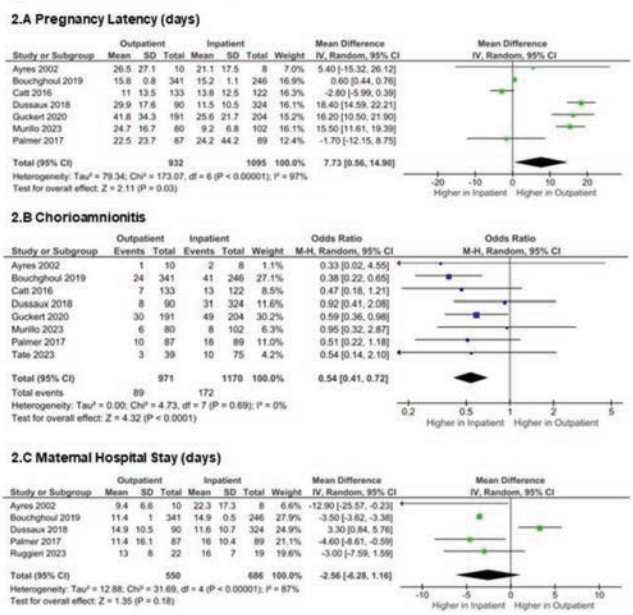

600 | Prepregnancy or Delivery BMI? Identifying the Better Predictor of Adverse Outcomes

Raina A. Meka[1]; Nandini Raghuraman[1]; Alison G. Cahill[2]; Jeannie C. Kelly[1]; Katherine H. Bligard[1]; Antonina I. Frolova[3]
[1]Washington University School of Medicine in St. Louis, St. Louis, MO; [2]Dell Medical School Health Transformation Research Institute, Dell Medical School, The University of Texas at Austin, Austin, TX; [3]Washington University School of Medicine, St. Louis, MO

4:00 PM - 6:00 PM

Objective: Prepregnancy BMI (preBMI) represents baseline health status before pregnancy and is used to guide counseling and management to prevent adverse perinatal outcomes. However, preBMI is often unavailable or unreliable due to recollection bias. Delivery BMI (delBMI) encompasses the cumulative effects of preBMI and gestational weight gain (GWG). We sought to compare the ability of preBMI and delBMI to predict adverse maternal and neonatal outcomes.

Study Design: This was a secondary analysis of a prospective cohort study of all individuals with a singleton gestation who presented for induction or spontaneous labor at ≥ 37 weeks' gestation at a single institution from 2010-2014. Only individuals with a measured weight in the chart during the year prior to pregnancy were included in this analysis, allowing for accurate calculation of preBMI. Receiver operating characteristic (ROC) curves were used to compare the abilities of preBMI and delBMI to predict labor, maternal, and neonatal adverse outcomes.

Results: Among 8,580 patients in the original cohort, 2,964 had a prepregnancy weight recorded and were included in this study. In isolation, delBMI and preBMI were poor predictors of adverse outcomes. However, delBMI was a better predictor than preBMI of labor outcomes including primary cesarean section (Figure 1), labor > 24 hours, prolonged second stage of labor, and shoulder dystocia (Table 1). DelBMI was also a better predictor of hypertensive disorders of pregnancy (HDP), while preBMI was a better predictor of gestational diabetes (GDM) (Table 1). There was no difference in the ability of delBMI and preBMI to predict neonatal outcomes, including composite adverse neonatal outcome, fetal acidemia, NICU admission, and neonatal hypoglycemia (Table 1).

Conclusion: PreBMI and delBMI are individually poor predictors of adverse pregnancy outcomes. However, delBMI is a better predictor of adverse labor outcomes and HDP, while preBMI is a better predictor for GDM. Comprehensive risk assessment may need to reflect maternal weight throughout pregnancy, incorporating preBMI, delBMI and GWG as a dynamic measure.

Figure 1. ROC for Primary Cesarean Delivery by BMI

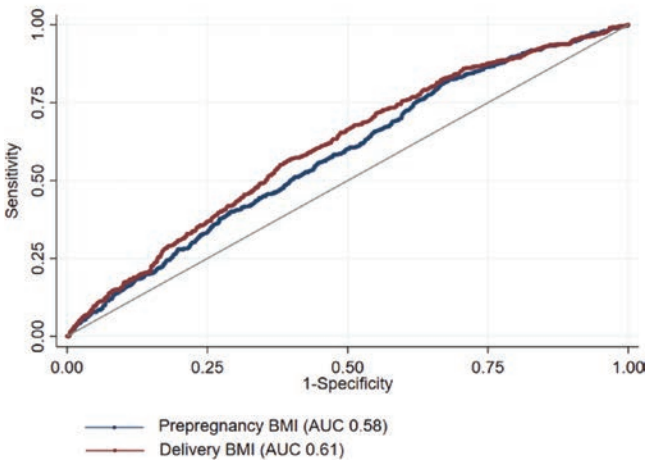

Table 1. Comparison of Area Under the Curve for Prepregnancy and Delivery BMI

	AUC Prepregnancy BMI	AUC Delivery BMI	P-value
Labor Outcomes			
Primary Cesarean Delivery	0.58 (0.55-0.60)	**0.61 (0.58-0.63)**	<0.001

601 | Confirmation of the Physiological Principles of the Sequential Laser Technique for Twin-Twin Transfusion Syndrome

Tucker E. Doiron[1]; Lisa M. Korst[2]; Arlyn Llanes[3]; Martha A. Monson[4]; Andrew H. Chon[5]; Ramen H. Chmait[3]
[1]Saint Louis University, St. Louis, MO; [2]Childbirth Research Associates, North Hollywood, CA; [3]Keck School of Medicine, University of Southern California, Los Angeles, CA; [4]Intermountain Healthcare, University of Utah Health, Salt Lake City, UT; [5]Oregon Health & Science University, Portland, OR

4:00 PM - 6:00 PM

Objective: To assess changes in middle cerebral artery peak systolic velocity (MCA-PSV) after sequential vs selective laser surgery for twin-twin transfusion syndrome (TTTS).

Study Design: This is a post hoc analysis of data from the Sequential Trial, a randomized controlled trial (RCT) that compared laser techniques for TTTS patients between 18-26 weeks of gestation. Patients received either the original (selective) or a modified selective (sequential) laser surgery, in which arteriovenous (AV) anastomoses with unidirectional blood flow from donor to recipient are laser-ablated first, followed by ablation of AV anastomoses from recipient to donor that should allow for a net intraoperative blood transfer from the hypervolemic recipient to the hypovolemic donor twin. We compared the difference (Delta) in donor MCA-PSV multiples of the median (MoM) (postoperative minus preoperative) by surgical technique.

Because anemia is associated with a higher MCA-PSV, a negative Delta is consistent with an increased blood volume.

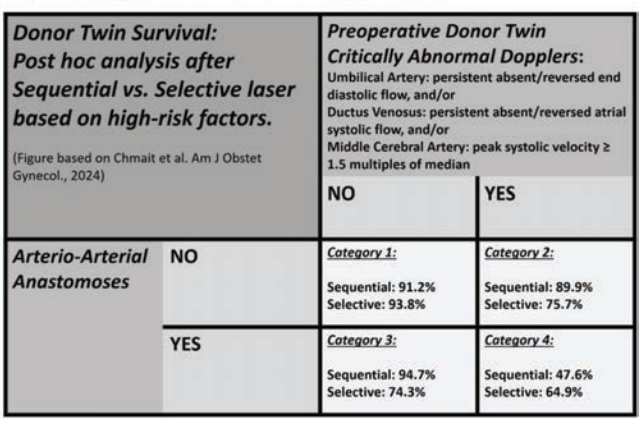
Results: In the 606 study patients, the mean (SD) Delta MCA-PSV MoM for the donor twin was -0.067 (0.301) (P< .0001) for the sequential and -0.017 (0.288) (P = .4186) for the selective techniques, with P< .0001 for the technique comparison. Based on donor critical abnormal Dopplers (CAD) and arterioarterial (AA) anastomoses, 4 risk Categories with donor survival rates were established (Figure). Mean (SD) Deltas for the sequential vs selective procedures are shown by Category in the Table. Linear regression for Delta, controlling for the risk groups, yielded a coefficient for the sequential vs selective techniques of -0.079 (0.024 SE), P = .0009.

Conclusion: Overall, patients receiving the sequential vs the selective technique had a greater drop in the mean donor MCA-PSV MoM, suggesting that the sequential technique facilitated an intraoperative net blood transfusion to the donor. This benefit was apparent in all risk groups except Category 4, which had poor donor survival. Further study is needed to understand and optimize outcomes of Category 4 patients.

Table. Mean (standard deviation) of the Delta MCA-PSV MoM (postoperative minus preoperative) for those undergoing the sequential vs selective procedures by risk group. CAD: critical abnormal Dopplers; AA: arterioarterial anastomosis. A negative value for Delta is consistent with an intraoperative net blood transfusion to the donor.

Risk Group	Sequential Procedure	Selective Procedure	*P*-value
Category 1 (n=341) no CAD or AA	-0.039 (0.266)	0.017 (0.250)	.0083
Category 2 (n=133) CAD no AA	-0.188 (0.335)	-0.020 (0.317)	.0013
Category 3 (n=68) no CAD with AA	-0.043 (0.263)	0.113 (0.308)	.0220
Category 4 (n=64) both CAD and AA	0.048 (0.345)	-0.010 (0.394)	.4438

Figure: Donor twin survival according to Category as established in the Sequential Trial (Chmait et al. Am J Obstet Gynecol., 2024).



602 | Twin-Twin Transfusion Syndrome with Intermittent (Stage I) versus Persistent (Stage III) Umbilical Artery Doppler Abnormalities

Raphael C. Sun[1]; Andrew H. Chon[2]; Lisa M. Korst[3]; Arlyn Llanes[4]; Martha A. Monson[5]; Ramen H. Chmait[4]

[1]Department of Surgery, Division of Pediatric Surgery, Department of Obstetrics and Gynecology, Oregon Health & Science University, Portland, OR; [2]Oregon Health & Science University, Portland, OR; [3]Childbirth Research Associates, North Hollywood, CA; [4]Keck School of Medicine, University of Southern California, Los Angeles, CA; [5]Intermountain Healthcare, University of Utah Health, Salt Lake City, UT

4:00 PM - 6:00 PM

Objective: Per Quintero staging for twin-twin transfusion syndrome (TTTS), umbilical artery (UA) Doppler with *intermittent* absent or reversed end diastolic flow (A/REDF) is classified as Stage I, and UA with *persistent* A/REDF is classified as Stage III. We compared laser outcomes in Stage I patients with UA normal vs Stage I with *intermittent* A/REDF vs Stage III with *persistent* A/REDF.

Study Design: Cases of monochorionic diamniotic twins with TTTS Quintero stages I and III treated with laser (2006-2023) were reviewed and 3 groups analyzed: Stage I with no Doppler abnormalities (Stage-I-normal), Stage I with donor *intermittent* A/REDF of the UA (Stage-I-intermittent), and Stage III with donor *persistent* A/REDF of the UA (Stage-III). The outcome was donor twin intrauterine fetal demise (IUFD).

Results: Of 349 study patients, 101 were classified as Stage-I-normal, 36 were Stage-I-intermittent, and 212 were Stage III. Arterio-arterial (AA) communications were most common in Stage-I-intermittent: 27.7% vs 69.4% vs 42.5%, *P*< .0001. The rate of donor IUFD was lowest in Stage-I-normal compared to Stage-I-intermittent and Stage-III: 3.0% vs 25.0% vs 29.2%, *P*< .0001. At-least-one survivorship did not differ among the 3 groups (Table 1); dual survivorship was highest for Stage-1-normal and differed from both Stage-I-intermittent and Stage-III in pairwise comparisons. In a multivariable logistic regression model, Stage-I-intermittent patients were 7 times more likely to have donor twin IUFD (OR 7.23 [1.69-30.82], *P* = .0075), as were Stage-III patients (7.24 [2.06-25.47], *P* = .0020), compared to Stage-I-normal patients. (Table 2) In this same model, patients with AA were 3.6 times more likely to have donor IUFD (OR 3.59 [1.95-6.61]; *P*< .0001).

Conclusion: TTTS stage I patients with *intermittent* A/REDF UA findings were at increased risk of donor IUFD after laser surgery. It is unknown whether laser surgery or expectant management is the optimal approach for this subset of patients. The role of AA anastomoses in TTTS needs further investigation.

Table 1. Patient characteristics by study population. Continuous variables are presented as mean (standard deviation)

	Stage 1 No doppler abnormality (n=101)	Stage 1 Intermittent A/REDF of UA (n=36)	Stage 3 Donor-involved with persistent A/REDF of UA (n=212)	*P*-value

603 | Group B Streptococci Colonization and the Expectant Management of Late Preterm Prelabor Rupture of Membranes

Raneen Abu Shqara[1]; Lior Lowenstein[2]; Maya Frank Wolf[3]
[1]Galilee Medical Center, Nahariya, HaZafon; [2]Galilee Medical center, Nahariya, HaZafon; [3]Galilee Medical Center, Naharyia, HaZafon

4:00 PM - 6:00 PM

Objective: The impact of maternal group B streptococci (GBS) colonization on outcomes of expectant management of late premature prelabor rupture of membranes (PPROM) is controversial. We explored maternal and neonatal infectious outcomes in women who presented with PPROM at 34-36.6 weeks according to GBS colonization status.

Study Design: This retrospective cohort study included 412 women who presented with late PPROM and were admitted for expectant management. Outcomes were compared according to positive GBS status (n = 73) and negative GBS status (n = 339). The co-primary outcomes were clinical chorioamnionitis and latency duration (ROM-delivery duration). Expectant management consisted of betamethasone administration and 7-day antibiotics regimen. Induction was performed at 37 weeks or earlier if chorioamnionitis or non-reassuring fetal status was suspected. After delivery, chorioamniotic swabs were obtained. The required sample size was calculated to be at least 398, considering a 10% effect size in the rate of women with latency > 48 hours, with a power of 80% and an alpha of 5%.

Results: Gestational age at PPROM was similar between the groups (Table). The rates of intrapartum fever, clinical chorioamnionitis, postpartum fever, latency duration, latency >48 hours, and delivery week were similar. For the positive vs. negative GBS status group, antibiotic administration in the neonatal intensive care unit was more common: 11.1% vs 3.5%, p = 0.013. Rates of neonatal complications such as early onset sepsis, respiratory distress syndrome, invasive ventilation, and meconium aspiration syndrome were similar between the groups. The distributions of pathogens in chorioamniotic swab cultures were similar (p = 0.461) (Figure).

Conclusion: Among women with PPROM at 34-36.6 weeks, we report similar maternal and neonatal adverse outcomes. The increased neonatal antibiotic administration may be attributed to preventive measures related to the positive GBS status. Expectant management of PPROM in women with GBS colonization is reasonable.

Obstetrical and neonatal outcomes in women with PPROM 34-36.5 weeks, according to group B streptococci colonization status.

	Negative GBS status (n=339)	Positive GBS status (n=73)	P-value
PROM week	35.6 (34.0-36.5)	35.5 (34.0-36.5)	0.115
Latency (days)	1.7 (0.5-16.6)	1.7 (0.5-18.9)	0.244
Latency >48 hours	88 (25.9)	15 (20.5)	0.454

604 | Comparing Two Prophylactic Antibiotic Protocols for Treating Preterm Pre-Labor Rupture of Membranes

Raneen Abu Shqara[1]; Gabriela Goldinfeld[2]; Lior Lowenstein[3]; Maya Frank Wolf[4]
[1]Galilee Medical Center, Nahariya, HaZafon; [2]Bar-Ilan university, Bar-Ilan University, HaZafon; [3]Galilee Medical center, Nahariya, HaZafon; [4]Galilee Medical Center, Naharyia, HaZafon

4:00 PM - 6:00 PM

Objective: Following our randomized trial, we changed the prophylactic antibiotic protocol for preterm pre-labor rupture of membranes (PPROM) in our department from ampicillin-roxithromycin to cefuroxime-azithromycin. We compared the infectious morbidity of these two regimens.

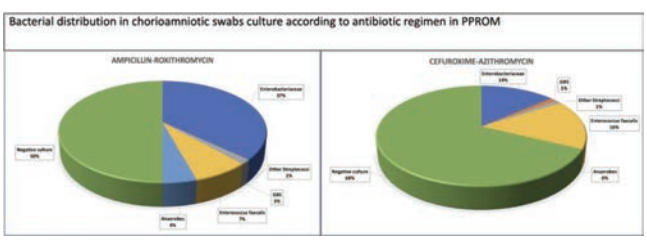
Study Design: This retrospective study included 170 women with PPROM < 37 weeks, managed expectantly with betamethasone and prophylactic antibiotics. According to protocol, chorioamniotic membrane cultures were obtained after delivery. Maternal and neonatal outcomes were compared between 83 women who received ampicillin-roxithromycin (February 2022 - March 2023) and 87 who received cefuroxime-azithromycin (April 2023 - May 2024). A composite maternal postpartum infectious outcome consisted of endometritis, antibiotic treatment and surgical site infection. A composite neonatal adverse outcome consisted of early onset sepsis, admission to the neonatal intensive care unit, antibiotic treatment, sepsis workup and respiratory distress syndrome.

Results: Gestational age at PPROM, parity, group B Streptococcus status and the median latency duration were comparable in the two periods. Among women treated with ampicillin-roxithromycin vs. cefuroxime-azithromycin, a greater proportion had intrapartum fever, clinical chorioamnionitis, cesarean delivery and a postpartum infectious outcome: 9.6% vs 1.1%, p = 0.013; 8.4% vs 1.1%, p = 0.046; 33.7% vs 19.5%, p = 0.036; and 4.8% vs. 0%, p = 0.038, respectively (Table). The composite neonatal adverse outcome did not differ between the groups (p = 0.874). Following the ampicillin-roxithromycin vs. cefuroxime-azithromycin regimen, prevalences were greater of positive chorioamniotic membrane cultures (50.0% vs. 32%, p< 0.001) (Figure) and of ampicillin-resistant Enterobacteriaceae spp. (23% vs. 10%, p = 0.027).

Conclusion: Cefuroxime-azithromycin compared to ampicillin-roxithromycin as a prophylactic for PPROM < 37 weeks showed less maternal peripartum infections, which was supported by the bacteriologic findings.

Maternal outcomes of the two antibiotic protocols

	Cefuroxime-Azithromycin (n=87)	Ampicillin-Roxithromycin (n=83)	P-value
Latency (ROM duration)	4.25±10.75	3.75±6.62	0.717
Spontaneous labor	58 (66.7%)	53 (63.9%)	0.749
Intrapartum fever	1 (1.1%)	8 (9.6%)	0.013
Clinical chorioamnionitis	1 (1.1%)	7 (8.4%)	0.046
Delivery week	35.5 (27-37.1)	35.6 (24-37.1)	0.994
Cesarean delivery	17 (19.5%)	28 (33.7%)	0.036
Pathological findings Acute chorioamnionitis	2 (2.4%)	10 (11.5%)	0.013
Postpartum antibiotics	2 (2.3%)	8 (9.6%)	0.042
Puerperal endometritis	0 (0%)	3 (3.6%)	0.074
Surgical site infection	0 (0%)	1 (1.2%)	0.305
Composite postpartum infection outcome (postpartum antibiotics, puerperal endometritis and surgical site infection)	0 (0%)	4 (4.8%)	0.038
Postpartum hospitalization length (days)	2.1 (1-6)	3 (1-6)	<0.001



605 | Ehr-Integration of an Evidence-Based Calculator for Cesarean Risk During Induction: Impact on Utilization and Outcomes

Rebecca F. Hamm[1]; Mary C. Steele[1]; Allison Dreier[2]; Sameh Saleh[3]; Mika Epps[1]; Madeline Fagen[1]; Mucio K. Delgado[1]; Lisa D. Levine[1]

[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Sidney Kimmel Medical College at Thomas Jefferson University, Philadelphia, PA; [3]Inova Health System, Fairfax, VA

4:00 PM - 6:00 PM

Objective: We developed a validated calculator to predict individualized likelihood of cesarean delivery (CD) for patients undergoing induction (IOL) [Levine 2018]. In a prospective cohort, calculator implementation via an external website was associated with reduced maternal morbidity and CD [Hamm 2020]. Here, we aimed to determine if Electronic Health Record (EHR) integration of the CD risk calculator would further improve utilization and clinical outcomes.

Study Design: This prospective cohort evaluated calculator utilization, maternal morbidity, and CD for 6 months PRE (10/2022-4/2023) vs. 6 months POST EHR-release of the CD risk calculator (4/2023-10/2023) in 2 units. Prior to EHR-integration, Site#1 had a 2018 push for calculator website use, while Site#2 had not. EHR-integration recognized eligibility, allowed clinicians to confirm and utilize EHR variables for score automation, visible on electronic display. Patients were calculator eligible if undergoing term IOL with a singleton, intact membranes, and dilation ≤2cm without prior CD. Calculator utilization was measured as a score recorded in the EHR. Analysis was stratified by site and risk of CD based on calculator results (< 20%, 20-39.9%, 40-59.9%, ≥60%).

Results: 2018 patients met eligibility (PRE:998; POST:1010) with more IOLs for fetal indications, earlier gestational age, and higher rates of hypertension in the POST group. Calculator utilization significantly increased POST-EHR implementation (Table). There were no differences PRE to POST in maternal morbidity overall (aRR 1.18 [0.91-1.53]), by site or CD risk strata. There was no difference in CD overall (aRR 1.19 [0.99-1.43). However, an increase in CD was found at Site#2 POST EHR-integration (aRR 1.30 [1.02-1.66]), specifically in the ≥60% CD risk strata.

Conclusion: EHR-integration of a CD risk calculator was associated with substantial increases in utilization. While CD increased at one site PRE to POST, PRE rates were lower than anticipated, and POST rates consistent with institutional data. Care should be taken this calculator is not used to perform CD outside of clinical indications.

Table: Outcomes PRE- and POST-EHR integration of a cesarean delivery (CD) risk calculator.

	Pre n(%)	Post n(%)	p-value	Adjusted relative risk (aRR) [95% Confidence Interval]
CD risk calculator utilization	134/998 (13.4)	789/1020 (77.4)	<0.001	
Maternal morbidity[a,b]	106/998 (10.6)	127/1020 (12.5)	0.20	1.18 [0.91-1.53]
Cesarean delivery[b]				
Overall	209/998 (20.9)	257/1020 (25.2)	0.02	1.19 [0.99-1.43]
Site#1 Overall	92/458 (20.1)	106/499 (21.2)	0.66	1.06 [0.80-1.40]
Site #1 CD Risk <20%	3/148 (2.0)	10/162 (6.2)	0.07	
Site #1 CD Risk 20-39.9%	33/174 (19.0)	35/198 (17.7)	0.75	
Site #1 CD Risk 40-59.9%	39/95 (41.1)	41/104 (39.4)	0.82	
Site #1 CD Risk ≥60%	17/41 (41.5)	20/35 (57.1)	0.17	
Site#2 Overall	117/540 (21.7)	151/521 (29.0)	0.006	1.30 [1.02-1.66]
Site #2 CD Risk <20%	7/143 (4.9)	13/124 (10.5)	0.08	
Site #2 CD Risk 20-39.9%	37/201 (18.4)	45/193 (23.3)	0.23	
Site #2 CD Risk 40-59.9%	46/141 (32.6)	55/148 (37.2)	0.42	
Site #2 CD Risk ≥60%	27/55 (49.1)	38/56 (67.9)	0.045	

[a]≥1 of the following: estimated or quantitative blood loss ≥1000cc, endometritis, blood transfusion, wound infection or separation (requiring intervention), venous thromboembolism, hysterectomy, intensive care unit admission, readmission, and death within 30 days of delivery [b]adjusted for indication for induction and chronic hypertension

606 | Implementation of a Standardized Protocol for Labor Induction: Impact on Obstetric Disparities

Rebecca F. Hamm[1]; Sunni Mumford[1]; Markolline Forkpa[2]; Nicholas J. Seewald[1]; Stefanie N. Hinkle[1]; Rinad S. Beidas[3]; Sindhu K. Srinivas[1]; Samuel Parry[4]; Lisa D. Levine[1]

[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Pennsylvania Medicine Women's Health Clinical Research Center, Philadelphia, PA; [3]Feinberg School of

Medicine, Northwestern University, Chicago, IL; [4]University of Pennsylvania, Philadelphia, PA

4:00 PM - 6:00 PM

Objective: Prior retrospective data demonstrated that standardization of labor induction (IOL) may reduce racial disparities in cesarean delivery (CD) and morbidity. Here, we aimed to determine the impact of prospectively implementing an IOL protocol on racially disparate outcomes.

Study Design: This was a prespecified secondary analysis of a type I hybrid effectiveness-implementation trial comparing 2 years before (PRE) and 2 years after (POST) implementation of a standardized IOL protocol at 2 sites (2018-2022). The protocol had 8 components and recommended active IOL management, frequent cervical exams, and amniotomy by first exam ≥4cm. All singletons ≥37 weeks with intact membranes requiring cervical ripening were eligible; prior CD was excluded. This analysis included only those with self-recorded race, divided into Black, Indigenous, People of Color (BIPOC) and non-BIPOC. Poisson regression with interaction terms evaluated the protocol's impact on disparities in CD and morbidity. Fidelity to the protocol was defined as adherence to ≥75% of the 8 protocol components.

Results: 8386 were included (PRE = 4167; POST = 4219); 59.3% identified as BIPOC. BIPOC patients differed in delivery site, insurance, BMI, parity, maternal age, diagnosis of diabetes and hypertension, gestational age, and IOL indication, included as confounders. BIPOC patients were more likely to undergo CD in both PRE (aRR 1.36[1.18-1.58]) and POST (aRR 1.55[1.33-1.70]) groups, even when controlling for these differences. Adjusted relative risk of maternal morbidity was greater among BIPOC patients both PRE (aRR 1.25[1.07-1.46]) and POST (aRR 1.34[1.14-1.58]). There was no difference by race in neonatal morbidity in either PRE or POST. There was no differential effect of the protocol by race on CD or morbidity (Table). Protocol fidelity increased PRE to POST for both BIPOC (58.4% to 64.3%, p< 0.001) and non-BIPOC patients (43.6% to 53.1%, p< 0.001; interaction p = 0.15).

Conclusion: Despite increased utilization of a standardized IOL protocol across races, this intervention did not mitigate observed racial disparities in CD or maternal morbidity.

Table: Outcomes compared by patient race among PRE and POST-standardization at 2 sites from 2018-2022.

	PRE-standardization n(%) N=4167				POST-standardization n(%) N=4219				Interaction p[a]

4:00 PM - 6:00 PM

Objective: Social determinants of health impact access to care for patients with complex pregnancies. This study aimed to determine whether patients diagnosed with twin-to-twin transfusion syndrome presented with more progressive disease as measured by Quintero stage (I-IV) at presentation for evaluation for intervention based on their type of insurance coverage.

Study Design: This retrospective cohort study included monochorionic-diamniotic pregnant patients diagnosed with twin-to-twin transfusion syndrome who underwent laser photocoagulation at our fetal center between 11/2011-5/2024. Patients were categorized based on their type of insurance coverage, defined as commercial/private insurance (Private) or The Children's Health Insurance Program/Medicaid/No Insurance (Public). The primary outcome was the Quintero stage (I-IV) at the initial consultation for surgery. Secondary outcomes included gestational age at intervention, selective fetal growth restriction (sFGR), latency from referral to evaluation, location of evaluation, gestational age at delivery, and survival at 30 days. Patients without 30-day outcomes available were excluded.

Results: 484 patients underwent laser photocoagulation for TTTS at our center. Patients with public insurance were more likely to present with a higher Quintero stage than those with private insurance (3 [2,3], 3 [2,3], p = 0.046). The public insurance group was also more likely to be White/Hispanic (45.7% v 19.5%, p< 0.001) or Black/Non-Hispanic (15.7% v 6.6%, p< 0.001), be evaluated as an inpatient (69% v 55%, p = 0.002), have sFGR (47% v 36%, p = 0.014) and have a higher gestational age at intervention (20.7[18.6,22.4] v 19.9[17.9,22.0], p = 0.015). Latency from referral to evaluation and GA at delivery were similar, and we found no difference in survival at 30 days between groups.

Conclusion: Our study shows that social disparities exist in this population, and insurance status may be a surrogate of these inequities. However, long-term patient outcomes are equivalent with prompt, comprehensive care, aligning with the principle of distributive justice and the fair opportunity rule.

Table 1. Demographics and Outcomes by Insurance Type

Demographics and Outcomes	Private Insurance (n=287)	Public Insurance (n=197)	p-value
Race/Ethnicity

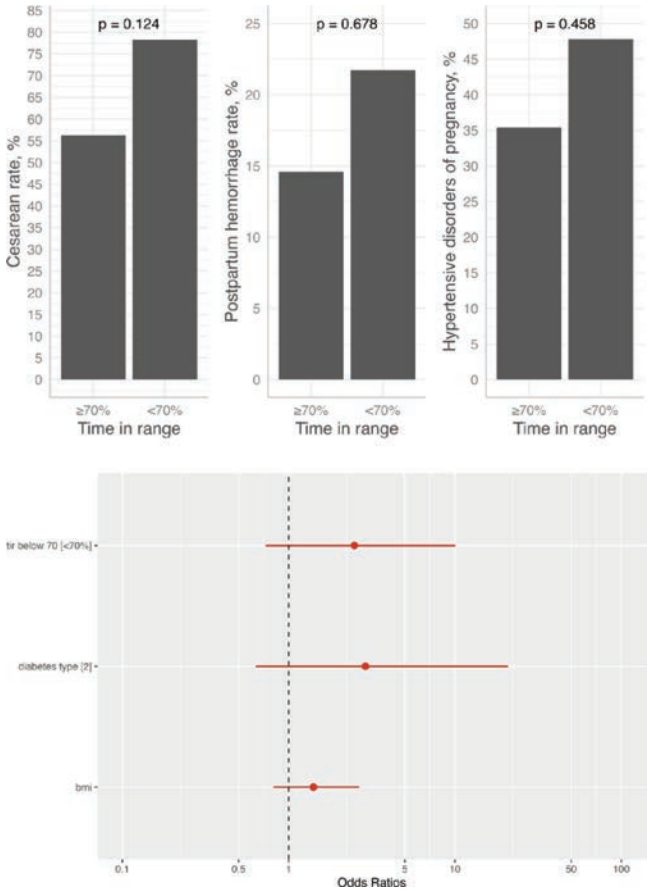
608 | Continuous Glucose Monitor Time in Range: Maternal Outcomes Amongst Pregnant Patients with T2Dm & Gdm

Yara Hage Diab[1]; Lauren A. Forbes[2]; Erkan Kalafat[3]; Theresa Corbine[1]; Margaret Mlynarczyk[1]; Marwan Ma'Ayeh[1]; George R. Saade[1]; Rebecca Horgan[1]
[1]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [2]Eastern Virginia Medical School, Norfolk, VA; [3]Koc University Hospital, Istanbul, Istanbul

4:00 PM - 6:00 PM

Objective: The Advanced Technologies & Treatments for Diabetes consensus group recommends target time in range (TIR) with a continuous glucose monitor (CGM) of 70% for pregnant patients with type 1 diabetes but concluded that there is inadequate evidence to recommend target TIR for type 2 diabetes (T2DM) or gestational diabetes (GDM). Our objective was to determine the impact of TIR categories on maternal outcomes amongst pregnant patients with T2DM and GDM.
Study Design: This retrospective cohort study included pregnant patients with T2DM or GDM using CGM for at least 30 days at our tertiary center from January 2020 to December 2022. Exclusion criteria were type 1 diabetes, multiple gestation, and unavailable delivery records. Target range for glucose on CGM was 63-140 mg/dL. Mean TIR for duration of CGM use during pregnancy was recorded. Primary outcome was maternal adverse events defined as having a cesarean delivery, postpartum hemorrhage or developing a hypertensive disorder of pregnancy. Maternal outcome in TIR groups were compared with Fisher's Exact test and logistic regression.
Results: 71 patients were included, of whom 48 and 23 had a mean TIR ≥70% and < 70%, respectively. Patients with mean TIR ≥70% had lower rates of cesarean delivery (56.2% vs. 78.3%, P = 0.12), postpartum hemorrhage (14.6% vs. 21.7%, P = 0.68) and hypertensive disorders of pregnancy (35.4% vs. 47.8%, P = 0.46) but the differences did not reach statistical significance (Figure 1). Patients with mean TIR ≥70% had a reduced odds of composite maternal outcome after adjusting for maternal BMI and diabetes type (adjusted OR: 0.40, 95% CI: 0.10-1.37, P = 0.166), but again the difference did not reach statistical significance.
Conclusion: All indicators trend towards better outcomes in pregnant patients with T2DM or GDM with mean TIR ≥70% on CGM compared with those with mean TIR < 70%. However, a larger sample size may be needed to statistically confirm this difference.



609 | Cgm Initial Time in Range & Trajectory: Impact on Neonatal Outcomes in T2Dm and Gdm

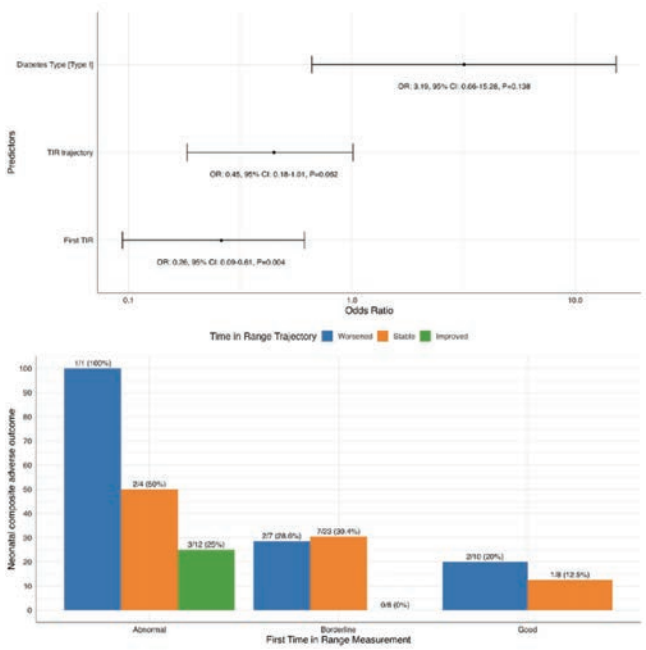
Rebecca Horgan[1]; Yara Hage Diab[1]; Lauren A. Forbes[2]; Erkan Kalafat[3]; Theresa Corbine[1]; Margaret Mlynarczyk[1]; George R. Saade[1]; Marwan Ma'Ayeh[1]
[1]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [2]Eastern Virginia Medical School, Norfolk, VA; [3]Koc University Hospital, Istanbul, Istanbul

4:00 PM - 6:00 PM

Objective: Continuous glucose monitor (CGM) is increasingly utilized to manage pregnant patients with type 2 diabetes (T2DM) and gestational diabetes (GDM), with target time in range (TIR) the main measure of glucose control. We sought to evaluate the independent contributions of initial TIR versus TIR trajectory during pregnancy on neonatal outcomes.
Study Design: This retrospective cohort study included pregnant patients with T2DM or GDM using CGM for ⩾ 30 days from Jan 2020 to Dec 2022. Exclusion criteria were type 1 diabetes, multiple gestation, and unavailable delivery records. Target glucose values on CGM were defined as 63-140 mg/dL. Initial TIR was defined as mean TIR after 2 weeks of CGM use. The primary composite neonatal outcome was macrosomia, birth trauma, significant hyperbilirubinemia, stillbirth, or neonatal death. TIR values were modeled with mixed effect generalized additive models. TIR groups were formed using sample quartiles (Initial TIR: good, borderline, abnormal; TIR trajectory: worsened, stable and improved).

Results: 71 patients were included in the analysis. Initial TIR was abnormal in 17, borderline in 30, and good in 18, with the primary outcome occurring in 35%, 30%, and 17%, respectively. TIR trajectory worsened in 18, remained stable in 35, and improved in 12, with 28%, 29%, and 25%, respectively having the primary outcome. When initial TIR and trajectory were considered together, the primary outcome rates in patients with abnormal initial TIR were 25%, 50%, and 100% for improved, stable, and worsened TIR trajectory. For borderline initial TIR, rates were 0%, 30.4%, and 28.6%, respectively. For good initial TIR, rates were 12.5% and 20% for stable and worsened TIR. Initial TIR (aOR 0.26, 95% CI: 0.09-0.61) and TIR trajectories (aOR 0.45, 95% CI: 0.18-1.01) were independently associated with adverse outcomes after adjusting for diabetes type.

Conclusion: Pregnant patients with T2DM and GDM should be counseled that poor initial TIR values on CGM is associated with increased risk of adverse neonatal outcomes, and improvement in TIR during pregnancy reduces this risk significantly.



610 | Machine Learning Prediction of NICU Admission at the Point of Care

Reetam Ganguli[1]; Stephen Wagner[2]
[1]Elythea, San Jose, CA; [2]Beth Israel Deaconess Medical Center, Boston, MA

4:00 PM - 6:00 PM

Objective: NICU admissions significantly raise neonatal mortality risk and cost up to $168,000. No universal assessments predict NICU admission risk at the point of care. Literature shows early prenatal risk assessment and education/nutrition intervention reduced NICU admissions by 56% and NICU days by 59%. This study aims to develop an ML model predicting NICU admissions using early prenatal variables and demographic/clinical history.

Study Design: ML models were trained on sociodemographic, medical history, and obstetric variables obtainable at the point of care. Models were trained on years 2018-2020 of the CDC Vital Statistics System and were tested on year 2021. NICU patients from years 2014-2017 (with the exception of year 2015 due to an unavailable data file) were included in training to reduce class imbalance.

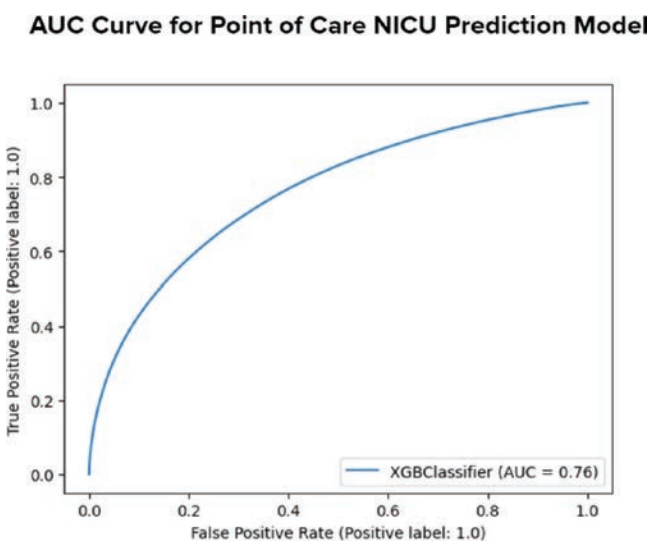
Exclusion criteria: missing NICU data and non-reporting hospitals. The primary outcome was immediate NICU admission post-delivery. Weight scaling algorithms enhanced training for preterm labor patients and NICU patients from prior years up to 2014 were used to improve class imbalance.

Results: 44 clinical variables obtainable in the 1st trimester across 12,127,124 patients were included in the training data. 2,041,555 (16.83%) experienced NICU admissions.

The model was tested on 3,219,217 patients, of which 351,787 (10.93%) had a NICU admission. The developed model had an area under the receiver operating characteristic curve of 0.76, 77% accuracy, sensitivity of 0.60, and F1 score of 0.77 at a standard 50% threshold.

When Youden's J statistic was calculated, the optimal threshold was 45.55%, which yielded 0.66 sensitivity.

Conclusion: Machine learning models can identify nearly 2/3rds of all NICU admissions at the point of care using routinely collected factors. This early identification can potentially allow for targeted interventions to prevent over half of all NICU admissions and lead to cost savings for health plans.



611 | Predicting Severe Hemorrhage in Operative Cesarean Deliveries Using Machine Learning

Reetam Ganguli[1]; Julia Sroda Agudogo[2]; Stephen Wagner[2]
[1]Elythea, San Jose, CA; [2]Beth Israel Deaconess Medical Center, Boston, MA

4:00 PM - 6:00 PM

Objective: Maternal hemorrhage necessitating transfusion is a significant complication in cesarean deliveries. This study aims to develop machine learning (ML) classifiers to predict hemorrhage necessitating transfusion in mothers undergoing cesarean delivery.

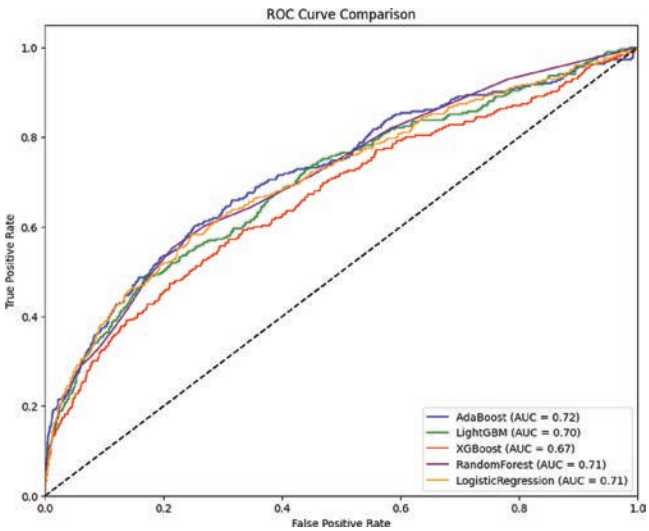
Study Design: AdaBoost, LightGBM, XGBoost, RandomForest, and Logistic Regression mdoels were developed. The models were trained and tested on data from the American College

of Surgeons National Surgical Quality Improvement Program database from years 2009 to 2021. Included patients underwent any cesarean delivery identified by specific Current Procedural Terminology (CPT) codes: 59510, 59514, 59515, 59618, 59620, and 59622 with complete data for the outcome. Cases with missing data on the primary outcome were excluded. Training data included preoperative blood biomarkers, clinical history, and sociodemographic information. All models were evaluated using 5-fold cross-validation to ensure robustness. The training data included preoperative clinical and sociodemographic variables for a large cohort of obstetric patients. The primary outcome was severe hemorrhage requiring transfusion.

Results: Of the total 43,713 patients, 1,425 (3.3%) experienced the outcome of maternal transfusion. AdaBoost and RandomForest models demonstrated the highest accuracy and AUC ROC scores among the evaluated models. Specifically, the AdaBoost model achieved an AUC ROC of 0.72 (95% CI: 0.72-0.72) and an accuracy of 96.52% (95% CI: 96.34%-96.71%). The RandomForest model showed similar performance with an AUC ROC of 0.71 (95% CI: 0.71-0.71) and an accuracy of 96.59% (95% CI: 96.45%-96.73%).

Conclusion: AdaBoost and RandomForest models show the highest potential for predicting severe hemorrhage requiring transfusion in operative cesarean deliveries. These models can assist in early identification and intervention, potentially improving patient outcomes.

Model	AUC ROC (95% CI)	Accuracy (95% CI)
AdaBoost	0.72 (0.72-0.72)	96.52% (96.34%-96.71%)
LightGBM	0.70 (0.70-0.70)	96.60% (96.46%-96.75%)
XGBoost	0.67 (0.67-0.67)	96.43% (96.27%-96.60%)
RandomForest	0.71 (0.71-0.71)	96.59% (96.45%-96.73%)
LogisticRegression	0.71 (0.71-0.71)	96.49% (96.33%-96.64%)



612 | Cost-Effectiveness of Manual Rotation in the Setting of Persistent Occiput Posterior Position

Riane Bradbury-Huang[1]; Aaron B. Caughey[2]
[1]Barnard College of Columbia University, Portland, OR; [2]Oregon Health & Science University, Portland, OR

4:00 PM - 6:00 PM

Objective: Persistent occiput posterior position during the second stage of labor occurs in approximately 5% of annual pregnancies. This fetal position is associated with longer labors, higher cesarean rates, and increased perinatal complications. Manual rotation of the fetal occiput can resolve the malposition in a subset of pregnancies. We examined the outcomes and costs of manual rotation versus expectant management in the setting of persistent occiput posterior position in the second stage of labor.

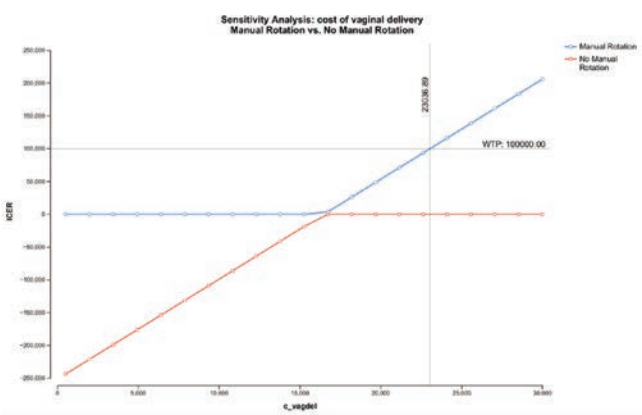
Study Design: We developed a decision-analytic model using TreeAge to compare outcomes between manual rotation versus expectant management for a theoretical cohort of 70,400 individuals, the annual number of nulliparous patients with persistent fetal OP position. Outcomes included cesarean delivery, post-op infection, instrumental delivery, severe perineal laceration, postpartum hemorrhage, and maternal death in addition to costs and quality-adjusted life years (QALYs). The willingness-to-pay (WTP) threshold was set at $100,000/QALY. We conducted literature searches to find inputs for the model, and conducted sensitivity analyses to discover and vary the drivers of the model in order to study its strengths.

Results: Within the theoretical cohort of 70,400 pregnancies, manual rotation prevented 24,119 cesarean sections, 1,206 post-op infections, 7,040 instances of postpartum hemorrhage, and 3 maternal deaths. However, it also resulted in an increased 10,353 instrumental deliveries and 4,796 severe perineal lacerations due to the reduction of cesareans. The manual rotation strategy was dominant to expectant management, resulting in more QALYs for lower costs. Sensitivity analyses demonstrated that manual rotation remained cost-effective until the cost of vaginal delivery was above $23,037.

Conclusion: We found manual rotation led to better outcomes and lower costs for nulliparous patients with persistent fetal OP position compared to expectant management. Further study of the impact of manual rotation and how it can be more widely trained and adopted is important for future research.

Table 1. Outcomes prevented in a theoretical cohort of 70,400 persistent OP nulliparous pregnancies assigned to either manual rotation or expectant management.

Outcome	Manual Rotation	Expectant Management	Difference
Cesarean Section	11,714	35,833	-24,119
Post-op Infection	586	1,792	-1,206
Maternal Death	3	6	-3
Instrumental Delivery	28,638	18,285	+10,353
Severe Tearing	21,853	17,057	+4,796
Postpartum Hemorrhage	16,262	23,302	-7,040
Cost (USD)	$1,500,809,728	$1,606,415,682	-$105,605,954
Effectiveness (QALYs)	1,852,514	1,850,932	+1,582



613 | Cerebrospinal Fluid Analysis in Fetuses with Myelomeningocele

Romain Corroenne[1]; Enrico R. Barrozo[2]; Roopali V. Donepudi[3]; Ahmed A. Nassr[3]; Brian Burnett[1]; Rebecca M. Johnson[1]; William E Whitehead[2]; Michael A. Belfort[3]; Magdalena Sanz Cortes[3]
[1]Baylor College of Medicine, Houston, TX; [2]Baylor College of Medicine and Texas Children's Hospital, Houston, TX; [3]Texas Children's Hospital and Baylor College of Medicine, Houston, TX

4:00 PM - 6:00 PM

Objective: Fetuses with myelomeningocele (MMC) often present with ventriculomegaly (VMG). If severe, the pressure exerted on the brain parenchyma may potentially cause axonal demyelination and lead to neurological deficits. Previously, using flow cytometry, we observed heterogeneity in cellular populations in fetal cerebrospinal fluid (CSF) obtained immediately prior to beginning fetal surgery. We hypothesized that differences in proportional microglia and neuronal progenitor cells in fetal CSF correlate with neurological deficits observed in children with MMC and may reflect the degree of brain tissue injury.

Study Design: Retrospective study of CSF from 9 fetuses who underwent a laparotomy-assisted fetoscopic MMC repair. Before surgery, fetal MRI and ultrasound scans were performed. Ventricular atrial width measurements, anatomical level of the lesion, and presence/absence of clubfeet were recorded. At birth, motor function was evaluated. Fetal CSF was collected from the MMC sac immediately prior to starting the fetoscopic MMC repair and subjected to single-cell RNA-sequencing (scRNA-seq; n = 9, 25.1[23.7-25.9] weeks gestation) to quantify proportional cell counts. Proportions of cellular populations were compared between cases with different neurological characteristics and outcomes.

Results: A total of 18 distinct CSF cellular subpopulations were identified (Figures 1A, 1B). Significantly fewer macrophages were found in the CSF from fetuses with VMG compared to those with no VMG (Figure 1, C). Cases with an anatomical lesion higher than L2 had fewer immature neurons as compared to those where the lesion was < L2 (Figure 1, D). When club foot was present at the time of the surgery there were more trophoblast-like cells than in those without club foot. Infants with impaired MF at birth, and those with club foot, showed significantly less proportional microglia cells than their counterparts (Figure 2).

Conclusion: In fetuses with MMC there are changes in the CSF cellular footprint that can be observed at midgestation and which may be associated with specific neurologic findings present at birth.

Figure 1. Comparison of the proportional fetal CSF cells and neurological characteristics

A-B, Fetal CSF from MMC repair cases were subject to scRNA-seq. A total of 20,228 cells were annotated based on marker gene expression (A) Proportional cell counts were analyzed in fetal CSF specimens, neuronal subtypes, and macrophage cells (B).

C, Ventriculomegaly (VMG) was defined as an atrial width >=10mm.

D, Anatomical level of the lesion was determined by ultrasound. High anatomical lesion level was defined as L2 or higher.

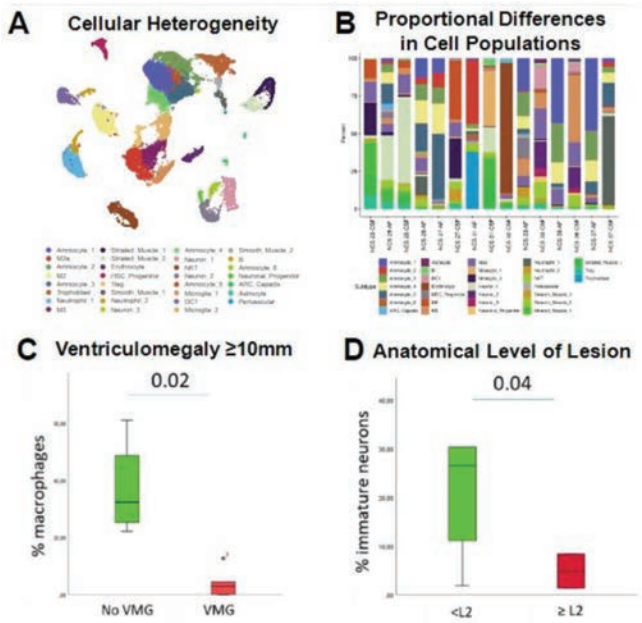


Figure 2. Comparison of the percentage of fetal CSF cell subtypes and neurological outcomes

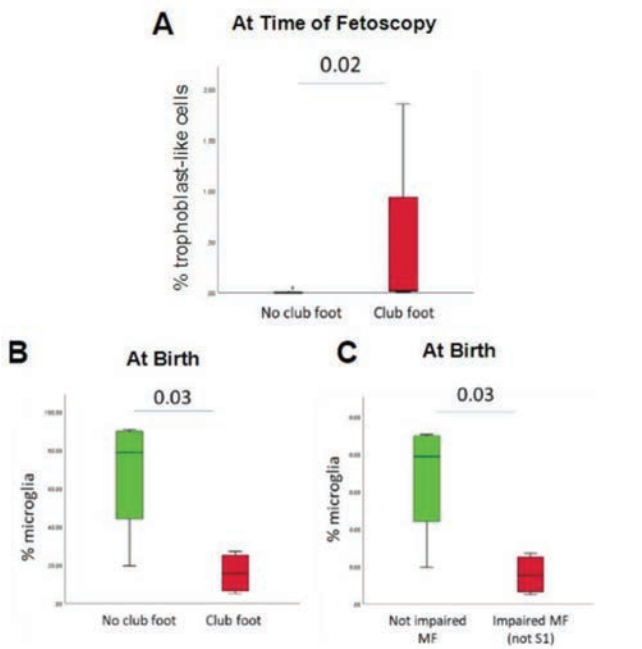
A. Club foot versus no club foot at the time of the prenatal MMC repair
B. Club foot versus no club foot at birth
C. Children without motor function impairment (MF) at S1 versus those with impaired MF above S1 at birth



614 | Predicting Severe Blood Loss Before Cesarean Hysterectomy (CH): A Novel Method Focusing on Bladder Vascularity

Rosa Drummond; Mevlut Bucak; MaryEllen Mangione; Ozhan M. Turan
University of Maryland Medical Center, Baltimore, MD

4:00 PM - 6:00 PM

Objective: Placenta accreta spectrum (PAS) grade 3b&c pose the highest risk for severe blood loss (SBL) during CH, primarily due to bladder dissection. Interventions like interval hysterectomy, conservative management and aortic occlusion (REBOA) are proposed to reduce SBL but come with complications. Current preoperative assessments are unreliable in identifying SBL cases. We hypothesize that cystoscopic (C) evaluation can accurately predict SBL.

Study Design: PAS cases had preoperative ultrasound, MRI, and postoperative pathological grading. Standardized cystoscopy and bilateral stents were used in non-urgent cases. Quantitative blood loss (QBL), surgical complications, and transfusions were recorded. Same surgeon, standardized techniques, and blinded evaluation of C recordings were inclusion criteria (Figure 1). Odds ratio (OR) for cystoscopy variables were calculated using postoperative grading. The Cystoscopy Index (CI) was calculated from OR sums. Postoperative grades 3b&c were high grade (HG); 1, 2, and 3a were low grade (LG). Primary outcome was CI prediction of SBL > 2000ml. Secondary outcomes included surgical complications and REBOA placement. C results were analyzed using descriptive statistics, correlation, and ROC curve.

Results: Of 66 cases, 31 were HG and 35 LG. Postoperative grading identified more HG cases than preoperative ($p = 0.002$), with grade 3b being the most common (38%). Bridging vessels (BV) and distortion of the trigone (DT) were the strongest predictors of HG (odds ratios 3.5 and 5.1, $p = 0.01$). CI correlated with QBL ($p = 0.036$). ROC analysis calculated CI ≥ 2.8 is the predictor for HG cases (AUC:0.68, $p = 0.009$). CI ≥ 2.8 was identified in 82% (14/17) of cases with SBL and required >4U RBC transfusion ($p = 0.01$ and 0.03) (Table 1). DT was significantly related to cystotomy ($p = 0.007$). Two HG cases required REBOA and had CI ≥ 2.8.

Conclusion: Preoperative cystoscopy and CI can identify cases resulting in SBL, unavoidable cystotomy, and REBOA. High CI can guide discussions about alternatives like interval hysterectomy or REBOA. This tool aids in randomizing patients for conservative management.

Figure 1. Cystoscopy variables

	CI <2.8 (n=35)	CI ≥ 2.8 (n=31)	p value
Maternal age (median, IQR)	34.5 (4)	35 (7)	NS
BMI (median, IQR)	35 (9)	35 (9)	NS
GA at delivery (median, IQR)	35 (1)	35 (2)	NS
>3 c-sections (n, %)	10 (29%)	9 (29%)	NS
Placenta previa (n, %)	21 (92%)	30 (97%)	NS
Postoperative grading (n, %) Low grade High grade	 21 (60%) 9 (26%)	 22 (71%) 14 (45%)	0.015
SBL (n, %)	3 (9%)	14 (45%)	0.01
Transfusion of ≥ 4 units RBC (n, %)	0 (0%)	6 (19%)	0.028
Cystotomy (n, %)	8 (23%)	11 (35%)	NS
REBOA (n, %)	0 (0%)	2 (6%)	

Table 1. Distribution of maternal demographics and surgical outcomes based on cystoscopy index (CI.)
BMI = body mass index, GA = gestational age, IQR = interquartile range, NS = not significant, RBC = red blood cells, REBOA = resuscitative endovascular balloon occlusion of the aorta, SBL = severe blood loss.

615 | Association Between Nt-Probnp and Persistent Postpartum Hypertension Among Individuals with Hypertensive Disorders of Pregnancy

Rosemary Shay[1]; Carrie Bennett[1]; Caroline Smith[2]; Janet Catov[3]; Arun Jeyabalan[2]; Robin E. Gandley[4]; Malamo Countouris[1]; Alisse Hauspurg[5]
[1]University of Pittsburgh Medical Center, Pittsburgh, PA; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA; [3]Magee-Womens Hospital, Pittsburgh, PA; [4]Magee-Womens Research Institute, Pittsburgh, PA; [5]Alpert Medical School of Brown University, Providence, RI

4:00 PM - 6:00 PM

Objective: Natriuretic peptide (NP) concentrations are increased in hypertensive disorders of pregnancy (HDP), but the association of NP levels with postpartum outcomes among hypertensive individuals has not been well explored. Our objective was to evaluate the association of N-terminal pro B-type natriuretic peptide (NT-proBNP) concentration at delivery with persistent postpartum hypertension (HTN) and blood pressure (BP) trajectory in the first two weeks postpartum among individuals with HDP.

Study Design: This cohort study included individuals with new-onset HDP (gestational hypertension, preeclampsia) who participated in a remote BP monitoring program and an obstetric biobank. NT-proBNP was measured from maternal plasma at delivery. Postpartum BP data were collected from delivery hospitalization, six-week remote BP program, and outpatient visits. Outcomes were compared between low-NT-proBNP (< 150 pg/mL) and high-NT-proBNP (≥150 pg/mL) groups, with cut-off of 150 pg/mL based on previously published reference intervals

in pregnancy. We used repeated BP measures to fit mixed-effects linear regression models using restricted cubic splines. Persistent HTN was defined as BP ≥140/90 mmHg or antihypertensive medication.

Results: Of 111 individuals with HDP, 31 (28%) had low NT-proBNP, and 80 (72%) had high NT-proBNP. Those with high NT-proBNP had higher maximum DBP during the delivery hospitalization (101 vs. 94 mmHg, p = 0.01), higher maximum SBP during remote monitoring (145 vs. 139 mmHg, p = 0.049), and higher likelihood of being on antihypertensives at any time postpartum (49% vs. 23%, p = 0.01) compared with those with low NT-proBNP. High NT-proBNP was associated with persistent HTN at six weeks postpartum (40% vs. 19%, p = 0.04) compared with low NT-proBNP. The high-NT-proBNP group had a significantly different SBP trajectory from the low-NT-proBNP group over the first two weeks postpartum (p = 0.04 for SBP, p = 0.13 for DBP).

Conclusion: Individuals with elevated NT-proBNP may be at increased risk for ongoing HTN in the postpartum period and could warrant closer monitoring after delivery.

Table. Clinical outcomes by NT-proBNP level

	Low NT-proBNP (n=31)	High NT-proBNP (n=80)	p value
Stage 2 HTN or antihypertensive medication at 6 weeks postpartum	6 (19%)	32 (40%)	0.04
Maximum postpartum SBP from delivery hospitalization	147±11	153±19	0.10
Maximum postpartum DBP from delivery hospitalization	94±11	101±13	0.01
Median number of home BP values	23[19,27]	20[13,27]	0.26
Maximum SBP from home BP monitoring	139±11	145±14	0.049
Maximum DBP from home BP monitoring	92±8	96±10	0.10
Any severe-range BP	10 (32%)	38 (48%)	0.15
SBP at 6 weeks postpartum	119±10	122±12	0.14
DBP at 6 weeks postpartum	78±8	78±8	0.97
Antihypertensive medication at any point between delivery and 6 weeks postpartum	7 (23%)	39 (49%)	0.01
Antihypertensive medication at 6 weeks postpartum	4 (13%)	25 (31%)	0.048
Stage 1 or greater HTN or antihypertensive medication at 6 weeks postpartum	18 (58%)	53 (66%)	0.42
Weight change from admission to postpartum visit (kg)	-10±3	-10±12	0.74

Low NT-proBNP defined as less than 150 pg/mL, high NT-proBNP greater than or equal to 150 pg/mL
Data are mean±SD, median[IQR], or n(%)
BNP, B-type natriuretic peptide; SBP, systolic blood pressure; DBP, diastolic blood pressure; BP, blood pressure; HTN, hypertension
Stage 1 or greater HTN defined as SBP≥130 mmHg or DBP≥80 mmHg, stage 2 HTN defined as SBP≥140 mmHg or DBP≥90 mmHg

616 | Preeclampsia Compared to Gestational Hypertension Increases Short-Term Renal Disease Morbidity

Ruby Lin[1]; Rachel Lee[1]; Emily E. Daggett[2]; Morgan C. Dunn[3]; Emily B. Rosenfeld[1]; Cande V. Ananth[1]
[1]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; [2]Rutgers Robert Wood Johnson Medical School, Edison, NJ; [3]Rutgers Robert Wood Johnson, New Brunswick, NJ

4:00 PM - 6:00 PM

Objective: Despite the physiologic differences, gestational hypertension and preeclampsia without severe features are managed similarly. We hypothesize that the presence of proteinuria in preeclampsia increases the risk of short-term renal disease morbidity.

Study Design: Using the Healthcare Cost and Utilization Project Nationwide Readmissions Database, we performed a retrospective cohort study of hospital delivery discharges in the United States from 2010 to 2020. We used ICD 9 and 10 codes to identify deliveries complicated by hypertensive disease in pregnancy, as well as hospital readmissions within the calendar year of delivery for renal disease, including acute and chronic kidney disease. Chronic hypertension and superimposed preeclampsia were excluded to avoid the possibility of baseline renal disease due to preexisting hypertension. Associations were derived from Cox proportional hazard models expressed in the confounder-adjusted hazard ratio (HR) with a 95% confidence interval (CI).

Results: There were 3,425,221 deliveries complicated by gestational hypertension, preeclampsia without severe features, or severe preeclampsia. Renal disease hospitalization rates for gestational hypertension, preeclampsia without severe features, and severe preeclampsia were 247, 408, and 648 per 100,000 delivery hospitalizations, respectively. Compared to those with gestational hypertension, preeclampsia without severe features was associated with increased risks of acute renal disease (HR 1.49, 95% CI 1.31-1.68); risks for chronic renal disease were even higher (HR 2.31, 95% CI 1.70-3.13). Patients with severe preeclampsia were at substantially increased risk of renal disease hospitalizations.

Conclusion: Preeclampsia has a 1.5- fold and severe preeclampsia a 2.4-fold increase in renal disease morbidity compared to gestational hypertension. These findings highlight the different prognoses between gestational hypertension, non-severe preeclampsia, and severe preeclampsia. Patients who have preeclampsia may warrant closer surveillance for long-term kidney disease.

Table
Hazard ratios for renal disease readmission based on type of preeclampsia compared to gestational hypertension (reference) within one calendar year in the United States, 2010-2020

Renal disease hospitalizations	Adjusted hazard ratio (95%CI)	
	Preeclampsia without severe features	Severe Preeclampsia
Any renal disease	1.55 (1.41-1.71)	2.44 (2.23-2.68)
Any acute renal disorder	1.49 (1.31-1.68)	2.57 (2.30-2.87)
Acute kidney failure	1.66 (1.43-1.94)	3.28 (2.87-3.75)
Acute tubulointerstitial nephritis	1.29 (1.05-1.57)	1.45 (1.19-1.78)
Any chronic renal disorder	2.31 (1.70-3.13)	6.03 (4.54-8.01)
Chronic kidney disease	2.54 (1.80-3.59)	8.03 (5.94-10.86)
Hypertensive kidney disease	3.07 (2.07-4.57)	8.55 (6.05-12.07)
Chronic tubulointerstitial nephritis	0.47 (0.09-2.44)	0.34 (0.06-2.06)
Glomerular and proteinuria disease	2.63 (1.75-3.97)	5.03 (3.37-7.50)

Hazard ratios were adjusted for year of delivery, maternal age, insurance status, income quartile, hospital bed size, hospital type, and hospital teaching status in a weighted Cox-proportional regression model

617 | Disparities in Fetal Autopsy and Placental Histopathology following Stillbirth in the United States

Sabrina Montgomery[1]; Katherine Bianco[2]; Hayley E. Miller[2]; Ruth B. Lathi[2]; Stephanie A. Leonard[2]
[1]Charles R. Drew University of Medicine and Science, College of Medicine, Inglewood, CA; [2]Stanford University, Palo Alto, CA

4:00 PM - 6:00 PM

Objective: Efforts to eliminate well-known disparities in stillbirth require an improved understanding of the causes of death. Clinical guidelines recommend fetal autopsy and placental histopathology following a stillbirth, but many stillbirths do not receive these evaluations and remain unexplained. We sought to examine whether rates of fetal autopsy and placental histopathology following a stillbirth differ among racial/ethnic and education groups.

Study Design: We conducted a population-based study using the U.S. CDC national fetal death files between 2020-2022. We included singleton births ≥20 weeks' gestation with complete information on study variables. The study outcomes were fetal autopsy and placental histopathology, categorized as none or yes: completed or planned. Birth parent race, ethnicity, and education were self-reported and categorized by the CDC. We performed multivariable logistic regression models to evaluate differences in the outcomes among racial/ethnic and education groups. Covariates included age, late or no prenatal care, prior live birth, and gestational age.

Results: In this study of 43,954 stillbirths, 18% received a fetal autopsy and 67% had placental histopathology performed (Table 1). Among racial/ethnic groups, Non-Hispanic (NH) Black people had higher rates of fetal autopsy (aOR 1.34, 95% CI: 1.26-1.42) but lower rates of placental histopathology (aOR 0.87, 95% CI: 0.82-0.92) than NH White people (Table 2). NH American Indian or Alaska Native and NH Asian people also had significantly lower rates of placental histopathology. Among education groups, increasing level of education was associated with increasing rate of both fetal autopsy and placental histopathology.

Conclusion: Utilization of fetal autopsy and placental histopathology was lower than expected across all groups, with differences among racial/ethnic and education groups. Further research is needed to understand structural barriers, patient preferences, and causes of disparities in clinical evaluation following stillbirth.

618 | Gender Representation in Mfm Fellowship Leadership: a Cross-Sectional Analysis

Sally Kuehn[1]; Colleen P. Judge-Golden[2]; Rachel L. Wood[3]; Sarah K. Dotters-Katz[1]
[1]Duke University School of Medicine, Durham, NC; [2]Duke University Hospital, Durham, NC; [3]Duke University, Durham, NC

4:00 PM - 6:00 PM

Objective: Women hold far fewer leadership positions in academic medicine than men. The purpose of this study was to describe the gender breakdown of maternal fetal medicine(MFM) fellowship program directors(PD) and to evaluate the association between gender and academic rank in this cohort.

Study Design: After IRB exemption, an inclusive list of active MFM fellowship programs was collected. Using online search tools, PD gender identity (extrapolated from written pronouns in online profiles), PD academic rank, number of years since PD fellowship graduation, and number and gender identity of current fellows were collected for each program. Data were analyzed using descriptive statistics and bivariate analyses.

Results: Biographical information was available for 104 of 106(98.1%) MFM fellowship PDs and 387 fellows representing 88 programs. Of the fellowship PDs, 63(61%) were women. On average, male directors had spent significantly more years out of fellowship than their female counterparts (21.0 yrs vs 15.1 yrs, p = 0.004) and were more likely to be full professors (54% vs. 30%, p = 0.03). However, when stratifying by number of years in practice (< 10 years, 10-19 years, 20+ years), no difference in academic rank was seen between men and women within groups (Figure). Of fellows, 87(22.5%) were men. The proportion of male PDs was significantly higher than the proportion of male fellows (39% vs. 23%, p = 0.0008). There was no association between fellow gender identity and the gender identity of their respective PDs (Table).

Conclusion: Even in OBGYN—one of the few predominantly female specialties—gender disparities still exist in medical education leadership. In MFM, males are overrepresented in fellowship leadership compared to the gender distribution of current fellows. Our data suggest that this finding, and the difference in academic rank between male and female PDs, is related to males having been in practice for longer. As the specialty continues to evolve, attention must be paid to ensure that medical education leadership is reflective of the trainees it serves.

Table. Sample Characteristics.

619 | Postpartum Mental Health Following Unplanned Modes of Delivery: Understanding Birth Trauma

Samantha L. Kruger[1]; Nicola C. Perlman[1]; Elizabeth B. Sherwin[1]; Yasser Y. El-Sayed[2]; Deirdre J. Lyell[1]; Elliott K. Main[2]; Suzan L. Carmichael[1]; Katherine L. Wisner[3]; Pervez Sultan[1]; Stephanie A. Leonard[1]; Danielle M. Panelli[1]
[1]Stanford University, Palo Alto, CA; [2]Stanford University, Stanford, CA; [3]Children's National Hospital, Washington, DC

4:00 PM - 6:00 PM

Objective: Birth trauma is an increasingly recognized and prevalent problem, yet the relationship between potentially traumatic birth events (such as unplanned mode of delivery) and postpartum mental health conditions is understudied. We evaluated associations between unplanned delivery modes and new onset postpartum mental health conditions.

Study Design: This was a retrospective cohort study of singleton live births between 2008-2022 from the MarketScan Commercial Database. We excluded births with mental health conditions diagnosed during pregnancy, discontinuous insurance enrollment, preterm birth (< 37 weeks), contraindications to labor, and planned cesareans. The exposure was spontaneous vaginal delivery (SVD), successful operative vaginal delivery (OVD) with vacuum or forceps, unplanned cesarean without OVD attempt, or cesarean after failed OVD. The outcome was a mental health condition (depression, anxiety, post-traumatic stress disorder (PTSD), or other serious psychiatric conditions) diagnosed between delivery and 6 months postpartum. Multivariable logistic regression models were conducted to assess associations between mode of delivery and any postpartum mental health condition, adjusting for confounders. Secondarily, models were replicated to evaluate each individual mental health condition as an outcome.

Results: A total of 829,917 births were included. Compared with SVD, postpartum mental health conditions were increased after unplanned cesarean without OVD [adjusted odds ratio (aOR) 1.15, 95% confidence interval (CI) 1.13-1.18] and after unplanned cesarean with failed OVD (aOR 1.20, 95% CI 1.03-1.38, Table 1). Prevalence of PTSD was significantly increased in all modes of delivery compared to SVD, most notably for failed OVD (aOR 1.60 95% CI 1.09-2.26, Figure 1).

Conclusion: Postpartum mental health conditions were increased among people with unplanned cesarean births, most notably PTSD in those with failed OVD. Screening for PTSD

should be considered, especially for people who have failed OVD attempts that result in cesarean birth.

Table 1. Postpartum mental health conditions by mode of delivery among term, singleton, livebirths in a commercial claims database who were eligible for labor in the United States between 2008 and 2022, N=829,917)

620 | Expectant Management versus. Prompt Laser Therapy for Stage II Twin-Twin-Transfusion-Syndrome before 18 weeks

Sami Backley[1]; Eric P. Bergh[2]; Saul Snowise[3]; Anthony Johnson[4]; Jimmy Espinoza[1]; Nick Juckel[3]; Ashley Salazar[5]; Ramesha Papanna[6]; Clifton O. Brock[3]

[1]Division of Fetal Intervention, Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern Medical School at UTHealth Houston, Houston, TX; [2]UT Health, Houston, TX; [3]Midwest Fetal Care Center, Children's Minnesota, MN, Minneapolis, MN; [4]McGovern Medical School University of Texas Health Science Center at Houston (UThealth), Houston, TX; [5]Division of Fetal Intervention, Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern Medical School at UT Health Houston, Houston, TX; [6]McGovern Medical School at UTHealth Houston, Houston, TX

4:00 PM - 6:00 PM

Objective: In some reports, fetoscopy before 18 weeks (wks) gestational age (GA) is associated with a greater risk of poor perinatal outcomes. We assessed efficacy of expectant management (EM) followed by fetoscopic placental laser ablation (FLA) at 18 wks versus prompt intervention (PI) in patients with early-Stage II twin-to-twin transfusion syndrome (TTTS).

Study Design: This is a secondary analysis of prospectively collected data from monochorionic diamniotic (MCDA) pregnancies with Stage 2 TTTS prior to 18 wks GA at two fetal centers. We compared outcomes between patients that had FLA promptly after evaluation (PI) to those where expectant management (EM), with twice-weekly surveillance and intent to perform FLA at 18 wks GA, was undertaken. For the EM group, we assessed incidence of early FLA (i.e., < 18 wks) for progressive polyhydramnios or worsening severity of disease (i.e., upstaging). Ultrasound characteristics, GA of delivery, incidence and timing of preterm prelabor rupture of membranes (PPROM) and survival were compared between groups.

Results: Stage 2 TTTS prior to 18 wks was confirmed in 54 MCDA pregnancies with 18 (33.3%) in the EM group and 36 (66.7%) in the PI group. In the EM group, 12 patients had FLA at 18 weeks, while 6 had early FLA (Figure). The PI group presented 3.5 days later than the EM group ($p = 0.02$), while time between evaluation and PLA was greater in the EM group (6 vs. 1 days, $p < 0.01$). Ultrasound characteristics between the groups were similar (Table). Rates of PPROM were similar between groups. However, the GA of PPROM trended later in the EM group (24.8 vs. 19.6 wks, $p = 0.08$) while the FLA to PPROM interval trended longer (6.7 v. 3.3 days, $p = 0.31$). GA at delivery was similar between groups. Dual survival rates were 88.9% and 75.0% ($p = 0.30$) in the EM and PI groups respectively. In the EM group, dual survival occurred in all upstaged cases.

Conclusion: Expectant management for early Stage II TTTS was noninferior to prompt intervention. The timing of PPROM, when it occurs, may be more favorable with EM, however further study is required to assess this possibility.

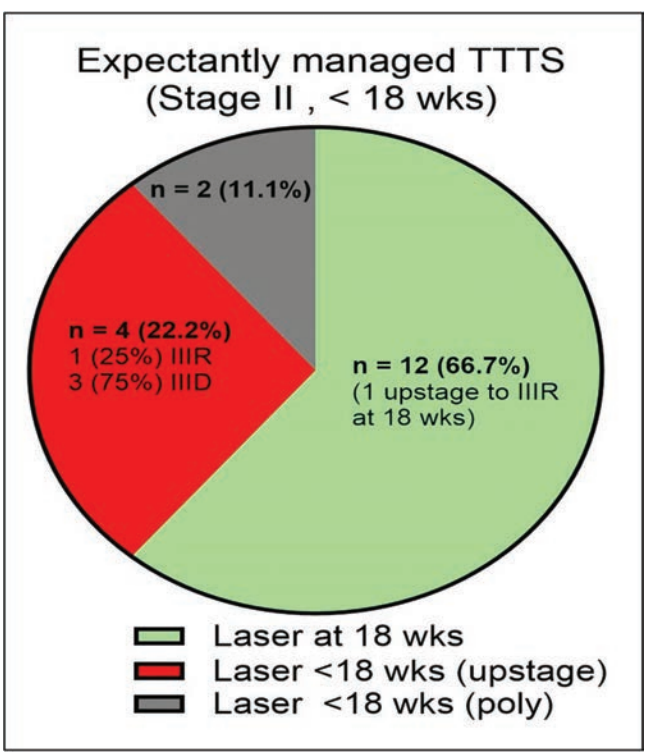

Table: Characteristics of patients that had fetoscopic laser surgery for Stage II TTTS (< 18 wks)

Characteristic	Expectant Management (n = 18)	Prompt Intervention (n = 36)	p-value
Maternal Age	30.1 ± 4.3	29.1 ± 6.2	0.52
BMI	28.6 ± 6.2	27.2 ± 7.8	0.51
GA at presentation (wks)	16.7 ± 0.7	17.2 ± 0.5	0.02

4:00 PM - 6:00 PM

Objective: Undiagnosed vasa previa (VP) has devastating consequences due to fetal hemorrhage. Despite the evidence, there is a lack of screening guidelines. Utilizing the universal cervical length (CL) screening protocol at our center, the objective of the study was to identify and characterize the vasa previa distance from the internal os using color Doppler (CD) sweep on transvaginal ultrasound.

Study Design: This was a retrospective cohort study of singleton pregnancies that underwent universal transvaginal CL screening with CD, transvaginal sweep between 2016-2024. VP cases were identified from an ultrasound database query. The images/clips were analyzed using the following screening methods: 1) midline still image with CD, 2) CD sweep over the cervix, and 3) CD sweep to the lateral lower uterine segment (Fig 1A). Quantitative assessment was performed for vessel type (artery, vein or both), Doppler flow (cm/sec), and distance from the internal os (cm) for each image.

Results: 139 of 67,369 pregnancies with transvaginal CL had VP in the diagnostic field. 98 (0.14%) VP were diagnosed of which: 47 (45%) were Type 1, 33 (34%) were Type 2 and 21 (21%) were Type 3. Midline CD view alone diagnosed 32 (33%) of cases. CD flow over the cervix diagnosed an additional 39 (40%) cases. CD flow in the lateral lower uterine segment provided diagnosis of 27 (27%) additional cases. The incidence of resolving placenta previa and velamentous cord insertion were similar in all groups. VP type 3 was more likely to be diagnosed on lateral sweep ($p = 0.02$). The distance between the cervical os and the fetal vessel was further away in cases diagnosed on lateral sweep compared to midline view and midline CD sweep of internal cervical os (Fig 1B).

Conclusion: Color Doppler sweep of the cervix and lateral lower uterine segment identifies a higher proportion of vasa previa prenatally. Fetal vessels lateral to the cervix constitute 1 in 5 of vasa previa cases. Guidelines to standardize the screening for vasa previa to include lateral aspects of the cervix should be considered.

Table 1: Ultrasound parameters on the three ultrasound screening methods.

	Midline color	Sweep over cervix only	Lateral sweep	*p*-Value
VP type				**0.02**
1	22 (68.8%)	14 (35.9%)	8 (29.6%)	
2	7 (21.8%)	16 (41%)	10 (37%)	
3	3 (9.4%)	9 (23.1%)	9 (33.4%)	
GA at ultrasound (weeks)	25.20 ± 5.1	26.14 ± 5.13	23.50 ± 4.4	0.15
Cervical length at diagnosis (mm)	37.00 ± 5.3	38.95 ± 6.3	39.89 ± 6.5	0.20
Fetal vessel				1.0
Artery	11 (34.3%)	14 (35.9%)	11 (40.7%)	
Vein	8 (25%)	9 (23.1%)	5 (18.6%)	
Both artery and vein	13 (40.7%)	16 (41%)	11 (40.7%)	
Resolved placenta previa	23 (71.8%)	26 (66.7%)	13 (48.1%)	0.14

[1]Duke Univeristy, Durham, NC; [2]Duke University, Durham, NC; [3]Duke University School of Medicine, Durham, NC

4:00 PM - 6:00 PM

Objective: Our aim was to assess whether pregnant patients with comorbid anemia in the setting of cardiac disease experience an increased risk of severe maternal morbidity (SMM) and other adverse pregnancy outcomes.

Study Design: This was a retrospective cohort study using the 2016-2021 National Readmissions Database of all patients with cardiac disease who delivered a singleton infant between 24 and 41 weeks. Patients with cardiac disease as identified by diagnosis codes were included and categorized based on modified World Health Organization (mWHO) criteria, which due to coding limitations was dichotomized as mWHO I or II disease (I-II) versus mWHO II/III, III or IV (II/III+) disease. Logistic regression was used to assess the association between anemia and adverse pregnancy outcomes. A subgroup analysis of patients with iron-deficiency anemia was conducted. Models were adjusted for age, ZIP code, median household income, primary payer, hospital size, hospital teaching status, delivery mode, and comorbid conditions.

Results: Cardiac disease was identified in 61,542 patients in our cohort (47,767 (77.6%) with mWHO I-II disease and 13,775 (22.4%) with mWHO II/III+ disease). Of these patients, 16,122 (26.2%) had anemia. Comorbid anemia was associated with higher odds of SMM/mortality in both mWHO I-II (aOR 4.65, 95% CI 4.16, 5.18) and mWHO II/III+ (aOR 2.25, 95% CI 2.05, 2.47) patients. Comorbid anemia was also associated with blood product transfusion, non-transfusion SMM/mortality, preterm birth, and cesarean delivery (Figure). This relationship persisted for the subgroup of patients with iron-deficiency anemia, with an increased odds of SMM in the setting of anemia seen for patients with both mWHO I-II (aOR 3.68, 95% CI 2.95, 4.58) and mWHO II/III+ (aOR 2.14, 95% CI 1.77, 2.58) (Table).

Conclusion: Comorbid anemia, including iron-deficiency anemia, adversely impacts pregnancy outcomes in pregnant patients with cardiovascular disease. Identifying and treating this modifiable risk factor offers an opportunity to reduce morbidity in this high-risk population.

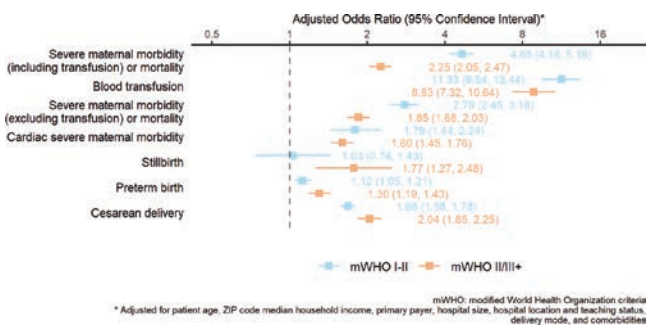

Table: Association between anemia and pregnancy outcomes by WHO cardiac risk categories among patients with iron-deficiency anemia.

Outcomes	Interaction p-value	WHO cardiac risk	Adjusted[a] OR (95% CI)	P-value
SMM (including transfusion) or Mortality	<0.001	Class I or II	3.68 (2.95, 4.58)	<0.001
		Class II/III, III, or IV	2.14 (1.77, 2.58)	<0.001
Blood products transfusion	0.979	--	9.22 (7.48, 11.36)	<0.001
Non-transfusion SMM or Mortality	0.647	--	1.89 (1.60, 2.22)	<0.001
Composite cardiac SMM	0.836	--	1.60 (1.32, 1.95)	<0.001
Stillbirth	0.336	--	0.86 (0.45, 1.64)	0.639
Preterm birth	0.567	--	1.42 (1.25, 1.60)	<0.001
Cesarean delivery	0.044	Class I or II	1.24 (1.09, 1.42)	0.002
		Class II/III, III, or IV	1.63 (1.32, 2.03)	<0.001

[a] Adjusted for age, ZIP code median household income, primary payer, hospital size, hospital teaching status, delivery mode, gestational diabetes, HIV/AIDs, pre-existing diabetes, previous cesarean birth, pulmonary hypertension, asthma, bleeding disorder, BMI at delivery ≥40, pre-existing cardiac disease, and chronic hypertension

623 | Stigmatizing Language and the Association with Patient-Related Factors in Pregnant Individuals with Diabetes

4:00 PM - 6:00 PM

Objective: Healthcare providers' biases can negatively influence the quality of care patients receive and exacerbate health disparities. These biases can manifest through verbal and written communication. In this study, we aimed to identify the prevalence of stigmatizing language in clinical notes and to identify the clinician and patient demographic characteristics associated with the use of such language in a population of pregnant individuals with diabetes.

Study Design: We conducted a retrospective cohort study from 2018-2019 of individuals with singleton, non-anomalous pregnancies diagnosed with pre-existing or gestational diabetes using an academic-community obstetric outcomes database. Using a Natural Language Processing (NLP) algorithm, we identified pre-specified stigmatizing terms in electronic health record clinic notes (Fig. 1). We then compared the characteristics of patients with and without documented stigmatizing language in their medical records.

Results: Out of 1433 individuals, 128 (9%) had stigmatizing language in their medical records during their pregnancy, comprising 259 unique notes and a median of 2.0 (range 1.0-12.0) notes per patient. The most frequently used terms were "noncompliant" (47%) and "refused" (42%). Physicians (48%), nurses (22%), and mid-level providers (12%) were the primary providers who used this language. When adjusting for diabetes type, providers were 70% less likely to use stigmatizing language when describing white individuals compared to their black and other race counterparts (aOR 0.26, 95% CI 0.17-0.39; p< 0.001). Additionally, all providers were almost five times more likely to use stigmatizing language when describing patients on public versus private insurance (aOR 4.95, 95% CI 3.26-7.73; p< 0.001) (Table 1).

Conclusion: Non-white birthing individuals and those on public insurance diagnosed with diabetes in pregnancy were significantly more likely to have stigmatizing language documented within their medical records. This documentation may contribute to health inequities for marginalized birthing individuals.

4:00 PM - 6:00 PM

Objective: Healthcare providers' biases can influence patients' care and health outcomes. These biases can manifest through verbal and written communication. In this study, we evaluated the impact of stigmatizing language in clinical notes on maternal and neonatal outcomes among individuals with perinatal diabetes.

Study Design: We conducted a retrospective cohort study from 2018-2019 of individuals with singleton, non-anomalous pregnancies diagnosed with pre-existing or gestational diabetes using an academic-community obstetric outcomes database. Using a Natural Language Processing (NLP) algorithm, we identified ADA-specified stigmatizing terms in electronic health record notes. We then compared the characteristics and outcomes of patients with and without documented stigmatizing language in their medical records.

Results: Out of 1433 individuals, 128 (9%) had stigmatizing language documented in their medical records during their pregnancy. Black individuals and those of another race were over three times more likely to have stigmatizing language than white individuals ($p< 0.001$). Individuals described with stigmatizing language had birth one week earlier than their counterparts (median 38w0d vs 39w0d, $p< 0.001$). HgbA1c before birth was comparable between cohorts (median 5.9 vs. 5.5). Both groups had similar rates of glucose documented in the two weeks before birth, and those without stigmatizing language had more abnormal blood glucose levels recorded than those with stigmatizing language (73% vs 47%, $p< 0.001$). After adjusting for diabetes type and gestational age at delivery, no differences were seen between individuals with and without stigmatizing language in hypertensive disorders of pregnancy, NICU admission, or LGA infants.

Conclusion: The presence of stigmatizing language documented in medical records was used more often in Black and other minoritized racial groups than white individuals and was not clearly associated with markers of worse glucose control. No differences in clinical outcomes were identified, suggesting stigmatizing language may be used biasedly.

4:00 PM - 6:00 PM

Objective: Risk factors for placenta accreta spectrum (PAS) other than prior cesarean delivery (CD) and placenta previa remain unclear. In those with placenta previa, there is limited data regarding the role of dilation and curettage (D&C) and risk of PAS. We examined whether an association between D&C and PAS in pregnancies with placenta previa exists.

Study Design: Retrospective cohort study of pregnancies with finding of placenta previa on third trimester ultrasound from 2016–2024 and delivery within our hospital system. Pregnancies were divided into group 1: CD≤1 and group 2: CD≥2, and then subclassified according to history of D&C. PAS was diagnosed based on pathology findings. Logistic regression was performed to calculate adjusted relative risk for PAS controlling for gestational age at delivery.

Results: A total of 274 pregnancies with third trimester placenta previa and delivery outcomes at our hospital were reviewed. Characteristics including maternal age, parity, BMI, and IVF were similar within groups (Table 1). The rate of PAS was not different among those with and without D&C in group 1 (26% versus 15%, $p = 0.4$) or group 2 (74% versus 67%, $p = 0.2$). Delivery at < 36 weeks was more frequent in those with D&C among group 1 (69% versus 47%, $p = 0.016$), and not different in group 2 (89% vs 83%, $p = 0.73$). Figure 1 demonstrates PAS pathology in both groups according to history of D&C.

Conclusion: In this cohort of pregnancies with placenta previa, rate of PAS was not changed based on history of D&C. We did note an association with increased placental invasion with history of D&C, although not statistically significant. Interestingly in those with prior CD≤1 and history of D&C, preterm delivery < 36 weeks was 1.5 times more likely than in those without history of D&C. A large trial is needed to evaluate the role of D&C with incidence of PAS and preterm labor.

4:00 PM - 6:00 PM

Objective: There is controversy concerning the degree of maternal hyperglycemia associated with adverse neonatal outcomes. Continuous glucose monitoring (CGM) is an innovative technology that allows for individualized glycemic profiles. We aimed to determine whether CGM metrics during screening for gestational diabetes (GDM) can identify individuals who experienced adverse neonatal outcomes compared to those who did not.

Study Design: This was a prespecified, secondary analysis of a multi-clinic, randomized controlled trial of individuals being screened for GDM with the use of CGM compared to the 2-step method. Participants assigned to the 2-step method had a blinded CGM (Dexcom G6 Pro) placed at the time of the 1-hour glucose challenge test (GCT). CGM metrics evaluated included the mean glucose, time in range (TIR; 63–140 mg/dL), and time above the target range (TAR; >140mg/dL) expressed as % of all readings. The primary outcome was a composite of neonatal adverse outcomes (CNAO), including shoulder dystocia, birth injury, large for gestational age, need for IV/PO glucose, respiratory distress, and fetal/neonatal death. We compared CGM metrics for those with or without the CNAO.

Results: Of the 814 individuals randomized, 613 (75%) had CGM metrics that were analyzed (N = 331; CGM group, N = 282; 2-step blinded CGM group). Of those 196 (32%) had the CNAO and 417 (68%) did not have CNAO. The CNAO was higher among individuals diagnosed with GDM (28% v 16%; p = 0.003) and those treated with hypoglycemic agents (10% v 5%, p = 0.04). Neonates with the CNAO had a higher mean CGM glucose (108.9 v. 105.0, p = 0.007, Figure), coefficient of variation (17.8 v. 17.1, p = 0.02), and TAR (6.5% v. 3.8%, p = 0.001) compared to those without (Table).

Conclusion: In this secondary analysis, CGM metrics at 24-32 weeks of elevated mean glucose, higher coefficient of variation, and elevated TAR were associated with worse neonatal outcomes. Our findings suggest that further studies are needed to evaluate the role of various CGM metrics in diagnosing maternal hyperglycemia and related adverse outcomes.

627 | Interval to Cerclage Placement and Delivery Timing in Patients with an Extremely Short Cervix

Sarah H. Abelman; Frank I. Jackson; Nathan A. Keller; Julie Chen; Luis A. Bracero; Cara S. Wetcher; Matthew J. Blitz
Northwell, New Hyde Park, NY

4:00 PM - 6:00 PM

Objective: Patients with a very short cervical length < 1cm may benefit from cerclage placement, even in the absence of prior preterm birth. As with exam-indicated cerclages, it is often assumed that rapid cerclage placement improves the benefit of the intervention. This study aimed to determine whether length of time from diagnosis of cervical length < 1cm to cerclage placement affects delivery timing.

Study Design: This was a retrospective cohort study of all patients who received an ultrasound-indicated cerclage due to a transvaginal cervical length measurement of < 1cm during pregnancy, between January 2018 and December 2023, within a large health system in New York. Patients were excluded if they had a history of prior preterm birth. Patients were categorized based on time elapsed between this diagnosis and cerclage placement. The primary outcome evaluated was gestational age at delivery. Outcomes were compared using a linear mixed model regression analysis and were then adjusted for obesity and gestational age at diagnosis of short cervix.

Results: 99 patients were included who had an ultrasound-indicated cerclage placed for a diagnosis of a cervical length < 1cm, with no prior history of preterm birth. The mean wait time for cerclage placement after diagnosis was 2.3 days. 58 (59%) patients received a cerclage the next day, and 41 (41%) waited 2 or more days. The mean cervical length at diagnosis was 5.8mm ± 2.7 mm in the next-day placement group and was 6.9 mm ± 1.7 mm in the later placement group. The mean gestational age at diagnosis of a short cervix was 20.8 ± 1.8 weeks in the next-day placement group and was 20.1 ± 1.7 weeks in the later placement group. The mean gestational age at delivery in the next-day placement group was 35.4 ± 4.1 weeks, and in the later placement group was 34.7 ± 5.8 weeks, with no significant difference detected between the groups ($P = 0.51$).

Conclusion: For patients receiving an ultrasound-indicated cerclage for a short cervix < 1cm, there was no benefit to rapid next-day cerclage placement compared to longer wait times of 2 or more days.

628 | Accuracy of Placenta Accreta Spectrum Administrative Coding and Outcomes Inside and Outside of Referral Centers

Savvy Benipal[1]; Matthew Givens[2]; Amanda A. Allshouse[1]; Ibrahim Hammad[3]; Robert M. Silver[1]; Jason D. Wright[4]; Koji Matsuo[5]; Bret D. Einerson[6]
[1]University of Utah, Salt Lake City, UT; [2]Intermountain Health, Salt Lake City, UT; [3]Intermountain Health, Intermountain Health, UT; [4]Columbia University Irving Medical Center, New York, NY; [5]University of Southern California/Los Angeles General Medical Center, Los Angeles, CA; [6]University of Utah Health, Salt Lake City, UT

4:00 PM - 6:00 PM

Objective: Since 2015, ICD-10 codes for placenta accreta spectrum (PAS) have been used for research for this life-threatening pregnancy condition. However, this set of diagnostic codes have yet to be validated thoroughly and previous analyses suggest morbidity may be worse in referral centers. We sought to examine the accuracy of PAS ICD-10 codes in and outside of PAS referral centers and to characterize the associated outcomes.

Study Design: We conducted a case series of all ICD-10 diagnostic codes for PAS at two PAS referral centers within two health systems compromised of 17 delivery hospitals, representing the majority of deliveries in our state between September 2015 and December 2023. We performed ICD-10 code validation to assess accuracy of codes and stratified results based on true and false positives. True positive codes were those cases with histopathologic evidence of PAS or FIGO clinical criteria for PAS in the absence of histopathology. We compared composite maternal morbidity with logistic regression adjusted for delivery characteristics (maternal age, prior caesarean, and gestational age) overall, stratified by PAS center.

Results: Of 394 deliveries with a PAS diagnostic code, 68% occurred at a PAS referral center. False positive rate of PAS diagnosis was significantly higher at non-referral centers compared to referral centers (74% vs 24%, p< 0.001). All cases of PAS3/Percreta and nearly all cases of PAS2/Increta were managed at referral centers (Table). There was a higher odds of composite maternal morbidity at PAS centres compared to non-referral centres (aOR 2.57; 95% CI 1.42-4.68), but when excluding false positive cases, this association was not seen (aOR 1.55; 95%CI 0.65-3.69, Figure). Absence of PAS3/Percreta at non-referral centers precluded analysis of morbidity by severity.

Conclusion: In contrast to referral centers, the PAS ICD-10 code is most often inaccurate at non-referral centres with three-quarters being misdiagnosed. Among true positive PAS cases, despite a higher PAS severity at referral centers, maternal morbidity was not increased.

Table

Characteristics and Outcomes	PAS Referral Centers N=269	Non-referral Centers N=125	P
False positive PAS code	64 (23.8)	92 (73.6)	<.001
Reason for False positive diagnosis

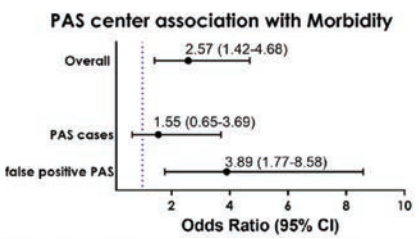
Values reported as frequency (column percent) with p-value from chi-square, or mean ± standard deviation (SD) with p-value from two-sample t-test



Estimates from logistic regression, each model outcome is a composite morbidity defined as: short-term post-operative complication (reoperation, shock, disseminated intravascular coagulation/coagulopathy, acute kidney injury, genitourinary (GU) or gastrointestinal (GI) injury diagnosed post-operatively, deep venous thrombosis or pulmonary embolism, or other), estimated blood loss >= 1500 mL, or a post-operative length of stay > 4 days. Both models adjusted for maternal age (>=/<35), prior cesarean (yes/no), and gestational age at delivery (<26 weeks, 26-<32, 32-<37, term), and true diagnosis, 2nd model includes an interaction between PAS center and true diagnosis

629 | Evaluation of Short-term Perinatal Outcomes with Expanded Gestational Weight Gain Parameters

Savvy Benipal[1]; Susan Dalton[1]; Amanda A. Allshouse[1]; Torri D. Metz[1]; Ann M. Bruno[2]

[1]University of Utah, Salt Lake City, UT; [2]University of Utah Health, Salt Lake City, UT

4:00 PM - 6:00 PM

Objective: Most pregnant patients in the U.S. gain more weight than the Institute of Medicine (IOM) recommends. There is ongoing debate as to whether the weight cutoffs, especially for patients with obesity, optimize outcomes. We aimed to evaluate concordance with IOM gestational weight gain (GWG) guidelines compared with 10 additional pounds (lbs) and perinatal outcomes in a contemporary U.S. cohort.

Study Design: Secondary analysis of a prospective multicenter cohort study of nulliparous, singleton pregnancies (2010-2013). Patients with a pre-pregnancy body mass index (BMI) of 18.5 kg/m^2 or greater, with pregnancy GWG within IOM guidelines or up to 10 lbs above were included. Pregnancies affected by genetic or structural anomalies, pregnancy loss < 20 weeks', or missing key outcome data were excluded. The primary outcomes were a composite maternal morbidity and neonatal morbidity and mortality. We estimated the incidence of maternal and neonatal composites by GWG. Logistic regression modeling compared morbidity composites between individuals within IOM GWG guidelines compared with up to an additional 10 lbs, stratified by BMI category.

Results: Of 4487 pregnancies, 2137 (48%) had GWG within IOM guidelines and 2350 (52%) had up to an additional 10 lbs gained. Additional weight gain was associated with higher pre-pregnancy BMI and age < 35 years. There was a higher odds of composite maternal morbidity (aOR 1.29, 95% CI 1.14-1.47) but not neonatal morbidity (aOR 0.94, 95% CI 0.83-1.08) in those with additional weight gain (Table). Findings were the same when stratified by BMI category among people with normal and overweight BMI but inference was limited among the obesity subgroups with statistical insignificance and wide confidence intervals (Figure).

Conclusion: Expanded GWG (10 lbs above IOM guidelines) was associated with higher odds of short-term adverse maternal outcomes but not neonatal outcomes when compared with GWG within IOM guidelines. Further research is needed to identify GWG targets which optimize both maternal and neonatal health.

Table. Association between expanded gestational weight gain (GWG) of 10 lbs above Institute of Medicine (IOM) guidelines compared with GWG within IOM guidelines and selected outcomes

Outcome	GWG within IOM guidelines (N= 2137)	Expanded GWG (>10 lbs above) (N=2350)	OR (95%CI)	aOR‡ (95%CI)

≥ 4500g	5 (0.2)	30 (1.3)	5.51 (2.14, 14.24)	*
Stillbirth	6 (0.3)	9 (0.4)	1.37 (0.49, 3.84)	*

GWG, gestational weight gain; IOM, Institute of Medicine; OR, odds ratio; CI, confidence interval; NICU, neonatal intensive care unit; GA, gestational age

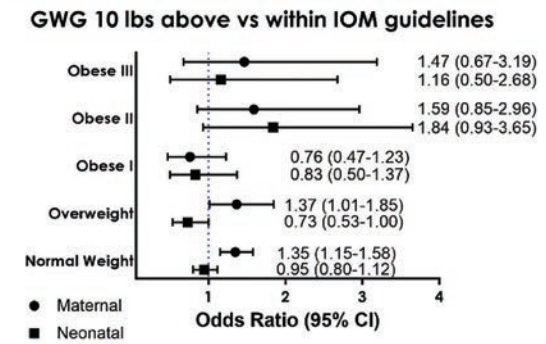
‡Adjusted for body mass index (BMI), maternal age, chronic hypertension, or diabetes, active tobacco, or THC use. Neonatal outcomes adjusted further by gestational diabetes or gestational hypertension, and gestational age at delivery (neonatal composite and preterm birth outcome not adjusted for gestational age).

+Maternal morbidity composite included cesarean delivery, postpartum hemorrhage requiring transfusion, hypertensive disorders of pregnancy, or gestational diabetes.

†Neonatal morbidity composite included stillbirth, preterm delivery, NICU admission for greater than 2 days, neonatal death, respiratory distress syndrome, small for gestational age or larger for gestational age birth weight.

* Adjusted analysis not calculated for fewer than 60 events.

Figure. Odds of maternal and neonatal morbidity and mortality composites with expanded gestational weight gain (10 lbs above Institute of Medicine guidelines) compared with within guidelines, stratified by body mass index (BMI) categories



GWG, gestational weight gain; IOM, Institute of Medicine; CI, confidence interval; BMI, body mass index
Obese I; BMI 30-34.9 kg/m², Obese II; BMI 35-39.9 kg/m², Obese III; BMI 40 kg/m² or greater
Maternal morbidity composite included cesarean delivery, postpartum hemorrhage requiring transfusion, hypertensive disorders of pregnancy, or gestational diabetes.
Neonatal morbidity composite included stillbirth, preterm delivery, NICU admission for greater than 2 days, neonatal death, respiratory distress syndrome, small for gestational age or larger for gestational age birth weight.

630 | Should Tranexamic Acid be Re-dosed for Patients with Postpartum Hemorrhage Based on Blood Volume?

Sean C. Halsey[1]; Allison Dunn[1]; Sebastian Seifert[2]; Sixtine Gilliot[3]; Anne-Sophie Ducloy-Bouthors[3]; Haleem Shakur-Still[4]; Amber Geer[4]; Naomi L. Luban[5]; Johannes van den Anker[6]; Jogarao Gobburu[1]; Ian Roberts[4]; Homa K. Ahmadzia[7]
[1]University of Maryland School of Pharmacy, Baltimore, MD; [2]Brigham & Women's Hospital, Boston, MA; [3]University of Lille, Lille, Nord-Pas-de-Calais; [4]London School of Hygiene & Tropical Medicine, London, England; [5]Children's National Hospital, Washington, DC; [6]University Children's Hospital, Basel, Basel-Stadt; [7]Inova Health System, Falls Church, VA

4:00 PM - 6:00 PM

Objective: The objective of this study is to identify the relationship between blood loss and drug clearance and between blood loss and volume of distribution for tranexamic acid use at delivery to determine the need for scheduling subsequent doses at a fixed rate or based on the magnitude of blood loss.

Study Design: Four pharmacokinetic studies were reviewed, and estimates of drug clearance (CL) and volume of distribution in the central compartment (Vc) and the peripheral compartment (Vp) from prior modeling work were compared with volume of blood loss. Data from 205 individuals was divided into five equal groups based on volume of blood loss, ranging from 160 mL to 10 L. Then the relationships of interest were visualized and described. The data was further described by dividing it into clinically meaningful groups based on blood loss of < 1 L, 1-2 L, 2-3 L, and > 3 L. All data analysis and visualization were performed using R Statistical Software (version 4.2.2, R Core Team (2022), Viena, Austria, https://www.R-project.org/).

Results: Of the 205 individuals studied, 67 experienced blood loss of at least 1 L and ten experienced a blood loss of at least 2 L. Clearance and distribution were both identified to have a minimal relationship with volume of blood lost, with CL having a weak positive trend as shown in Figure 1 (R-squared of 0.44), and Vc and Vp having slightly negative trends (R-squared of 0.055 and 0.20, respectively). Figure 2 shows the trend generated by Vc and blood loss. Data derived from clinically meaningful groups were very similar to that previously described with R-square values for CL, Vc, and Vp equating 0.0061, 0.024, and 0.028, respectively.

Conclusion: No strong correlations were identified among the groups of interest, indicating that blood loss does not greatly affect the pharmacokinetic action of tranexamic acid. Therefore, there may be no need to base TXA redosing frequency on the magnitude of blood loss. Additional data in patients with blood loss >2 L would help to validate these findings.

4:00 PM - 6:00 PM

Objective: To investigate the association between maternal hepatitis C virus (HCV) infection status and the development of preeclampsia during pregnancy.

Study Design: A retrospective cohort study was conducted using a total of 22,846,383 pregnant women who delivered preterm from 2015 to 2021. The primary exposure was HCV infection, while the primary outcome was preeclampsia. The data were obtained from medical records. Chi-squared analyses were performed to evaluate the association between HCV and preeclampsia.

Results: A total of 22, 846, 383 women were included in the study, with 104, 006 (0.46%) identified with HCV infection. Among women who are HCV negative, the prevalence of preeclampsia was 7.00% compared to 7.21% among women who are HCV positive. A significant association was indicated through chi-squared test showing a significant association between HCV and preeclampsia (Chi-squared = 7.4596, Pr = 0.006).

Analysis revealed that HCV infection was associated with an increased risk of preeclampsia (adjusted OR = 1.07, 95% CI: 1.04 - 1.10, P < 0.001). Other factors contributing to the risk of preeclampsia included higher BMI categories and a history of DM or chronic hypertension. Racial disparities were noted, with Black and Asian women having higher odds of preeclampsia compared to Hispanic women.

Conclusion: Maternal HCV infection is associated with an increased risk of developing preeclampsia.

632 | Ultrasound Alone versus Last Menstrual Period for Gestational Age Assignment: Implications for Fetal Growth Restriction

Shae Boguslawski[1]; Elise Turke[2]; Rebekah Pitpitan[2]; Kyra Orton[3]; Majid Shaman[4]; Sun Kwon Kim[4]; Gregory Goyert[4]
[1]*Henry Ford Health System, Department of Obstetrics and Gynecology, Detroit, MI;* [2]*Wayne State University School of Medicine, Wayne State University School of Medicine/Detroit, MI;* [3]*Michigan State University College of Human Medicine, Michigan State University College of Human Medicine/East Lansing, MI;* [4]*Henry Ford Health, Detroit, MI*

4:00 PM - 6:00 PM

Objective: Accurate pregnancy dating is crucial for evaluating fetal growth and diagnosing fetal growth restriction (FGR). In the first trimester, both the last menstrual period (LMP) and crown-rump length (CRL) are typically used to determine gestational age. Our primary objective was to compare the rates of FGR diagnosed using LMP and CRL with those diagnosed using CRL alone. The secondary objective was to assess the differences in pregnancy outcomes between these two groups.

Study Design: This cohort study utilized an ultrasound database including all singleton pregnancies with a first-trimester ultrasound from 2015 to 2023. We identified two groups of FGR: those dated by LMP and CRL and those dated by CRL alone. FGR was diagnosed based on an estimated fetal weight or fetal abdominal circumference below the 10th percentile. Exclusion criteria included cases without a first-trimester ultrasound (gestational age < 14 weeks 0 days), multiple pregnancies, in vitro fertilization pregnancies, and cases lacking a delivery record.

Results: We identified 1067 pregnancies affected by FGR in our cohort (n = 14116): 733 out of 9251 pregnancy episodes were dated by LMP and CRL, and 334 out of 4865 were dated by CRL alone. The rate of FGR was higher in those dated by LMP and CRL compared to those dated by CRL alone (7.9% vs 6.8%, p<0.001). A higher rate of FGR dated by LMP and CRL resolved by the end of pregnancy compared to FGR dated by CRL alone (28.6% vs 21.0%, p = 0.008). There were no significant differences between the groups in mean gestational age at delivery, mode of delivery, preterm births, severe FGR, abnormal umbilical artery Dopplers, and composite adverse neonatal complications.

Conclusion: Although FGR diagnosed by CRL alone did not show statistically significant differences in pregnancy outcomes, the lower rate of FGR in this group suggests a potential over-diagnosis when using both LMP and CRL. Future research should focus on the impact of modifying gestational age determination methods to potentially reduce the false positive rate of FGR and unnecessary antepartum interventions.

Table. Demographic characteristics and obstetrical outcomes of the study population

Variable	FGR pregnancy episodes dated by LMP + CRL (n = 733)	FGR pregnancy episodes dated by CRL alone (n = 334)	P-values
Maternal characteristics			
Age (year)	29.0 ± 5.5	28.5 ± 5.6	0.163
Gravidity	2.8 ± 1.9	2.9 ± 1.8	0.067
Nulliparity	203 (27.7)	80 (24.0)	0.227
BMI (kg/m^2)	27.9 ± 7.8	28.6 ± 9.0	0.266
Chronic hypertension	61 (8.3)	26 (7.8)	0.766
Gestational hypertension	22 (3.0)	8 (2.4)	0.579
Preeclampsia	35 (4.8)	22 (6.6)	0.222
Pregestational diabetes	31 (4.2)	18 (5.4)	0.401
Gestational diabetes	40 (5.5)	16 (4.8)	0.651
Obstetrical outcomes			
Severe fetal growth restriction	261 (35.6)	131 (39.2)	0.256
Resolved fetal growth restriction	210 (28.6)	70 (21.0)	0.008
Abnormal umbilical artery Dopplers	82 (11.2)	34 (10.2)	0.624
Birth weight (g)*	2477 ± 347	2460 ± 438	0.431
Gestational age at delivery (week)*	37.3 ± 3.5	37.4 ± 3.7	0.576
Preterm birth <37 weeks*	287 (39.2)	142 (42.5)	0.332
Cesarean section*	242 (35.6)	111 (36.8)	0.817
Composite adverse neonatal outcomes	53 (7.2)	27 (8.1)	0.623
NICU admission	85 (11.6)	52 (15.6)	0.072
Fetal/neonatal demise	26 (3.5)	11 (3.3)	0.834

Abbreviations: FGR, fetal growth restriction. LMP, last menstrual period. CRL, crown-rump length. BMI, body mass index. NICU, neonatal intensive care unit.
Data are expressed as number (percentage) or mean ± SD.
*Out of live births
**Including one or more of the following conditions: neonatal sepsis, retinopathy of prematurity, intracranial hemorrhage, chronic lung disease, respiratory distress syndrome, patent ductus arteriosus

633 | Distant, But Connected: Pregnancy App Utilization in Maternity Care Deserts

Shannon Malloy; Katie Noddin; Leslie Saltzman
Ovia Health, Boston, MA

4:00 PM - 6:00 PM

Objective: Maternity care deserts (MCDs), or counties with no hospitals or birth centers offering obstetric care and no obstetric providers, account for one-third of all U.S. counties. MCDs are expected to grow with projected obstetric provider shortages. Digital health solutions are positioned as solutions to deliver prenatal education and care for pregnant patients in MCDs. However, little is known about digital health utilization among pregnant patients in MCDs. This analysis explores in-app

behavior, demographics, and maternity care desert status of a pregnancy tracking app's userbase.

Study Design: Deidentified self-reported demographic and app usage data from users who downloaded a popular mobile pregnancy tracking app between 1/1/2022 and 7/31/2024 were assessed. The app provides gestational-age appropriate educational content and encourages symptom logging throughout pregnancy. MCD status was assigned using self-reported ZIP code.

Results: A total of n = 411,617 users qualified for inclusion. Users represented all 50 states. Almost 9% of app users lived in a maternity care desert, over double the proportion of U.S. women aged 18-44 living in MCDs (3.8%). Comparatively, 79% of app users lived in counties with full access (FA) to maternity care, where 89% of women aged 18-44 live. Users in MCDs were more likely to be multiparous, have a high school degree or lower educational attainment, subscribe to public insurance, report financial insecurity, and identify as American Indian or Alaska Native than users in full access counties. Users in MCDs were active in the app for 3.2 months on average, compared to 4.2 months for FA users. Almost all users enrolled in their first trimester of pregnancy. Users in MCDs logged fewer total sessions and had shorter engagement durations than FA users.

Conclusion: These results suggest reproductive-aged women in MCD's are proportionally more likely to download this pregnancy tracking app compared to those in full access counties, and indicate pregnant people in MCDs may be receptive to digital health interventions to support prenatal and reproductive health.

634 | Female versus Male Fetuses—Variation in Fetal Heart Rate Tracing and Adverse Outcomes at Term

Shareen Patel[1]; Aaron W. Roberts[2]; Kristen A. Cagino[3]; Fabrizio Zullo[4]; Rachel L. Wiley[5]; Claudia J. Ibarra[1]; Christina Cortes[1]; Khalil M. Chahine[1]; Natalie L. Neff[6]; Kimen S. Balhotra[1]; Tala Ghorayeb[1]; Holly Flores[7]; Hector M. Mendez-Figueroa[1]; Suneet P. Chauhan[8]

[1]McGovern Medical School at UTHealth, Houston, TX; [2]McGovern Medical School at UTHealth Houston, Houston, TX; [3]UT Houston, Houston, TX; [4]University of Rome La Sapienza, Rome, Lazio; [5]University of California, San Diego, San Diego, CA; [6]McGovern Medical School at UT Health, Houston, TX; [7]University of Texas Health Science Center, Houston, TX; [8]Delaware Center of Maternal-Fetal Medicine at Christiana Care, Delaware, DE

4:00 PM - 6:00 PM

Objective: To compare the fetal heart rate tracing (FHRT) and adverse outcomes among female versus male newborns delivered at term (> 37 weeks). We hypothesized that compared to female, pregnancies with male fetuses will have more frequent FHRT abnormalities and adverse outcomes.

Study Design: The inclusion criteria of the retrospective study were non-anomalous singletons, delivered at > 37 weeks after labor, whose sex at birth was either female or male. The consecutive deliveries occurred over 15 months. Using the guidelines by ACOG (Practice Bulletins 106 and 116), clinicians—blinded to maternal characteristics, gender, and outcomes—interpreted the FHRT for the last 120 min of labor. Composite neonatal and maternal adverse outcomes (CNAO and CMAO) were compared between the groups. Adjusted odds ratio (aOR) and 95% confidence intervals (CI) were calculated.

Results: Of the 5,160 deliveries during the study period, 3,165 (61%) met the inclusion criteria and among them 1,514 (48%) were female and 1,651 (52%), male. Compared to female, the FHRT among male was significantly more likely to have marked variability (P = 0.044), and prolonged deceleration (P = 0.039). The classification of FHRT as categories I, II or III were similar (Table 1). Cesarean delivery for non-reassuring FHRT was more common among male (11.3%) than female newborns (6.9%; aOR 1.67; 95% 1.30-2.14). CNAO for male (2.2%) was significantly higher than female newborns (0.9%; aOR 2.52; 95% CI 1.33-4.77). Apgar score < 7 at 5 min (aOR 3.12, 95% CI 1.26-7.77) was the component of the CNAO that differed significantly. CMAO was also significantly higher for individuals who delivered male (9.3%) vs female (6.3%; aOR 1.45, 95% CI 1.10-1.92) newborns (Table 2).

Conclusion: Among singleton pregnancies delivered at term, male fetuses are significantly more likely to have abnormalities for fetal heart rate, and adverse outcomes to neonatal-maternal dyad. Investigations to elucidate the etiology and intervention trials to mitigate the disparate adverse outcomes are warranted.

Table 1. Fetal heart tracing features present for ≥ 50% of time in the last 60 minutes.

	Female (n=1,514)	Male (n=1,651)	P Value
Fetal Tachycardia	52 (3.4%)	51(3.1%)	0.584

635 | Amniocentesis Prior to Physical Exam-Indicated Cerclage Placement and Time to Delivery

Shweta Hosakoppal[1]; Jenna C. Meiman[1]; T. Caroline Bank[1]; Sofia Baena[1]; Courtney Denning-Johnson Lynch[2]; Heather A. Frey[1]; Christine P. Field[1]
[1]The Ohio State University, Columbus, OH; [2]The Ohio State University College of Medicine, Columbus, OH

4:00 PM - 6:00 PM

Objective: To assess the association between amniocentesis prior to physical exam-indicated cerclage and latency from presentation to delivery.

Study Design: This is a single center retrospective cohort study of pregnant individuals who presented for a physical exam-indicated cerclage at 16w0d-23w6d gestation from June 2012 through June 2023. The primary exposure was amniocentesis for evaluation of infection prior to attempted cerclage. The primary outcome was the latency from presentation for possible cerclage placement to delivery. Secondary outcomes were a neonatal morbidity composite, delivery < 28 weeks, delivery < 37 weeks, chorioamnionitis or endometritis, and postpartum hemorrhage. Latency from presentation to delivery was assessed by amniocentesis status using Kaplan-Meier curves and the log-rank test. Modified Poisson regression was used to estimate the relative risk for secondary outcomes, adjusting for confounding factors. A sensitivity analysis was performed, including only individuals with successful cerclage placement.

Results: Of the 78 individuals included who presented for exam-indicated cerclage, 35 (44.9%) underwent amniocentesis. Those who underwent amniocentesis were more likely to have mild symptoms at presentation (54.3% vs 18.6%, p< 0.05), but had similar cervical length, dilation, gestational age at presentation, and history of preterm birth. Among those in the amniocentesis group, 12 (34.3%) did not receive a cerclage compared to 3 (7%) who did not receive a cerclage in the no amniocentesis group. There was no significant difference in latency from presentation to delivery between those who underwent amniocentesis and those who did not (Figure 1). In adjusted analysis, there were no significant difference in secondary outcomes between groups (Table 1). The results were similar when limited to those with successful cerclage placement (Figure 1).

Conclusion: We found no association between amniocentesis prior to cerclage and latency from presentation to delivery. Given our modest sample size, these findings await confirmation in a larger study.

	Amniocentesis not performed n=42	Amniocentesis performed n=34		
Diagnosis of chorioamnionitis or endometritis[5]	4 (9.5)	5 (14.7)	–	–
Postpartum hemorrhage[5]	2 (4.8)	3(8.8)	–	–

1. Relative risk estimated using Poisson regression with robust error variance estimators.
2. Model adjusted for variables at time of presentation including gestational age, cervical dilation and presence of mild symptom including pelvic pressure, spotting, vaginal discharge and mild cramping.
3. Neonatal morbidity and mortality composite includes perinatal mortality, grade 3-4 neonatal intraventricular hemorrhage, neonatal sepsis, necrotizing enterocolitis, retinopathy of prematurity and respiratory distress syndrome.
4. For perinatal mortality N=39 for amniocentesis not performed group and N=33 for amniocentesis performed group.
5. Unadjusted and adjusted relative risk not calculated due to small sample size
*Results were similar in sensitivity analysis in which only those who underwent cerclage were included.

636 | Success of Labor Induction in Patients with Class III Obesity

Siddharth Hariharan; Shaun R. Wesley; Mary C. Gallo; Sarah Crimmins

University of Rochester, Rochester, NY

4:00 PM - 6:00 PM

Objective: Labor induction in patients with class III obesity poses significant challenges and has been associated with higher complication rates. This study evaluates the success rate of labor induction and identifies factors influencing successful vaginal delivery in this population.

Study Design: We conducted a retrospective cohort study using US Vital Statistics Natality Birth Data from 2018 to 2022. The study included patients with class III obesity (BMI ≥ 40) who underwent labor induction. Statistical analyses included descriptive statistics and logistic regression to identify significant predictors of successful induction. Adjusted odds ratios (aOR) were calculated.

Results: Among the 1,053,085 patients with class III obesity who underwent induction of labor, the vaginal delivery was 25.1%.

Compared to White mothers, Black (aOR = 0.79, 95% CI: 0.78-0.80), Asian (aOR = 0.80, 95% CI: 0.76-0.84), and Native Hawaiian or Other Pacific Islander (aOR = 0.76, 95% CI: 0.71-0.81) mothers had lower odds of successful induction.

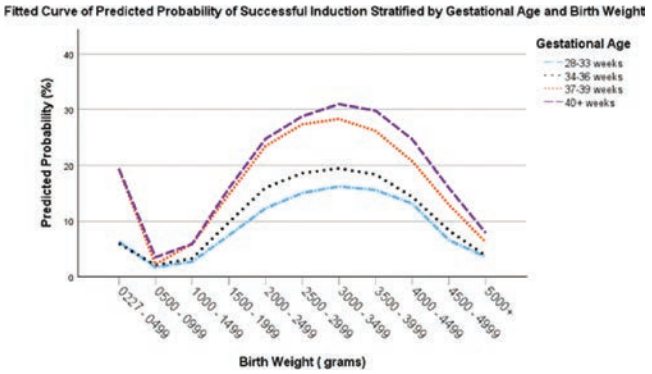
Increasing maternal age was associated with decreased odds of successful induction, particularly in mothers aged 40+ years (aOR = 0.54, 95% CI: 0.52-0.56).

Higher parity was associated with increased odds of success, especially at and after grand multiparity (aOR = 2.50, 95% CI: 2.40-2.60).

Induction success rates were significantly lower at gestational age less than 37 weeks compared to 37 weeks and above (aOR = 0.567, 95% CI: 0.556-0.577). The highest statistically significant success was at 40 weeks (aOR = 1.09, 95% CI: 1.081-1.095) (Figure 1); this is likely not clinically significant given a small change in predictive probability.

At any gestational age, induction success against final birthweight followed a fitted parametric curve with peak at reference group of 3000-3499g. ($p < 0.001$) (Figure 2).

Conclusion: The success rate of labor induction in patients with class III obesity is 25.1%. Identifying predictive factors can aid in better management and counseling. Targeted strategies are needed to improve induction success among diverse racial groups and older maternal age categories.



637 | Preconception Counseling: Understanding the Patient Experience

Simone Boney[1]; Parisa Khaligh[2]; Virginia Lijewski[3]; Jeanelle Sheeder[1]; Teresa Harper[4]

[1]University of Colorado School of Medicine, Aurora, CO; [2]University of Colorado, University of Colorado Obstetrics and Gynecology, CO; [3]University of Colorado, School of Medicine, Aurora, CO; [4]University of Colorado, Aurora, CO

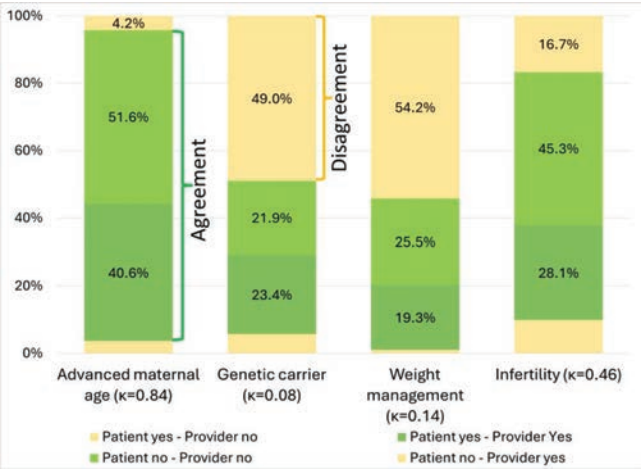
4:00 PM - 6:00 PM

Objective: To characterize health conditions addressed during MFM preconception counseling and to evaluate patient understanding of these with visit satisfaction and provider recommendations regarding future conception.

Study Design: This is a prospective study of patients receiving preconception counseling by MFM specialists at the University of Colorado School of Medicine Clinics (8/20-12/20). Consented patients were asked to complete a 1-week follow-up survey about health conditions discussed at the appointment, conception recommendations, and satisfaction with counseling. Concordance of conditions discussed was defined as the patient identifying ≥80% of the conditions documented by the MFM as having been discussed. SAS was used to perform appropriate statistics.

Results: Of the 192 study participants, most were ≥30 years (77%), married/partnered (94%), and non-Hispanic white (85%). Topics discussed with the highest patient-provider agreement were advanced maternal age (k = 0.84), hypothyroidism (k = 0.80), chronic hypertension (k = 0.70), uterine abnormalities (k = 0.68), and prior poor OB outcomes (k = 0.68). Topics with the lowest agreement were infertility (k = 0.5), genetic carrier (k = 0.08), and weight management (k = 0.14) (Figure 1). Patient satisfaction was high (97%) and similar for all topics except that those with low agreement were less likely to believe that the preconception visit would increase their chances for a healthy pregnancy (7 6.1% vs. 90.0%; p = 0.01).

Conclusion: Patient-provider agreement was lowest for standardized preconception topics (e.g. weight, infertility) indicating that patients were less likely to recall topics they had not intended to discuss. Low agreement in counseling topics also impacted patients' belief that they will have a healthy future pregnancy. Providing patient-centered counseling using shared decision-making is essential to improving preconception care.



638 | Obstetric Antecedent Factors and Therapeutic Hypothermia: Associations with Magnetic Resonance Imaging

Sneha Paranandi[1]; Fabrizio Zullo[2]; Kelley Kovatis[1]; Anthony C. Sciscione[1]; Matthew K. Hoffman[1]; Suneet P. Chauhan[3]
[1]Christiana Care Health System, Newark, DE; [2]University of Rome La Sapienza, Rome, Lazio; [3]Delaware Center of Maternal-Fetal Medicine at Christiana Care, Delaware, DE

4:00 PM - 6:00 PM

Objective: Magnetic resonance imaging (MRI) abnormalities following neonatal therapeutic hypothermia (THT) for hypoxic ischemic encephalopathy (HIE) are associated with long-term neurocognitive impairment. We compared the obstetric antecedent factors among newborns who underwent THT for HIE and had abnormal versus abnormal MRI findings.

Study Design: Utilizing ICD-10 codes, newborns at a large teaching hospital with clinically diagnosed HIE and who underwent THT were identified. Data was extracted from each chart by an obstetrician. Inclusion criteria for analysis were THT for HIE at $\geq$ 36 weeks on a non-anomalous singleton newborn, who had a brain MRI during admission. The MRI was considered abnormal if the following were noted: basal ganglion injury; white matter/watershed-predominant pattern of injury; or, near total injury. A Chi-square test was done with $P < 0.05$ considered significant.

Results: During the 5 year study period (2019-2023), 136 neonates out of 32,765 live births received THT for moderate to severe HIE (4 per 1,000 births). Among them 117 (86%) met inclusion criteria and 28 (23%) had abnormal MRI findings. Nulliparity ($P = 0.048$) and tobacco use ($P = 0.003$) were more common among mothers of those neonates with abnormal MRIs. Fetal heart tracing (FHRT) categorization within 60 minutes of delivery was not significantly associated with neonatal MRI abnormalities (Table 1). Newborns delivered vaginally had a higher incidence of abnormal MRI ($P = 0.006$) compared to those delivered by cesarean. Apgar scores < 5 at 5 and 10 minutes and umbilical arterial base deficit were similar for the two groups. Small for gestational age neonates were more likely to have abnormal MRI findings ($P = 0.003$; Table 2).

Conclusion: Hypoxic ischemic encephalopathy requiring therapeutic hypothermia occurred in 4 per 1,000 births, and among them maternal tobacco use is a modifiable risk factor for abnormal MRI. Fetal heart tracing, Apgar scores at 5 and 10 min, and umbilical arterial acid-base status did not differentiate between abnormal versus normal MRI, a surrogate for long term sequelae.

639 | Risk Factors for Post-Operative Rectus Sheath Hematoma Following Cesarean Delivery: a Case Control Study

Sonya Fabricant; Ojiugo Onwumere; Camelita Thrift; Naomi Greene; Gabriela Dellapiana; Mariam Naqvi
Cedars Sinai Medical Center, Los Angeles, CA

4:00 PM - 6:00 PM

Objective: To identify risk factors for rectus sheath hematoma (RSH) after cesarean delivery.

Study Design: We conducted a case-control study of cesarean deliveries performed at a quaternary academic hospital between January 1, 2013 and December 31, 2023. Cases were patients who developed RSH following cesarean delivery and were identified using the Deep6 natural language processing search engine. Controls were patients without RSH and were matched 1:3 by

age, race, and prior cesarean history. Demographic data, operative details, and perinatal outcomes were abstracted from the medical record and compared between cases and controls using t-test and chi-square as appropriate. Multivariable logistic regression was then performed to identify independent risk factors for RSH.

Results: Of 22,104 cesarean deliveries during the study period, 32 (0.15%) developed postoperative RSH. There were no significant differences between groups in the rates of rectus muscle closure, rectus muscle transection, peritoneal closure, or bladder flap creation (Table 1). Univariate analysis revealed an increased odds of RSH with hypertensive disorders of pregnancy (14.6 vs 34.4%, p = 0.01), placental abruption (0 vs 6.3%, p = 0.01), multiple gestation (3.1 vs 12.5%, p = 0.04), longer duration of cesarean (60.8 vs 78.1 minutes, p = 0.004), anticoagulation during hospitalization (1.0% vs 9.4%, p = 0.02) and post-operative anticoagulation (0 vs 9.4%, p = 0.002) (Table 2). After multivariable adjustment, independent predictors of RSH were anticoagulation during hospitalization (adjusted odds ratio [aOR] 16.3, 95% confidence interval [CI] 1.5–174), multiple gestation (aOR 7.5, 95% CI 1.4–38.3), and cesarean duration > 90 minutes (aOR 8.7, 95% CI 2.8–27.3).

Conclusion: Anticoagulation and prolonged surgical time are independent risk factors for RSH after cesarean delivery. Notably, rectus muscle closure was not associated with RSH.

640 | Association Between Induction of Labor and Birth Experience: a National Population-Based Study

Sophia Braund[1]; Francois Goffinet[2]; Aurélien Seco[3]; Camille Le Ray[4]

[1]Université paris cité, inserm, CRESS, EPOPE, Paris, Ile-de-France; [2]Université Paris Cité, Inserm, Centre for Research in Epidemiology and StatisticS (CRESS), Obstetrical Perinatal and Pediatric Epidemiology Research Team (EPOPé), Paris, Ile-de-France; [3]Université Paris Cité, Inserm, Centre for Research in Epidemiology and StatisticS (CRESS), Obstetrical Perinatal and Pediatric Epidemiology Research Team (EPOPé)„ Paris, Ile-de-France; [4]INSERM UMR 1153, Obstetrical, Perinatal and Pediatric Epidemiology Research Team (Epopé), Center for Epidemiology and Statistics, FHU PREMA, Université de Paris, Paris, Ile-de-France

4:00 PM - 6:00 PM

Objective: Induction of labor (IOL) is rising in high income countries. The ARRIVE trial, with a selected population due to randomized trials, found increased satisfaction among induced women. However, birth experience in case of IOL should be assessed in real life. Our objective is to assess the association between IOL and birth experience using a national population-based survey

Study Design: Using the French national perinatal survey 2021, we included women with a term singleton cephalic infant and a trial of labor. At 2 months, women answered the question "What kind of memories do you have about your childbirth?". We used univariate and multivariate analyses to assess the association between IOL and birth experience, and weighting to account for missing data. We identified and assessed as potential mediators prolonged labor ≥12 hours and 'birth with intervention or complication' (caesarean and/or operative vaginal delivery and/or PPH and/or OASIS and/or NICU), and estimated the indirect and residual effects using mediation modelling.

Results: Of the 6271 women included in the main analysis, 1800 (28.7 %) underwent IOL. Overall, women with IOL had more often a bad birth experience than women with spontaneous onset of labor (SOL) (16.4% vs 8.8%, p< 0.01), and the association remained significant after adjustment (ORa 1.78 (1.47-2.16)). In case of cervix ripening, the rate of bad birth experience rose to 18.8%. Analyses on a subgroup of women at low maternal risk found similar results. Prolonged labor explained only 6% of the association between IOL and bad experience. Birth with complications or interventions concerned 43.8% of women with IOL and 31.1% with SOL (p< 0.01) and explained 26% of this association.

Conclusion: IOL was associated with a higher risk of bad birth experience than SOL. Only a small part of this association is mediated by medical complications or interventions and prolonged labor. In the context of increase in inductions, our findings underline the importance of considering birth experience in the decision-making and information for women and the need to explore consequences of IOL.

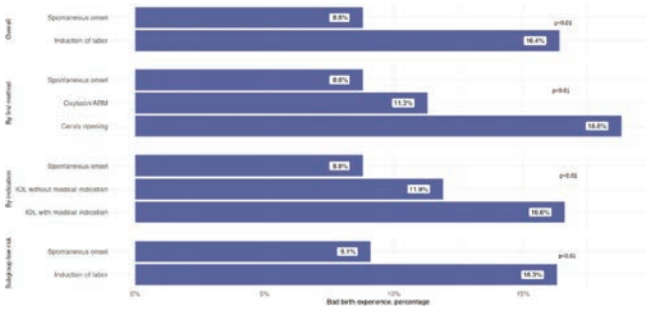

Table 2: Multivariate analysis, to assess the association between IOL and bad birth experience

	Risk of bad experience Adjusted OR
Onset of labor

Results are expressed as OR with 95% confidence interval. IOL= induction of labor, y.o.= years old, cs= caesarean, wks=weeks, Ref= reference.

[a] The deprivation index considers the following criteria: not living with a partner, receiving RSA, receiving AME state medical aid, or having neither social insurance nor living in their personal dwelling (as owner or leaseholder)

[b] Health literacy measures individuals' motivation and skills for acceding to, understanding, assessing, and using information to make decisions about their health. Health literacy was assessed at 2 months using module 6 (ability to engage with healthcare professionals) of the Health Literacy Questionnaire

[c] composite criterion for maternal risk defined as >= 1 of the following: high medical risk (according to the HAS classification), gestational diabetes, gestational hypertensive disorders

641 | Association of Maternal Hypotension with Abnormal Uterine Artery Dopplers and Small for Gestational Age Neonates

Stephanie Pearson[1]; Baillie A. Bronner[2]; Annie Dude[3]; Samantha de los Reyes[1]

[1]Rush University Medical Center, Chicago, IL; [2]MAHEC, Asheville, NC; [3]University of North Carolina, Chapel Hill, NC

4:00 PM - 6:00 PM

Objective: To evaluate the association of abnormal uterine artery (UtA) dopplers in patients with persistent hypotension with delivery of a small for gestational age (SGA) neonate. We hypothesize that abnormal blood flow to the uterus may result in smaller neonates.

Study Design: This was a secondary analysis of the Nulliparous Pregnancy Outcomes Study: Monitoring Mothers-to-Be of patients with a singleton gestation at $\geq$ 24 weeks with abnormal UtA dopplers (defined as pulsatility index > 95th percentile for gestational age or presence of a diastolic notch) between 18 weeks 0 days and 23 weeks 6 days gestation. Persistent hypotension was defined as systolic blood pressure < 100 mmHg and/or diastolic blood pressure < 60mmHg at all 3 study visits between 6 weeks 0 days and 29 weeks and 6 days gestation. The primary outcome was delivery of an SGA neonate. Univariable analyses were performed to evaluate demographic and clinical associations with the primary outcome. Multivariable analyses were performed to adjust for potential confounders selected a priori (age, race and ethnicity, insurance status, pre-pregnancy body mass index (BMI), and history of chronic hypertension).

Results: 5,092 patients met inclusion criteria; 137 (2.7%) had persistent hypotension, 4,955 (97.3%) did not. Patients in the hypotension group were less likely to be of White race and Asian ethnicity, and more likely to have public insurance and a lower pre-pregnancy BMI, and less likely to use tobacco within 3 months of pregnancy (Table 1). Patients with persistent hypotension and abnormal UtA dopplers were more likely to deliver an SGA neonate (11.8 vs. 18.2%, p-value 0.025) but this did not persist in multivariable analysis (aOR 1.43, 95% CI 0.91, 2.24). In univariable analysis of secondary outcomes, the hypotension group had a lower median birth weight (3,323 vs. 3,239 grams, p-value 0.01) (Table 2).

Conclusion: In patients with abnormal UtA dopplers, persistent hypotension was not associated with an increased risk of an SGA neonate.

642 | Hybrid Closed-Loop Therapy Versus Standard Therapy for Type 1 Diabetes in Pregnancy: a Meta-Analysis

Lucas G. Miranda-Martinez[1]; Molly Beestrum[2]; Charlotte M. Niznik[1]; Lynn M. Yee[1]; Stephanie A. Fisher[1]

[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Galter Health Sciences Library, Northwestern University Feinberg School of Medicine, Chicago, IL

4:00 PM - 6:00 PM

Objective: Hybrid closed-loop (HCL) therapy, which integrates an insulin pump with a continuous glucose monitor to automatically adjust basal insulin rates, improves glycemic control in non-pregnant individuals with type 1 diabetes (T1DM). Although it is not yet approved for pregnancy, recent studies suggest potential benefits to HCL in pregnant people with T1DM. This meta-analysis aims to evaluate clinical outcomes associated with HCL vs. standard therapy (ST) during pregnancy.

Study Design: In this meta-analysis, a predefined, systematic, librarian-assisted search of Ovid MEDLINE, Embase, Scopus, Cochrane, ClinicalTrials.gov, and World Health Organization International Clinical Trial Registry Platform initially yielded 295 studies related to HCL in pregnancy. Glycemic metrics (time-in-range, TIR [63-140mg/dL]; time-above-range, TAR; time-below-range, TBR; coefficient of variation, CV; mean glucose; hemoglobin A1c, HbA1c), were compared by trimester in those exposed to HCL vs. ST (i.e. sensor-augmented pump therapy or multiple daily injections). Maternal and neonatal outcomes were secondarily assessed. We calculated standardized mean differences (SMD) and pooled odds ratios (OR) with 95% confidence intervals (CI) using random effects models.

Results: Five studies (3 randomized trials, 1 prospective cohort, 1 case series) published from 2022-24 met eligibility criteria and evaluated 183 pregnancies exposed to HCL vs. 178 exposed to ST. TIR and TAR did not differ by HCL vs. ST in any trimester (Table 1). TBR was lower with HCL use in the 2nd (-1.1% [-2.2%, -0.03%]) and 3rd (-1.4% [-1.9%, -0.8%]) trimesters. CV was also lower with HCL use in the 1st (33.8 vs. 36.1%, SMD -2.6% [95%CI -4.3%, -0.8%]), 2nd (31.6% vs. 33.6%, SMD -2.1% [95%CI -2.9%, -1.3%]), and 3rd (29.1% vs. 30.9%, SMD -1.5% [95%CI -2.2%, -0.8%]) trimesters. Maternal and neonatal outcomes did not differ between groups (Table 2).

Conclusion: Use of HCL for pregnant people with T1DM is associated with lower TBR and glycemic variability, with similar maternal and neonatal outcomes, suggesting a potential safety benefit that warrants further study.

Table 1. Glycemic metrics associated with hybrid closed-loop therapy in pregnancy

Outcome	Hybrid Closed-Loop		Standard Therapy		SMD (95% CI)

NICU admission	4	41/171 (24.0)	40/166 (24.1)	0.04 (-0.5, 0.6)

Abbreviations: OR—odds ratio, SMD—standardized mean difference, CI—confidence interval, HDP—hypertensive disorders of pregnancy, GWG—gestational weight gain, BW—birthweight, LGA—large-for-gestational age neonate, SGA—small-for-gestational age, NICU—neonatal intensive care unit

[1]Means are weighted based on number of participants in each treatment arm for each study.

[2]GWG was reported for 163 pregnant individuals using hybrid-closed loop therapy versus 159 pregnancies managed with standard therapy.

[3]Neonatal hypoglycemia is defined as capillary blood glucose <40mg/dL in the first 24 hours of life.

643 | Clinical Outcomes in Pregnant People with Type 1 Diabetes: Does Age of Diabetes Onset Matter?

Lucas G. Miranda-Martinez; Charlotte M. Niznik; Lynn M. Yee; Stephanie A. Fisher

Northwestern University Feinberg School of Medicine, Chicago, IL

4:00 PM - 6:00 PM

Objective: Metabolic differences exist between childhood- and adult-onset type 1 diabetes mellitus (T1DM), yet how these may be associated with perinatal outcomes is poorly understood. We aimed to evaluate the association of age of onset of T1DM with antenatal glycemic control and perinatal outcomes.

Study Design: In this single-center retrospective cohort study (2018-2023), we compared pregnant people with childhood- (< 18 years of age) vs. adult-onset (≥18 years of age) T1DM who used a continuous glucose monitor (CGM). We assessed maternal (gestational weight gain [GWG], hypertensive disorders of pregnancy [HDP], cesarean birth), neonatal (preterm birth [PTB], large-for-gestational age, neonatal intensive care unit admission, hypoglycemia), and glycemic outcomes (CGM metrics, hemoglobin A1c [HbA1c]; by trimester). Multivariable logistic and linear regression were used to determine adjusted odds ratios (aOR) or β-coefficients (β) and 95% confidence intervals (CI), adjusted for pre-gravid body mass index (BMI).

Results: Of 102 eligible individuals, 61 (60%) had childhood-onset T1DM. Individuals with childhood-onset (vs. adult-onset) T1DM were younger (32 vs. 35 years old, p = 0.01) and had higher pre-gravid BMI (26 vs. 24 kg/m^2, p = 0.01). Although HDP was more frequent among those with childhood-onset T1DM (39% vs. 27%), adjusted odds of all maternal outcomes were similar by age of onset (Table 1). The adjusted odds of PTB (aOR 3.48 [95% CI 1.02, 11.8]) were higher in individuals with childhood-onset, compared to those with adult-onset T1DM, but all other neonatal outcomes were similar. Childhood-onset (vs. adult-onset) T1DM was associated with lower 1st trimester time-in-range (57% vs. 65%, β -7.36 [95% CI 0.63, 14.08]); all other per-trimester glycemic metrics were similar between groups (Table 2).

Conclusion: Childhood-onset, compared to adult-onset, T1DM is associated with higher odds of PTB, but similar glycemic

control in pregnancy aside from lower 1st trimester TIR. These findings may inform risk counseling and surveillance in those with childhood-onset T1DM to mitigate risk of adverse perinatal outcomes.

644 | Diagnostic rate of Pulmonary Embolism during Pregnancy: An update on VQ vs CT

Suzanne O'Nan[1]; Julia Burd[2]; Nandini Raghuraman[3]; Antonina I. Frolova[4]; Michael Dombrowski[5]; Roxane Rampersad[2]; Jeannie C. Kelly[3]
[1]University of Minnesota, Minneapolis, MN; [2]Washington University in St. Louis, St. Louis, MO; [3]Washington University School of Medicine in St. Louis, St. Louis, MO; [4]Washington University School of Medicine, St. Louis, MO; [5]Washington University in Saint Louis, St. Louis, MO

4:00 PM - 6:00 PM

Objective: Diagnosing pulmonary embolism (PE) during pregnancy can be challenging. We sought to compare PE diagnosis rates during pregnancy based on the original imaging modality of ventilation-perfusion (VQ) scan versus CT angiography (CTA).

Study Design: We performed a retrospective chart review of pregnant participants who underwent either VQ scan or CTA due to clinical suspicion of PE from January 2018- April 2024 at a single academic institution. Patients who underwent imaging for other clinical reasons, postpartum patients, and deliveries at an outside hospital were excluded. Our primary outcome was a scan considered diagnostic by the radiology read. Secondary outcomes included if a second imaging modality was pursued for diagnosis and reasons why initial imaging was non-diagnostic. Chi-squared, Fisher's exact, Student's t and Wilcoxon Rank sum tests were used as appropriate.

Results: 113 patients were included; 80 (71%) were imaged by VQ scan, and 33 (29%) were imaged by CTA. Baseline demographics and major VTE risk factors were similar between groups, including BMI and trimester of pregnancy; most patients were in the third trimester (Table 1). Diagnostic rates were similar between VQ and CTA groups (62.5% v 72.7%, P = 0.29), and 33.3% of patients in each group with non-diagnostic findings underwent further testing to evaluate for PE (Table 2). PE was present in a minority of patients in both cohorts, and most non-diagnostic scans were due to poor timing of dye/opacification of vessels (Table 2).

Conclusion: Despite improvements in technological imaging studies, many studies of both VQ and CTA are non-diagnostic to exclude PE in pregnancy. Causes for non-diagnostic imaging studies should be investigated in the future.

645 | First-Trimester Fasting Glucose Levels Associated with Abnormal Glucose Challenge and Tolerance Tests Later in Pregnancy

Tamar Katzir[1]; Tal Schiller[2]; Ronit Koren[3]; Moran Frid[4]; Alon Ben Arie[5]; Edi Vaisbuch[2]; Oren Barak[5]
[1]Kaplan Medical Center, Tal shahar, HaMerkaz; [2]Kaplan Medical Center, Rehovot, HaMerkaz; [3]Shamir medical center, Shamir medical center, HaMerkaz; [4]Kaplan Medical Center, Kaplan medical center, HaMerkaz; [5]Kaplan medical center, rehovot, HaMerkaz

4:00 PM - 6:00 PM

Objective: Gestational diabetes mellitus (GDM) is diagnosed using an initial glucose challenge test (GCT), and if exceeds 140 mg/dL is followed by an oral glucose tolerance test (OGTT). The definition of pathological first-trimester fasting glucose (FG) is controversial, and its correlation with abnormal GCT and OGTT is not well established. This study aims to evaluate the association between first-trimester FG levels and pathological GCT and OGTT results.

Study Design: We retrospectively analyzed the electronic medical records of a large healthcare provider searching for individuals who delivered between 2012 and 2024. Inclusion criteria were singleton pregnancies and a documented first-trimester FG, excluding those with preexisting diabetes. Only the first documented pregnancy was included. We assessed the cohort's distribution of first-trimester FG values and compared the rates of abnormal GCT and OGTT between those with FG above and below the 95th percentile (two standard deviations). The primary outcome was the incidence of abnormal GCT and OGTT above vs. below the 95th percentile of FG.

Results: The study comprised 202,960 individuals who met the inclusion criteria. The mean first-trimester FG level was 84.6±9.9 mg/dL, and the 95th percentile was 100 mg/dL. Those with an FG≥100 mg/dL were older and had a higher BMI (31.0±5.7 vs. 29.8±5.5 years, p< 0.001 and 28.2±6.7 vs. 25.1±14.9 kg/m^2, p< 0.0001, respectively). Moreover, they had higher pathological rates of GCT and OGTT (19.2% vs. 13.1%, p>0.001, and 6.9% vs. 2.4%, p>0.001, respectively). We observed a positive association between increasing FG levels and pathological GCT and OGTT results **(Fig. 1)**.

Conclusion: First-trimester fasting glucose levels of 100mg/dL or higher are significantly associated with increased rates of pathological glucose challenge test and oral glucose tolerance test. Further consideration should be given to adjusting pregnancy management for these high-risk populations.

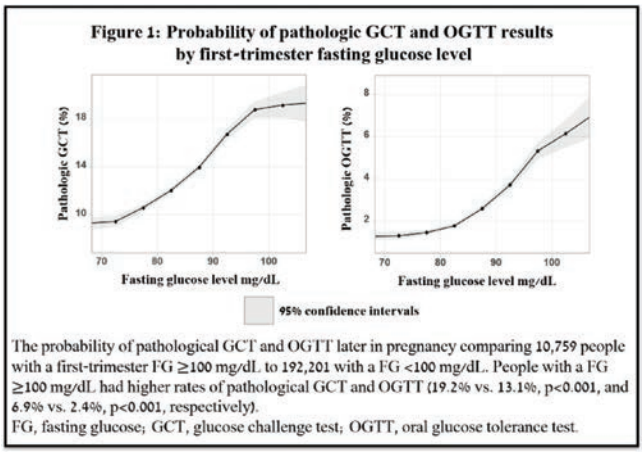

Figure 1: Probability of pathologic GCT and OGTT results by first-trimester fasting glucose level

The probability of pathological GCT and OGTT later in pregnancy comparing 10,759 people with a first-trimester FG ≥100 mg/dL to 192,201 with a FG <100 mg/dL. People with a FG ≥100 mg/dL had higher rates of pathological GCT and OGTT (19.2% vs. 13.1%, p<0.001, and 6.9% vs. 2.4%, p<0.001, respectively).
FG, fasting glucose; GCT, glucose challenge test; OGTT, oral glucose tolerance test.

646 | Fetal Fibronectin for Prediction of Spontaneous Labor at Term

Taylor S. Freret[1]; Anjali J. Kaimal[2]; William H Barth, Jr.[3]; Shuo Wang[4]; Amy Herring[4]; Julianna Schantz-Dunn[5]; Michael Ruma[6]; Sarah E. Little[1]
[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]University of South Florida, Tampa, FL; [3]Massachusetts General Hospital, Boston, MA; [4]Duke University, Durham, NC; [5]Brigham and Women's Hospital, Boston, MA; [6]Perinatal Associates of New Mexico, Albuquerque, NM

4:00 PM - 6:00 PM

Objective: Elective induction of labor (IOL) at 39 weeks reduces cesarean delivery; however, many individuals hope to labor spontaneously and be informed participants in IOL decision-making. Fetal fibronectin (fFN) predicts risk of spontaneous preterm delivery. We sought to determine if fFN predicts spontaneous term labor.

Study Design: Prospective observational multicenter study within one healthcare system. Nulliparous patients without a medical indication for IOL prior to 41 weeks were offered enrollment at their 38-week prenatal visit. After informed consent, a provider collected a fFN and performed a cervical exam. The primary outcome was spontaneous onset of labor. The predictor of interest, quantitative fFN value, was dichotomized to positive (≥50 ng/mL) or negative (< 50 ng/mL) based on qualitative standards in the US. Secondary outcomes included time from study visit until delivery admission. Logistic and Cox proportional hazards regression were used; adjusted models controlled for gestational age and Bishop score at study visit.

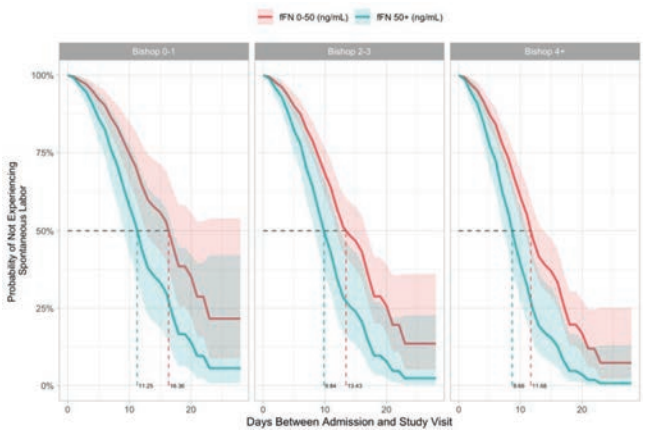
Results: 290 patients consented, of whom 284 were included in the analysis with a mean age of 30.1 years and BMI of 24.9. 59% were White, and 22% delivered by cesarean. 173 (60.9%) went into spontaneous labor and 109 (38.4%) were induced, of which 32 (29.4%) were medically indicated and 67 (61.5%) were elective inductions prior to 41 weeks. Mean quantitative fFN value was 46 ± 109 ng/mL, and mean Bishop score was 3.6 ± 2.2 cm. A positive fFN was associated with an increased odds of spontaneous labor (aOR 2.16, 95% CI 1.04–4.86, Table). All patients with a positive fFN who were not induced prior to 40w6d (medically indicated or elective) entered labor spontaneously. A positive fFN was associated with an increased adjusted hazard of spontaneous labor (aHR 1.88, 95% CI 1.27–2.78, Figure), which

persisted after accounting for potential informative censoring due to non-spontaneous deliveries.

Conclusion: A positive fFN is associated with an increased odds of spontaneous labor after 38 weeks. Our findings may help in counseling patients considering elective IOL after 39 weeks.

Table. *Unadjusted and adjusted odds ratios (OR) for spontaneous labor at term*

	Unadjusted OR (95% CI)	Adjusted OR (95% CI)
fFN ≥ 50 vs < 50 (ng/mL)	2.29 (1.11, 5.11)	2.16 (1.04, 4.86)
GA at visit (days)	1.00 (0.87, 1.14)	1.00 (0.87, 1.15)
Bishop Score		
≤ 1	Referent	Referent
2-3	1.44 (0.72, 2.88)	1.44 (0.72, 2.89)
≥ 4	2.11 (1.07, 4.20)	2.05 (1.03, 4.10)



647 | Neonatal Outcomes in Individuals with Periviable Pre-Eclampsia

Tejumola Apata; Sarah Crimmins; On behalf of the Maternal-Fetal Medicine Units (MFMU) Network and NICHD
University of Rochester, Rochester, NY

4:00 PM - 6:00 PM

Objective: To compare neonatal outcomes in pregnancies complicated by pre-eclampsia versus patients without pre-eclampsia between 22w0d and 25w0d.

Study Design: Retrospective cohort study utilizing the Registry of Obstetrical Determinants of Neonatal Survival (ODNS) of pregnancies with delivery between 22w0d-25w0d. Individuals with preeclampsia were compared to individuals delivered during the same gestational age without preeclampsia. The primary outcome is a composite measure of neonatal outcomes which includes neonatal death (death within 120 days of delivery), seizures, necrotizing enterocolitis requiring surgery, oxygen dependence at discharge or at 120 days of age, Grade III or IV retinopathy of prematurity and Grade III/IV CNS hemorrhage. Multivariate analysis was performed with Pearson Chi-squared tests, fisher's exact test to analyze categorical variables and two tailed test to analyze continuous variables.

Results: A total of 339 pregnancies met inclusion criteria. 18(5.3%) was delivered for severe pre-eclampsia while 321(94.75%) delivered for other indications. Both groups were similar in terms of umbilical pH, estimated gestational age, number of days on a ventilator and number of days spent in the NICU. There was a significant difference in the median birth weight of the pre-eclampsia group compared to the non-pre-eclampsia group (519grams versus 614gram, P = 0.016) In the pre-eclampsia group, 6(33.3%) of neonates were alive at 120 days of birth, compared to 121(37.7%) in the non-pre-eclampsia group(p = 0.806). The composite neonatal outcome was similar between both groups (16(88.%) for preE vs 274(84.8%), p = 0.638).

Conclusion: Infants born in the periviable period secondary to preeclampsia experience similar neonatal outcomes in comparison to other indications for preterm delivery.

	No pre-Eclampsia n(%)	Pre-Eclampsia n(%)	P-Value
Gestational age at delivery in weeks (Median)	24	23.8	0.712
Birth weight in grams (Median)	614	519	0.036
Composite outcome	274(84.8)	16(88.9)	0.638
Neonatal death	200(62.3)	12(66.7)	0.710
Retinopathy of prematurity	44(13.6)	3(6.4)	0.936
Oxygen requirement	43(13.3)	3(16.7)	0.486
Intraventricular hemorrhage	50(15.5)	2(11.1)	0.317
Necrotizing enterocolitis	11(3.4)	0	0.661
Seizures	28(8.7%)	0	0.416
Umbilical cord PH(Median)	7.31	7.26	0.122
Number of days on mechanical Ventilator (Median)	6	4	0.897
Number of days in NICU (Median)	12	14	0.345
Number of days infant survived (Median)	3	8	0.695

648 | Neonatal Survival in Individuals with Periviable Pre-Eclampsia

Tejumola Apata; Sarah Crimmins
University of Rochester, Rochester, NY

4:00 PM - 6:00 PM

Objective: To compare neonatal survival in pregnancies complicated by preeclampsia versus patients without pre-eclampsia(preE) between 22w0d and 24w6d.

Study Design: Retrospective cohort study utilizing the US Vital Statistic Natality Birth Data of pregnancies with delivery between 22w0d-24w6d from 2018 to 2022. Individuals with preeclampsia were compared to individuals delivered during the same gestational age without preeclampsia. The primary outcome is infant survival as documented at the time of birth certificate report . Secondary outcomes include neonatal seizures and assisted ventilation for >6 hours. Multivariate analysis was completed with Pearson Chi-squared tests to analyze categorical variables.

Results: A total of 38,024 met inclusion criteria. 253(0.7%) of pregnancies were affected by PreE while 37,660(99.0%) did not have preE. At the time of the birth certificate report, 201(79.4%) infants survived in the preE group compared to 26,691(70.9%) infants in the non-preE group(P< 0.003, OR 1.6; 95% CI: 1.18-2.20). However, when analyzed by gestational age week by week, neonatal survival rates were similar between the two groups: [22 weeks (18(52.9%) preE vs. 3,832(44.7%) non-preE, P = 0.336), 23 weeks(69(78.4%) preE vs. 8,922(72.1%) non- preE, P = 0.095, and at 24 weeks(114(87.0%) preE vs.13,937(84.4%) non- preE, p = 0.530]. There is a statistically significant difference in number of neonates with seizures (0.4% in the preE group vs 0.2% in the non- preE group P< 0.001) and neonates requiring ventilation for more than 6 hours (33.1% in the preE group versus 32.9% in the non-preE group p< 0.001).

Conclusion: The overall survival of neonates born in the periviable period in pregnancies complicated by preeclampsia

is 79.4%. The chance of survival increases with each week of continued pregnancy in the periviable period. Given the rarity of periviable preeclampsia, the rates of survival are similar to neonates born in the periviable period for other indications.

649 | Deliveries with a Disability Diagnosis and Risk for Adverse Maternal Outcomes in the U.S., 2000-2021

Teresa C. Logue[1]; Fabrizio Zullo[2]; Suneet P. Chauhan[3]; Kartik K. Venkatesh[4]; Timothy Wen[5]
[1]Christiana Care Health System, Newark, DE; [2]University of Rome La Sapienza, Rome, Lazio; [3]Delaware Center of Maternal-Fetal Medicine at Christiana Care, Delaware, DE; [4]The Ohio State University, Columbus, OH; [5]University of California, San Diego, Irvine, CA

4:00 PM - 6:00 PM

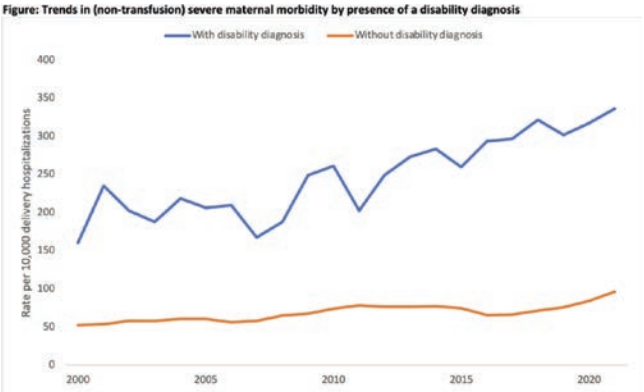
Objective: There is limited data on pregnancy outcomes of people with disabilities. People with disabilities are more likely to have chronic conditions and adverse social determinants of health, which are risk factors for pregnancy complications. We evaluated the association between disability diagnosis and severe maternal morbidity (SMM) and other adverse outcomes.
Study Design: We conducted a serial cross-sectional analysis of delivery hospitalizations with a physical, intellectual or sensory disability diagnosis in the National Inpatient Sample during 2000-2021. Our primary outcome was non-transfusion SMM. Secondary outcomes were transfusion, hypertensive disorders of pregnancy (HDP), preterm delivery (PTD), and maternal death. We described temporal trends in SMM by presence of any disability, reporting average annual percent change (AAPC). We fit logistic regression models to evaluate the association between any disability and our outcomes, adjusting for demographic and obstetric factors and chronic conditions. In subgroup analyses, we evaluated risk for SMM by disability type.
Results: Of 83.7 million total deliveries, 857,876 (1.0%) had a disability diagnosis, with 83.8% of disabilities physical, 6.0% intellectual, and 10.2% sensory. Deliveries with any disability had threefold higher risk of SMM (2.7% vs 0.7%; adjusted OR [aOR] 3.33, 95% CI 3.22, 3.44) as well as higher risk for transfusion (aOR 2.02, 95% CI 1.94, 2.09), HDP (aOR 1.50, 95% CI 1.47, 1.52), PTD (aOR 1.38, 95% CI 1.36, 1.41) and death (unadjusted OR 8.26, 95% CI 6.43, 10.61). Risk for SMM was elevated across all disability types but highest in the setting of physical disability (aOR 3.37, 95% CI 3.25, 3.49). Incidence of SMM among deliveries with any disability increased from 2000 to 2021 (AAPC 3.1%, 95% CI 2.4%, 3.8%).
Conclusion: Pregnant people with disabilities have threefold higher risk of SMM, even after adjusting for social risk factors and chronic disease. This risk persists across all disability types and is increasing over time. Future research is needed to develop interventions to improve pregnancy outcomes in this population.

Table: Unadjusted and adjusted odds for adverse maternal outcomes with a disability diagnosis

	Any disability diagnosis (n=857,876)	No disability diagnosis (n=82,795,931)	Unadjusted odds ratio (95% CI)	Adjusted odds ratio (95% CI)
Adverse outcomes				
Severe maternal morbidity	22,762 (2.7%)	565,792 (0.7%)	3.96 (3.83, 4.10)	3.33 (3.22, 3.44)
Sensitivity analysis of SMM by disability type:				
Physical disability			*3.94 (3.81, 4.09)*	*3.37 (3.25, 3.49)*
Intellectual disability			*3.43 (3.01, 3.90)*	*2.79 (2.45, 3.18)*
Sensory disability			*4.35 (3.99, 4.74)*	*3.03 (2.78, 3.31)*
Blood transfusion	16,940 (2.0%)	757,202 (0.9%)	2.18 (2.10, 2.26)	2.02 (1.94, 2.09)
Hypertensive disorders of pregnancy	117,159 (13.7%)	6,932,913 (8.4%)	1.73 (1.70, 1.76)	1.50 (1.47, 1.52)
Preterm delivery	75,606 (8.8%)	5,175,062 (6.3%)	1.45 (1.42, 1.48)	1.38 (1.36, 1.41)
Maternal death	360 (0.04%)	4,212 (0.01%)	8.26 (6.43, 10.61)	-

Estimates in the table demonstrate likelihood of adverse outcomes in the presence compared to the absence of a disability diagnosis. All adjusted models include maternal age category, race, payer, presence of obstetrical factors (including multiple gestation) and presence of chronic medical conditions (including obesity, pregestational diabetes, chronic hypertension and smoking.) Adjusted analyses were not performed for maternal death given the small numerators involved.

Figure: Trends in (non-transfusion) severe maternal morbidity by presence of a disability diagnosis



The rate of non-transfusion severe maternal morbidity among patients with a disability diagnosis increased from 161 to 336 per 10,000 delivery hospitalizations over 2000-2021 (AAPC 3.1%, 95% CI 2.4%, 3.8%) compared to 53 to 97 per 10,000 delivery hospitalizations among patients without a disability diagnosis (AAPC 2.7%, 95% CI 1.2%, 4.2%).

650 | Patient-Directed Discharge During Antepartum Hospitalization and Risk for Adverse Outcomes at Delivery

Teresa C. Logue[1]; Timothy Wen[2]; Fabrizio Zullo[3]; Fiamma van Biema[4]; Alexander M. Friedman[5]
[1]Christiana Care Health System, Newark, DE; [2]University of California, San Diego, Irvine, CA; [3]University of Rome La Sapienza, Rome, Lazio; [4]Hackensack Meridian School of Medicine, Hackensack Meridian School of Medicine, NJ; [5]Columbia University Irving Medical Center, New York, NY

4:00 PM - 6:00 PM

Objective: Antepartum (AP) hospitalizations are typically unplanned and often cause social stress. Patients with social and mental health risk factors may be more likely to leave the hospital via patient-directed discharge (PDD). We evaluated predictors of PDD at AP hospitalization and the effect of AP PDD on risk for adverse outcomes at delivery.
Study Design: We conducted a serial cross-sectional analysis of October-December delivery hospitalizations with an AP admission in the preceding 9 months included in the National Readmissions Database during 2016-2021. Our primary exposure was PDD (versus routine discharge) at first AP hospitalization. Using the chi-square test, we evaluated the association between demographic and clinical factors and AP PDD. Using survey-adjusted logistic regression, we evaluated the association between AP PDD and the following adverse outcomes at delivery: non-transfusion severe maternal morbidity (SMM), transfusion, hypertensive disorders (HDP), preterm delivery (PTD) and stillbirth.
Results: We identified 152,748 AP hospitalizations with delivery follow-up in NRD during 2016-2021, with 3.3% of AP discharges

categorized as PDD. Compared to routine discharge, AP PDD was associated with higher likelihood of any mental health condition (38.4% vs 27.0%; p< 0.01), any substance use disorder (44.4% vs 14.1%, p < 0.01), lowest income quartile (45.2% vs 36.0%; p< 0.01), and Medicaid insurance (78.8% vs 57.9%; p < 0.01). At delivery, history of AP PDD was associated with increased risk for SMM (adjusted OR [aOR] 1.42, 95% CI 1.16, 1.73), transfusion (aOR 1.63, 95% CI 1.32, 2.02), HDP (aOR 1.44, 95% CI 1.28, 1.61), PTD (aOR 1.45, 95% CI 1.29, 1.63) and stillbirth (aOR 1.80, 95% CI 1.39, 2.33).

Conclusion: About 3% of antepartum patients will self-discharge. Patient-directed discharge is more common in patients with adverse social determinants of health and mental health conditions. PDD is associated with higher risk of adverse delivery outcomes. Screening for PDD risk factors during antepartum admission and providing interventions to at-risk patients may reduce adverse delivery outcomes.

Figure: Percent of antepartum patient-directed discharges associated with any mental condition, any substance use disorder, lowest income quartile and Medicaid insurance:

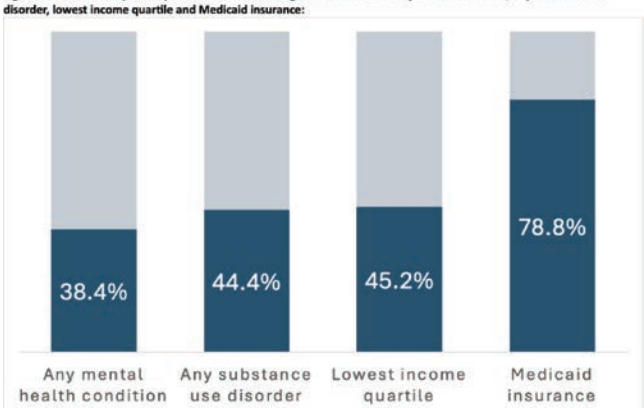


Table: Unadjusted and adjusted odds for adverse delivery outcomes following antepartum patient-directed discharge (PDD)

	Patient-directed discharge at antepartum hospitalization (n=5,077)	Routine discharge at antepartum hospitalization (n=147,671)	Unadjusted odds ratio (95% CI)	Adjusted odds ratio (95% CI)
Adverse maternal outcomes				
Severe maternal morbidity	203 (4.0%)	3784 (2.6%)	1.59 (1.30, 1.93)	1.42 (1.16, 1.73)
Blood transfusion	204 (4.0%)	3619 (2.5%)	1.67 (1.36, 2.05)	1.63 (1.32, 2.02)
Hypertensive disorders of pregnancy	1218 (24.0%)	27188 (18.4%)	1.40 (1.25, 1.56)	1.44 (1.28, 1.61)
Preterm delivery	758 (14.9%)	15585 (10.6%)	1.49 (1.33, 1.67)	1.45 (1.29, 1.63)
Stillbirth	135 (2.7%)	1983 (1.3%)	2.00 (1.56, 2.57)	1.80 (1.39, 2.33)

Estimates in the table demonstrate odds in the presence of patient-directed discharge compared to provider-directed discharge at antepartum hospitalization. All adjusted models include maternal age category, payer, presence of obstetrical factors (including multiple gestation) and presence of chronic medical comorbidities (including obesity, pregestational diabetes, chronic hypertension and smoking.)

651 | Environmental Protection Agency (EPA) National Walkability Index: Does it Effect Weight Gain in Gdm Pregnancies?

Thomas Owens[1]; Erica Glaser[2]; Johanna Suskin[3]; Guillaume Stoffels[4]; Mia A. Heiligenstein[5]; Olivia Grubman[6]; Xiteng Yan[2]; Zainab Al-Ibraheemi[1]; Lois Brustman[1]

[1]Icahn School of Medicine at Mount Sinai West, New York, NY; [2]Mount Sinai West, New York, NY; [3]Mount Sinai West, New York City, NY; [4]Icahn School of Medicine at Mount Sinai, New York, NY; [5]Mount Sinai West, Astoria, NY; [6]Westchester Medical Center, Westchester, NY

4:00 PM - 6:00 PM

Objective: An important factor in the management of gestational diabetes (GDM) is exercise. The primary aim of this study was to assess neighborhood walkability and weight gain from time of diagnosis of GDM, and total weight gain of the pregnancy.

Study Design: This is a retrospective cohort study of pregnant patients that were diagnosed with GDM at an academic center between 2018-2023. Patients' addresses at the time of their gestation were correlated with the EPA National Walkability Index. The categories of walkability index included: least walkable(score 1-5), below average(6-10), above average(11-15), and most walkable(16-20). Descriptive statistics and restricted cubic spline plot were used. Multivariate analysis was conducted adjusting for median income, age, BMI, gravidity, parity, race, and hypertension.

Results: 1231 patients were identified. There were 81 patients(6.6%) in the least walkable group, 225 patients(18.3%) in the below average walkable group, 428 patients(34.8%) in the above average walkable group, and 497 patients(40.4%) in the most walkable group.The above-average walkable group(scores 10.51 to 15.25) was defined as the reference group, as it included the median walkability score. In multivariable analysis, the total weight gain of patients in the least walkable group was, on average, 5.42 pounds greater compared to the reference group(p< 0.0001)(table 1). The relationship between walkability score and total weight gain was approximately linear(Fig. 1). In the adjusted linear trend analysis, each unit increase in walkability score was associated with a 0.40-pound decrease in total weight gain (p< 0.0001)(table 1). Additionally, each unit increase in walkability score was associated with a 0.25-pound decrease from time of GDM diagnosis(p< 0.0001).

Conclusion: This study suggests that patients with GDM who live in a lower walkability area are more likely to gain weight during their pregnancy. Therefore, it's important when providers are counseling patients with GDM to stress the relationship of exercise to weight gain and how that may impact blood glucose control.

		Unadjusted		Adjusted	
(Table 1) Outcome	**Walkability score**	**Odds ratio or Absolute change (95% CI)**	**P value**	**Odds ratio or Absolute change (95% CI)**	**P value**
Total weight gain§§					
	1-5.75	5.00 (2.32, 7.68)	0.0003	5.42 (2.73, 8.12)	<0.0001
	5.76-10.50	1.63 (-0.19, 3.45)	0.08	1.68 (-0.14, 3.49)	0.07

	15.26-20	-1.36 (-2.82, 0.10)	0.07	-1.45 (-2.89, -0.01)	0.049
	Linear trend	-0.38 (-0.55, -0.21)	<0.0001	-0.40 (-0.56, -0.24)	<0.0001
Weight gain since GDM diagnosis§§					
	1-5.75	3.92 (2.07, 5.77)	<0.0001	3.93 (2.04, 5.82)	<0.0001
	5.76-10.50	1.36 (0.10, 2.61))	0.03	1.51 (0.24, 2.79))	0.02
	10.51-15.25 (ref)	1.00	--	1.00	--
	15.26-20	-0.44 (-1.45, 0.56)	0.39	-0.42 (-1.44, 0.59)	0.41
	Linear trend	-0.24 (-0.36, -0.13)	<0.0001	-0.25 (-0.37, -0.14)	<0.0001

§ Binary outcomes were analyzed using both univariable (unadjusted) and multivariable (adjusted) logistic regression models. The effect of the walkability score was quantified using odds ratios. For the linear trend, the odds ratio was calculated for a one-point increase in the walkability score.
§§ Continuous outcomes were analyzed using both univariable (unadjusted) and multivariable (adjusted) linear regression models. The effect of the walkability score was quantified as the absolute change in the outcome variable. For the linear trend, the absolute change was calculated for each one-point increase in the walkability score.
In all multivariable models, adjustment variables included median income, age, BMI, gravidity, parity, race and HTN.
† Neonatal adverse outcome included NICU admission, LGA, APGAR score at 5 minutes < 7, and neonatal hypoglycemia

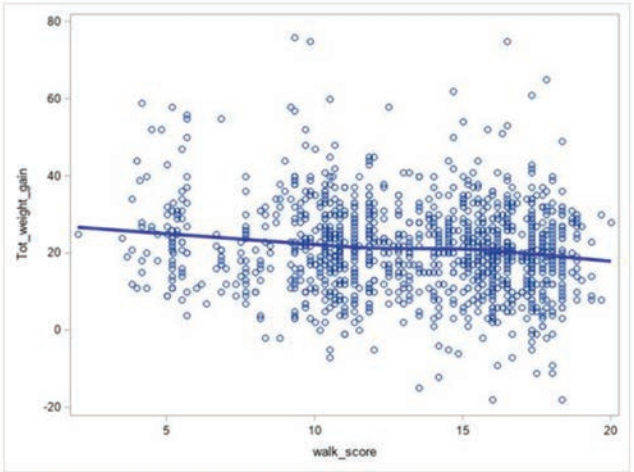

Figure 1 Relationship between walkability and total weight gain

652 | Environmental Protection Agency (EPA) National Walkability Index and its Impact on the Severity of Gdm

Thomas Owens[1]; Johanna Suskin[2]; Erica Glaser[3]; Guillaume Stoffels[4]; Mia A. Heiligenstein[5]; Olivia Grubman[6]; Xiteng Yan[3]; Zainab Al-Ibraheemi[1]; Lois Brustman[1]
[1]Icahn School of Medicine at Mount Sinai West, New York, NY; [2]Mount Sinai West, New York City, NY; [3]Mount Sinai West, New York, NY; [4]Icahn School of Medicine at Mount Sinai, New York, NY; [5]Mount Sinai West, Astoria, NY; [6]Westchester Medical Center, Westchester, NY

4:00 PM - 6:00 PM

Objective: An important factor in the management of gestational diabetes (GDM) is exercise. The aim of this study is to assess neighborhood walkability and need for hypoglycemic agents (HA) in patients with GDM.

Study Design: A retrospective cohort study of pregnant patients that were diagnosed with GDM at an academic center between 2018-2023. Patients' addresses at the time of their gestation were correlated with the Environmental Protection Agency (EPA) National walkability index. The categories of EPA walkability index included:least walkable (score 1-5), below average (6-10), above average (11-15), and most walkable (16-20). A2GDM was defined as patients requiring HA. Secondary analysis included a neonatal composite outcome consisting of neonatal hypoglycemia(NH), large for gestational age(LGA), NICU admission, and APGAR score< 7. Descriptive statistics and restricted cubic spline plot (RP) were used. Multivariate analysis was conducted adjusting for median income, age, BMI, gravidity, parity, race, and hypertension.

Results: 1231 patients identified. There were 81 patients(6.6%) in the least walkable group, 225 patients(18.3%) in the below average walkable group, 428 patients(34.8%) in the above average walkable group, and 497 patients(40.4%) in the most walkable group. In multivariable analysis patients in the least walkable and below-average walkable groups had a significantly higher likelihood of having A2GDM(least walkable: p = 0.004; below average walkable: p = 0.02 (Table 1)). A RP showed that the relationship between walkability score and the probability of A2GDM was linear(Fig. 1).When walkability score was treated as continuous, each one-unit increase in walkability score was significantly associated with a 6% decrease in the odds of A2GDM(p = 0.0001). Neonatal composite did not differ between the groups(p = 0.30).

Conclusion: Patients who live in a higher walkability area are less likely to need medication. Thus, providers counseling patients with GDM should stress the importance of exercise in the control of blood glucose and its relationship to the severity and subsequent management.

(Table 1) Outcome	Walkability score	Unadjusted Odds ratio or Absolute change (95% CI)	Unadjusted P value	Adjusted Odds ratio or Absolute change (95% CI)	Adjusted P value

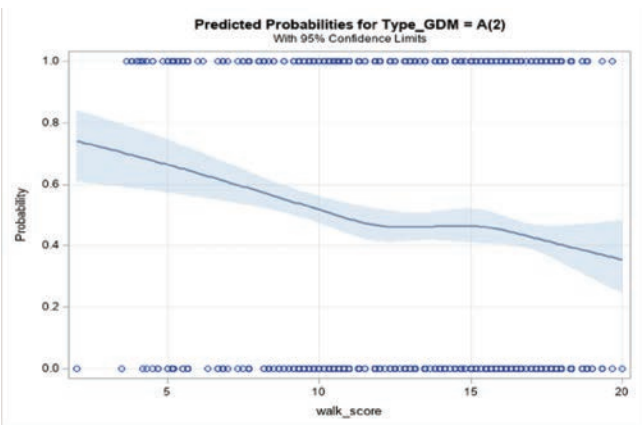
Adverse neonatal outcome§†					
	1-5.75	1.28 (0.77, 2.13)	0.34	1.27 (0.74, 2.16)	0.39
	5.76-10.50	0.96 (0.67, 1.37)	0.80	0.94 (0.65, 1.37)	0.76
	10.51-15.25 (ref)	1.00	--	1.00	--
	15.26-20	1.26 (0.95, 1.68)	0.10	1.36 (1.02, 1.82)	0.04
	Linear trend	1.01 (0.98, 1.04)	0.58	1.02 (0.99, 1.05)	0.30

§ Binary outcomes were analyzed using both univariable (unadjusted) and multivariable (adjusted) logistic regression models. The effect of the walkability score was quantified using odds ratios. For the linear trend, the odds ratio was calculated for a one-point increase in the walkability score.
§§ Continuous outcomes were analyzed using both univariable (unadjusted) and multivariable (adjusted) linear regression models. The effect of the walkability score was quantified as the absolute change in the outcome variable. For the linear trend, the absolute change was calculated for each one-point increase in the walkability score.
In all multivariable models, adjustment variables included median income, age, BMI, gravidity, parity, race and HTN.
† Neonatal adverse outcome included NICU admission, LGA, APGAR score at 5 minutes < 7, and neonatal hypoglycemia.



653 | Does Early Administration of IV Iron During Pregnancy Improve Maternal Morbidity?

Tina M. Bui; Guillermo Valenzuela; Kristina Roloff; Mary Tsaturian; Phoebe Jen
Arrowhead Regional Medical Center, Colton, CA

4:00 PM - 6:00 PM

Objective: Anemia in pregnancy is a significant contributor to maternal morbidity, including increased risks of blood transfusion, longer hospital stays, depression, preterm birth, and low birth weight. Oral (PO) iron has been traditionally recommended for its simplicity and cost-effectiveness but often suffers from poor adherence and gastrointestinal side effects. This study aims to investigate whether early administration of IV iron can improve hemoglobin (Hgb) levels prior to delivery and decrease the need for blood transfusion.

Study Design: Patients with a ferritin level < 30 ng/mL were recruited. Exclusion criteria included age < 18, multifetal gestations, thalassemia or sickle cell disease, and chronic kidney or

liver disease. After obtaining consent, patients were randomly assigned to either the PO or IV iron groups. The PO iron group received Ferrous sulfate 325 mg every other day, while the IV iron group received Venofer 200 mg every other day until the iron deficit was corrected. Hgb and ferritin levels were assessed before treatment and four weeks after treatment initiation. Patients also completed an anemia symptom questionnaire at enrollment and at the 4-week mark. Statistical comparisons were conducted using two-tailed T-tests with significance set at $P < 0.05$.

Results: The IV iron group showed a significant increase in Hgb and ferritin levels compared to the PO iron group four weeks after treatment, with P-values of 0.002 and 0.0001, respectively. The blood transfusion rate was 3.7% in the PO iron group and 0% in the IV iron group.

Conclusion: Our findings demonstrate a significant improvement in ferritin levels among patients treated with IV iron compared to those receiving PO iron therapy. Additionally, the absence of blood transfusions in the IV iron group highlights its potential in reducing alloimmunization and blood transfusion reactions, suggesting that early administration of IV iron during pregnancy can improve maternal health outcomes.

	PO iron	IV iron	P-value
Age	27.61 (5.92)	25.41 (5.07)	0.062
GA at enrollment	23w4d (7.01)	24w6d (7.32)	0.379

654 | Perceived Racism and Placentally Mediated Adverse Pregnancy Outcomes

Joy McNeal; Sarah Heerboth; Ashlyn Tolbert; Johanna Quist-Nelson; Rebecca Fry; Tracy A. Manuck
University of North Carolina, Chapel Hill, NC

4:00 PM - 6:00 PM

Objective: Racism is consistently implicated in obstetric disparities and is associated with hypertension (HTN) among non-pregnant individuals. We sought to quantify the extent to which racism, including its characteristics (domains, timing), is associated with placentally-mediated pregnancy complications (plac-comps).

Study Design: Primary analysis of a prospective cohort. Participants identifying as Black, White, and/or Hispanic, with singleton, non-anomalous gestations were recruited < 22 weeks, 2017-2022, and completed the validated Perceived Racism Scale at enrollment to assess any-time (at any time during life) and recent (within the last year) racism in 11 public/personal, 3 public/observed experience, and 7 employment domains. The primary outcome was a diagnosis of plac-comps (HTN disorders of pregnancy, birthweight < 10% for GA and sex, ± placental abruption).

Results: 414 individuals (47% Black, 42% White, 11% Hispanic) were included; 93 (22.4%) had plac-comps. Surveys were completed at a mean of 17.3 (IQR 16.1-20.0) wks. Clinical factors are shown in Table 1. Compared to those without plac-comps, those with plac-comps were more likely to experience racism at any time (65% vs. 47%, $p = 0.02$) and racism across a greater number of domains any-time (8.1 v. 5.6, $p = 0.002$) and recently (mean 4.6 v. 2.6, $p< 0.001$). Differences were most pronounced in public/personal domains, as those with plac-comps had higher any-time perceived racism in 7 of 11 public/personal domains and higher recent perceived racism in 7 of 11 public/personal domains (all $p< 0.05$), Figure. In regressions, each additional any-time racism domain conferred a 9% increased odds of plac-comps (aOR 1.09, 95% CI 1.03-1.15). Similarly, each additional recent racism domain conferred a 8% increased odds of plac-comps (aOR 1.08, 95% CI 1.03-1.13).

Conclusion: Among pregnant individuals at high-risk for adverse pregnancy outcomes, racism is present across multiple facets of daily life. Perceived racism was associated with an increased risk of adverse placental outcomes, irrespective of the timing of the exposure.

Table. Demographic and obstetric characteristics by those with and without racism reported in a high total number of domains at any time during life (≥ 7 of 20 evaluated domains, ≥ 75th centile for cohort). Data are presented as n(%) unless otherwise noted.

Characteristic	High # (≥7) of total racism domains at any time n=112	Lower # (<7) of total racism domains at any time n=302	P
Mom age, mean years ± SD	31.8 ± 5.2	31.4 ± 5.1	0.47
Black race	100 (89)	94 (31)	<0.001
More than one race	13 (11.6)	20 (6.6)	0.10
Public insurance	67 (60)	126 (42)	0.001
Pre-pregnancy BMI, mean kg/m² ± SD	32.7 ± 9.6	30.0 ± 8.9	0.008
Chronic hypertension	27 (24)	44 (15)	0.02
Pre-gestational diabetes mellitus	4 (4)	16 (5)	0.47
Prior spontaneous preterm birth <35 weeks' gestation	85 (76)	186 (62)	0.007
≥ 1 prior term delivery	64 (57)	202 (67)	0.07
Earliest prior delivery, mean weeks	26.1 ± 9.5	30.6 ± 8.5	<0.001

Figure 1. Proportion of participants reporting life-long racism by domain and specific scenario. Numbers in each box represent the percentage of individuals reporting racism at any time during their life, for the overall cohort and for those with and without placental complications. Data are shown in 'heat map' fashion, with darker colors representing larger %, as per legend below.

*Statistically significant comparisons (between those with and without plac-comps) are noted with bolded box outlines. *p<0.05; **p<0.001*

Domain	Racism Scenario	All participants N=414	NO Plac-comps n=321	Plac-comps n=93

655 | Objective Quantification of Sleep Throughout Pregnancy, Preterm Birth, and Delivery Gestational Age

Emily Gascoigne[1]; Megan Ragusa[2]; Ashlyn Tolbert[2]; Annie Dude[2]; Rebecca Fry[2]; Tracy A. Manuck[2]
[1]UNC Chapel Hill School of Medicine, Carrboro, NC; [2]University of North Carolina, Chapel Hill, NC

4:00 PM - 6:00 PM

Objective: Sleep quality and quantity (evaluated using traditional duration/stage measures and novel metrics including the sleep regularity index, a parameter assessing sleep pattern regularity and consistency) are associated with health outcomes. We sought to determine which sleep parameters are associated with PTB.

Study Design: Primary analysis of a prospective cohort enriched for those at high *a priori* risk of PTB. Participants identifying as Black, White, and/or Hispanic, with singleton, non-anomalous gestations were recruited < 14 weeks, 2017-2022. Participants were provided FitBit wristband activity trackers at enrollment and instructed to maintain their usual activity. Those with ≥7 nights of sleep monitoring (verified by FitBit recorded heart rate) were included. The primary outcomes were delivery gestational age and PTB < 35 weeks. We evaluated individual sleep parameters and a composite 'poor sleep' score based on previously established metrics of sleep health. The poor sleep score was calculated by adding +1 point for (1) mean total min/asleep < 360 min/night; (2) mean % time in REM < 20%; (3) mean sleep efficiency (time asleep/time in bed) < 85%; (4) >50% of sleep midpoints ≥ 05:00; (5) ≥ 2 median night awakenings; (6) sleep regularity index in lowest quartile (< 95.2). Cox regression models included adjustments for multiple and differing numbers of observations per subject.

Results: 154 individuals were included, delivering at a median 38.2 (IQR 37.0, 39.3) weeks; 25% had PTB < 37 and 14% PTB < 35 weeks. The median sleep score was 2 (IQR 1,3); range 0-5. Clinical characteristics are shown in Table 1. Each sleep parameter's variation over gestation is shown in Figure 1. In cox regression models, a poor sleep score (≥3; aHR 1.49, 95% CI 1.04, 2.13) and % time in REM sleep (aHR 0.21, 95% CI 0.06-0.73) were associated with delivery gestational age.

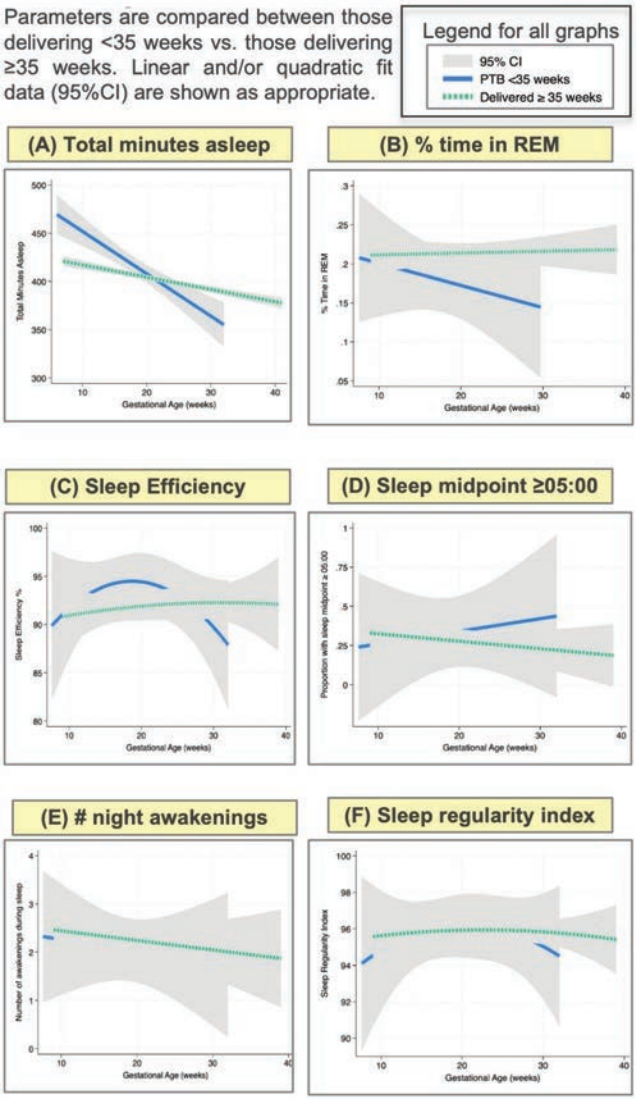
Conclusion: Several sleep metrics vary across gestation, though tend to be similar among those with PTB < 35 weeks vs. those with later delivery. However, individuals with ≥3 poor sleep habits throughout pregnancy carried a higher risk of early delivery.

Table. Demographic, obstetric, and sleep characteristics and initial outcomes stratified by those with and without poor sleep (defined composite sleep score ≥ 2). Data are n(%), as applicable, unless noted.

Characteristic	Poor sleep score (≥2) N=40	Better sleep score (<2) N=114	P-value
Age, mean years ± SD	32.1 ± 5.2	32.1 ± 4.8	0.95
Black race	21 (53)	33 (29)	0.007
White race	15 (38)	68 (60)	0.02
Hispanic ethnicity	5 (13)	18 (16)	0.62
Pre-pregnancy BMI, mean kg/m² ± SD	31.2 ± 10.6	28.6 ± 7.5	0.10
Pregestational diabetes mellitus	5 (13)	4 (4)	0.04
Chronic hypertension	7 (18)	14 (12)	0.41
Prior PTB <35 weeks	33 (83)	71 (62)	0.02
Short cervical length <25mm	15 (38)	23 (20)	0.03
Mean number of sleep nights monitored, ± SD	52 ± 47	90 ± 62	0.001
Average bedtime (military time) ± SD in HH:MM	00:06 ± 02:12	23:18 ± 01:18	0.004
Average wake time (military time) ± SD in HH:MM	08:30 ± 02:42	07:30 ± 01:48	0.008
Mean delivery gestational age, weeks ± SD	36.8 ± 3.2	37.5 ± 3.7	0.33
PTB <37 weeks'	12 (30)	26 (23)	0.17
PTB <35 weeks'	8 (20)	13 (11)	0.36

Figure 1. Shown is the variation in each sleep parameter included in the composite sleep score across gestation,

Parameters are compared between those delivering <35 weeks vs. those delivering ≥35 weeks. Linear and/or quadratic fit data (95%CI) are shown as appropriate.



656 | Impact of Low-Dose Furosemide on Breastfeeding and Newborn Weight: a Randomized Controlled Trial Secondary Analysis

Ukachi N. Emeruwa[1]; Kysha Mercader[2]; Chaukim Peters[3]; Shai Bejerano[4]; Toluwalasé A. Ajayi[5]; Gregory A. Aarons[6]; Bonnie Kaiser[6]; Sarah Averbach[6]; Michelle Leff[6]; Russell S. Miller[4]; Cynthia Gyamfi-Bannerman[1]

4:00 PM - 6:00 PM

Objective: Growing evidence supports loop-diuretic use to reduce postpartum (PP) hypertensive morbidity, but little is known about how these medications affect breastfeeding and associated neonatal outcomes. We aimed to explore breastfeeding rates and newborn weight loss among lactating patients taking low-dose furosemide after delivery.

Study Design: This was a secondary analysis of the Lasix for the Prevention of de novo Postpartum Hypertension Trial (PMID: 38641089), which randomized 82 normotensive patients at high risk for de novo PP hypertension to 5 days of daily furosemide 20mg PO or placebo within 8 hours after delivery. Parent trial participants completed electronic surveys at 2 and 6 weeks PP, which included infant feeding practice questions. Data on feeding practices and neonatal weight were also abstracted from electronic medical records. The primary outcome of this analysis was exclusive breastfeeding (EBF) continuation rates among those who reported EBF intent on delivery admission. Secondary outcomes included EBF rates among those practicing EBF at discharge, any breastfeeding rates, formula supplementation reasons, and newborn delivery to discharge weight change.

Results: Of 79 parent trial participants enrolled through 6 weeks PP, 70 (89%) at least partially completed the 2 week survey; 55 (70%) at least partially completed the 6 week survey. There was no difference in EBF continuation rates for participants randomly assigned to furosemide who intended to exclusively breastfeed (54% at 2 weeks; 64% at 6 weeks) compared to placebo (38% at 2 weeks, p = 0.43; 31% at 6 weeks, p = 0.11). (**Figure 1**) Of reported supplementation reasons, there was no difference in milk supply or neonatal concerns between groups. Newborn weight declined a median of 5% [IQR -7,-3%] in the furosemide group and 6% [IQR -8,-4%] in the placebo group (p = 0.17) by discharge, consistent with physiologic norms. (**Table 1**)

Conclusion: There is no evidence in our trial that low-dose furosemide impacts breastfeeding continuation rates or physiologic newborn weight loss. These data are reassuring for loop-diuretic use in lactating people.

Figure 1. Breastfeeding rates at 2 and 6 weeks postpartum by intervention group

657 | Automated Unattended Office BP: Is Your Clinician Raising Your Blood Pressure?

Whitney A. Booker[1]; Patrick Conley[2]; Marissa Petralia[2]; Jeannette Pacheco[2]; Eliza C. Miller[3]; Uma M. Reddy[4]; Ying Kuen K. Cheung[3]; Mariam Naqvi[5]; Natalie A. Bello[5]
[1]Columbia University, new York, NY; [2]Cedars Sinai Medical Center, Cedars Sinai, CA; [3]Columbia University Medical Center, New York, NY; [4]Columbia University, New York, NY; [5]Cedars Sinai Medical Center, Los Angeles, CA

4:00 PM - 6:00 PM

Objective: There is emerging data that in non-pregnant adults measuring clinic blood pressure (CBP) without a clinician present (unattended CBP) may reduce the "white coat effect" and be closer to mean out-of-clinic blood pressure (BP) compared to traditional CBP measurements that involve a clinician in the room (attended CBP). Our objective was to compare unattended CBP with attended CBP in pregnant women with hypertension (HTN).

Study Design: Pregnant patients with a history of chronic or gestational HTN defined using ACOG diagnostic criteria were included in this analysis. Demographic variables were described as median [IQR] for continuous variables and frequencies for categorical variables. Automated attended and unattended CBP were measured at up to two prenatal visits and compared using a paired t-test to account for repeated measures and between-subject variability. Bland-Altman plots were created to evaluate the agreement between unattended and attended CBP.

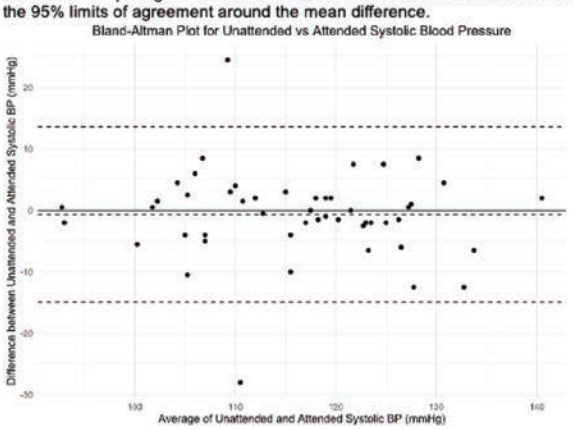
Results: Of 26 pregnant patients with HTN, women were on average 36.5 [5.1] years old and 24 weeks pregnant, with a BMI of 32.2 [8.3] kg/m^2, 19% had diabetes, and the majority were working full time (**Table**). In 49 paired measurements, the mean unattended CBP was 115.8/72.3 mmHg and the mean attended CBP was 116.5/71.5 mmHg. The mean difference (95% CI) between unattended and attended systolic BP was 0.69 (-1.40, 2.78) and diastolic BP was 0.00 (-1.02, 1.02); both mean differences were not statistically significant P >0.5 (**Figure**).

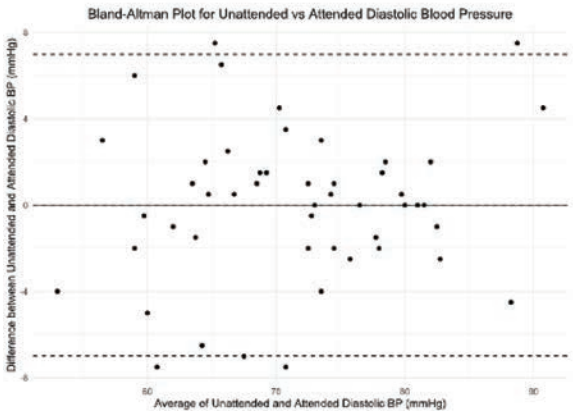
Conclusion: In pregnant patients with HTN, having a provider present during CBP measurements did not result in a statistically significant BP elevation. Based on these findings unattended CBP measurement may not be able to replace out-of-office BP measurement for the diagnosis of white coat hypertension; further research is needed.

Table. Maternal characteristics of the 26 pregnant patients

Maternal age, years	36.5 [5.1]
Gestational age, weeks	24.0 [5.8]
Self-reported Race	
Asian	8 (32.0%)
Black	3 (12.0%)
Native Hawaiian/Pacific Islander	3 (12.0%)
White	11 (44.0%)
Prefer not to answer/unknown	1 (3.8%)
Hispanic/Latino/a/x or Spanish Ethnicity	4 (15.4%)
Maternal Body Mass Index (kg/m^2)	32.2 [8.3]
Heart rate (beats/minute) - Observed	91 [13]
Heart rate (beats/minute) - Unobserved	91 [13]
Diabetes Mellitus (gestational or pre-pregnancy)	5 (19.2%)
Married/living with partner	23 (88.5%)
Employed full time	24 (92.3%)
Private Health Insurance	25 (96.2%)
Education	
High school	1 (3.8%)
Some college	3 (11.5%)
2-year degree	1 (3.8%)
4-year degree	9 (34.6%)
Professional degree	9 (34.6%)
Doctorate	3 (11.5%)
Cigarette Use	
Never	22 (84.6%)
Past Smoker	4 (15.4%)
Current Alcohol Use	2 (7.7%)

Figure. Bland-Altman plots of systolic and diastolic BP demonstrate no proportional bias when comparing unattended and attended measurements. Dashed lines indicate the 95% limits of agreement around the mean difference.





658 | Differential Expression of Placental CD300 Receptors in Preeclampsia (PE) and Preterm Birth (PTB)

William E. Ackerman, IV[1]; Meera M. Thakkar[1]; Guomao Zhao[1]; Zoe B. Strong[1]; Elizabeth Feoktistov[2]; Ekaterina Snegovskikh[2]; Catalin S. Buhimschi[1]; Irina A. Buhimschi[1]
[1]*University of Illinois at Chicago, College of Medicine, Chicago, IL;* [2]*University of Illinois at Chicago, Chicago, IL*

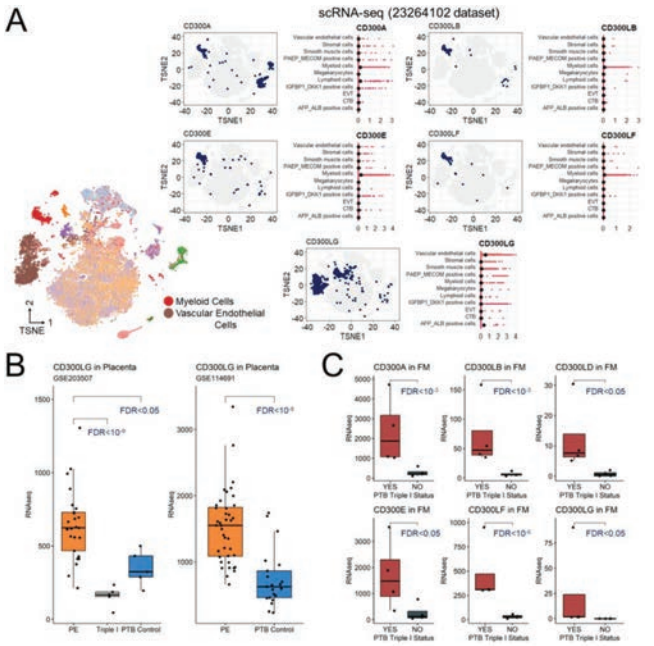
4:00 PM - 6:00 PM

Objective: Through their binding to lipids and other ligands, the 7 member CD300 family of receptors is poised to have a significant role in biological processes with an inflammatory component. Their roles in major inflammatory obstetrical syndromes such as PE and PTB +/- Triple I have not been fully elucidated. We performed a targeted computational analysis of existing placental datasets with transcriptional profiling to understand the expression and distribution of placental CD300 receptors in these pathological contexts.

Study Design: We interrogated bulk and single-cell (sc) placental RNA sequencing (RNAseq) datasets (GEO: GSE73714, GSE203507, GSE114691, GSE173193; Figshare: 23264102) for CD300 expression in PE (n = 65) and PTB (NO-Triple I n = 26; YES-Triple I, n = 5). This analysis was complemented by RNAseq in a new set of 8 fetal membrane (FM) samples as follows: YES-Triple I (n = 4, GA 28±3w), NO-Triple I (n = 4, GA 32±1w). Selected targets were cross validated by qPCR.

Results: Across placental RNAseq datasets, all 7 CD300 mRNAs could be detected, with *CD300LG* predominating in the villous placenta and *CD300A* and *-E* most abundant in FM. By scRNAseq, *CD300LB*, *-E*, and *-LF* displayed myeloid-limited expression, *CD300A* was expressed in myeloid and lymphoid cells, *CD300LG* was abundant in vascular endothelial cells, and *CD300LC* and *-D* expression fell below detection limits. Villous *CD300LG* was significantly more abundant in PE than non-PE samples (FDR< 0.05). In Triple I, *CD300A*, *-LB*, *-LD*, *-E*, *-LF*, and *-LG* were elevated (FDR< 0.05) in FM but not villous placenta by RNAseq, with CD300LF being most significant. Increased expression of placental *CD300LG* in PE and FM *CD300LF* in Triple I were confirmed by qPCR (p< 0.05).

Conclusion: The CD300 family of receptors is present in the human placenta. In pregnancy conditions with strong inflammatory components the signaling pathways emanating from this family of receptors are likely diverse based on disease and their location.



659 | Early Recognition of Fetal Growth Restriction via Clinical Features, Metabolomic Profiles and Polygenic Risk Scores

Xiaoqing He[1]; Jun Zhang[2]; Yun Huang[2]
[1]*Ministry of Education-Shanghai Key Laboratory of Children's Environmental Health, Xinhua Hospital, affiliated with School of Medicine, Shanghai Jiao Tong University, Shanghai, China, Shanghai, Shanghai;* [2]*Shanghai Jiao Tong University School of Medicine, Shanghai, Shanghai*

4:00 PM - 6:00 PM

Objective: To integrate various factors to predict FGR, enabling early identification and risk stratification of high-risk populations.

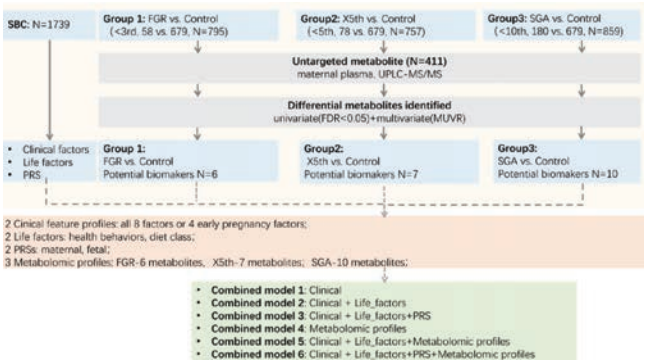
Study Design: This study was conducted based on a prospective birth cohort. A total of 1,739 mother-child pairs were included. Three nested case-control studies were further conducted: 1) 58 FGR cases (< 3rd percentile); 2) 78 X5th cases (< 5th percentile); 3) 180 SGA cases (< 10th percentile). The control group included 679 healthy controls (BW in the 25th to 75th percentile, without major complications). We developed 6 risk prediction models for birth outcomes (FGR, X5th, and SGA) using clinical risk factors, life factors, maternal and fetal polygenic risk scores (PRSs), and maternal plasma metabolic profiles in early pregnancy.

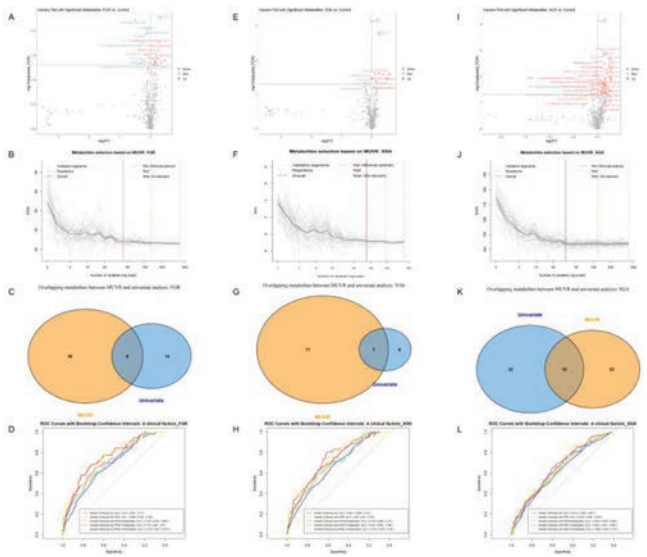
Results: Eight clinical factors and two life factors (health behaviors and diet class) were included. Both maternal and fetal PRSs were derived from the 2019 GWAS meta-analysis for birth weight from the EGG consortium. Univariate analysis and the Unbiased Variable selection in R (MUVR) package identified potential metabolomic biomarkers. For the three case-control groups, 6, 7, and 10 metabolites were identified as potential biomarkers for FGR, X5th, and SGA, respectively.

The final model based on 8 clinical features, 2 life factors, maternal and fetal PRSs, and the 6 metabolite sets demonstrated the best predictive ability, achieving a maximum AUC of 0.826 (95% CI: 0.763-0.879) for predicting FGR. A model built solely on

early pregnancy data achieved a maximum AUC of 0.744 (95% CI: 0.681-0.806) for predicting FGR.

Conclusion: The inclusion of metabolic and genetic information significantly enhanced predictive performance compared to traditional models. Integrating genetic and metabolic data enhances the accuracy of fetal growth assessments, enabling earlier and more precise identification of high-risk pregnancies and facilitating timely interventions to improve outcomes.





660 | Risk Factors for Adverse Outcomes in Uterine Conserving Cesarean Deliveries for Placenta Accreta Spectrum

Yonatan Dror[1]; Elias Castel[2]; Raanan Meyer[3]; Lior Fridrich[2]; Nizan Mor[2]; Aviran Ohayon[2]; Michal Axelrod[4]; Alina Weissmann-Brenner[2]; Gabriel Levin[5]; Shlomi Toussia Cohen[2]

[1]Chaim Sheba Medical Center, Tel-Hashomer, Ramat-Gan, Israel, Chaim Sheba Medical Center, Tel-Hashomer, Ramat-Gan, Israel, HaMerkaz; [2]Sheba Medical Center, Ramat Gan, HaMerkaz; [3]Cedars Sinai Medical Center, Los Angeles, CA; [4]Department of Obstetrics and Gynecology, Sheba Medical Center, Tel HaShomer, Ramat Gan, HaMerkaz; [5]McGill University, Montreal, PQ

4:00 PM - 6:00 PM

Objective: While uterine conserving cesarean delivery for placenta accreta spectrum (PAS) has become more common, data on outcomes are still limited. The aim of this study is to describe the characteristics of patients undergoing uterine conserving cesarean for PAS with and without adverse maternal outcomes, and identify risk factors for their occurrence.

Study Design: A retrospective cohort study conducted at a single tertiary center between 03/2011 and 01/2022. Women with PAS who underwent uterine conserving cesarean delivery were included. Women with scheduled cesarean hysterectomy were excluded. A composite of adverse maternal outcome was defined as the occurrence of at least one of the following: bladder injury, ureteral injury, bowel injury, ≥6 units of blood transfusion, postoperative fever, unplanned cesarean hysterectomy, relaparotomy, intensive care unit admission and hospital readmission.

We compared patients with and without the composite adverse outcome.

Multivariable regression analysis was used to identify factors associated with the composite of adverse outcome.

Results: 238 women with PAS were included in the study group, 70 had composite adverse maternal outcome and 168 did not. The maternal adverse outcome group had earlier gestational age at delivery (median $36^{0/7}$ vs. $36^{3/7}$ weeks), higher preoperative uterine rupture rates (6.2% vs. 0.6%), longer cesarean delivery duration (median 118.5 vs. 68.0 minutes), more drainage placement (72.5% vs. 23.8%) and higher estimated blood loss (median 2500.0 vs. 1200.0 ml).

In multivariable logistic regression analysis, earlier gestational age at delivery, and the sonographic findings of lacunae, bridging vessels and loss of clear zone were independently associated with the composite adverse maternal outcome.

Conclusion: Among women undergoing uterine conserving cesarean delivery for PAS, an earlier gestational age at delivery, and three sonographic findings, are associated with adverse maternal outcomes.

Table 1. Characteristics and operative outcomes of women with and without adverse outcomes in uterine conserving cesarean deliveries for placenta accreta

Characteristics	Adverse outcome n=70	No adverse outcome n=168	p value
Age, years	35.00 [31.3,39.0]	36.00 [32.0, 39.0]	0.824
Body mass index, mean, kg/m2	29.7 [25.2, 34.8]	28.84 [25.6, 31.6]	0.391
Placental bladder invasion perceived by surgeons	16 (22.9)	0 (0.0)	**<0.001**
Sonographic presence of lacunae	55 (78.6)	90 (53.6)	**<0.001**
Sonographic presence of subplacental hypervascularity	17 (25.0)	22 (14.1)	**0.056**
Sonographic presence of bridging vessels	16 (23.5)	12 (7.7)	**0.002**
Sonographic loss of clear zone	52 (78.8)	80 (51.0)	**<0.001**
Gestational age at delivery, weeks	$36^{0/7}$ [$35^{4/7}$, $36^{5/7}$]	$36^{3/7}$ [$35^{6/7}$, $37^{3/7}$]	**<0.001**
Preoperative ureter catheter insertion	9 (12.9)	20 (11.9)	0.830
Preoperative balloon occlusion of vessels	12 (17.1)	11 (6.5)	**0.016**
Uterine artery ligation	6 (15.8)	28 (16.7)	>0.999
Emergent cesarean	12 (17.6)	28 (17.2)	>0.999
Preoperative uterine rupture	4 (6.2)	1 (0.6)	**0.021**
Cesarean delivery duration, minutes	118.5 [100.8, 160.3]	68.0 [49.5, 98.5]	**<0.001**
Blood transfusion during cesarean	58 (82.9)	68 (40.5)	**<0.001**
Number of packed RBCs transfused during operation*	6.0 [3.0, 9.0]	3.0 [2.0, 4.0]	**<0.001**
FFP transfusion during cesarean	48 (68.6)	43 (25.6)	**<0.001**
Number of FFP units transfused*	4.0 [4.0, 6.0]	3.0 [2.0, 4.0]	**0.004**
Cryoprecipitate transfusion during cesarean	42 (60.0)	43 (25.6)	**<0.001**
Number of cryoprecipitate units transfused*	12.0 [10.0, 12.0]	10.0 [8.0,12.0]	0.096
Platelets transfusion during cesarean	3 (4.3)	2 (1.2)	0.153
Misoprostol administration	21 (30.0)	72 (42.9)	0.080
Carboprost administration	13 (18.6)	19 (11.3)	0.147
Methergin administration	13 (18.6)	33 (19.6)	>0.999
Drainage placement	50 (72.5)	40 (23.8)	**<0.001**
Estimated blood loss, ml	2500.0 [2000.0, 4000.0]	1200.0 [700.0, 2000.0]	**<0.001**
Estimated blood loss ≥3000 ml	31 (44.3)	17 (10.1)	**<0.001**
Blood transfusion after cesarean	20 (28.5)	24 (14.2)	**0.028**
Urinary tract infection	2 (2.9)	4 (2.4)	>0.999

Data are presented as number (%) or median [interquartile range]

Table 2. Multivariable regression analysis of factors associated with adverse outcomes

Characteristics	Adjusted odds ratio (95% Confidence interval)	p value
Gestational age at delivery	0.98 (0.96-0.99)	**0.044**
≥3 previous cesarean deliveries	1.63 (0.87-3.05)	0.128
Sonographic presence of lacunae	2.15 (1.06-4.36)	**0.035**
Sonographic presence of bridging vessels	2.84 (1.20-6.69)	**0.017**
Sonographic loss of clear zone	2.04 (1.03-4.03)	**0.041**

Multivariable regression analysis including the following covariates: gestational age at delivery, ≥3 previous cesarean deliveries, sonographic presence of lacunae, sonographic presence of subplacental hypervascularity, sonographic presence of bridging vessels

661 | Maternal Outcomes Associated with Antepartum versus Postpartum Eclampsia

Yossi Bart[1]; Farah H. Amro[1]; Ghamar Bitar[1]; Sandra Sadek[2]; Sean C. Blackwell[1]; Baha M. Sibai[1]
[1]*McGovern Medical School at UTHealth Houston, Houston, TX;* [2]*University of Texas Health Science Center in Houston, McGovern Medical School, Houston, TX*

4:00 PM - 6:00 PM

Objective: The data on eclampsia-related outcomes in the literature relies mainly on studies performed over two decades ago. Our objective was to compare maternal outcomes associated with the timing of eclampsia using a contemporary dataset.

Study Design: We conducted a retrospective cohort study of all patients diagnosed with eclampsia between June 2011 and June 2024 at a tertiary medical center. Patients with antepartum eclampsia (AE) were compared to those with postpartum eclampsia (PPE). The primary outcome was defined as a composite maternal morbidity including stroke, neurologic deficits at discharge, cardiac arrest, myocardial infarction, liver infarction or rupture, pulmonary edema, acute kidney injury, HELLP, disseminated intravascular coagulation, or death. Maternal outcomes were reported using Chi-Square or Fisher's exact tests.

Results: Overall, 80 patients met the inclusion criteria; 39 (49%) had AE, and 41 (51%) had PPE. Baseline maternal characteristics (age, race, BMI, chronic hypertension, diabetes mellitus) were similar between the groups. Four out of every five patients reported symptoms before the seizure, including headache (70%) and visual symptoms (31%), evenly distributed between groups. Simultaneous severe range blood pressure at the time of eclampsia diagnosis was reported in 52 (73%) of the patients, with similar rates between groups. PPE occurred >2 days after delivery in 90% of the cases and >7 days after delivery in 32%. Patients with AE had higher rates of composite maternal morbidity (59.0% vs. 31.7%, p = 0.01), driven mainly by higher rates of acute kidney injury and hemolysis, elevated liver enzymes, and low platelets syndrome (Table). There were also higher rates of post-seizure intubation (30.8% vs. 7.3%, p = 0.01) and intensive care unit admission (51.3% vs. 26.8%, p = 0.02) among patients who had AE.

Conclusion: Eclampsia continues to serve as an important contributor to maternal morbidity and mortality nowadays. Compared to postpartum eclampsia, antepartum eclampsia was associated with higher rates of maternal morbidity.

Table – Antepartum versus postpartum eclampsia and the association with adverse maternal outcomes

Outcome	Antepartum eclampsia (N=39)	Postpartum eclampsia (N=41)	P
Composite maternal morbidity	23 (59.0)	13 (31.7)	**0.01**
Ischemic stroke	3 (7.7)	2 (4.9)	0.67
Hemorrhagic stroke	4 (10.3)	5 (12.2)	>0.99
Neurologic deficits at discharge	3 (7.7)	2 (4.9)	0.67
Cardiac arrest	1 (2.6)	0	0.49
Myocardial infarction	1 (2.6)	0	0.49
Liver infarction	1 (2.6)	0	0.49
Liver rupture	1 (2.6)	0	0.49
Pulmonary edema	3 (7.7)	2 (4.9)	0.67
Acute kidney injury *	12 (30.8)	4 (9.8)	**0.02**
Dialysis	2 (5.1)	0	0.23
HELLP	11 (28.2)	3 (7.3)	**0.02**
DIC	1 (2.6)	0	0.49
Death	0	1 (2.4)	>0.99
RBC Transfusion	11 (28.2)	5 (12.2)	0.10
Intubation after seizure	12 (30.8)	3 (7.3)	**0.01**
ICU admission	20 (51.3)	11 (26.8)	**0.02**

HELLP, hemolysis, elevated liver enzymes, and low platelets; DIC, disseminated intravascular coagulation; RBC, red blood cell; ICU, intensive care unit.
Bolded if significant.
* Acute kidney injury defined as creatinine > 1.2

662 | Do Maternal Outcomes Differ by Specific Blood Pressure Parameters?

Yossi Bart[1]; Hector M. Mendez-Figueroa[2]; Farah H. Amro[1]; Baha M. Sibai[1]
[1]*McGovern Medical School at UTHealth Houston, Houston, TX;* [2]*McGovern Medical School at UTHealth, Houston, TX*

4:00 PM - 6:00 PM

Objective: The role of severe hypertension (sHTN) based on isolated severe systolic or diastolic blood pressure has not been well studied. We aimed to evaluate adverse maternal outcomes in those with isolated sHTN to those with both severe systolic and diastolic hypertension.

Study Design: We conducted a secondary analysis of the Assessment of Perinatal Excellence database. All the patients who had sHTN at the time of delivery, defined as systolic BP (SBP) ≥ 160 mmHg and/or diastolic BP (DBP) ≥ 110 mmHg on two occasions at least 30 minutes apart were included. Individuals with isolated SBP or DBP in the severe range (iSRBP) were compared to those with both (bSRBP). The primary outcome was defined as a composite of maternal outcomes, including hypertensive stroke, pulmonary edema, acute kidney injury, disseminated intravascular coagulation, cardiopulmonary arrest, and death. Multivariate logistic regression was applied to address confounders.

Results: A total of 7,788 individuals met the inclusion criteria. Of those, 5,968 (77%) had isolated SBP ≥ 160, 272 (3%) had isolated DBP ≥ 110 mmHg, and 1,548 (20%) had both. In comparison to those with bSRBP, individuals with iSRBP were older, had higher rates of obesity and multifetal gestation, and lower rates of chronic hypertension. Compared to bSRBP, those with iSRBP had lower composite outcome rates (adjusted relative risk 0.44, 95% CI 0.34-0.57), driven mainly by lower rates of pulmonary edema and acute kidney injury (Table). Intensive-care unit admission rate was also lower among individuals with iSRBP. In a sub-analysis of iSRBP, comparing individuals with isolated SBP vs. isolated DBP in the severe range, no differences in maternal outcomes were noted. Another comparison following further stratification by blood pressure showed a lower composite outcome rate among those with iSRBP compared to bSRBP when SBP was ≥ 180 mmHg (Figure).

Conclusion: Isolated severe systolic or diastolic hypertension was associated with lower rates of maternal morbidity compared

to sHTN with both. This was primarily driven by lower rates of acute kidney injury and pulmonary edema.

Table – The association between severe hypertension based on isolated severe systolic or diastolic blood pressure and maternal outcomes, compared to both

Outcome	bSRBP [a] (N=1,548)	iSRBP [a] (N=6,240)	Adjusted RR [b] (95% CI)
Composite maternal outcome	93 (6.0)	172 (2.8)	**0.44 (0.34-0.57)**
Hypertensive stroke	5 (0.3)	13 (0.2)	0.64 (0.23-1.81)
Pulmonary edema	32 (2.1)	73 (1.2)	**0.56 (0.37-0.85)**
Acute kidney injury [c]	59 (3.8)	81 (1.3)	**0.33 (0.24-0.47)**
DIC	4 (0.3)	12 (0.2)	0.74 (0.24-2.31)
Cardiopulmonary arrest	0	1 (0.0)	-
Maternal death	1 (0.1)	1 (0.0)	-
ICU admission	131 (8.5)	234 (3.8)	**0.42 (0.38-0.53)**

Data presented as N (%).

663 | Doulas In Black Birthing Experiences: Perceptions And Utilization Among Black Participants Following Doula-led Education Initiative

Yuliya Faryna[1]; Tonya Simone Wright[2]; Melissa Haslam[2]
[1]Pennsylvania State College of Medicine, Hershey, PA; [2]Penn State College of Medicine, Hershey, PA

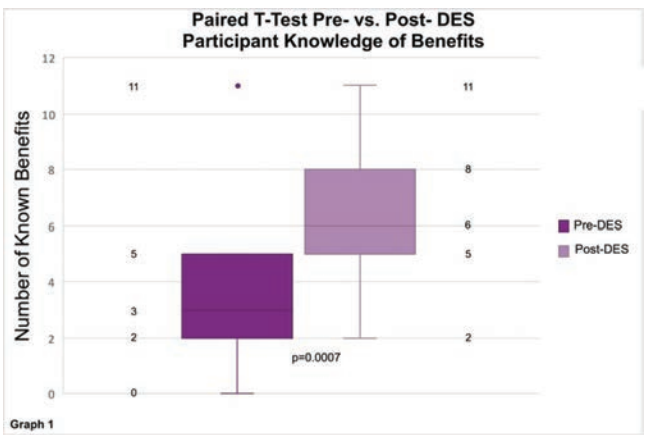
4:00 PM - 6:00 PM

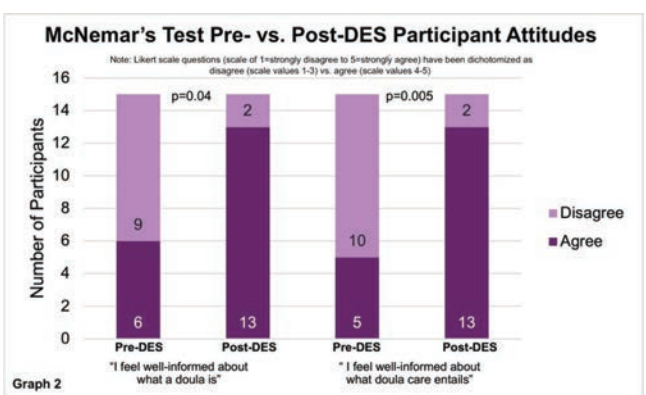
Objective: ACOG and CDC endorse doula use as an evidence-based practice to narrow disparities in Black maternal health outcomes. Despite their benefit, doulas remain underutilized, particularly in Black birthing experiences. Our objective is to assess baseline doula awareness, knowledge, and utilization among Black birthing people and evaluate changes in their attitudes toward integrating doulas into obstetric spaces following an education initiative.

Study Design: During a Black maternal health community initiative, three Black doulas led 15-minute education sessions with small groups. Surveys were given to assess participant knowledge and awareness of doula care, pre- and post-doula education sessions (pre-DES and post-DES). Inclusion criteria were Black participants of reproductive age. Data were analyzed using paired t-tests and McNemar's tests; p-values < 0.05 were considered significant.

Results: Fifteen participants met criteria. All reported no previous doula use or physician-dispensed doula education. Pre-DES, 40% felt well-informed about doulas, compared to 87% post-DES, p = 0.04. Participants knew an average of 4.1 doula health benefits pre-DES and 6.5 benefits post-DES, p = 0.0007 (Graph 1). This mirrors the 54% increase in people who felt more well-informed about what doula care entails post-DES, p = 0.005 (Graph 2). There was no significant difference in number of cited barriers to doula use pre- vs. post-DES, p = 0.31, but the main barrier changed from not knowing how to access doulas (N = 7) to lacking doula insurance coverage (N = 9). Lastly, 87% indicated intent to use doulas in the future.

Conclusion: While baseline knowledge of doula health benefits was high, DES still increased participant knowledge and intent to use doulas in future pregnancies. However, their utilization barriers reveal that increasing doula use among Black birthing people will require an equity framework for better integration of doulas into our health system. Reform is needed in medical trainee education on doula care and patient resourcing, health policy, and legislation for equitable doula insurance coverage and reimbursement.





664 | Variations in MFM Fellowship Clinical Competency through Curriculum Requirements Surpassing ACGME/ABOG Minimums by Geographic Region

Zenobia Gonsalves[1]; Rachel Lee[2]; Chaitali Korgaonkar-Cherala[3]; Kimberly Herrera[4]; Cassandra Heiselman[1]
[1]Stony Brook University Hospital, Stony Brook, NY; [2]Stony Brook University Hospital, Lake Grove, NY; [3]Stony Brook University

Hospital, Stonybrook, NY; [4]Stony Brook University, Stony Brook, NY

4:00 PM - 6:00 PM

Objective: To evaluate curricular differences across geographic regions for fellowship programs by assessing the variations in the distribution of specific types of rotations above the minimum core MFM requirements as defined by ACGME and ABOG.

Study Design: This was a cross-sectional analysis of MFM fellowship curricula conducted in July 2024 for the 109 ACGME-accredited programs. All fellowship program websites were evaluated for rotation schedules. If not available online, programs were contacted via email. The total number of mandated months by rotation for each program were tallied across the three years of fellowship: supervisory L&D (min: 2 mo), inpatient/antepartum service (no minimum), outpatient MFM clinic (min: 2 mo), ultrasound (min: 3 mo), genetics/genomics (min: 2 mo), research (min: 12 mo), electives, and program-specific mandated rotations. For each rotation, the percentage of programs that exceeded ACGME/ABOG minimum duration requirements were compared across geographic regions (Northeast, Midwest, South, and West). Chi-square and Fisher's exact analyses were performed with a p-value < 0.05.

Results: Rotation schedules were available for 64 (59%) of programs. The percentage of total programs that exceeded minimums were 87% for outpatient, 83% for ultrasound, 31% for research, 28% for labor and delivery, and 12% for genetics. When comparing the percentage of programs surpassing minimums by geographic region, only ultrasound requirements differed across regions (Figure 1), specifically 100% of Northeast programs exceeded ultrasound requirements versus 44% in the South ($p = 0.006$). Twenty programs (31%) specified requirements for non-OB, non-ACGME/ABOG rotations, most frequently NICU, anesthesia, and pathology (Table 1). Of these programs, anesthesia was more frequently required in the South ($p = 0.013$). 100% of programs offered flexible elective time.

Conclusion: While there are curricular differences among individual MFM fellowship programs, variability above minimum requirements was only noted for ultrasound and non-obstetric rotations across geographic regions.

Figure 1: Clinical Competency through Curriculum Requirements Surpassing ACGME/ABOG Minimums by Geographic Region

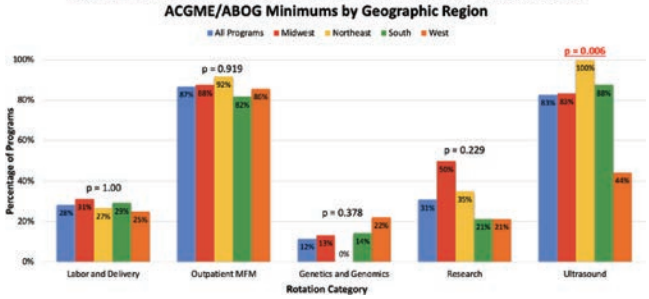


Table 1: Clinical Competency through Program-Specific Mandated Rotations by Geographic Region

Rotation	All Programs	Midwest	Northeast	South	West	p value
Program-Specific Mandated Rotations	20 (53%)	5 (50%)	3 (30%)	9 (64%)	3 (75%)	0.322
Anesthesia	6 (50%)	0 (0%)	1 (50%)	4 (100%)	1 (50%)	0.013
NICU	10 (83%)	2 (50%)	2 (100%)	4 (100%)	2 (100%)	0.273
Pathology	3 (25%)	0 (0%)	1 (50%)	1 (25%)	1 (50%)	0.491
Other Required Rotations	5 (42%)	2 (50%)	0 (0%)	2 (50%)	1 (50%)	0.758

Data are represented as n (%)

665 | Developing Core Endpoints with Stakeholders for Perinatal Clinical Trials

Zoe Butters[1]; Jannik Aagerup[2]; Clare Whitehead[3]; Lene Seidler[2]
[1]Royal Women's Hospital, Melbourne, Victoria; [2]NHMRC Clinical Trials Centre, University of Sydney, Sydney, New South Wales; [3]Royal Women's Hospital, University of Melbourne, Melbourne, Victoria

4:00 PM - 6:00 PM

Objective: The use of core outcome sets (COS) in obstetric and perinatal clinical trials is essential to standardise trial reporting and allow evidence synthesis, but there has been limited assessment of how these outcomes were developed and how they can be used to compare endpoints in clinical trials. Identifying the outcomes that are most meaningful to patients, healthcare professionals and society and standardising their definitions will ensure trial endpoints can be reliably collected and allow results to more rapidly lead to changes in clinical practice.

Study Design: MEDLINE, Embase, PsycINFO, CINAHL and the COMET registry were systematically searched in September 2023. Two authors independently screened abstracts/full texts and performed data extraction. A third reviewer resolved conflicts. The characteristics of each COS, stakeholders and consensus methods were extracted. The development methodology quality was evaluated according to the COS-STAR statement.

Results: 789 studies were screened and 29 COS included. The top 5 reported obstetric outcomes were maternal mortality, patient satisfaction with intervention, adverse outcome of intervention, delivery mode, and breastfeeding at discharge. The top 5 neonatal outcomes were neonatal mortality, gestational age at birth, birthweight, congenital anomaly, and hypoxic ischaemic encephalopathy. Only 59% of COS demonstrated compliance with COS-STAR. 100% included clinician/expert stakeholders. 90% included patients or patient representative stakeholders, although the proportion varied between 4.1% to 81.6%. Standardised definitions and measurement tools are proposed for each of the top 10 outcomes.

Conclusion: We have identified a minimum COS with standardised definitions and measurement tools that can be included in perinatal trials in order to improve the quality of endpoint reporting and implementation. Future research will rank outcomes according to both clinician and patent preference, to develop an ordinal scale that improves trial efficiency and identification of clinically meaningful evidence.

666 | Diagnostic Performance of Three Methods of Fetal Growth Restriction Diagnosis

Abby R. Rubenstein[1]; Stephanie L. Pierce[1]; Morgan McDougal[1]; Jennifer Peck[1]; Erin Schone[1]; Angela Xing[1]; Matthew Harter[1]; Rachel Jillson[1]; Dakota St Pierre[1]; Rodney Edwards[2]
[1]University of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]University of Florida College of Medicine, Gainesville, FL

10:30 AM - 12:30 PM

Objective: Recent guidelines changed the diagnostic criteria for fetal growth restriction (FGR) from estimated fetal weight (EFW) < 10%ile alone to EFW and/or abdominal circumference (AC) < 10%ile. Prior studies suggested this change would not substantially affect the number of pregnancies diagnosed with FGR. This study compares 3 methods of FGR diagnosis.

Study Design: This retrospective cohort study classified three groups of women delivering at our institution based on timing of how we diagnosed FGR: Group 1 (7/1/17-6/30/18; EFW < 10%ile), Group 2 (4/1/20-3/31/21; EFW < 10%ile or EFW 10-19%ile and AC < 5%ile), and Group 3 (8/1/21-7/31/22; EFW and/or AC < 10%ile). Multifetal gestations and fetuses with major anomalies were excluded. Cases of neonatal small for gestational age (SGA) were also identified in each time period. The primary outcome was prevalence of FGR among all deliveries in each time period. Test performance characteristics of the three methods of FGR diagnosis for predicting SGA were evaluated.

Results: 320 pregnancies with FGR were identified (n = 44 Group 1, n = 96 Group 2, n = 180 Group 3). Maternal characteristics were similar between groups (Table 1). For groups 1, 2 and 3 respectively, the prevalence of FGR was 1.16%, 2.74% and 4.82% (p< 0.0001), and the prevalence of SGA was 3.39%, 4.44% and 4.53% (p = 0.02). Test performance characteristics of each approach are shown in Table 2.

Conclusion: Application of the newest diagnostic criteria for FGR resulted in a quadrupling of the rate of FGR diagnosis. Though the prevalence of FGR diagnosis with the newest criteria was similar to the prevalence of SGA, this approach identified less than half of neonates with SGA. Given this substantial increase in diagnoses, most of which are false positives, further investigation regarding resource utilization and neonatal outcomes is warranted.

Table 1. Maternal characteristics of deliveries with FGR diagnosis during three study time periods.

	Group 1 (n=44)	Group 2 (n=96)	Group 3 (n=180)	Total (n=320)	P-value
Maternal Age (years)	28.7 (6.2)	26.8 (6.5)	26.7 (6.3)	27.0 (6.4)	0.17
Body Mass Index (kg/m²)	29.5 (8.4)	29.5 (7.7)	29.2 (8.0)	29.4 (7.9)	0.96

667 | Resource Utilization and Neonatal Outcomes with Three Methods of Fetal Growth Restriction Diagnosis

Abby R. Rubenstein[1]; Stephanie L. Pierce[1]; Morgan McDougal[1]; Jennifer Peck[1]; Erin Schone[1]; Angela Xing[1]; Matthew Harter[1]; Rachel Jillson[1]; Dakota St Pierre[1]; Rodney Edwards[2]
[1]University of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]University of Florida College of Medicine, Gainesville, FL

10:30 AM - 12:30 PM

Objective: Fetal growth restriction (FGR) is a known cause of neonatal morbidity. Recent new guidelines changed the diagnostic criteria from estimated fetal weight (EFW) < 10%ile alone to EFW and/or abdominal circumference (AC) < 10%ile. Diagnosing and treating FGR is important to optimize fetal and neonatal outcomes, however does require increased antenatal surveillance. This study compares neonatal outcomes across 3 methods of FGR diagnosis.

Study Design: This secondary analysis of a retrospective cohort study classified three groups of women who delivered at our institution based on timing of how we diagnosed FGR: Group 1 (7/1/2017-6/30/2018; EFW < 10%ile), Group 2 (4/1/2020-3/31/2021; EFW < 10%ile or EFW 10-19%ile and AC < 5%ile), and Group 3 (8/1/2021-7/31/2022; EFW and/or AC < 10%ile). Inclusion criteria were FGR diagnosis and dating ultrasound (US) prior to 22 weeks. Multifetal gestations and fetuses with major anomalies were excluded. The primary outcome was a composite of neonatal complications. Continuous outcome variables were compared across the three groups using ANOVA. Categorical outcomes variables were compared using X^2. P-value < 0.05 was statistically significant.

Results: 320 pregnancies with FGR diagnosis were identified (n = 44 Group 1, n = 96 Group 2, n = 180 Group 3). Overall, gestational age at delivery was similar between groups (Table 1). Compared to Group 1, numbers of growth US and BPP were higher in Group 2 and highest in Group 3. The neonatal complications composite rate was 56.8% in Group 1, 45.8% in Group 2, and 37.2% in Group 3 (p = 0.046; Table 2). NICU admission rate was 54.6% in Group 1, 41.1% in Group 2, and 34.1% in Group 3 (p = 0.04).

Conclusion: The newest method of FGR diagnosis resulted in the highest numbers of prenatal growth US and BPP. The composite complication rate for neonates with prenatal FGR diagnosis was lower during the time period using the new FGR criteria, however this may be due to the inclusion of neonates with less severe FGR and/or absence of SGA. Further investigation is needed into whether broader definitions of FGR result in improved neonatal outcomes.

668 | Wernicke'S Encephalopathy in Pregnancy: a Systematic Review of Pregnancy and Neonatal Outcomes

Abirami Kirubarajan[1]; Julia Hollingsworth[1]; Misgav Rottenstreich[1]; Katherine Steckham[1]; Conor Cox[1]; Bryon DeFrance[2]; Jon F. Barrett[2]; Eran Ashwal[2]
[1]McMaster University, Hamilton, ON; [2]McMaster university, Hamilton, ON

10:30 AM - 12:30 PM

Objective: To assess and report pregnancy and neonatal outcomes related to Wernicke's encephalopathy in pregnancy.

Study Design: We conducted a systematic review of six databases (MEDLINE, EMBASE, Emcare, the Cochrane Library, Web of Science: Core Collection, and Scopus). Articles from January 1st, 2000 until June 1st, 2024 were included.

We included original observational articles that reported neonatal or fetal outcomes following a diagnosis of Wernicke's encephalopathy in the context of a live intrauterine pregnancy. Descriptive statistics were used to aggregate results, as well as a nonparametric chi-square test and ANOVA. The Oxford Center of Evidence-Based Medicine grading tool was used to assess quality of evidence

Results: After screening 1005 references, a total of 65 studies encompassing 88 patients were eligible for analysis, all of which were case series or case reports. The mean gestational age of Wernicke's diagnosis was 16 ± 4.4 weeks. The majority of patients (55/88, 62.5%) had a live delivery, with 35 (63.6%) being reported as term delivery. Mean birthweight was 2523.64 grams. A total of 29 (32.9%) patients experienced pregnancy loss, with the majority (22/29, 75.9%) occurring before 20 weeks of gestation. Pregnancy loss was significantly associated with severe Wernicke's disease (p = 0.006), as well as delayed diagnosis (p = 0.02). A total of 40 studies reported the mode of delivery, with 22 (55%) involving Cesarean deliveries and 18 (45%) involving vaginal deliveries. There was limited data available regarding neonatal outcomes, especially regarding long-term follow-up. Among the 54 live births, 35 (64.8%) were described simply

as “healthy” or “eutrophic”. Seven cases specifically noted no neonatal neurological concerns at birth.

Conclusion: Although evidence regarding Wernicke’s encephalopathy in pregnancy is limited, it is crucial to counsel patients about the increased risk of pregnancy loss associated with severe Wernicke’s disease. Prompt diagnosis and treatment are essential, as delayed diagnosis is also more likely to result in pregnancy loss.

669 | Evaluating the Impact of a Novel Shared Medical Appointment Model for Gestational Diabetes Care

Adina R. Kern-Goldberger[1]; Easha Patel[2]; Maeve Hopkins[2]; Cara D. Dolin[2]; Stacey Ehrenberg[2]
[1]*Cleveland Clinic Lerner College of Medicine, Cleveland, OH;*
[2]*Cleveland Clinic Foundation, Cleveland, OH*

10:30 AM - 12:30 PM

Objective: Optimizing care delivery for gestational diabetes (GDM) has the potential to improve maternal and fetal/neonatal outcomes. The Shared Medical Appointment (SMA) has emerged as a novel tool to improve access as well as patient engagement and satisfaction by providing group care for patients sharing a common diagnosis. This study evaluated the impact of introducing an SMA model for GDM care.

Study Design: This a retrospective cohort study with a pre/post design at 2 hospitals in a single health system. All patients with a diagnosis of GDM who delivered >20 weeks from 1/1/2018-12/31/2022 were included. The SMA model was initiated 1/1/2021 with 8 patient slots/week, capturing 45% of the GDM patient population. Prior to this, all patients with GDM had traditional MFM consults. Patient demographic and clinical data were compared before and after initiation of the SMA. The primary outcome was a composite of GDM-related adverse obstetric outcomes including fetal demise, macrosomia (> 4000g), NTSV cesarean delivery, and NICU admission. Multivariable logistic regression evaluated the primary outcome before and after instituting the GDM SMA. Yearly incidence of the primary outcome was evaluated for the entire obstetric population during this period to assess for a secular trend.

Results: 2,309 patients with GDM were included (4.8% of all delivered patients during the study period) with 821 cases of the primary outcome (35.6%). Patient characteristics pre/post introduction of the SMA are depicted in Table 1. Significant differences were noted in maternal age and OBCMI (higher post-SMA) and nulliparity and pregravid BMI (higher pre-SMA). On adjusted analysis, there was a lower adjusted odds ratio (aOR) for the primary outcome (0.826, 95% CI 0.685-0.995, p = 0.044) with the SMA, driven by decreased odds of NICU admission (Table 2). There was no evidence of a secular trend in the primary outcome.

Conclusion: Innovations in care delivery for pregnancy complications like GDM have potential to improve obstetric outcomes. Further research can clarify implementation strategies and generalizability of this approach.

Table 1. Patient Characteristics Pre- and Post-Introduction of the SMA Model for GDM Care

	Pre-SMA *N = 1,373*	Post-SMA *N = 936*	P-value

670 | Predictors of Successful Induction of Labor in Patients with Class 3 Obesity

Adina R. Kern-Goldberger[1]; Easha Patel[2]; Kirat Sandhu[2]; Stacey Ehrenberg[2]; Cara D. Dolin[2]; Maeve Hopkins[2]
[1]*Cleveland Clinic Lerner College of Medicine, Cleveland, OH;*
[2]*Cleveland Clinic Foundation, Cleveland, OH*

10:30 AM - 12:30 PM

Objective: Maternal obesity is a known risk factor for cesarean delivery, but risk may be differential based on obesity severity. This study explores predictors of successful vaginal delivery in patients with class 3 obesity undergoing induction of labor.

Study Design: This is a retrospective cohort study of singleton deliveries with BMI $\geq$ 40 following induction of labor $\geq$ 20 weeks at a multi-hospital academic health system from 1/1/2022-6/30/2024. Patients with prior cesarean were excluded. The primary outcome was vaginal delivery. Patient clinical data were extracted from the medical record and demographics, clinical risk factors, and outcomes were compared in univariable analyses by mode of delivery. Based on identified significance in these analyses, a multivariable logistic regression model was utilized to evaluate the impact of potential predictors on adjusted likelihood of vaginal delivery.

Results: 610 total patients were included, 457 of whom delivered vaginally (74.9%). Patients who delivered vaginally had lower pregravid BMI (43.6 v. 44.5, p = 0.01) and lower delivery BMI (46.3 v. 49.4, p < 0.01) [Table 1]. Patients with Medicaid compared to commercial insurance were more likely to delivery vaginally, as were patients who were not nulliparous, did not require cervical ripening at induction, and did not have severe preeclampsia. Patients who delivered by cesarean had higher rates of NICU admission and extended postpartum length of stay, as well as blood loss. Nulliparity was identified as the most significant negative predictor of vaginal delivery on adjusted analysis (aOR 0.01, 95% CI 0.06-0.18, p < 0.01) [Table 2]. Other significant

negative predictors were higher delivery BMI, cervical ripening, and chronic hypertension.

Conclusion: Nulliparous patients with class 3 obesity who require cervical ripening have significantly lower odds of vaginal delivery. These data can help guide counseling and physician decision making surrounding optimizing induction of labor for this patient group.

Table 1. Demographics, Clinical Characteristics, and Obstetric Outcomes by Mode of Delivery among Singleton Pregnancies with Class 3 Obesity undergoing Induction of Labor

	Cesarean Delivery N = 153	Vaginal Delivery N = 457	P-value

671 | Neonatal Outcomes in Fetuses with Resolved Growth Restriction

Aleksandra Polic; Trey McGonigle; Shi Huang; Catherine Phillips; Matthew Grace
Vanderbilt University Medical Center, Nashville, TN

10:30 AM - 12:30 PM

Objective: Fetal growth restriction (FGR) is associated with neonatal morbidity and mortality, but 17% of fetuses with FGR will return to normal growth prior to delivery (resolved FGR, rFGR). Neonatal outcomes of this group have not been studied, and insufficient data exist to guide management. The aim of this study was to compare neonatal outcomes of pregnancies complicated by rFGR to pregnancies with no history of FGR.

Study Design: This was a retrospective cohort study of live, term singleton deliveries without known or suspected structural or genetic abnormalities from 2018-2023 at a tertiary medical center. The exposed cohort had an ultrasound diagnosis of FGR (either by AC or EFW < 10th percentile) followed by resolution of FGR on a subsequent ultrasound preceding delivery. Maternal demographics, clinical characteristics and delivery outcomes were compared by FGR status (no FGR, FGR and rFGR) at the time of delivery. We fit separate logistic regression models to estimate the association between rFGR and NICU admission, hypoxic ischemic encephalopathy (HIE), and neonatal death, adjusting for confounders. Birth weight, length of hospital stay, and APGAR scores were modeled using linear and proportional odds ordinal regression models.

Results: A total of 11,957 pregnancies were analyzed, of which 393 were complicated by rFGR. No differences were observed between rFGR and no FGR patients in rates of hypertensive disorders, diabetes, gestational age at delivery, or mode of delivery (Table 1). Compared to no FGR, birth weights in the rFGR cohort were lower by 366g (95% CI -422.37, -310.39; p< 0.001). No other significant effects of rFGR were observed in any of the neonatal outcomes assessed (Table 2). Although not statistically significant, the direction of the effect suggests that neonates with rFGR (vs. no FGR) may have increased odds of NICU admission, HIE, neonatal death, and longer duration of hospital stay.

Conclusion: When compared to pregnancies not complicated by FGR, the diagnosis of rFGR did not increase the risk of adverse neonatal outcomes in this cohort.

Table 1: Descriptive Statistics

	No history of FGR[1] (N = 10,873)	FGR (N = 691)	Resolved FGR (N = 393)	*p* value (all 3 groups)	*p* value (no FGR vs FGR)

672 | Mid-Trimester Rupture of the Membranes:Irish Perspective from a Tertiary Unit Following Liberalisation of Top Legislation

Alex K L Taylor[1]; Ruta Petkute[2]; Hayley Jackson[2]; Sorcha Lynch[2]; Silvia Carlotta Rosalia[3]; Jack Diviney[4]; Gillian Corbett[5]; Helena C. Bartels[6]; Siobhan Corcoran[7]
[1]Royal College of Physicians Ireland, National Maternity Hospital, Dublin; [2]National Maternity Hospital, National Maternity Hospital, Dublin; [3]University of Insubria, Varese, Lombardia; [4]Royal College of Surgeons in Ireland, Dublin, Dublin; [5]UCD Perinatal Research Centre, Dublin, Dublin; [6]University College Dublin, University College Dublin, Dublin; [7]National Maternity Hospital, Dublin, Dublin

10:30 AM - 12:30 PM

Objective: Midtrimester pre-mature pre-labour rupture of membranes(MTPPROM) between 14+0-23+6 gestation age(GA) is a rare complication of pregnancy associated with poor maternal and fetal outcomes. This study measures outcomes between 2018-2024 at a tertiary referral centre in Ireland with approximately 7000 deliveries per annum. Since the Health (Regulation of Termination of Pregnancy (TOP)) Act, 2018, parents can opt to TOP after 12+GA where there is a risk to the "life or health" of the woman or where the fetus is "likely to die within 28 days of life".This legislative change means that accurate data is critical for counselling families. Our objective is to describe the outcomes following MTPPROM and compare to a similar study conducted prior to liberalisation of the TOP legislation.

Study Design: Retrospective cohort study of consecutive MTPPROM January 2018 to February 2024.

Results: 109 patients met inclusion criteria, at a prevalence rate of 0.2%. The median maternal age was 33 and median GA at MTPPROM was 21+0, with an median latency period of 7 days(IQR 26 days, range 0-147 days). 77% experienced maternal morbidity, with no maternal mortalities. The neonatal survival to discharge (NSTD) was 27.5%. Outcomes are compared to the publication by Linehan et al. paper(Table 1) prior to the Health Act 2018 showing a 5% NSTD rate. MTPPROM between 14+0-19+6 had a lower NSTD compared to those over 20+ GA(10%vs41%, p value = 0.0003). These cases also had a higher rate of MROP(30%vs13%, p value = 0.02). Anhydramnios was associated with 0% NSTD. Singleton pregnancies with oligohydramnios had a lower NSTD compared to those with normal liquor volume(21%vs51%, p value = 0.007). 90% of the patients who opted for TOP had a deepest vertical pool of less than 2cm and had a higher rate of chorioamnionitis(34%vs73%, p value = 0.01) (Table 2).

Conclusion: While NSTD is higher for patients with normal liquor volume and PPROM over 20+ GA, mortality and morbidity still continues to be high. The majority of patients who opted for TOP were diagnosed with chorioamnionitis and oligohydramnios reflecting a higher NSTD percentage post legislation.

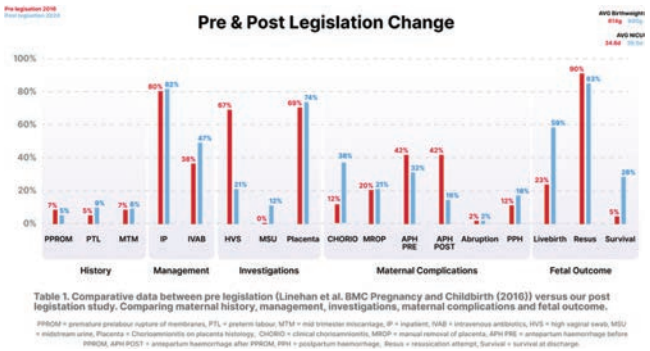

Table 1. Comparative data between pre legislation (Linehan et al. BMC Pregnancy and Childbirth (2016)) versus our post legislation study. Comparing maternal history, management, investigations, maternal complications and fetal outcome.

PPROM = premature prelabour rupture of membranes, PTL = preterm labour, MTM = mid trimester miscarriage, IP = inpatient, IVAB = intravenous antibiotics, HVS = high vaginal swab, MSU = midstream urine, Placenta = Chorioamnionitis on placenta histology, CHORIO = clinical chorioamnionitis, MROP = manual removal of placenta, APH PRE = antepartum haemorrhage before PPROM, APH POST = antepartum haemorrhage after PPROM, PPH = postpartum haemorrhage, Resus = resuscitation attempt, Survival = survival at discharge.

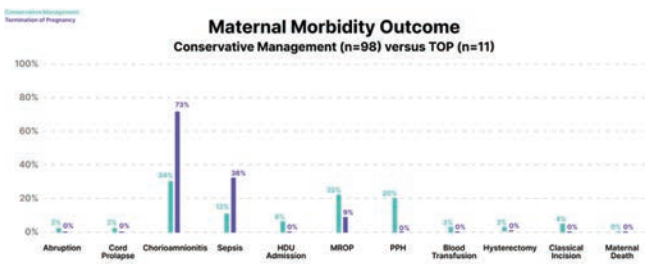

Table 2. Comparative data of maternal morbidities between patients who opted for termination of pregnancy versus conservative management.

TOP = Termination of Pregnancy, HDU = High Dependency Unit, MROP = Manual Removal of Placenta, PPH = Postpartum haemorrhage over 500ml

673 | Mechanical Cervical Ripening Among Patients with a Bmi Greater Than 30

Alexander M. Saucedo[1]; Miriam Alvarez[2]; Alison G. Cahill[3]; Lorie M. Harper[2]
[1]Baylor College of Medicine, Houston, TX; [2]Dell Medical School, Austin, TX; [3]Dell Medical School Health Transformation Research Institute, Dell Medical School, The University of Texas at Austin, Austin, TX

10:30 AM - 12:30 PM

Objective: Patients with obesity undergoing induction of labor (IOL) are at an increased risk for a prolonged labor duration. The efficacy of a combination of a cervical ripening balloon (CRB) plus vaginal misoprostol (VM) in this population is not well described. We aimed to determine the effect of CRB + VM versus VM alone on time from IOL to delivery in patients with obesity.

Study Design: Secondary analysis of a single center, double-blinded RCT between 6/2022 and 7/2023, which randomized near-term, singleton gestations with a BMI $\geq$ 30 kg/m^2 undergoing IOL, with a cervical dilation $\leq$ 3cm, to either 25mcg or 50mcg of VM. For this analysis, we included only those patients from the primary study who received a CRB +VM upon induction initiation and compared them to those patients receiving only VM. The primary outcome was time from induction initiation to delivery. Multivariable linear regression was used for the primary outcome with adjustments made for randomization group, nulliparity, and cervical dilation on admission.

Results: This secondary analysis included 125 participants: 55 (44%) receiving CRB + VM versus 70 (56%) receiving VM alone. Baseline characteristics were similar, however those with a CRB were younger (26.2 years vs. 29.1 years; p = 0.03) and with fewer Hispanic patients (69.1% vs. 82.9%; p = 0.04). 65 (52%) patients received the 50mcg dose versus 60 (48%) received the 25mcg dose which was used as a covariate in our final model. Following adjustment, patients with a CRB+VM had a reduced time to

delivery (14.7 hrs vs. 17.7 hrs; p = 0.02) and reduced time to active labor (11.8 hrs vs. 14.6 hrs; p = 0.02). No differences in cesarean delivery or adverse maternal/neonatal outcomes were seen.

Conclusion: In patients with obesity undergoing IOL, a combination of CRB+VM reduced time to delivery and active labor by an average of 3 hours. Given this population's increased risk for prolonged delivery times and perinatal morbidity, a combination of mechanical dilation with misoprostol administration should be considered.

674 | Factors Related to Patient Participation in an Obstetric Clinical Trial

Alexander M. Saucedo[1]; Miriam Alvarez[2]; Alison G. Cahill[3]; Lorie M. Harper[2]

[1]Baylor College of Medicine, Houston, TX; [2]Dell Medical School, Austin, TX; [3]Dell Medical School Health Transformation Research Institute, Dell Medical School, The University of Texas at Austin, Austin, TX

10:30 AM - 12:30 PM

Objective: Factors related to patient participation in an obstetric clinical trial have not been well described in literature which is vital towards appropriate study design. We aimed to determine factors which may influence participation in an obstetric clinical trial.

Study Design: Cross-sectional survey of persons eligible for a single center, double-blinded, labor induction RCT between 6/2022 and 7/2023. Prior to trial enrollment, we administered a 15-question validated survey which assessed both motivation and barrier factors on a scale from 0 (no influence) to 4 (most influence). Patients were excluded if they voluntarily declined the survey. Comparisons were made between those participating in the trial versus those that declined. The primary outcomes were mean scores obtained in each of the four subset of questions (motivations and barriers). Secondarily, we analyzed differences in these subsets between self-reported ethnicity. Multivariable linear regression was used for all outcomes.

Results: A total of 273 eligible patients were approached for the trial with 180 participating and 93 declining. There were 73 survey respondents with 60 (82.2%) participating in the trial versus 13 (17.8%) declining. Individual questions of the motivation/barrier scales all reached an acceptable level of agreement with Cronbach's alpha scores all > 0.7. Patients who declined the trial expressed less overall influence (0.96 vs. 1.99; p< 0.01) and lower influence by either barriers (p< 0.01) or motivating factors (p = 0.03). Hispanic patients expressed increased influence by motivation 2 questions, such as concordant provider language (1.84 vs. 0.67; p< 0.01) in addition to experiencing an increased impact to barrier 1 and 2 questions, such as family and religious concern (p< 0.05).

Conclusion: Patients who declined trial participation had lower motivating and barrier factors which may be due to overall disinterest in research participation. However, Hispanic patients had an increased desire to participate when there was concordant race/ethnicity, language, and sex with their providers.

Table 1. Reliability assessment for factors related to clinical trial participation scale

Group	*Survey Question*	*Mean*	*SD*	*Cronbach's alpha*
Overall	--	1.81	1.06	0.93
Motivation 1	My relationship with my doctor	2.51	1.56	0.86
	Doctor's reputation in the community	2.35	1.61	
	How well the research study was explained to me	2.83	1.40	
	Knowledge learned from my participation will benefit someone in the future	2.81	1.43	
Motivation 2	My desire to please the doctor	1.76	1.61	0.85
	The doctor conducting the research is the same gender (sex) as me	1.24	1.69	
	The doctor conducting the research is the same race/ethnicity as me	0.97	1.44	
	The doctor conducting the research speaks the same language as I do	1.57	1.62	
Barrier 1	Time commitment	2.15	1.47	0.80
	No follow-up visits related to the study	2.09	1.54	
	Risk of unknown side effects to myself or my baby	2.07	1.47

675 | Deepest Vertical Pocket with Reflex Amniotic Fluid Index as a Screening Approach for Polyhydramnios

Alexandra JD Phelps[1]; Amelie Pham[1]; Niharika Ravichandran[1]; Matthew Grace[1]; Trey McGonigle[1]; Shi Huang[1]; Aleksandra Polic[1]; Catherine Phillips[1]; Lisa C. Zuckerwise[2]

[1]Vanderbilt University Medical Center, Nashville, TN; [2]University of Virginia Health, Charlottesville, VA

10:30 AM - 12:30 PM

Objective: To describe concordance between amniotic fluid index (AFI) and deepest vertical pocket (DVP) in the assessment of amniotic fluid volume and to determine the utility of using DVP alone as a screening test for clinically significant polyhydramnios.

Study Design: We performed a retrospective cohort study of all outpatient ultrasounds (US) performed at 20.0-41.6 weeks gestation at an academic institution from 2018-2022. Measurements from the US most proximate to delivery were used to analyze the occurrence of polyhydramnios, defined by DVP (≥ 8cm) or AFI (≥ 24cm). We classified severity using accepted definitions by each methodology. Tests of diagnostic performance were calculated using AFI as the accepted gold standard. Pearson correlation coefficient was calculated to describe the relationship between DVP and AFI.

Results: Measurements from 11,688 US met inclusion criteria. Polyhydramnios was diagnosed in 739 (6.3%) US using AFI and 875 (7.5%) using DVP. Using DVP of ≥ 8cm as a cutoff identified all cases of moderate or severe polyhydramnios by AFI (Table). However, it also indicated polyhydramnios in 337 cases where AFI was normal, a false positive rate of 3.1%. Of 193 patients with moderate or severe polyhydramnios by AFI, 171 (88.6%) were misclassified as mild by DVP. Using DVP as a screening tool to identify moderate or severe polyhydramnios yielded sensitivity of 100% (95% CI 98.1-100%), specificity of 94.1% (95% CI 93.6-94.5%), positive predictive value of 53.1% (95% CI 51.3-54.9%), and negative predictive value of 100% (95% CI 99.9-100%). DVP and AFI were highly correlated (Figure, $r = 0.84$, $p < 0.01$).

Conclusion: Using DVP as a screening tool, with reflex measurement of AFI if DVP is ≥ 8cm, is predicted to identify all cases of moderate or severe polyhydramnios and reduce over-diagnosis of mild polyhydramnios both in cases of normal AFI and in those with more significant polyhydramnios.

Table: Diagnosis of polyhydramnios by DVP and AFI

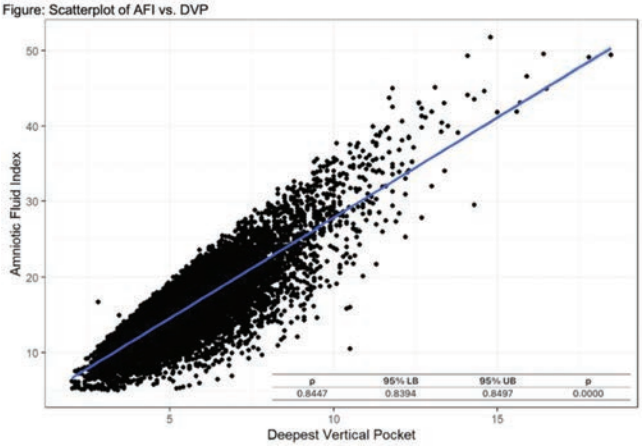
			DVP[2]				
				Polyhydramnios[4]			
			Normal	Mild	Moderate	Severe	Any (n=875)
AFI[1]	Polyhydramnios[3]	Normal	10,612	337	0	0	337
		Mild	201	344	1	0	345
		Moderate	0	122	2	0	124
		Severe	0	49	16	4	69
		Any (n=739)	201	515	19	4	

[1]AFI=amniotic fluid index | [2]DVP=deepest vertical pocket

[3]Polyhydramnios severity by AFI was classified as: mild ≥24cm and <30cm, moderate ≥30cm and <35cm, and severe ≥35cm

[4]Polyhydramnios severity by DVP was classified as: mild ≥8 and <13cm, moderate ≥13cm and <16cm, and severe ≥16cm

Figure: Scatterplot of AFI vs. DVP



676 | Self-Perception of Pregnancy Risk and Contraceptive Safety Among Women with Cardiac Disease

Alisa M. Goldrich[1]; Jamie Woodley[2]; Margaret English[2]; Hindi Stohl, JD[3]

[1]University of California Davis Medical Center, University of California Davis Medical Center, CA; [2]Harbor UCLA Medical Center, Harbor UCLA Medical Center, CA; [3]UCLA David Geffen School of Medicine Harbor-UCLA Medical Center, Los Angeles, CA

10:30 AM - 12:30 PM

Objective: To assess perceived safety of contraceptive use and pregnancy among women with cardiac disease in a public hospital setting.

Study Design: Women ages 18-45 with cardiac disease were recruited from the adult congenital cardiac disease or high risk obstetrics clinic at Harbor-UCLA Medical Center from June 2018 - September 2019. A cross-sectional survey was administered regarding contraception use, pregnancy history, and perceptions of risk associated with pregnancy in the context of their cardiac condition. Participants were stratified by WHO Classification (Class 1/2 versus Class 3/4) and tested for differences using Wilcoxon Rank Sum tests for numeric variables and Fisher's Exact tests for categorical variables.

Results: 42 participants completed the survey: 31 with Class 1/2 disease (73.8%) and 11 with Class 3/4 disease (26.2%). 72.7% of participants with WHO Class 3/4 disease, as well as 61.3% of Class 1/2 participants perceived pregnancy as "Dangerous" or "Very Dangerous". All (100%) of Class 3/4 group and 87% of Class 1/2 group reported oral contraceptives, regardless of hormone type, as "not safe" or "unsure" about safety. For non-pill, progesterone-only methods, most participants, regardless of WHO Class, regarded these as "not safe" or "unsure" (DMPA 80.5%, Nexplanon 85.4%, LNG IUD 75%).

Conclusion: High risk cardiac participants accurately recognize pregnancy as dangerous in the context of their disease; however, they are uncertain of safe methods of preventing pregnancy. Low-risk cardiac patients also perceive pregnancy as dangerous, even though their risk is not significantly different from the general population. The majority of participants with cardiac disease perceive hormonal birth control to be unsafe regardless of disease severity or hormone type. This study highlights the need for improved patient education to increase utilization of effective methods of contraception in this high-risk patient population.

677 | Antenatal Mood Disorders in Placenta Accreta Spectrum

Alison M. Asirwatham[1]; Lindsay Issokson[2]; Hannah Caldwell[2]; Gianna L. Wilkie[2]; Anna R. Whelan[3]
[1]UMass Chan Medical School, Worcester, MA; [2]University of Massachusetts Chan Medical School, Worcester, MA; [3]University of Massachusetts Chan School of Medicine, Worcester, MA

10:30 AM - 12:30 PM

Objective: Placenta Accreta Spectrum (PAS) is a disorder of abnormal invasion of the placenta into or through the myometrium typically treated by cesarean hysterectomy and is associated with increased morbidity and mortality. PAS is associated with increased risks of postpartum mood disorders, but no studies have directly explored antenatal mood disorders in patients with PAS. We aimed to assess antenatal rates of depression and anxiety in those with PAS compared to those with a diagnosis of placenta previa and all pregnancies without these placental diagnoses.

Study Design: We performed a retrospective cohort study using data from the EpicCosmos dataset which combines information from >1500 hospitals and >260 million patients. We queried all pregnancies between 7/1/2015-7/1/2024. We identified those with a diagnosis of placenta accreta, increta, percreta, or placenta previa during pregnancy as well as new diagnoses of depression or anxiety during pregnancy using ICD-10 codes. Demographic and mood disorder data was compared between groups using chi-square for categorical variables and ANOVA for continuous variables.

Results: In our cohort, we identified 13,944 patients with PAS, 315,756 patients with placenta previa, and 8,153,662 other pregnancies. Mean maternal age was older in those with PAS (37 +/-6years). Placenta previa had a significantly higher association with antenatal diagnosis of depression (12.1%) and anxiety (18.2%) compared to both PAS (9.9% and 14.5%) and all other pregnancies (9.5% and 13.6%). PAS had non-significantly increased rates of depression, but significantly increased rates of anxiety compared to all other pregnancies (14.5% vs 13.6%). There were no differences between the subgroups of PAS.

Conclusion: In our large cohort, placenta previa was associated with higher rates of depression and anxiety. PAS was associated with higher rates of anxiety compared to all other pregnancies. Given these findings, further investigations focused on how to best screen for perinatal mood disorders and support those affected by placental conditions requiring surgical delivery is needed.

[4]University of California- Irvine, Irvine, CA; [5]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [6]University of Utah, Salt Lake City, UT; [7]Northwestern, Northwestern/Chicago, IL; [8]Cedars-Sinai Medical Center, Los Angeles, CA; [9]NIH/NHLBI, Bethesda, MD; [10]The Ohio State University, Columbus, OH; [11]The Ohio State University College of Nursing, Columbus, OH; [12]Magee-Womens Hospital, Pittsburgh, PA

10:30 AM - 12:30 PM

Objective: We sought to assess whether the timing of onset of a hypertensive disorder of pregnancy (HDP) was related to the risk of incident hypertension 2-7 years after delivery.

Study Design: This is a secondary analysis of the NuMoM2b-Heart Health Study (NuMoM2b-HHS), a multi-site cohort that enrolled nulliparous pregnant individuals in their first trimester who were followed during pregnancy and subsequently underwent a cardiovascular screening visit at 2-7 years after delivery. For this analysis, we excluded individuals with pre-pregnancy chronic hypertension. We compared rates of hypertension (blood pressure ≥130/80 mmHg or use of anti-hypertensive medications) at the 2-7 year postpartum study visit based on timing of onset of HDP (categorized as antepartum, intrapartum, postpartum) versus no HDP (referent). Multivariable logistic regression models adjusted for baseline covariates (age, insurance, tobacco use, diabetes, and early pregnancy body mass index). Interaction analysis was performed to evaluate effect modification by the presence of severe features of HDP.

Results: Of 4,342 individuals included in this analysis, 23% had a HDP and underwent follow up at a mean of 3.2± 0.9 years after their first birth. Hypertension at follow up was more prevalent among those with antepartum (37.6%) or postpartum HDP (40.0%) compared to those with intrapartum HDP (26.0%) or no HDP pregnancies (16.5%). Compared to those with non-HDP pregnancies, those with HDP had higher odds of incident hypertension at follow up regardless of the timing of onset (Table). Findings were similar regardless of the presence of severe features (interaction p = 0.56).

Conclusion: Individuals with HDP, regardless of whether it is diagnosed antepartum, intrapartum or postpartum appear to have similarly increased odds of incident hypertension at 2-7 years postpartum, compared with individuals without HDP in their first birth.

Table 1. Characteristics in pregnancy and at 2-7 year follow up by timing of onset of hypertensive disorder of pregnancy (HDP).

679 | The Influence of Epidural Analgesia on Neonatal Outcomes After Balloon Induction of Labor at Term

Alla Saban[1]; Noa Leybovitz Haleluya[2]; Adi Y Y. Weintraub[3]; Reli Hershkovitz[4]; Maayan Elnir Katz[3]; Tamar Eshkoli[3]
[1]Soroka University Medical Center, Beer Sheva, HaDarom; [2]Soroka Medical Center, Meitar, HaDarom; [3]Soroka University Medical Center, Soroka University Medical Center, HaDarom; [4]Soroka medical center, Soroka medical center, HaDarom

10:30 AM - 12:30 PM

Objective: Epidural analgesia is commonly used for labor and delivery and is generally considered safe. However, it can affect the fetus either directly, through the placental transfer of local anesthetics or opioids, or indirectly, via maternal hypotension. Previous studies have largely focused on comparisons between epidural analgesia and systemic opioids regarding neonatal status. Balloon induction of labor has also become popular due to its minimal side effects. However, only a few studies have specifically addressed the influence of epidural analgesia in the context of balloon induction of labor. This study aims to investigate the association between the use of epidural analgesia following balloon induction of labor and the risk of neonatal adverse outcomes.

Study Design: A population-based retrospective cohort study was conducted, including all term (≥37 weeks of gestation) singleton pregnancies that underwent balloon induction of labor at a tertiary medical center between
February 2020 and January 2022. Neonatal adverse outcomes were compared based on the use of epidural analgesia during delivery.

Results: The study population included 3,424 deliveries, of which 2,400 (70.1%) used epidural anesthesia and 1,024 (29.9%) delivered without epidural. Neonatal adverse outcomes for both groups are shown in the table. Rates of neonatal adverse outcomes, including low Apgar scores, low cord pH, neonatal intensive care unit (NICU) admission, mortality, and a composite of adverse neonatal outcomes, were comparable between the groups. No significant differences were observed in these outcomes between the groups.

Conclusion: The use of epidural analgesia during delivery following balloon induction of labor at term is not associated with an increased risk of short-term neonatal adverse outcomes.

Table: *Adverse neonatal outcomes of women underwent balloon induction of labor with and without epidural analgesia*

Characteristics	Women with epidural analgesia n=2, 400 (%)	Women without epidural analgesia n=1,024 (%)	P
1-minute APGAR score ≤7	136 (5.7)	66 (6.4)	0.376

680 | The Association Between Timing of Tobacco Smoking Cessation and Fetal Growth Restriction

Allie Sakowicz[1]; Jordan Buzzett[1]; Reyna Segovia Molina[1]; Elizabeth Malone[1]; David M. Stamilio[2]
[1]*Wake Forest University School of Medicine, Winston-Salem, NC;*
[2]*Wake Forest University School of Medicine, Winston Salem, NC*

10:30 AM - 12:30 PM

Objective: Tobacco smoking is a leading cause of fetal growth restriction (FGR). Our objective was to estimate the association between timing of tobacco smoking cessation and FGR in a cohort of current or former smokers.

Study Design: This retrospective cohort study includes all pregnant patients who received prenatal care and delivered in a university health system, delivered a viable neonate between 4/1/22 and 3/31/23, and reported tobacco smoking either during pregnancy or within one year prior to conception. FGR was defined as estimated fetal weight (EFW) or abdominal circumference (AC) < 10% on the most recent ultrasound prior to delivery. Bivariable and multivariable logistic regression analyses were performed. Adjusted odds ratios (aOR) are reported.

Results: Of 343 patients included in this study (10.5% of the delivery cohort), 148 (43.2%) quit smoking in the year prior to conception or in the first trimester of pregnancy, 22 (6.1%) quit in the 2nd trimester, 16 (4.4%) quit in the 3rd trimester and 157 (43.6%) continued smoking. Compared to patients who quit smoking early, those who continued smoking beyond the 1st trimester were more likely to identify as Black or Other/unknown race and to be nulliparous. After controlling for confounders, patients who quit tobacco in the year prior to pregnancy or in the first trimester were significantly less likely to be diagnosed with FGR (aOR 0.48, 95% CI 0.24–0.96). Smoking cessation any time prior to delivery was also associated with reduced odds of FGR (aOR 0.46, 95% CI 0.23–0.89) but risk reduction from quitting in the 3rd trimester appeared attenuated.

Conclusion: Smoking cessation pre-pregnancy or in the first trimester is associated with a 52% reduction in FGR compared to continued smoking later in pregnancy. These findings can be used to direct counseling on the benefits of tobacco cessation as early as possible.

681 | The Relationship between Neighborhood Food Environment and Readmissions for Postpartum Hypertension and Cardiovascular Complications

Allison Kurzeja; Nicole Beckley; Lindsay Yeh; Sean Young; Donald D. McIntire; David B. Nelson
University of Texas Southwestern Medical Center, Dallas, TX

10:30 AM - 12:30 PM

Objective: Postpartum readmissions have negative consequences on patients and the healthcare system. Some of the most frequent etiologies for postpartum readmission are hypertensive and cardiovascular-related. Few studies have assessed the effects of social factors on postpartum readmissions. We aimed to determine whether the neighborhood food environment impacts the frequency of readmission for hypertensive and cardiovascular complications.

Study Design: A regional hospital dataset was queried for cardiovascular and hypertension-related readmissions in the postpartum period using ICD 9/10 codes. We looked at readmissions within 12 weeks of delivery for hypertension and 12 months for cardiovascular complications between 2014 and 2018. Each encounter included a patient's GEO-ID which allowed linkage to geospatial datasets. The neighborhood food environment was then assessed by measuring the density/distance to select business points-of-interest obtained from Data Axle. The Wilcoxon rank-sum test was used to compare the cohort of patients requiring readmission to those who did not. The effect size was then quantified by quantile regression estimating with 95% confidence the difference in medians.

Results: There were 443,578 deliveries in the study timeframe. Of these, 432,947 had associated Data Axle information available and were included in the study. 5,363 (1.2%) patients had a readmission for hypertension within 12 weeks. 2,165 (0.5%) patients had a cardiovascular readmission within 365 days. Patients who required hypertensive-related readmission were shown to have a significantly lower density of eating places within one kilometer ($p = < 0.001$). Similarly, individuals who required readmission for cardiovascular-related complications also had a lower density of eating places within one kilometer ($p = < 0.002$).

Conclusion: It is imperative to consider the interplay of social factors such as the neighborhood food environment on pregnancy outcomes. Differences in food density may impact patients' ability to access healthy foods, which may relate to subsequent increased readmissions and other health consequences.

682 | Postpartum Glycemic Trends Among People with Gestational Diabetes Using Continuous Glucose Monitoring

Alyssa R. Hersh[1]; Alexandra C. Gallagher[2]; Lucy Ward[1]; Christian Huertas-Pagán[1]; Monica Rincon[1]; Amy M. Valent[1]
[1]Oregon Health & Science University, Portland, OR; [2]Stanford University, Palo Alto, CA

10:30 AM - 12:30 PM

Objective: The immediate changes in glycemia following delivery have not been well characterized among pregnant people with gestational diabetes mellitus (GDM), particularly considering the heterogeneity of GDM. Therefore, we sought to characterize postpartum glycemia using continuous glucose monitoring (CGM) data and explore postpartum glycemic trends among people with GDM by GDM and delivery characteristics.

Study Design: This was a secondary analysis of pregnant people with GDM randomized to using CGM versus capillary blood glucose for management of GDM. Our primary outcome was mean glucose by hour from delivery through 48 hours after delivery. We stratified by GDM type, mode of delivery and time in range during pregnancy (≥90%, 70-140) to determine influence on glycemia postpartum.

Results: Of the 111 participants in the original analysis, 79 participants with postpartum data were included in this analysis, 22.8% with A1GDM and 77.2% with A2GDM. In the overall cohort, glucose values had a slight downward trend over the first 48 hours post-delivery (Figure 1a). Upon stratification, participants with A1GDM had lower glucose by 48 hours compared to those with A2GDM (Figure 1b), as did participants with high time-in-range compared with lower time-in-range during pregnancy (Figure 1c). After cesarean delivery, participants initially had lower glucose values compared to vaginal delivery, which then rose after the first 24 hours prior to returning to baseline by 48 hours (Figure 1d).

Conclusion: In this study, we found that postpartum glycemia had a downward trend after delivery and was impacted by multiple pregnancy and delivery characteristics. These results highlight the physiologic changes that are occurring in regard to glycemia during the postpartum period. Future studies should assess whether differences in postpartum glycemic parameters are associated with clinically relevant outcomes.

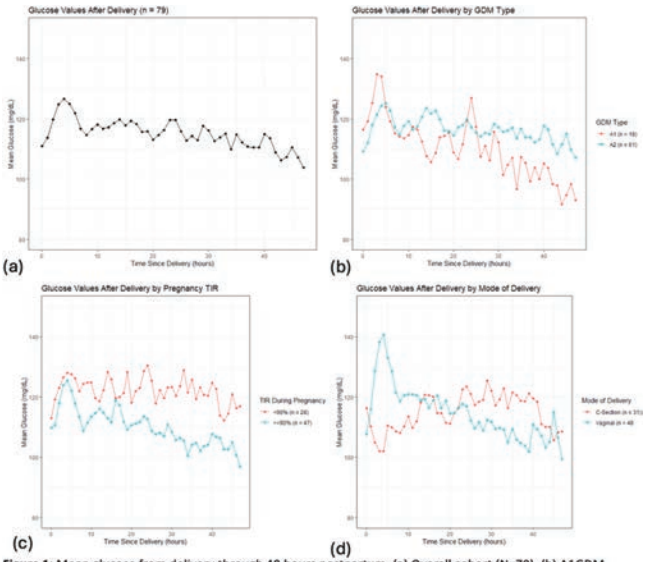

Figure 1: Mean glucose from delivery through 48 hours postpartum. (a) Overall cohort (N=79), (b) A1GDM (N=18) versus A2GDM (N=61), (c) TIR ≥90% (N=47) versus <90% (N=28), (d) vaginal (N=48) versus cesarean (N=31) birth
X axis: Time. Y-axis: Glucose (mg/dL) 0-48 hours. Time 0 represents delivery.

683 | Postpartum Glucose Tolerance Test Results Among People with Gestational Diabetes Using Continuous Glucose Monitoring

Alyssa R. Hersh[1]; Alexandra C. Gallagher[2]; Lucy Ward[1]; Christian Huertas-Pagán[1]; Monica Rincon[1]; Amy M. Valent[1]
[1]Oregon Health & Science University, Portland, OR; [2]Stanford University, Palo Alto, CA

10:30 AM - 12:30 PM

Objective: The glycemic profile of people with gestational diabetes mellitus (GDM) at the time of postpartum oral glucose tolerance testing (OGTT; 75 gram 2-hour challenge) is not well understood. Therefore, we assessed continuous glucose monitoring (CGM) data during the postpartum OGTT, stratifying by normal versus abnormal OGTT and GDM type.

Study Design: This was a secondary analysis of pregnant people with GDM randomized to using CGM versus capillary blood glucose (CBG) for management of GDM. Our primary outcome was mean glucose during an OGTT comparing people who had abnormal postpartum OGTT (fasting ≥100 mg/dL or 2-hour ≥140 mg/dL) compared to normal OGTT results. We performed additional stratified analyses of those by GDM type.

Results: Of the 111 participants in the initial trial, there were 51 that had postpartum data available for inclusion of this secondary analysis. Participants had higher fasting (104.3 ± 10.5 vs 89.8 ± 5.2) and 2-hour plasma glucose (129.9 ± 37.5 vs 103.5 ± 17.9) in the group with abnormal postpartum OGTT results compared to those with a normal OGTT response. Additionally, the glucose excursion following the 75 grams of glucose and mean CGM glucose at all time points were higher in the group with abnormal OGTT results (Figure). When stratified by GDM type, mean CGM glucose was similar between groups.

Conclusion: This study demonstrates that CGM values follow the expected trend regarding physiologic response to the OGTT, and those with abnormal OGTT results had a distinct glycemic pattern in response to the OGTT with higher mean CGM glucose at all time points assessed. Future studies will need to assess the predictability of CGM in identifying those with abnormal

glycemia postpartum (i.e. prediabetes) with an elevated risk for development of type 2 diabetes mellitus.

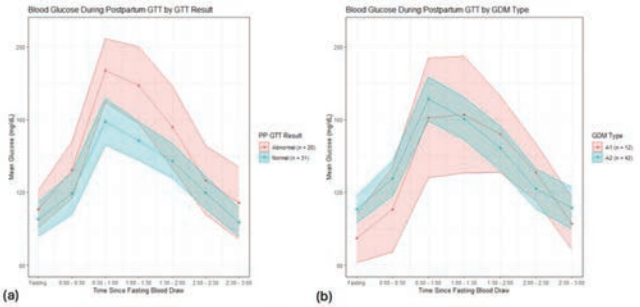

Figure: Mean glucose measurements with CGM during OGTT (start 1 hour before fasting blood draw to 1 hour after 2-hour blood draw; figure demonstrates mean value at 30-minute time increments with 95% confidence intervals). (a) Normal versus abnormal OGTT result; (b) A1GDM versus A2GDM.
X axis: Time. Y-axis: Mean glucose (mg/dL).
Abnormal OGTT = Fasting ≥100 mg/dL or 2-hour ≥140 mg/dL
Fasting = 8 hours before

684 | Impact of a Surgical Bundle on Hospital Readmission Rates in Obese Women Undergoing Cesarean Delivery

Alyssa Savelli Binsted; Emily Peters; George R. Saade; Tetsuya Kawakita
Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA

10:30 AM - 12:30 PM

Objective: To assess whether implementing an obesity surgical bundle for patients with a BMI of 40 kg/m^2 or greater reduces hospital readmission rates after unscheduled cesarean delivery.

Study Design: This was a pre- and post-intervention study of individuals with a BMI > 40 kg/m^2 undergoing unscheduled cesarean delivery at 24 weeks of gestation or greater between January 2018 and December 2022 at a single tertiary care center. In January of 2021, we implemented an obesity bundle that included vaginal preparation with povidone-iodine in the setting of ruptured membranes, and a 48-hour course of oral cephalexin and metronidazole. Our primary outcome was hospital readmission or emergency department visits within 6 weeks postpartum. We also examined the rate of hospital readmission alone. Relative risks with 95% confidence intervals (95% CI) were calculated using modified Poisson regression, adjusting for potential confounders.

Results: Of 1823 individuals who underwent unscheduled cesarean, 980 (54%) were in the pre-intervention period and 843 (46%) in the post-intervention period. Maternal demographics were overall similar, except for lower gestational age at delivery in the post-intervention period (Table 1). Compared to the pre-intervention period, the rate of hospital readmission or emergency department visits was significantly lower in the post-intervention period (35.0% vs. 28.7%, aRR 0.82 95%CI 0.72-0.94, P < 0.01). Hospital readmission alone was also significantly lower in the post-intervention period (33.0% vs. 26.2%, aRR 0.80 95%CI 0.69-0.92, P < 0.01) (Table 2).

Conclusion: The rate of hospital readmissions and emergency department visits decreased significantly after the implementation of a surgical bundle for individuals with a BMI greater than 40 kg/m^2 undergoing cesarean delivery.

Table 1. Maternal demographics

	Pre-intervention (n=980)	Post-intervention (n=843)	P-value
Age (yr)	30.4 (± 5.7)	30.8 (± 5.7)	0.14
GA (wk)	37.9 (35.9,39.1)	37.4 (35.4,39.0)	0.04
BMI (kg/m^2)	46.4 (43.3,52.2)	47.2 (43.4,53.0)	0.12
Rupture to delivery >3 hr	282 (28.8)	257 (30.5)	0.43
Race			0.50

685 | Smartphone Application use for Gestational Diabetes Management and Immediate Postpartum Glucose Tolerance Outcomes

Alyssa L. Trochtenberg[1]; Alysa St. Charles[1]; Devika Lekshmi[1]; Erika F. Werner[2]; Sebastian Z. Ramos[2]
[1]Tufts University School of Medicine, Tufts University School of Medicine, MA; [2]Tufts University School of Medicine, Boston, MA

10:30 AM - 12:30 PM

Objective: Use of smartphone applications for gestational diabetes (GDM) management has increased in recent years, but their effect on maternal postpartum glucose tolerance is unknown. This pilot randomized controlled trial investigated the effect of the Malama smartphone application, a glucose monitoring and interactive diet education tool, on early postpartum glucose tolerance and perinatal outcomes.

Study Design: Patients with GDM receiving prenatal care at an urban academic medical center were randomized 1:1 to Malama application use compared to standard care. The primary outcome was 2 hour oral glucose tolerance test (OGTT) level measured during the delivery hospitalization. Secondary outcomes included patient satisfaction, postpartum hemoglobin A1c (HbA1c), delivery outcomes, and perinatal morbidity.

Results: Twenty-eight participants were randomized (14 participants per group). Malama users had lower median 2 hour OGTT levels compared to patients receiving standard care (120 vs 155 mg/dL; $P = .05$; incident rate ratio, 0.78 [95% CI 0.61-0.99]). There were no differences in postpartum HbA1c, mode of delivery, birthweight, or other perinatal outcomes. Patient satisfaction with glucose logging methods was equivalent between groups. When the groups' baseline characteristics were compared, Malama users were younger than those receiving standard care (30.9±4.1 vs 36.4±3.8 years; $p = .001$), while other characteristics were similar between groups. After adjusting for maternal age, the difference in 2 hour OGTT was no longer significant (adjusted incident rate ratio, 0.92 [95% CI 0.69-1.23]).

Conclusion: Compared with standard glucose logging methods, Malama application use was acceptable to patients with GDM and was associated with improved early postpartum glucose tolerance values in the unadjusted model, but not after adjusting

for differences in age. Larger studies are needed, stratifying by age, to fully evaluate the impact of smartphone applications on postpartum glucose and perinatal outcomes.

686 | Association of Periviable Birth and Postpartum Psychiatric Morbidity in the Medicaid Population

Alyssa L. Trochtenberg[1]; Sebastian Z. Ramos[2]; Benjamin C. Koethe[2]; Mohak Mhatre[2]

[1]Tufts University School of Medicine, Tufts University School of Medicine, MA; [2]Tufts University School of Medicine, Boston, MA

10:30 AM - 12:30 PM

Objective: Publicly insured patients have increased risk of adverse obstetric outcomes and perinatal psychiatric morbidity. Although periviable birth is a significantly stressful obstetric event, its association with postpartum psychiatric outcomes has not been studied in this high-risk population.

Study Design: Singleton liveborn periviable births (22 0/7 to 25 6/7 weeks) vs non-periviable births (≥26 0/7 weeks) were identified using claims data in the Merative MarketScan Medicaid database from 2020-2022. The primary outcome was a composite of psychiatric morbidity, defined as one or more of the following within 12 months postpartum: emergency department (ED) or outpatient encounters associated with depression, anxiety, psychosis, posttraumatic stress disorder, adjustment disorder, self-harm, or suicide attempt; new psychotropic medication prescription; or inpatient psychiatry admission. Analysis was adjusted for maternal age, cesarean delivery (CD), severe maternal morbidity (SMM), maternal comorbidity index, and history of mental health disorder.

Results: Out of 639,971 deliveries, there were 3,518 (0.5%) periviable births (PB) and 636,453 non-periviable births (NPB) included for analysis. Baseline prevalence of mental health disorders was similar between groups. The incidence of SMM, hypertensive disorders of pregnancy, and CD was higher among individuals with PB. Compared to NPB, PB was associated with greater incidence of composite psychiatric morbidity (27.3% vs 22.5%, aOR 1.32 [95% CI 1.22-1.42]) and increased ED utilization for mental health disorders (5.1% vs 3.9%, aOR 1.37 [95% CI 1.17-1.60]); furthermore, patients with PB were more than twice as likely to have postpartum inpatient psychiatric admission (5.8% vs 2.8%, aOR 2.26 [95% CI 1.95-2.62]). PB was associated with increased incidence of new psychotropic medication prescriptions and outpatient behavioral health visits.

Conclusion: Despite increased outpatient behavioral healthcare utilization, publicly insured patients who experience periviable birth are at high risk for psychiatric morbidity requiring emergency or inpatient-level of care.

Table 1. Primary and secondary psychiatric outcomes within 12 months postpartum among publicly insured patients in MarketScan with and without a periviable birth, 2020-2022.

Outcome	PB (n = 3,518)	NPB (n = 636,453)	Adjusted OR (95% CI)
Composite of psychiatric morbidity	**960 (27.3)**	**142,962 (22.5)**	**1.32 (1.22, 1.42)**
ED visit	181 (5.1)	24,704 (3.9)	1.37 (1.17, 1.60)
New psychotropic medication	645 (18.3)	100,532 (15.8)	1.20 (1.10, 1.31)
New behavioral health visit	382 (10.9)	60,693 (9.5)	1.18 (1.06, 1.32)
Inpatient psychiatry admission	208 (5.9)	18,058 (2.8)	2.26 (1.95, 2.62

687 | Umbilical Artery Doppler Pulsatility Index as a Predictive Biomarker for Preterm Premature Rupture of Membranes

Amanda J. Jones[1]; Ernest Graham[2]; Irina Burd[3]; Ahizechukwu C. Eke[4]

[1]Christiana Care Health System, Newark, DE; [2]Johns Hopkins School of Medicine, Baltimore, MD; [3]University of Maryland,

Baltimore, MD; [4]Johns Hopkins University School of Medicine, Baltimore, MD

10:30 AM - 12:30 PM

Objective: Although known risk factors for preterm premature rupture of the fetal membranes (PPROM) can be assessed, otherwise predicting PPROM is not currently clinically feasible. The objective of this study was to assess the predictive value of umbilical artery Doppler pulsatility index (UA-PI) alone for PPROM, and when combined with previously established predictive risk factors.

Study Design: This was a retrospective cohort study of liveborn non-anomalous chromosomally normal infants admitted to the neonatology intensive care unit at a single tertiary care center from April 2009 to March 2016. All cases had umbilical artery (UA) Doppler studies routinely measured during second and third trimester ultrasounds. The pre-rupture UA-PI of patients whose pregnancies were complicated by PPROM were compared to gestational age-matched controls without PPROM. The area under the receiver operating characteristic curve (AUC) was used to estimate the predictive ability of pulsatility index (UA-PI) for predicting PPROM, and the Liu method was used to identify the UA-PI threshold that maximized both sensitivity and specificity. The AUC, sensitivity, and specificity were also assessed when maternal age, parity, and singleton vs multiple gestation as predictive variables were combined by forward selection with UA-PI.

Results: Of 1,145 high-risk gestations studied, 262 (23%) were complicated by PPROM and 883 (77%) were without PPROM. Multivariable analysis identified elevated UA-PI (AOR 1.24, 95% CI 1.18-1.31, $p = 0.002$) as an independent risk factor for PPROM. The AUC for UA-PI was 0.57 (95% CI 0.54-0.61) for an elevated UA-PI. When maternal age, parity, and singleton vs multiple gestation as predictive variables were combined by forward selection with UA-PI, the AUC increased to 0.65 (95% CI 0.62-0.68). The optimal UA-PI threshold was 0.95 (26% sensitivity, 73% specificity).

Conclusion: Elevated UA-PI is moderately predictive of PPROM, and inclusion in a predictive model for PPROM in high-risk pregnancies may be justified pending validation.

Table 1: Receiver Operating Characteristic (ROC) Summary of the association between Umbilical Artery Pulsatility Index and Preterm Prelabor Rupture of Fetal Membranes

Variable	Number of observations	ROC Area	Standard Error	95% Confidence Interval
UA-PI alone	1,145	0.57	0.017	0.54, 0.61
UA-PI plus maternal age	1,145	0.59	0.017	0.56, 0.62
UA-PI plus maternal age and parity	1,145	0.60	0.017	0.57, 0.63
UA-PI plus maternal age, parity, and singleton vs. multiple gestation	1,145	0.65	0.017	0.62, 0.68

688 | Hybrid versus Natural Immunity to Protect Against Neonatal Hospitalization: A Cost-Effectiveness Analysis

Amelia H. Gagliuso[1]; Lily Ben Avi[2]; Sarah K. Dzubay[2]; Nicole E. Marshall[2]; Aaron B. Caughey[2]
[1]Oregon Health & Sciences University, Portland, OR; [2]Oregon Health & Science University, Portland, OR

10:30 AM - 12:30 PM

Objective: Neonates are ineligible for COVID-19 vaccination and are at increased risk for complications from COVID-19 infections compared with vaccine-eligible populations. Passive immunity from maternal anti-SARS-COV-2 immunoglobulins crossing the placenta and in human milk demonstrates that vaccine-mediated immunity compared to natural immunity is clinically beneficial for both maternal and infant outcomes as shown with TdaP and influenza. The purpose of this analysis was to determine the cost-effectiveness of maternal hybrid immunity in protection against neonatal outcomes in the United States.

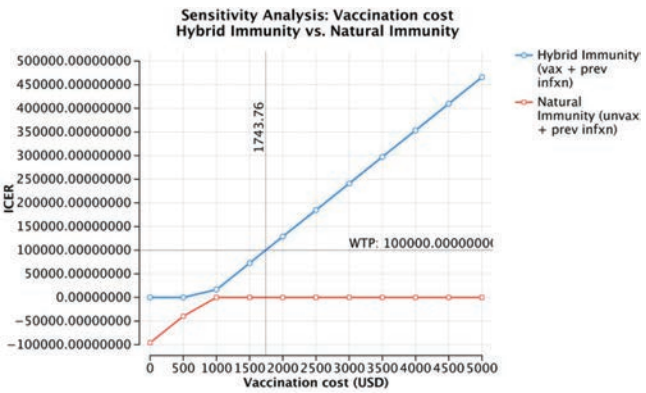
Study Design: A TreeAge model was constructed to compare outcomes for a theoretical cohort that were vaccinated with one dose and had a previous infection (Hybrid immunity) with those who received no vaccine and had a previous infection (Natural immunity). Our cohort contained 3,664,292 individuals, the estimated number of annual live births in the United States. Model outcomes included cases of neonatal deaths, neurodevelopmental disabilities, and neonatal hospitalization. Probabilities, utilities, and costs were derived from literature. QALYs were discounted at a rate of 3%.

Results: Hybrid immunity in our theoretical cohort was associated with a decrease in 462 neonatal deaths, 482 cases of neurodevelopmental delay, and 132 cases of neonatal hospitalization (Table 1). Hybrid immunity was the dominant strategy as it saved $2,981,154,191 and led to 32,619 additional QALYs (Table 1). Univariate sensitivity analysis demonstrated that the COVID-19 vaccine is cost-saving until the cost of the vaccine exceeds $500, which is far above the current price (Figure 1).

Conclusion: This study demonstrates that vaccination even among those with a previous infection improves outcomes and is cost saving in pregnant persons. Ensuring that all pregnant people are aware of the positive impact on their neonates from obtaining the COVID vaccine during pregnancy is important to achieve these potential benefits.

Table 1. Outcomes in a theoretical cohort of 3,664,292 annual pregnancies

	Hybrid Immunity	Natural Immunity	Difference (Treatment-No Treatment)
Neonatal Death	3,587	4,049	-462
Neurodevelopmental Delay	6,870	7,351	-482
Neonatal Hospitalization	77	209	-132
Cost ($)	38,142,930,398	41,124,084,592	-2,981,154,191
Effectiveness (QALYs)	208,065,504	208,032,885	32,619
Strategy	Dominant	Dominated	



689 | Recurrent Intrahepatic Cholestasis of Pregnancy-Incidence and Risk Factors

Inbar Lifshitz[1]; Geffen Kleinstern[2]; Roy Zigron[1]; Amihai Rottenstreich[3]
[1]Hadassah Medical Center, Hadassah Medical Center, NY; [2]Northwell Health and Rockefeller University, Haifa University, NY; [3]Northwell Health, Northwell Health, NY

10:30 AM - 12:30 PM

Objective: The incidence of intrahepatic cholestasis of pregnancy (ICP) varies throughout the world and is influenced by genetic, hormonal and environmental factors. However, data is highly limited regarding the risk of ICP recurrence in subsequent pregnancies. We aimed to incidence of recurrent ICP and its associated risk factors.

Study Design: A retrospective cohort study conducted at a university hospital, including all pregnant women who underwent serum bile acids (BA) levels testing due to suspected ICP in a 13-year period. Among women diagnosed with ICP, records were reviewed to identify those with a subsequent gestation.

Results: Of 640 women who met the inclusion criteria, 22.2% (n = 142) were diagnosed with ICP (fasting serum BA >10 mmol/L) in the index pregnancy. Of them, 51 (35.9%) had a subsequent pregnancy. The rate of recurrent ICP in the subsequent pregnancy was 29.4% (15/51). Timing of ICP diagnosis did not differ significantly between the index and subsequent gestation (median 33 [IQR 30-36] vs. 34 [IQR 31-35] weeks, P = 0.90). In multivariable analysis, fasting serum BA levels at the index pregnancy above 40 mmol/L was the only independent factor associated with ICP recurrence.

Conclusion: Recurrence of ICP is common, occurring in over one fourth of women with a history of ICP. BA levels at the first pregnancy in which ICP was diagnosed were found as the only independent factor associated with the occurrence of ICP in subsequent gestation.

690 | Long-Term Gastrointestinal Morbidity Among Twins Conceived by Assisted Reproductive Technology

Amir Snir[1]; Tamar Wainstock[2]; Gil Gutvirtz[3]; Eyal Sheiner[2]
[1]Soroka University Medical Center, Omer, HaDarom; [2]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom; [3]Soroka University Medical Center, Metar, HaDarom

10:30 AM - 12:30 PM

Objective: Using assisted reproductive technologies (ART) increased the incidence of multiple pregnancies, which has a negative effect on offspring health outcomes. The long-term health outcomes for singletons born after ART is well studied with numerous publications, however, studies on ART twin's long-term morbidities are scarce. This study aimed to investigate a possible association between ART resulting in twin pregnancy and long-term gastrointestinal (GI) morbidity of the offspring.

Study Design: A population-based cohort study was performed in a tertiary medical center including twin deliveries born between 1991-2021. Long-term GI morbidities among twins conceived via ART including ovulation induction (OI) and in-vitro fertilization (IVF) were compared with twins born following spontaneous pregnancies. The diagnoses of GI morbidities were defined based on ICD-9 codes as recorded in community clinics and hospitalization files. A Kaplan–Meier survival curve was used to compare the cumulative incidence of GI morbidity among the study group and a Cox proportional hazards model was constructed to control for confounders.

Results: A total of 7,790 twins met the inclusion criteria: 2,076 twins (26.6%) were conceived by ART. The total GI morbidity rate was significantly higher in twins conceived by ART as compared with twins from spontaneous pregnancies (34.9% for IVF, 34.3% for OI and 27.0% for spontaneous twins, $p< 0.001$, **Table**). In addition, the cumulative incidence of GI morbidity over time was elevated for twins conceived by ART (log-rank test, $p < 0.001$, **Figure**). The Cox model, controlling for confounders such as maternal age, gestational age, hypertensive disorders and diabetes mellitus found that using ART resulting in twin pregnancy is an independent risk factor for long-term GI morbidity of twin offspring (adjusted hazards ratio (aHR) for IVF vs. spontaneous = 1.42 (95%CI 1.27-1.58, $p< 0.001$; aHR for OI vs spontaneous = 1.38 (95%CI 1.20–1.60, $p< 0.001$).

Conclusion: In our cohort, twins conceived by ART have a higher risk for long-term GI morbidity as compared with twins from spontaneous pregnancies.

Figure. Kaplan-Meier survival curve demonstrating the cumulative incidence of gastrointestinal morbidity among study groups

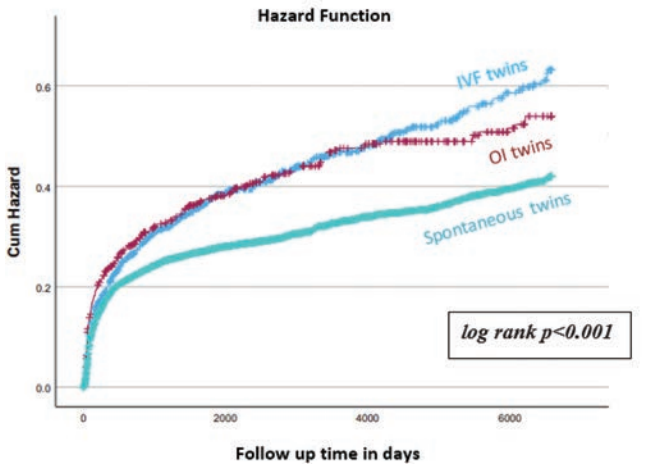


Table. Selected long-term gastrointestinal morbidities and total gastrointestinal morbidity rates in twins conceived by ART and spontaneously conceived twins

Gastrointestinal morbidity by organ function	IVF n = 1380	Ovulation Induction n = 696	Spontaneous Pregnancy n = 5714	P Value

691 | Empowering Patients to Conduct Nsts from Home: Success Rates from Over 2000 Remote Nsts

Nadav Schwartz[1]; Barak Laish[2]; Ohad Regev[3]; Amit Reches[4]
[1]University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA; [2]Nuvo Group Ltd, Tel Aviv, Tel Aviv; [3]Nuvo Group Ltd, NuvoCares, HaMerkaz; [4]Nuvo Group Ltd, Tel aviv, Tel Aviv

10:30 AM - 12:30 PM

Objective: Many pregnancies require multiple, in-person non-stress tests (NSTs), adding significant patient burden. Novel technologies can enable remote NSTs; however, the feasibility of this solution in real-world, clinical settings remains uncertain. We analyzed success rates for patients conducting home NSTs under the remote supervision of their healthcare providers.

Study Design: In this retrospective study, we queried an anonymized database to identify remote NST appointments conducted using an FDA-cleared, remote fetal monitoring device. All NSTs were prescribed and remotely monitored by local healthcare providers. We included remote NSTs conducted ≥32 wks outside of a medical office or research trial and excluded sites with < 10 NSTs. The primary outcome was successful NST appointment, defined as one with a clinically interpretable NST, as documented by the provider. An appointment window was defined as a day in which a remote NST was attempted. For one site conducting twice daily NSTs for de-hospitalized patients, the appointment was a half-day. We analyzed maternal age, pre-gravid BMI, gestational age (GA) and appointment number (appt#) as predictors of success.

Results: Between July 2022 and June 2024, 2080 NST appointments we performed in 227 subjects across 10 clinical sites. After excluding 5 subjects and 59 NSTs with no provider documentation, 2031 NST appointments in 222 patients were analyzed. A successful NST was obtained in 92.9% (N = 1887) of appointments. NST success was not related to maternal age (p = 0.51) but was associated with GA (P< 0.01), lower BMI (P< 0.01) and higher appt# (P< 0.01), with the appt# having the greatest impact on success variance (**Table**). Success rates < 85% were observed for first appt# (81%) and BMI≥50 (72%) (**Figure**).

Conclusion: Antenatal fetal surveillance is critical to reducing adverse pregnancy outcomes but adds significant burden. Remote NSTs can empower patients to access care from home, while remaining under healthcare team supervision. Our results demonstrate that patients can successfully obtain clinically interpretable NSTs at home in a real-world setting.

692 | Novel Amniotic Fluid Characterization Shows Significant Elevation of EPO and Sflt-1 in Early FGR Pregnancies

Amrita Roy[1]; Hannah Spector[2]; Sarah Crimmins[3]; Ponnila S. Marinescu[2]

[1]*Bridgeport Hospital / Yale New Haven Health, Bridgeport, CT;* [2]*University of Rochester Medical Center, Rochester, NY;* [3]*University of Rochester, Rochester, NY*

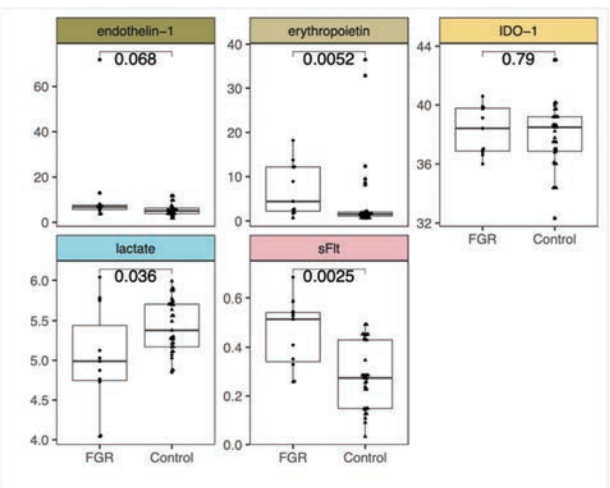
10:30 AM - 12:30 PM

Objective: Fetal growth restriction is a major contributor to fetal and neonatal morbidity/mortality. Early onset FGR [eFGR, diagnosed < 32 weeks] has a strong association with catabolism, and markers of chronic hypoxia are proportionally increased in this state, likely in amniotic fluid (AF). However, comparisons of AF analytes between eFGR and appropriately grown for gestational age (AGA) pregnancies are limited. We analyzed concentrations of AF lactate, endothelin-1 (ET-1), soluble fms-like tyrosine kinase 1 (sFlt-1), erythropoietin (EPO), and indoleamine-2,3-dioxygenase (IDO) in eFGR vs AGA control groups.

Study Design: Retrospective case control study using cryopreserved AF samples; eFGR (cases) and AGA (control) pregnancies were identified via EMR. Analyses of lactate, ET-1, EPO, IDO-1, and sFlt-1 were performed using ELISA. Primary outcome was concentration of AF analytes in eFGR versus control groups. Subgroup analyses assessed concentrations of AF analytes in eFGR, eFGR with brain sparing (eFGR+BS) and control groups.

Results: 44 AF samples were evaluated, 11 with eFGR [7 of which were eFGR+BS], 33 with AGA. AF concentrations of EPO and sFlt-1 were higher in the eFGR group (EPO eFGR 4.41mIU/mL vs. control 1.54 mIU/mL p = 0.005; sFlt-1 eFGR 0.51 ng/mL vs. control 0.27 ng/mL p = 0.002). AF lactate concentrations were lower in the eFGR group (eFGR 4.99 mmol/L vs. control 5.37 mmol/L p = 0.034). There were no statistically significant differences in ET-1 or IDO-1 between groups. AF concentrations of EPO and sFlt-1 were higher in the eFGR and eFGR+BS cohorts when compared to control (EPO eFGR 7.82 mIU/mL, eFGR+BS 4.41 mIU/mL vs. control 1.54 mIU/mL p = 0.005; sFlt-1 eFGR 0.56 ng/mL, eFGR+BS 0.40 ng/mL vs. control 0.27 ng/mL p = 0.002).

Conclusion: Our novel characterization of AF analytes shows that EPO and sFLt-1 are significantly elevated in pregnancies with eFGR and eFGR+BS. Ability to identify at risk pregnancies has the potential to meaningfully impact management, particularly in identifying time frame for intervention. Further studies will assess predictability of eFGR by AF analyte combinations.



Comparisons of amniotic fluid biomarker concentrations between fetal growth restriction and control groups. FGR, fetal growth restriction; IDO-1, indoleamine 2,3-dioxygenase-1; sFlt, soluble fms-like tyrosine kinase-1.

693 | Aortocaval Compression during Maternal Cardiac Arrest: An MRI Study of Uterus-Great Vessel Dynamics Across Trimesters

Andrea D. Shields[1]; Ava G. Holland[2]; Olatoyosi Olafuyi[3]; Makayla Murphy[4]

[1]*University of Connecticut Health, Avon, CT;* [2]*UConn Hospital, UConn Hospital, CT;* [3]*University of Connecticut, Farmington, CT;* [4]*University of Connecticut Health, University of Connecticut Health, CT*

10:30 AM - 12:30 PM

Objective: During maternal cardiac arrest (MCA), two crucial maneuvers to alleviate aortocaval compression caused by the gravid uterus are left uterine displacement (LUD) and resuscitative cesarean delivery (RCD). This study aims to examine the anatomic relationship between the uterus and aorta, as well as the presence of inferior vena cava (IVC) compression, using magnetic resonance imaging (MRI).

Study Design: Post-acquisition measurements were obtained from MRI imaging of pregnant women with singleton fetuses between 12+4–35+0 weeks for various indications. Measurements were obtained with patients in the supine position at the transverse plane just above the level of the aortic bifurcation, including the distance between the left aortic wall and right uterine wall (LAo-RUt) and presence of inferior vena cava (IVC) compression (Figure).

Results: Fifty MRIs in pregnant patients were analyzed and stratified by gestational age (Table 1). As expected, the LAo-RUt distance increased with advancing gestational age, with a range of 67.7–180.5 mm. MRI evidence of compression of the IVC was present in 36% of pregnant patients between 12+0–19+6 weeks, 75% of gravidas between weeks 20+0–23+6 weeks, and 90% of gravidas between 32+0 –35+0 weeks. The earliest gestational age IVC compression was noted was 15+5 weeks.

Conclusion: These findings indicate that most pregnant patients experience IVC compression beyond 20 weeks' gestation due to the uterus overlying the great vessels. LUD and RCD are most likely to be effective in alleviating aortocaval compression after 20 weeks. However, given that 1/3 of patients less than 20 weeks have evidence of IVC compression, LUD and RCD may also play a role in the resuscitation of patients after 15 weeks, especially those in refractory MCA.

Gestational Age Categories (weeks+days)	N	Gestational age (mean)	BMI (mean)	Mean left Aortic wall to right uterine wall (mm)	IVC compression (percent)	Mean right uterine wall to right abdominal wall (mm)	Mean anterior aortic wall to anterior abdominal wall (mm)	Mean uterine width (mm)	Mean uterine depth (mm)	Mean uterine length (mm)

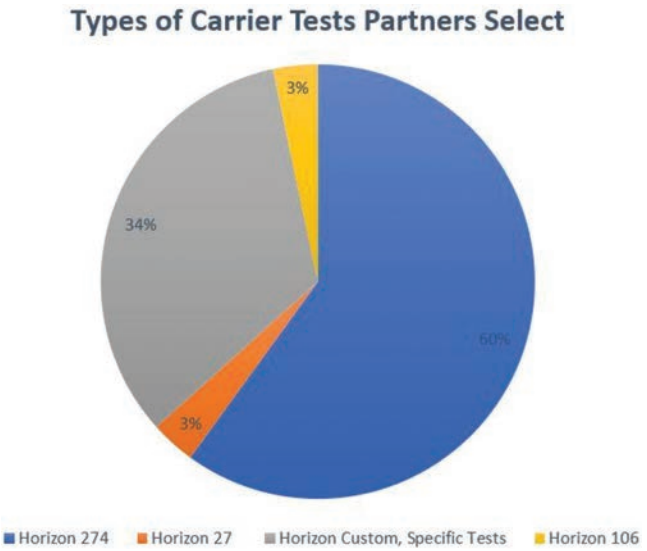
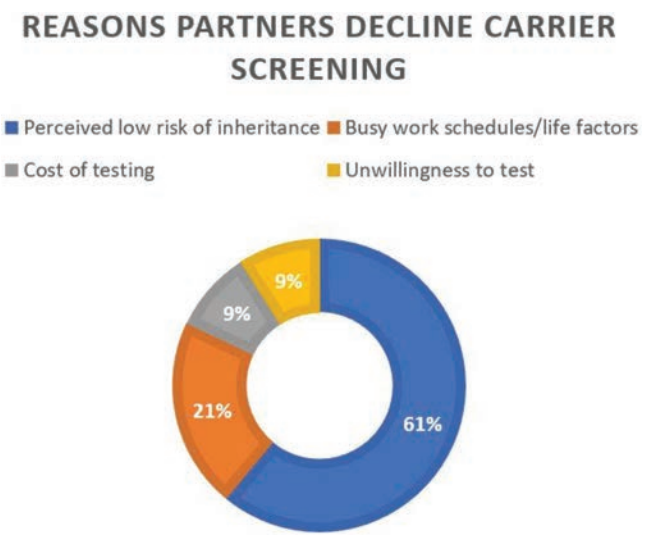
694 | Care-Ier to Be Screened Today? an Insight on Partner Genetic Screening Uptake Rates

Ajitha Chivukula[1]; Brittany Gancarz[2]; Makayla Murphy[2]; Andrea D. Shields[3]
[1]University of Connecticut School of Medicine, University of Connecticut School of Medicine, CT; [2]University of Connecticut Health, University of Connecticut Health, CT; [3]University of Connecticut Health, Avon, CT

10:30 AM - 12:30 PM

Objective: We aimed to analyze the uptake rates for genetic carrier screening in partners of pregnant people with abnormal carrier screens and investigate the reasons for deferred screening.
Study Design: A retrospective cohort analysis was conducted on pregnant patients with positive carrier screens and their partners at a tertiary academic medical center between 6/1/2021 and 5/31/2024. Inclusion criteria were pregnant people (18+) with singleton pregnancies who tested positive for an autosomal recessive condition in the first or second trimester and underwent genetic counseling. The primary outcome was uptake rates for genetic screening in partners of pregnant people with positive carrier screens. Secondary outcomes were reasons for deferring partner screening. Baseline characteristics were summarized using frequencies and percentages for categorical variables and mean and standard deviation for continuous variables.
Results: During the study period, 701 abnormal genetic screens were identified, of which 587 were in pregnant people who met inclusion criteria. Most abnormal screens (56.4%) were identified from pan-ethnic screening while 8% were identified through targeted carrier screening. The uptake rate of partner screening was 48.04%, with 33.3% undergoing targeted screening for a specific condition and 60% undergoing a panethnic panel. 38.9% of partners had discordant positive carrier results for conditions unrelated to the pregnant person's condition. Genetic screening by blood samples occurred in 76.7% of partner tests, while 23.3% were from saliva samples. The most common reasons partners deferred genetic screening included perceived low risk of inheritance for the condition (61%), busy work schedules/life factors (21%), and costs (9%).
Conclusion: Our results show that nearly half of the partners of pregnant individuals who receive genetic counseling for abnormal carrier screens accept targeted or enhanced genetic screening, mostly through blood sampling. Partners' perceptions of risk and screening convenience significantly influenced their decisions to defer screening.





695 | Increased Chronic Inflammation of the Placenta in COVID-19-Infected Pregnant Patients

Jasmine Rios[1]; Renee Odom-Konja[2]; Lauren S. Keenan-Devlin[3]; Linda M. Ernst[2]; Alexa A. Freedman[4]; Greg E. Miller[4]; Ann EB Borders[5]
[1]Pritzker School of Medicine, University of Chicago, Chicago, IL; [2]Endeavor Health, Evanston, IL; [3]Endeavor Health/ University of Chicago Pritzker School of Medicine, Endeavor Health, IL; [4]Northwestern University, Chicago, IL; [5]Endeavor Health, Evanston Hospital, Evanston, IL

10:30 AM - 12:30 PM

Objective: COVID-19 infection during pregnancy has been linked to adverse birth outcomes, potentially due to increased inflammation. This study compared placental inflammation in individuals with COVID-19 infection during pregnancy to placentas of those who delivered prior to the pandemic to understand inflammation associated with COVID-19 infection and timing.

Study Design: Participants were enrolled in the Stress, Pregnancy, and Health study from 2018-2022. Placentas were collected < 2 hours from delivery and histologically examined. Medical records were manually reviewed for evidence of COVID-19; infection timing, severity, symptoms, vaccination status were abstracted for those infected. The control group included placentas from births before December 1, 2019. Models were adjusted for maternal age, race/ethnicity, and socioeconomic characteristics.
Results: Among the 605 participants, 57 had confirmed COVID-19 infections and 214 delivered before December 1, 2019. Of the 57 positive cases, 5(8.7%) were asymptomatic, 39(68.4%) mild, 1(1.7%) severe, and 6(10.5%) did not have documented symptoms. Those infected with COVID-19 during pregnancy had increased odds of high-grade placental chronic inflammation (OR = 2.23, CI 1.06-4.69), particularly amongst those infected before 20 weeks gestation (OR = 3.57, CI 1.25-10.18). Prevalence of chronic basal villitis was higher in those infected with COVID-19 (p< 0.001). There were no significant differences in acute inflammation (p = 0.169), fetal vascular pathology (p = 0.488), or maternal vascular pathology (p = 0.255) between the infected and uninfected cohorts.
Conclusion: In a cohort of predominantly mild COVID-19 infections during pregnancy, COVID-19 was associated with increased odds of placental chronic inflammation, driven primarily by chronic basal villitis. Inflammatory patterns differed by timing of infection, with increased odds of chronic placental lesions among those infected early in pregnancy. These findings enhance understanding of COVID-19 infection's inflammatory effects in pregnancy, aiding in prevention and treatment of at-risk pregnant patients.

696 | Implementation of Birth Equity Strategies in a Statewide Quality Improvement Initiative Supports Equitable Care Efforts

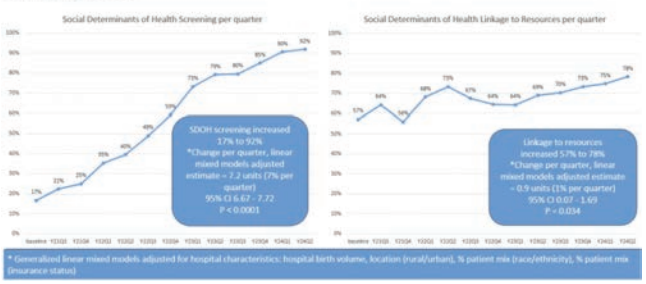
Patricia Lee King[1]; Aleena Surenian[1]; Lavisha Singh[2]; Alana Rivera[3]; Ann EB Borders[2]
[1]Illinois Perinatal Quality Collaborative, Northwestern University, Chicago, IL; [2]Endeavor Health, Evanston Hospital, Evanston, IL; [3]Illinois Perinatal Quality Collaborative, Endeavor Health, Evanston Hospital, Evanston, IL

10:30 AM - 12:30 PM
Objective: The Illinois Perinatal Quality Collaborative (ILPQC) Birth Equity (BE) quality improvement (QI) initiative, launched in July 2021 to implement key actionable strategies to address birth equity across Illinois hospitals. We aim to identify hospital team progress towards meeting initiative goals from baseline (Oct-Dec 2020) to initiative end and transition to sustainability (Jan-Mar/Q1 2024).
Study Design: ILPQC facilitated collaborative learning, rapid-response data and QI support for hospitals. Hospitals reported monthly progress on implementation of key systems changes, including staff respectful care and implicit bias education. Hospitals also conducted a monthly review of 10 randomly sampled patient charts to evaluate progress on Social Determinants of Health (SDOH) screening and documentation of linkage to resources. Chi-square tests analyzed birthing hospitals' progress on key systems changes and implementation differences by hospital characteristics from baseline to initiative end Q1 2024. Generalized linear mixed models, adjusted for hospital characteristics, were used to evaluate progress on staff education, SDOH screening and SDOH linkage.
Results: 63 participating hospitals were included. Hospital teams significantly increased implementation of all BE key systems changes between baseline and Q1 2024, regardless of hospital characteristics (Table 1). Staff receiving education on respectful care and implicit bias increased from 21% at baseline to 93% in Q1 2024 (p< .0001). SDOH screening increased from 17% at baseline to 92% in Q1 2024 (7% per quarter, p< .0001). SDOH linkage to resources increased from 57% at baseline to 78% in Q1 2024 (1% per quarter, p = .034, Figure 1).
Conclusion: The results suggest that a statewide collaborative can facilitate equitable implementation of key Birth Equity strategies through a QI initiative. Hospital teams submitted plans to sustain these improvements by engaging patient partners to obtain respectful care feedback, partner with community organizations to improve SDOH linkages and continue to disaggregate data by race, ethnicity and insurance status.

Table 1. Comparing birthing hospitals' progress on implementation of key Birth Equity Initiative systems changes at baseline Q4 2020 and initiative end and transition to sustainability Q1 2024

	Baseline Q4 2020 n=60	Q1 2024 n=63	
Key Systems Changes	**n (%)**	**n (%)**	**p-value**
Hospital has implemented standardized social determinants of health screening tools for screening all pregnant women during delivery admission in order to link patients to needed resources and services	11 (18.3)	63 (100)	<.0001
Hospital has implemented a protocol for improving the collection and accuracy of patient-reported race/ethnicity data	4 (6.7)	59 (93.7)	<.0001
Hospital has developed a process to review maternal health quality data stratified by race/ethnicity and Medicaid status	4 (6.7)	55 (87.3)	<.0001
Hospital has engaged patients and/or community members to provide input on quality improvement efforts	3 (5.0)	40 (63.5)	<.0001
Hospital has a strategy for sharing expected respectful care practices with delivery staff and patients (i.e. posting in L&D) including appropriately engaging support partners and/or doulas	6 (10.0)	58 (92.1)	<.0001
Hospital has implemented a Patient Reported Experience Measure (PREM) patient survey to obtain feedback from postpartum patients on respectful care practices and a process to review and share results	6 (10.0)	58 (92.1)	<.0001
Hospital has standardized system to provide all patients the recommended postpartum safety patient education materials prior to hospital discharge including urgent maternal warning signs and where patients call for immediate help with concerns as well as scheduling early postpartum follow-up	38 (63.3)	63 (100)	<.0001

Figure 1: Birthing hospitals' quarterly progress on Social Determinants of Health Screening during delivery admission and linkage to resources from baseline Q4 2020 to initiative end and transition to sustainability Q1 2024



697 | Cardiac and Obstetric Outcomes Among Individuals with Hereditary Thoracic Aortic Diseases: Leveraging Large EMR Data

Anna R. Whelan[1]; Lara Kovell[2]; Melissa L. Russo[3]; Gianna L. Wilkie[4]
[1]University of Massachusetts Chan School of Medicine, Worcester, MA; [2]UMass Memorial Health, Worcester, MA; [3]Women & Infants Hospital of Rhode Island / Alpert Medical School of Brown University, Providence, RI; [4]University of Massachusetts Chan Medical School, Worcester, MA

10:30 AM - 12:30 PM

Objective: Pregnancy, delivery, and the postpartum time period are times of increased risk for aortic dissection (AD) among patients with hereditary thoracic aortic diseases (HTAD). Due to the relative rarity of AD and HTAD, data on the risks of AD and other cardiac complications comes from small case series. We aimed to leverage Epic Cosmos, a large dataset comprised of electronic medical records from across the country to estimate current risks of AD and cardiac complications among patients with HTAD during pregnancy.

Study Design: We performed a descriptive analysis of a cohort of pregnancies from The Epic Cosmos dataset, which combines data from over 1500 hospitals and >250 million patients. Epic Cosmos was queried for patients with simultaneous diagnoses codes for HTAD (Marfan Syndrome, Loeys-Dietz Syndrome, Vascular Ehlers-Danlos Syndrome and bicuspid associated aortopathy) and pregnancy between July 5, 2021 and July 4, 2024. Rates of AD, other cardiac complications (including aortic rupture, cardiac arrest, cardiac arrhythmia), and pregnancy outcomes were abstracted for all included individuals.

Results: We identified 1171 individuals with HTAD and pregnancy in the selected time frame. Most individuals identified as White (81.6%). Marfan syndrome was the most common HTAD diagnosis (74.6%). The rate of AD in this cohort was 1.1% (n = 13). The most common cardiac complication experienced by these individuals was arrhythmia (18.4%). For 698 individuals, complete pregnancy and obstetric outcome data was available, and 46.8% were nulliparous. Approximately 20.8% of patients had a cesarean delivery and 30.5% had a preterm delivery (< 37 weeks). Twelve percent of individuals opted for a form a long-acting reversible contraception following pregnancy (Implant n = 27, IUD n = 113).

Conclusion: In this large, contemporary cohort rates of AD were 1.1% among patients with HTAD in pregnancy. Prospective studies are needed to assess the optimal management of pregnancy among patients with HTAD to decrease cardiac and obstetric complications.

698 | Association of CDC Social Vulnerability Index and Postpartum Care Attendance

Anna P. Staniczenko[1]; Julie Robin Dean[1]; Kristin M. Voegtline[2]; Caitlin Radford[2]; Charlene Thomas[2]; Steven Yen[2]; Evan Sholle[2]; Lauren M. Osborne[2]; Julianne R. Lauring[2]; Heather S. Lipkind[2]; Moeun Son[2]
[1]Weill Cornell Medical College, New York, NY; [2]Weill Cornell Medicine, New York, NY

10:30 AM - 12:30 PM

Objective: Increasing the rate of postpartum follow-up has been identified as a national priority to decrease maternal morbidity and promote maternal health. We sought to evaluate whether there is an association between the CDC's Social Vulnerability Index (SVI) and postpartum care attendance.

Study Design: This is a retrospective case control study of patients who delivered at ≥20 weeks' gestation at any of 3 hospitals within a New York City healthcare system from 1/1/2022 to 2/1/2024 and had at least one prenatal visit at an affiliated site prior to delivery. The outcome of postpartum care was dichotomized as at least one outpatient obstetric visit within 12 weeks of delivery. The exposure was CDC-defined SVI, using a validated technique for geocoding patient addresses to assign overall SVI as well as SVI theme scores. SVI was categorized into quartiles representing low to high social vulnerability; more vulnerable patients have higher SVI scores. Demographic, medical, and obstetric factors were examined, and bivariate and multivariate logistic regressions performed.

Results: A total of 21,864 patients were included. Overall, 89.2% attended their PPV, but 33.3% of those with public insurance

and 37.8% of those who delivered at community-based sites did not attend their PPV. Among all patients, the distribution of PPV attendance substantially varied based on SVI quartile (Figure), and the odds of attending at least one PPV significantly decreased as SVI increased in a dose-dependent fashion (Table). These patterns persisted among the socioeconomic, household, and housing/transport themes for SVI (Table). After adjusting for important potential confounders, the significant association between high SVI and decreased odds of attending PPV persisted (aOR 0.72, 95% CI 0.59, 0.88).

Conclusion: Social vulnerability is significantly associated with likelihood of postpartum visit attendance within 12 weeks of delivery: those with the highest vulnerability have the lowest odds of following up for postpartum care. The CDC's SVI may be an effective screening tool to identify those at risk of loss to follow-up postpartum.

Figure: Distribution of patients attending and not attending at least one postpartum (PP) visit within 12 weeks of delivery based on CDC Social Vulnerability Index (SVI)

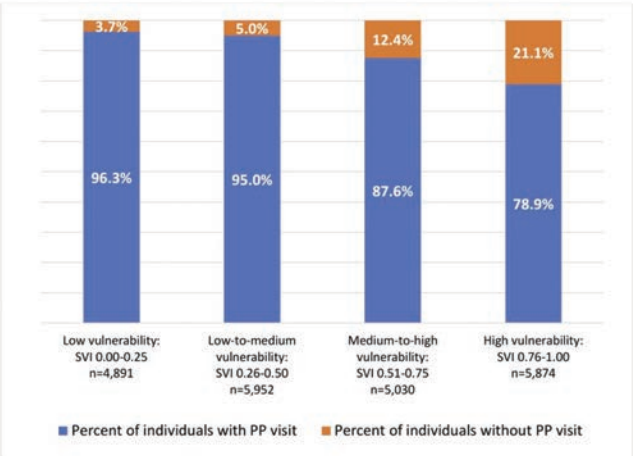

Table – Frequency and odds of attending at least one postpartum visit within 12 weeks of delivery by CDC Social Vulnerability Index (SVI)

Characteristic	Number of patients (n, %)		Odds of PP visit (OR, [95% CI])	Adjusted Odds of PP visit* (aOR, [95% CI])
	Did attend PP visit *n*=19,512	Did not attend PP visit *n*=2,352

Medium to high vulnerability	4,734 (24.4)	447 (19.0)	0.55 (0.41, 0.72)	
High vulnerability	12,130 (62.5)	1,736 (73.9)	0.36 (0.27, 0.47)	

SVI=social vulnerability index, PP=postpartum, OR=odds ratio, CI=confidence interval, aOR=adjusted odds ratio, SES=socioeconomic status

^The Centers for Disease Control and Prevention Social Vulnerability Index (SVI) uses 16 U.S. census variables from the 5-year American Community Survey; these variables are grouped into four themes (socioeconomic status, household characteristics, racial and ethnic minority status, housing type and transportation) and then combined into a single measure of overall social vulnerability.

*Multivariable analyses included characteristics that were significantly associated with attending one postpartum visit in the unadjusted analysis: maternal age, marital status, preferred language, insurance type, employment status, number of OB providers seen during prenatal care, GA at first visit, and mode of delivery. SVI themes, race/ethnicity, and insurance were excluded due to multicollinearity within the model.

**Those with unknown SVI were excluded from univariate and multivariate analyses.

699 | Association Between Breastfeeding and Neurodevelopmental Outcomes After Late Preterm Birth

Anna Palatnik; On behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network
Medical College of Wisconsin, Milwaukee, WI

10:30 AM - 12:30 PM

Objective: Despite the known benefits, it remains unclear whether breastfeeding improves neurodevelopmental outcomes. We tested the hypothesis that breastfeeding is associated with improved neurodevelopmental outcomes among children delivered late preterm.

Study Design: Secondary analysis of a prospective, follow-up study of ≥ 6 years old children enrolled in the NICHD Antenatal Late Preterm Steroid (ALPS) Trial, a multicenter study that assessed betamethasone administration in pregnancies at risk for late preterm birth (34-36wks). Term births and those with missing breastfeeding data or the Differential Ability Scales-II (DAS-II) were excluded. The exposure was breastfeeding at 3 months of life collected via interviews. The primary outcome was cognitive function at age ≥ 6, measured by DAS-II core components of the General Conceptual Ability (GCA) that includes verbal, non-verbal reasoning, and spatial abilities. General linear models were used to evaluate the association of breastfeeding with DAS-II GCA after controlling for pre-specified baseline characteristics (maternal age and education, gestational age at birth, child age, sex, tobacco use in pregnancy, ALPS study group, study center).

Results: Of 541 participants included in the analysis, 273 (50.5%) were breastfeeding at 3 months of life. Participants who breastfed were older, more likely to be white, have a college degree, be married, have private insurance, and less likely to use tobacco in pregnancy (Table 1). There was no difference in birthweight or gestational age at birth by breastfeeding status. The primary outcome, DAS-II GGA, was higher among children who were breastfed at 3 months, 98.9±13.3 vs. 93.0±12.9, mean difference of 5.90 (95% CI 3.59, 8.21, adjusted mean difference 2.27, 95% CI 0.03, 4.50) (Table 2). In secondary analyses, differences in the overall GCA appear to be driven by increased scores for spatial ability.

Conclusion: Among children born late preterm at 34-36 weeks, breastfeeding at 3 months of life was associated with improved neurodevelopmental outcomes at age 6 or older.

Table 1. Maternal and Child Characteristics by Breastfeeding Status at 3 Months

Characteristic	Breastfeeding (N=273)	No Breastfeeding (N=268)	P Value

700 | Risk Factors of Prostaglandin Failure in the Management of Postpartum Hemorrhage After Vaginal Delivery

Anne-Sophie BOUCHERIE[1]; ANNE ROUSSEAU[2]; PATRICK ROZENBERG[3]; THIBAUD QUIBEL[2]
[1]UVSQ, POISSY, Ile-de-France; [2]UVSQ, Poissy, Ile-de-France; [3]UVSQ, Neuilly sur seine, Ile-de-France

10:30 AM - 12:30 PM

Objective: To identify risk factors for prostaglandin E2 (sulprostone) failure in postpartum hemorrhage after vaginal delivery.

Study Design: We conducted a secondary analysis of the TUB trial, a multicenter randomized trial assessing the efficacy of intrauterine balloon tamponade (IUBT) used simultaneously with prostaglandin versus its use after prostaglandin failure. We selected women of the control group who received standard care, *i.e.* prostaglandin administration and then IUBT if bleeding persisted. Prostaglandin failure was defined as the need for IUBT to stop bleeding. We compared maternal and labor characteristics according to prostaglandin failure. Multivariate logistic regression was used to identify independent risk factors for prostaglandin failure and calculate adjusted odds ratios with 95% confidence intervals.

Results: Among the 193 women, 39 (20.2%) required IUBT for persistent bleeding despite prostaglandin administration. Maternal and labor characteristics did not differ between the groups. The mean time from birth to prostaglandin administration was 81±63 minutes in the success group and 76±55 minutes in the failure group (p-value .6). The rate of women receiving prostaglandin within 30 minutes after birth was 8.7% in the success group versus 10% in the failure group (p-value .8). The mean quantified blood loss at prostaglandin administration was 872 ± 286 mL in the success group and 955 ± 411 mL in the failure group (p-value .2). Thrombocytopenia (OR 15.8 [1.89-329], p-value .02) and multiple pregnancy (OR 2.76 [1.01-7.16], p-value .04) were identified as independent risk factors for prostaglandin failure.

Conclusion: Neither the time of administration of prostaglandins nor the amount of bleeding predicts failure of this treatment. Only thrombocytopenia and multiple pregnancy were independently associated with prostaglandin failure.

701 | Outcomes of Cesarean and Vaginal Delivery in Nulliparous Deliveries by Hospital Cesarean Delivery Rate

Annika Willy[1]; Bharti Garg[2]; Aaron B. Caughey[2]
[1]Oregon Health & Science University, Bend, OR; [2]Oregon Health & Science University, Portland, OR

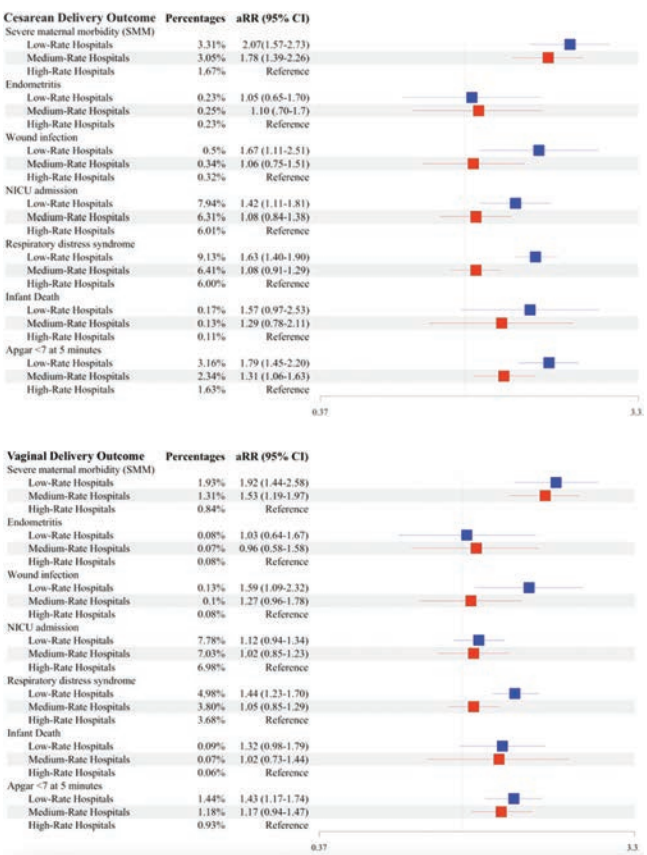
10:30 AM - 12:30 PM

Objective: It is unknown how outcomes differ among patients delivering in hospitals with differing rates of cesarean delivery. Therefore, we sought to assess an association between patients delivering at hospitals with different cesarean delivery rates and adverse perinatal outcomes stratified by cesarean or vaginal delivery.

Study Design: This was a retrospective cohort study of singleton, non-anomalous, term deliveries with vertex presentation in nulliparous individuals of California (2016-2020). Using the cesarean delivery rate in each hospital, we categorized hospitals into low (< 22%), medium (22.1-26.3%) and high (≥26.3%) cesarean rate hospitals. Multivariable Poisson regression models were used to examine the association of low and medium cesarean rate hospitals with adverse outcomes, using high cesarean rate hospitals as reference. These association were examined separately among patients delivering via cesarean or vaginally. Adjusted risk ratios (aRR) with 95% CI were estimated.

Results: In this study, we included 507,455 deliveries, of which 102,486 (20.2%) were cesarean and 404,968 (79.8%) were vaginal. As compared to high CD rate hospitals, individuals with cesareans in low CD rate hospitals had higher risk of SMM (3.31% vs 1.67%; aRR = 2.07 (1.57-2.73)), wound infection (0.50% vs 0.32%; aRR = 1.67 (1.11-2.51)), NICU admissions (7.94% vs. 6.01%; aRR = 1.42 (1.11-1.81)), and lower Apgar scores (3.16% vs. 1.63%; aRR = 1.79 (1.45-2.20)). Results were similar in individuals with vaginal deliveries, such as low CD rate hospitals had higher risk of SMM (1.93% vs 0.84%; aRR = 1.92 (1.44-2.58)), wound infection (0.13% vs 0.08%; aRR = 1.59 (1.09-2.32)) and lower Apgar scores (1.44% vs 0.93%; aRR = 1.43 (1.17-1.74)).

Conclusion: We found that patients delivering at hospitals with a low cesarean delivery rate had higher rates of several adverse outcomes in both cesarean and vaginal deliveries. Further investigation should be conducted to further evaluate this relationship.



702 | Cost-Effectiveness of Universal Screening for Measles Immunity in Pregnancy

Anuradha Devabhaktuni[1]; Sarah Boudova[2]; Elias Kassir[3]; Sohum Shah[4]; Neil Silverman[5]; Christina S. Han[1]

[1]UCLA, Los Angeles, CA; [2]Thomas Jefferson University, Philadelphia, PA; [3]University of Texas Health Science Center at Houston, McGovern Medical School, Houston, TX; [4]University of California, Los Angeles, Los Angeles, CA; [5]David Geffen School of Medicine at UCLA, Department of Obstetrics and Gynecology, Division of Maternal-Fetal Medicine, Los Angeles, CA

10:30 AM - 12:30 PM

Objective: Routine screening for measles immunity is not currently recommended in pregnancy. However, vaccination rates have declined and there have been over a dozen measles outbreaks in the United States in 2024. We aim to assess the cost-effectiveness of universal screening for measles immunity in pregnancy.

Study Design: We conducted a cost-effectiveness analysis comparing outcomes and costs associated with universal screening for measles immunity in pregnancy compared to no screening. We designed a Markov model that ran over 3 pregnancy cycles. Our outcomes included: measles exposure, measles infection including mild and severe infections, maternal death, fetal death, preterm delivery, vaccination, and vaccine response in addition to cost and quality-adjusted life years (QALYs). Model inputs were derived from the literature, with a willingness-to-pay threshold of $100,000 per QALY. Sensitivity analyses were conducted to evaluate the robustness of the results.

Results: Universal screening for measles immunity was the dominant strategy. Using the current measles rate of 0.1%, the incremental cost effectiveness ratio (ICER) of universal screening versus no screening was $25.07/QALY. Tornado one-way sensitivity analyses demonstrated that the costs of measles screening and cases, maternal death, and MMR vaccination, along with the probability of measles exposure had greatest impact on the cost-effectiveness of the screening strategy. Univariate sensitivity analysis demonstrated that universal screening for measles was cost-saving until the cost of testing for measles immunity passed $3,957, far exceeding the current average cost of screening, $44. When varying the measles exposure rate, screening remained the dominant strategy.

Conclusion: Universal screening for measles immunity during pregnancy was identified as a cost-effective strategy supporting its implementation. Until adopted, providers should consider screening their pregnant patients and recommending postpartum vaccination to ensure protection from measles in a subsequent pregnancy.

703 | Diagnostic Accuracy of Sonographic Fetal Weight Estimation for Intertwin Size Discordance

Arietta Vayenas[1]; Sophia Rahimi[2]; Nir Melamed[3]
[1]Sunnybrook Health Sciences Centre, Toronto, OR; [2]Temerty Faculty of Medicine, University of Toronto, Toronto, OR; [3]Division of Maternal Fetal Medicine, Department of Obstetrics and Gynecology, Sunnybrook Health Sciences Centre, Toronto, ON

10:30 AM - 12:30 PM

Objective: Antenatal diagnosis of intertwin size discordance can affect management decisions. Therefore, care providers need to be aware of the accuracy of antenatal ultrasound for size discordance at birth. The current study aimed to estimate the diagnostic accuracy of estimated fetal weight (EFW) and abdominal circumference (AC) for large birthweight discordance and the diagnosis of selective fetal growth restriction (sFGR) at birth.

Study Design: Retrospective cohort study of twin pregnancies followed at a single center (2011-2023) who had ultrasound within 14 days before birth. We compared the diagnostic accuracy of EFW discordance and AC discordance for birthweight discordance and the diagnosis of sFGR at birth.

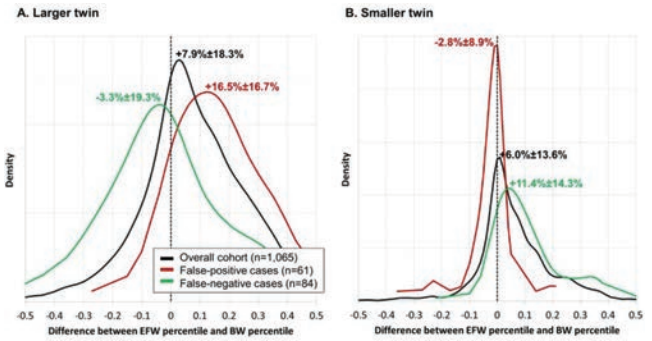
Results: Of the 1,065 twin pregnancies included, the rate of birthweight discordance > 20% and > 25% was 15.5% and 6.7%, respectively. EFW discordance was more accurate than AC discordance in estimating birthweight discordance, as reflected by a lower systematic error and mean absolute percentage error (**Table**). Still, both EFW and AC discordance had low diagnostic accuracy for large birthweight discordance and sFGR. For example, EFW discordance >20% had a sensitivity of 49.1% and a positive predictive value of 57.0% for birthweight discordance >20%, and the antenatal diagnosis of sFGR had a sensitivity of 45.8-54.4% and a positive predictive value of 50.9-55.2% for the postnatal diagnosis of sFGR. A false positive diagnosis of large birthweight discordance was mainly the result of overestimation of EFW percentile in the larger twin (**Figure A**), while failure to detect large birthweight discordance was mainly the result of overestimation of EFW percentile in the smaller twin (**Figure B**).

Conclusion: EFW discordance is more accurate than AC discordance in estimating birthweight discordance. However, both antenatal measures have low diagnostic accuracy for large birthweight discordance and sFGR. Care providers should be aware of the limited diagnostic accuracy when making management decisions on the timing and mode of delivery.

Table 1: Accuracy of fetal size discordance in estimating birthweight discordance

Measure of accuracy	EFW discordance vs. BW discordance	AC discordance vs. BW discordance	P-value
Systematic error (%, 95%-CI) [a]	-0.97% (-1.42%, -0.53%)	-6.43% (-6.85%, -6.00%)	**<0.001**
Random error (%, 95%-CI)	7.41% (7.11%, 7.74%)	7.02% (6.73%, 7.33%)	**0.011**
Mean absolute error (95%-CI)	5.70% (5.41%, 5.99%)	7.35% (6.99%, 7.71%)	**<0.001**
Proportion within 5% (% [95%-CI])	53.1% (50.1%, 56.1%)	45.4% (42.4%, 48.3%)	**<0.001**
Proportion within 10% (% [95%-CI])	84.3% (82.1%, 86.5%)	72.4% (69.7%, 75.1%)	**<0.001**
Proportion within 15% (% [95%-CI])	95.1% (93.8%, 96.4%)	87.0% (85.0%, 89.1%)	**<0.001**

[a] Negative and positive values for the systematic error reflect underestimation and overestimation of birthweight discordance, respectively.
EFW, estimated fetal weight; AC, abdominal circumference; BW, birthweight.



704 | Equity in First Trimester Congenital Anomaly Detection: Population Based Analysis in >1 Million Women in England

Jehan Karim[1]; Pranav Pandya[2]; Aris T. Papageorghiou[1]
[1]University of Oxford, Oxford, England; [2]University College Hospital, London, England

10:30 AM - 12:30 PM

Objective: As there is no unified policy for first trimester anatomical screening in England, our aim was to establish whether differences in screening methods impact on the timing of diagnosis of major congenital anomalies.

Study Design: We linked data from two sources: a nationwide survey of current first trimester practice distributed to all NHS maternity units in England (n = 131) that established current first trimester ultrasound practice; and data from the National Congenital Anomalies Disease Registry (NCARDRS) database. The proportion of major anomalies diagnosed prior to 16 weeks gestation was then evaluated based on current first trimester screening policy.

Results: We included 1,030,224 pregnancies including 5,598 fetuses with one of 14 major conditions. Overall, n = 1,929 (32.7%, 95% CI 31.5–33.9) of these anomalies were diagnosed < 16 weeks. The screening policy in the 110 responding was grouped into four first trimester anatomy screening policies: A. no routine evaluation (n = 27), B. basic (n = 22), C. intermediate (n = 45), and D. advanced assessment (n = 16). Early detection rates were lowest in Group A (27.7%, 95% CI 25.4–30.0) and an increase in detection was seen in Group B (31.2%, 95% CI 28.5–34.1), C (33.2%, 95% CI 31.3–35.2) and D (40.4%, 95% CI 37.3–43.4, p< 0.0001).

Conclusion: Most NHS hospitals in England offer women some form of first trimester anomaly screening. The absence of national recommendations means there are significant variations in practice, which are associated with differences in fetal anomaly detection rates prior to 16 weeks gestation at population level. Centres with clear protocols for first trimester fetal anomaly screening have higher early detection rates for major congenital anomalies. The differences in the standard of antenatal screening care offered to women across England has resulted in regional and local inequities in maternal care.

705 | Utilization of Genetic-Counseling and Carrier-Screening at a Single Center: A Quality Assessment Study

Maura Jones Pullins[1]; Mia Hodges[1]; Emily Hardisty[2]; Madeline Dyke[2]; Neeta L. Vora[2]; Asha N. Talati[2]

[1]University of North Carolina, Chapel Hill, NC; [2]University of North Carolina at Chapel Hill, Chapel Hill, NC

10:30 AM - 12:30 PM

Objective: To evaluate completion of basic carrier screening in a first pregnancy (G1) and factors associated with receipt.

Study Design: Chart review of G1 pregnancies at a single center between 01/2017–01/2024. Charts were randomly selected for quality assessment and were manually reviewed for provider notes to assess documentation (offered, accepted, declined); to review partner charts; and review neonatal charts for newborn screening (NBS) results. Patients were excluded if they received preconception care, infertility services, transferred into care above 20 weeks, or prenatal records were not available. Screening for variants in Cystic Fibrosis (CF), Spinal Muscular Atrophy (SMA), and Hemoglobinopathies (HB) defined complete carrier screening. Participants that elected for expanded carrier screening (ECS) were noted. Data was analyzed using descriptive statistics, t-test, and chi-square as appropriate. Analyses were completed using Stata 15.

Results: 450 maternal charts were reviewed. 158 were excluded (as above). The final cohort included 292 maternal, paternal, and neonatal charts (Table 1). 109 (37.3%) had genetic counseling and 98 (33.6%) had complete carrier screening. Of those that had genetic counseling, 54% had carrier screening; those that declined had 'declined' documented in the clinical note 100% of the time. Obstetric care providers did not routinely document declining carrier screening; this was identified 6 times in obstetric provider notes. 129 (44.2%) had CF screening, 109 (37.2%) had SMA screening, and 178 (61%) were screened for HB. Eleven (4%) of participants had ECS. No carrier couples or abnormal NBS were identified. Frequency of complete paternal testing when a maternal screen was positive is shown in Table 2. There were no significant differences in complete carrier screening or use of genetic counseling services based on race or insurance status.

Conclusion: One-third of randomly sampled G1 pregnancies since 2017 received complete carrier screening suggesting need to improve implementation and larger sample.

706 | Trends in Postpartum Sflt-1 Among Patients Diagnosed with Preeclampsia with Severe Features

Ashten B. Waks[1]; Devesh Naidoo[2]; Dongbao Chen[1]; Megan C. Oakes[3]
[1]University of California Irvine, Orange, CA; [2]MemorialCare Miller Children's and Women's Hospital Long Beach, Long Beach, CA; [3]MemorialCare Miller Children's and Women's Hospital Long Beach, Miller Children's and Women's Hospital, Long Beach, CA

10:30 AM - 12:30 PM

Objective: Because an excess of anti-angiogenic proteins like soluble fms-like tyrosine kinase 1 (sFlt-1) relative to pro-angiogenic proteins is thought to result in preeclampsia, placental delivery is regarded as curative for this condition. As there is little research on the impact of delivery on such placental proteins, this study sought to examine postpartum trends in sFlt-1 among patients with preeclampsia.

Study Design: A prospective pilot study of pregnant persons without chronic hypertension delivered for preeclampsia with severe features between 7/2023–6/2024. Subjects had at least 2 postpartum sFlt-1 levels drawn, the first within 24 hours of delivery and the second within 10 days of delivery. Primary outcome measures included change in sFlt-1 over time and postpartum half-life of sFlt-1. The normality of distribution for these continuous outcomes was tested by Kolmogorov-Smirnov test, and outcomes with normal distributions were presented as means while those with non-normal distributions were presented as medians. Half-life was calculated according to first-order elimination principles.

Results: Among 20 subjects with preeclampsia with severe features, 16 (80%) had at least 2 postpartum sFlt-1 levels drawn. Median sFlt-1 was 9,304pg/mL (IQR 7,060–25,051pg/mL) and 508pg/mL (IQR 402–855pg/mL) on postpartum day 1 and 7, respectively. This translated to a median reduction in sFlt-1 of 8,800 pg/mL (IQR 7,076–24,650pg/mL) and a median half-life of only 1.51 days (IQR 1.13–1.73 days). These trends did not vary when assessed according to variables including maternal age, ethnicity, body mass index, medical comorbidities, antenatal aspirin exposure, gestational age at diagnosis, blood pressure at delivery, or need for antihypertensives postpartum ($p \geq 0.32$).

Conclusion: Even in patients with preeclampsia with severe features, serum sFlt-1 levels declined rapidly over the first week postpartum. This suggests that factors other than clearance of abnormal placental proteins are likely responsible for persistent postpartum hypertensive disease.

707 | Results of Diagnostic Cardiac Testing Among Pregnant Persons with Positive Cardiovascular Disease Screening

Ashten B. Waks[1]; Heike Thiel de Bocanegra[1]; Jenny Chang[1]; Omotayo Balogun[1]; Anna Grodzinsky[2]; Maryam Tarsa[3]; Afshan B. Hameed[4]
[1]University of California Irvine, Orange, CA; [2]University of Missouri-Kansas City/Saint Luke's Hospital, Kansas City, MO; [3]University of California San Diego, San Diego, CA; [4]University of California, Irvine, Orange, CA

10:30 AM - 12:30 PM

Objective: Cardiovascular disease (CVD) is a significant cause of pregnancy-related morbidity and mortality, and global CVD risk assessment is a key step in mitigating this trend. Our practice includes referring patients with a positive CVD risk assessment for further cardiac testing. This study aimed to establish the rate of abnormal cardiac test results among this group.
Study Design: A prospective cohort study of 3 academic medical centers using our CVD risk assessment between 2020–2024. Primary outcome was an abnormal composite of cardiac test results (e.g. abnormal brain natriuretic peptide (BNP), electrocardiogram (EKG), or echocardiogram) calculated as a percentage. Bivariate analyses with two-sample t-tests and chi-square tests were performed to compare demographic and clinical characteristics between those with normal and abnormal results. Multivariate logistic regression was also fitted to evaluate the association between an abnormal test and patients' sociodemographic characteristics.
Results: A total of 16,900 patients had CVD risk assessment, of whom 334 (2%) had a positive and 16,655 (98%) had a negative result. Among those who screened positive, 207 (62%) went on to have diagnostic cardiac testing, including 117 BNP levels, 159 EKGs, and 81 echocardiograms. In this cohort, 78 (38%) had an abnormal composite cardiac test result, encompassing 14 (12%) abnormal BNP levels, 78 (38%) abnormal EKGs, and 2 (3%) abnormal echocardiograms. There were no significant differences between those with normal and abnormal composite cardiac test results with respect to age, ethnicity, insurance, medical conditions, symptoms, or total score on the CVD risk assessment ($p \geq 0.05$); however, in bivariate analysis, those with a heart rate above 110 were more likely to have an abnormal test ($p = 0.0458$).
Conclusion: Over one-third of patients with a positive CVD risk assessment had abnormal findings on subsequent cardiac testing. As there was inconsistency in the cardiac tests ordered following a positive screening, further research is required to determine which testing strategies have the highest yield for future use.

10:30 AM - 12:30 PM

Objective: Maternal heart disease remains one of the leading causes of preventable pregnancy-related deaths in the US. Limited data compares specific maternal and neonatal outcomes among this high-risk population. Therefore, we sought to investigate how multidisciplinary clinical care affects neonatal outcomes.

Study Design: This was a cohort study of pregnancies (n = 466) affected by maternal cardiac diseases that received multidisciplinary care (MFM/Cardiology/OB/Anesthesia/Cardiac Surgery/Genetics) in a single tertiary center between 2012 and 2024. The study groups consisted of pregnancies with maternal acquired heart disease (AHD) (n = 242), maternal congenital disease (CHD) (n = 224), and pregnancies without any cardiac disease (n = 183). Neonatal outcomes—birth weight, gestational age, Apgar scores, and NICU admissions—across these groups were compared by Pearson Chi-Square, Fisher Exact, and Kruskal-Wallis rank sum tests. A pairwise comparison was conducted for significant differences. The significance level was set at alpha = 0.05.

Results: This study showed increased adverse neonatal outcomes in the heart disease cohort, especially within the maternal CHD group compared to the group without heart disease. Infants born to people with CHD or AHD had lower birth weights, shorter gestational ages, lower Apgar scores, and higher rates of NICU admissions compared to those without heart disease (Table 1) (p value < 0.01 for all comparisons). The proportion of small for gestational age infants born to people with CHD was significantly higher than those born to people with AHD (p = 0.007). All other outcomes were similar in the CHD and AHD cohorts.

Conclusion: Maternal heart diseases are associated with an increased risk of adverse neonatal outcomes, necessitating a multidisciplinary approach in prenatal care and tailored strategies for CHD and AHD. In this study, infants born to people with CHDs had an increased risk for small for gestational age as compared to AHD, thus further studies are necessary to better understand this biological difference.

709 | Immediate Delivery versus Expectant Management in Twin Pregnancies with Late Preterm Rupture of Membranes

Avishag Abecassis[1]; Keren Zloto[2]; Chen Berkovitz[3]; Hadel Watad[4]; Shali Mazaki-Tovi[5]; Michal Fishel Bartal[6]
[1]Sheba Medical Center Tel Hashomer, Israel, Ramat Gan, HaMerkaz; [2]Sheba Medical Center, Ramat Gan, HaMerkaz; [3]Tel Aviv University Israel, Tel Aviv University Israel, HaMerkaz; [4]Sheba Medical Center, Jatt Village, HaZafon; [5]Department of Obstetrics and Gynecology, Sheba Medical Center, Tel HaShomer, Ramat Gan, HaMerkaz; [6]UTH Houston & Sheba Medical Center Israel, Houston, TX

10:30 AM - 12:30 PM

Objective: In recent years, the management of late preterm premature rupture of membrane (PPROM) has changed from expedient delivery towards expected management. Current literature provides limited information on preferred management in twin pregnancy. We aimed to compare maternal and neonatal outcomes in twin pregnancies presented with PPROM at 34-36 weeks.

Study Design:
A retrospective study was conducted at a single tertiary care center between 2011 and 2024. All individuals with twin pregnancies who presented with PPROM between 34.0 to 36.0 weeks of gestation were included. We compared those who were dispositioned for immediate delivery versus those managed expectantly. Maternal and neonatal outcomes were evaluated using frequentist statistics.

Results: During the study period, 146 twin pregnancies presented with PPROM and met inclusion criteria; 37 (25.3%) were managed expectantly, and 109 (74.7%) were dispositioned for delivery. Baseline and pregnancy characteristics were similar between the groups (Table 1). Expectant management was associated with a higher rate of intrapartum fever (8.1% vs. 0.9%, p = 0.05) and Cesarean delivery due to arrest of dilatation (13.5% vs. 1.8% p = 0.01) compared to immediate delivery. Furthermore, expectant management was associated with a higher rate of NICU admission (36.5% vs 23.9%, p = 0.03), respiratory distress syndrome (6.8% vs 1.4%, p = 0.01), and need for antibiotic treatment (63.5% vs. 28.9%, p< 0.01) compared to immediate delivery (Table 2).

Conclusion: In our cohort, expectant management for individuals with twin pregnancies presenting with PPROM at 34-36 weeks of gestation was associated with a higher rate of maternal and neonatal outcomes compared to immediate delivery.

710 | Association of Glucagon Like Peptide-1 Agonist (GLP1) use With Pregnancy Outcomes

Ayodeji Sanusi[1]; Yumo Xue[1]; Victoria C. Jauk[2]; Lynda Ugwu[2]; Charlotte B. McCarley[2]; Adrianna Tilton[2]; Ashley N. Battarbee[1]; Akila Subramaniam[1]; Alan T. Tita[2]; Rachel G. Sinkey[2]
[1]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL; [2]University of Alabama at Birmingham, Birmingham, AL

10:30 AM - 12:30 PM

Objective: Treatment of obesity with GLP1 improves metabolic health and national use is rising since approval in 2017. As unintended pregnancy rates are >40%, GLP1 pregnancy exposures may be increasing. Data are limited on pregnancy outcomes after exposure. We quantified the risks of adverse pregnancy outcomes after GLP1 exposure and how duration of use modifies these associations.

Study Design: Retrospective cohort study of singleton deliveries at a single US center from 2017-2024. Pregnancies after GLP1 use (Semaglutide, Tirzepatide) were matched (1:many ratio) on BMI and demographics to unexposed pregnancies using propensity scores. The primary outcome was a composite of hypertensive disorders of pregnancy (HDP), fetal macrosomia or growth restriction. Secondary outcomes included fetal anomalies, NICU admission, mode of delivery and gestational weight gain (GWG). Regression models estimated the association between GLP1 use and study outcomes. Stratification by duration of use prior to pregnancy (>1yr, ≤1yr) was performed.

Results: Fifty-eight exposed patients were matched to 1578 unexposed patients. Among 1636 patients, 86% were obese, 31% had pregestational diabetes and mean weight at first prenatal visit was 110±27kg. Forty-five patients used GLP1 for ≤1 year. Mean weight change with GLP1 use until pregnancy was -0.11±6.44kg. There were no significant differences between groups after propensity score matching. The primary outcome occurred in 37(64.0%) exposed patients and 864 (54.8%) unexposed patients (OR 1.46, 95% CI 0.84-2.51). Exposed patients had a higher odds of GWG (difference 2.36kg, 95% CI 1.43-3.29) and NICU admission (OR 1.85, 95% CI 1.10-3.13). Other secondary outcomes were similar between both groups. In stratified analysis, NICU admission and GWG risks were significantly higher only with preconception use ≤1yr.

Conclusion: GLP1 use was not associated with HDP/fetal growth disorders. However, preconception use ≤1yr may have higher NICU admission/GWG risks. Future studies of weight trajectories by use duration and timing of discontinuation are needed.

Figure: Primary Outcome and Individual Components for Pregnant Patients Exposed to GLP1 Agonists Compared to Controls

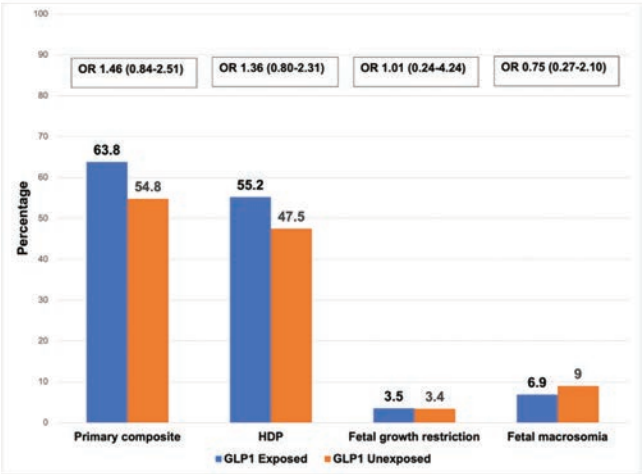

Table: Secondary Outcomes of Pregnant Patients Exposed to GLP1 Agonists Compared to Controls

	GLP1 Agonist Exposed (N = 58)	GLP1 Agonist Unexposed (N = 1578)	Odds Ratio / Difference (95% CI)
Maternal Secondary Outcomes			
Spontaneous abortion	0 (0.0)	31 (2.0)	-
Live birth	57 (98.3)	1511 (95.9)	2.41 (0.33-17.71)
Stillbirth	1 (1.7)	33 (2.1)	0.82 (0.11-6.10)
Preterm delivery <37 weeks	20 (34.5)	443 (28.1)	1.35 (0.78-2.34)
Gestational diabetes	7 (17.9)	235 (21.4)	0.78 (0.35-1.75)
Preeclampsia	25 (43.1)	578 (36.6)	1.31 (0.77-2.23)
Cesarean delivery	28 (48.3)	881 (55.8)	0.74 (0.44-1.25)
Excess gestational weight gain	6 (10.3)	88 (5.6)	1.95 (0.82-4.67)
Maternal gestational weight gain (kg)	10.5 ± 7.8	8.2 ± 10.7	2.36 (1.43-3.29)
Neonatal Secondary Outcomes			
Any fetal anomaly	3 (5.2)	78 (4.9)	1.05 (0.32-3.43)
SGA< 10th percentile	5 (13.5)	142 (9.9)	1.42 (0.54-3.70)
NICU admission	30 (51.7)	578 (36.6)	1.85 (1.10-3.13)
Low birth weight (<2500g)	11 (19.0)	293 (18.7)	1.02 (0.52-1.99)
Neonatal birth weight (g)	3005.8 ± 818.2	3024.1 ± 919.6	-18.3 (-102.60-66.01)

Data are N (%) or mean ± standard deviation as appropriate; Primary composite outcome – hypertensive disorder of pregnancy, fetal macrosomia or growth restriction; Patients with pregestational diabetes excluded from outcome of GDM; Excess gestational weight gain per IOM guidelines; SGA- small for gestational age.

Variables used to generate propensity score are: Age, Race/Ethnicity, Body mass index, Parity, Marital status, Previous cesarean delivery, Prior stillbirth, Health insurance type, Weight at first prenatal visit (kg), Pregestational diabetes, Chronic hypertension, spontaneous labor, Seizure disorder, Current tobacco use, Prior tobacco use, Alcohol use, Substance Abuse, History of substance use, Lupus, Rheumatoid Arthritis, Any sexually transmitted infections, Medications (Aspirin, Metformin, Insulin use, Lovenox/Heparin, Antidepressant use [Lithium/SSRI], Angiotensin converting enzyme inhibitor/ Angiotensin receptor blocker, Corticosteroids prior to delivery, Magnesium prior to delivery). Average standardized absolute mean difference= 0.014 ± 0.041; p value for differences in baseline characteristics between exposed and unexposed range 0.7-1.0.

711 | Late Gestation Iuts Enable Later Delivery Without Adverse Outcomes in Fetuses with Alpha Thalassemia Major

Billie R. Lianoglou[1]; Evangelia Vlachodimitropoulou[2]; Akos Herzeg[3]; Tippi C. MacKenzie[4]; Greg Ryan[5]; Juan Gonzalez[1]
[1]Center for Maternal-Fetal Precision Medicine, University of California San Francisco, San Francisco, CA; [2]Mount Sinai

Hospital and University of Toronto, Toronto, ON; [3]UCSF, San Francisco, CA; [4]University of California, San Francisco, San Francisco, CA; [5]University of Toronto, Toronto, ON

10:30 AM - 12:30 PM

Objective: To understand the impact of in-utero blood transfusion (IUT) performed > 35 weeks' gestation (WG) on perinatal outcomes in fetuses with alpha thalassemia major (ATM).

Study Design: UCSF established an international patient registry for patients affected by ATM which includes all patients referred to our institution and collaborating sites. We conducted a retrospective chart review and prospective enrollment of registry participants, including all singleton pregnancies with ATM who underwent IUTs and received their last IUT >32 WG. Data collected covered prenatal and postnatal outcomes, including details of IUTs. Patients were stratified into two groups based on the timing of the final IUT: **A**: 32-35 WG (N = 17), **B**: > 35 WG (N = 10). Fisher's exact test and unpaired t-test were used to assess the association between the gestational age (GA) of the final IUT and key outcomes such as survival rate, 5' APGAR scores, the need for mechanical ventilation, prolonged neonatal hospitalization, GA at delivery, and time between last IUT and delivery.

Results: There were no differences between groups in the mean age at first IUT (A 25.2, B 23.8; P = 0.41) or the presence of hydrops upon presentation. Extension of IUTs beyond 35 weeks allowed for delivery later in gestation (A 37.4, B 38.3; P< 0.0001), with a shorter time interval between IUT and delivery (A 3.4, B 2.07; P = 0.01). There were no adverse outcomes associated with extended IUTs as evidenced by survival rate (A 100%, B 90%; P = 0.37), 5' APGAR < 7 scores (A 88%, B 90%; P = >0.99), need for mechanical ventilation (A 24%, B 20%; P >0.99); there was a trend for decreased rates of prolonged hospitalization (A 53%, B 22%; P = 0.22).

Conclusion: Expert opinion recommends performing IUTs up to 35 WG, with subsequent planned delivery 2-3 weeks later. However, our analysis indicates that IUTs performed beyond 35 WG are not associated with higher morbidity but allow for later GA at delivery without an additional risk of urgent delivery or other adverse perinatal outcomes.

712 | Cost-Effectiveness of Implementing a Multidisciplinary Team Approach the Management of Placenta Accreta Spectrum

Binh Luu[1]; Megha Arora[2]; Ava D. Mandelbaum[2]; Andrew H. Chon[2]; Tania F. Esakoff[3]; Deirdre J. Lyell[4]; Aaron B. Caughey[2]
[1]Oregon Health and Science University, Vancouver, WA; [2]Oregon Health & Science University, Portland, OR; [3]Cedars Sinai Medical Center, Los Angeles, CA; [4]Stanford University, Palo Alto, CA

10:30 AM - 12:30 PM

Objective: **Objective**: Placenta accreta spectrum (PAS) is associated with high maternal morbidity. Recent studies have shown that a multidisciplinary team approach to managing PAS can improve outcomes. This study aimed to evaluate the cost-effectiveness of implementing a multidisciplinary team for the management of PAS.

Study Design: **Methods**: A decision-analytic model was built using TreeAge software to compare the outcomes and cost-effectiveness of the multidisciplinary team approach versus standard of care (i.e. without immediate availability of a gynecologic oncologist, anesthesiologist, etc.) The theoretical cohort included 5,000 individuals in the U.S. with PAS. Maternal outcomes included severe postpartum hemorrhage (>2000 mL estimated blood loss), adjacent organ injury, ICU admission, maternal death, and hospital readmission. The cost of the multidisciplinary team was estimated by assuming there would be specific MFM physician and nursing leadership assigned. Model inputs were derived from the literature. The cost-effectiveness threshold was $100,000/quality-adjusted life-year (QALY). Sensitivity analyses were performed to assess the robustness of the results.

Results: **Results**: A multidisciplinary team approach for the management of PAS resulted in 3,724 fewer severe postpartum hemorrhages, 139 fewer adjacent organ injuries, 506 fewer ICU

admissions, 87 fewer hospital readmissions within 6 months, and 1 fewer maternal death compared to standard of care (Table 1). When assuming a minimum baseline of 15 PAS cases per year, the multidisciplinary team approach was a dominant strategy resulting in a $8.8 million cost reduction and an increase of 59 QALYs relative to standard care. A one-way sensitive analysis on the number of PAS cases per medical center demonstrated the multidisciplinary team strategy remains cost-effective when centers treat [3] 8 PAS cases annually (Figure 1).

Conclusion: Implementing a multidisciplinary team was cost-effective and improved maternal outcomes. These findings may inform interventions that promote multidisciplinary teams in the management of this high-risk condition.

Table 1: Maternal outcomes, cost, and effectiveness associated with presence of multidisciplinary team versus standard of care in the management of PAS

	Multidisciplinary Team Approach	Standard of Care	Difference
Severe Postpartum Hemorrhage* (cases)	926	4,650	-3,724
ICU Admissions	506	645	-139
Adjacent Organ Injury (cases)	440	548	-108
Maternal Deaths	80	81	-1
Readmissions within 6 months	316	403	-87
Cost ($USD)	214,326,130	223,115,069	-8,788,939
Effectiveness (QALYs)	116,314	116,256	59
Strategy	Dominant	Dominated

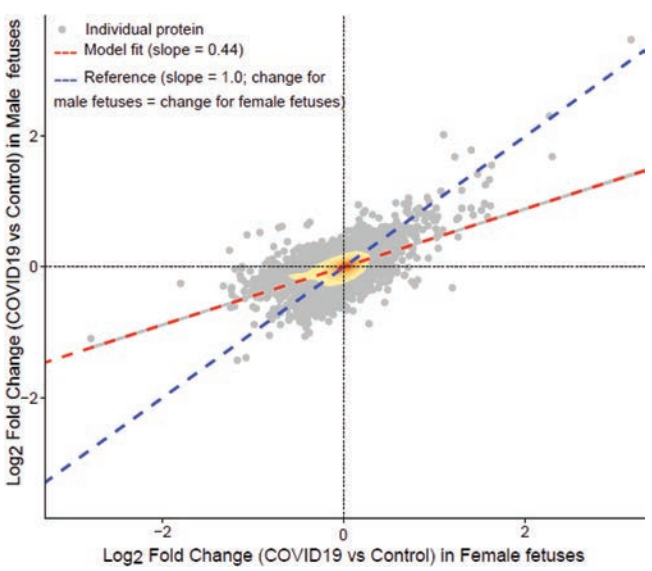
10:30 AM - 12:30 PM

Objective: Fetal sex influences physiological and pathological processes during pregnancy. This study was designed to determine the impact of fetal sex on the maternal response to SARS-CoV-2 infection using large-scale proteomics.

Study Design: This was a prospective observational study of 101 pregnant patients, including 72 with confirmed SARS-CoV-2 infection and 29 controls without infection. Severity was assigned according to the NIH classification for COVID-19. Large-scale plasma proteomics was undertaken with the SomaScan platform, which analyzes 7,288 proteins. Fetal sex-specific changes in the maternal proteome was assessed using linear models and moderated t-tests while accounting for COVID-19 severity and relevant clinical co-variates.

Results: 1) In normal pregnancy, fetal sex did not alter the maternal plasma proteome; 2) SARS-CoV-2 infection during pregnancy exhibited a fetal sex-dependent modulation of the plasma proteome; 3) pregnancies with a male fetus had a lower magnitude of plasma proteomic responses to SARS-CoV-2 infection compared to those with a female fetus (see figure; slope = 0.44, r = 0.61, $p < 0.001$); 4) the dampened maternal plasma proteomic response to infection in pregnancies with a male fetus was also noted according to disease severity; and 5) in severe COVID-19, proteins showing fetal sex-specific magnitude of change (interaction $p < 0.05$) were enriched for antiviral response pathways, endocytosis, and VEGF signaling, among others (adjusted $p < 0.1$).

Conclusion: 1) Fetal sex dimorphism in the maternal proteome is not present in normal pregnancy, but in patients with COVID-19; 2) pregnancies with male fetuses had a dampened proteomic response; and 3) these findings suggest that fetal sex is an important factor modulating the maternal response during SARS-CoV-2 infection and may determine disease progression and outcome.



714 | Nanoparticle-Based Fetal Intraperitoneal Injection is an Alternative to Intravascular Drug Delivery to the Pulmonary Endothelium

Braxton Forde[1]; Vladimir Kalinichenko[2]; Fatemeh Kohram[3]; Jose L. Peiro[4]; Alan Kenny[3]

[1]University of Cincinnati College of Medicine, Cincinnati, OH; [2]University of Arizona, Tempe, AZ; [3]Cincinnati Children's

Hospital Medical Center, Cincinnati, OH; [4]Cincinnati Children's Fetal Care Center, Cincinnati, OH

10:30 AM - 12:30 PM

Objective: Fetal intravascular injection of nanoparticle-based therapy is proposed as a technique for targeted in-utero therapies. However, in humans, umbilical cord access is limited both by gestational age and physician skillset, thus limiting the application of emerging therapies. Specifically in disorders of the fetal lungs, critical phases of development would be missed by waiting for the opportunity for umbilical cord access. Intraperitoneal transfusions have been used in early pregnancy when intravascular access is not feasible, therefore we sought to assess the feasibility of fetal intraperitoneal nanoparticle injections.

Study Design: Polyethylenimine-(5) myristic acid/ poly(ethylene glycol)-oleic acid/cholesterol (PEI-PEG) nanoparticles were created as per prior publications and were tagged with fluorescent-AF647 Dylight. Pregnant rats underwent midline laparotomy at E17.5-E18.5 to fetal injection. Three arms were pre-determined, either fetal intraperitoneal injection of nanoparticles, intra-amniotic injection of nanoparticles, or sham. Fetuses were harvested at E20.5 and cells were immediately isolated and sorted via flow cytometry. As these nanoparticles localize to the pulmonary endothelium in newborn rodents, flow cytometry was used to evaluate pulmonary vascular endothelial cell uptake.

Results: Cell sorting successfully isolated fetal lung tissue and CD31+ CD45- cell lines were considered pulmonary vascular endothelium. Pulmonary endothelium of fetuses that underwent intraperitoneal injection were found to have 50.2% of cells positive for Dylight, vs 0.2% in fetuses that had intra-amniotic injection and 0.0% in control ($p < 0.001$), Figure 1. Every fetus that had an intraperitoneal injection had at least 42% of pulmonary endothelial cells with nanoparticles present, and no intra-amniotic injection had greater than 1%.

Conclusion: Fetal intraperitoneal injection of PEI-PEG nanoparticles successfully targets pulmonary endothelium. IP injections of PEI-PEG nanoparticles provides a vehicle for targeted treatment of the fetal lungs early in gestation.

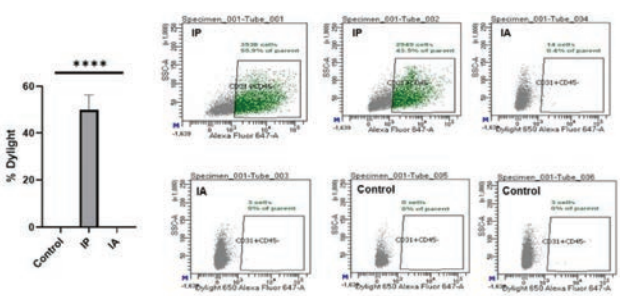


Figure 1. Flow cytometry reveals excellent pulmonary endothelial uptake of PEI-PEG nanoparticles with fetal intraperitoneal injections relative to control and intra-amniotic injections. IP= intraperitoneal, IA= intra-amniotic.

715 | The Association with Severe Lacerations and Increased Risk of Perinatal Depressive Symptoms

Brianna C. Sohl[1]; Mary F. Smith[2]; José Ibarra Rodriguez[2]; Nicole M. Hwang[2]; Samantha de los Reyes[3]

[1]Rush University Medical Center, Justice, IL; [2]Rush Medical College, Chicago, IL; [3]Rush University Medical Center, Chicago, IL

10:30 AM - 12:30 PM

Objective: To evaluate the association of severe perineal lacerations and increased risk of perinatal depressive symptoms at the 6-week postpartum visit.

Study Design: We performed a retrospective cohort study of patients who had a vaginal delivery between July 1, 2021-July 1, 2023. Perineal lacerations were classified as either severe (3rd or 4th degree) or non-severe (1st, 2nd degree or intact perineum). Positive perinatal depressive symptoms were defined as a score of ≥10 on the Edinburgh Postnatal Depression Scale (EPDS) or positive response to question 10 at the 6-week postpartum visit. Univariable analyses of demographic and clinical characteristics and positive EPDS scores at the 6-week postpartum visit were performed. Multivariable logistic regression was performed using variables determined a priori (multiparity, gestational age (GA) at delivery, mode of delivery, race/ethnicity, exclusively breastfeeding at 6-weeks postpartum) to evaluate the independent association of severe perineal laceration and positive EPDS scores at the 6-week postpartum visit.

Results: 689 patients met inclusion criteria with 661 (95.9%) with non-severe perineal lacerations and 28 (4.1%) with severe. In univariable analysis, those with severe perineal lacerations were more likely to be White non-Hispanic or of Asian race/ethnicity, be multiparous, have a lower admission body mass index, have an operative assisted delivery, be delivered at a later GA, have greater blood loss, have a shoulder dystocia or episiotomy, and require a laceration revision within 6 weeks postpartum compared to those without (Table 1). Patients with severe lacerations were less likely to have a positive EPDS at 6-weeks postpartum but these results were not significant (7.1 vs 9.9%, $p = 0.66$) and these findings persisted in adjusted analysis (aOR 0.62, 95%CI 0.13, 2.84).

Conclusion: Severe perineal lacerations was not associated with an increased risk of perinatal depressive symptoms at the 6-week postpartum visit.

Table 1: Maternal demographics and clinical characteristics

	Non-severe laceration n = 661	Severe laceration n = 28	P value

716 | Monochorionic Twins with Selective Fetal Growth Restriction: characteristics, course, management, and outcomes by type

Camille Shantz[1]; Laura Tan[2]; Christina Rivera[2]; Amelia Jiang-Yu[2]; Lindsey Herlands[3]; Michelle Kush[3]; Jena L. Miller[3]; Ahmet A. Baschat[3]; Mara Rosner[3]
[1]Johns Hopkins University, Baltmore, MD; [2]Johns Hopkins University, Baltimore, MD; [3]Johns Hopkins Medicine, Baltimore, MD

10:30 AM - 12:30 PM

Objective: To compare characteristics, Doppler course, and outcomes in Type I, II, and III selective fetal growth restriction (sFGR).

Study Design: Single-center retrospective review of monochorionic twins with sFGR from 6/2014 to 1/2024. Twin to Twin Transfusion Syndrome, high order multiples, and severe fetal anomalies were excluded. Type at diagnosis was assigned by Gratacos criteria. Doppler course (deterioration or improvement) was defined as progression of umbilical artery (UA) end diastolic flow patterns from best to worst: persistent forward →intermittent forward, absent →intermittent forward, absent, reversed→persistent absent→persistent reversed. Ultrasound characteristics at presentation, antenatal course, and obstetric outcomes were compared between groups via Kruskal-Wallis and Pearson Chi-Squared.

Results: Of 199 patients, 133 (67%) were Type I, 18 (9%) Type II, and 48 (24%) Type III. There was no difference in gestational age (GA) at diagnosis. The estimated fetal weight discordance was lowest in Type I and highest in Type II (p< 0.001). UA Doppler deterioration was frequent in all groups and occurred in 28.4% of Type 1, 76.9% of Type II, and 51.4% of Type III (P< 0.001). UA Dopplers also improved in some Type II (15.4%) and Type III (25.7%, p = 0.449). Management varied but was expectant for most (178/199, 89%) though 7 (4%) underwent laser (6/7 had Twin Anemia Polycythemia Sequence), 12 (6%) had selective reduction of the small fetus, and 2 (1%) terminated. Double survival was 89.6% in Type I, 25% in Type II, and 77.8% in Type III (p< 0.001). There was no difference in delivery GA between types, however, the majority of Type II were delivering a single fetus, and amongst all patients, those with 1 vs. 2 livebirths delivered later (36.1 [31.7-38.7] vs. 33.1 [30.9-34.3] weeks, p = 0.002). (Table 1)

Conclusion: Doppler deterioration is common in all Types of sFGR. Types II and III can improve in some cases and can be successfully managed to achieve favorable delivery gestational ages, however double survival is significantly lower in Type II.

717 | Effect of Dental Treatments on Reduction of Preterm Birth: a Systematic Review and Meta-Analysis

Camille Thomas[1]; Shakil Ahmed[2]; Rohan D'Souza[2]; Vincenzo Berghella[3]; Romina Brignardello-Petersen[2]; Mohamed El-Rabanny[2]; Catherine Devion[4]; Stefania Ronzoni[5]
[1]University of Toronto, Toronto, ON; [2]McMaster University, Hamilton, ON; [3]Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA; [4]Sunnybrook Health Sciences Centre, Toronto, ON; [5]Ontario Fetal Center and Mount Sinai Hospital, Toronto, ON

10:30 AM - 12:30 PM

Objective: This study aims to assess the effectiveness of treating dental disease during pregnancy in reducing the risk of preterm birth.

Study Design: We conducted a systematic review and meta-analysis of randomized controlled trials (RCTs). We searched EMBASE, MEDLINE, PubMed, and Cochrane Central Register of Controlled Trials from inception to December 2023 with no language restrictions for RCTs enrolling pregnant persons with any dental disease who were randomized to receiving dental treatment versus a control. Pairs of independent reviewers screened studies, and abstracted and assessed the risk of bias of the studies using the Cochrane Risk of Bias tool, RoB 2. We conducted meta-analysis using a random effects model with the Mantel-Haenszel variance estimate. We assessed the certainty of evidence using the Grading of Recommendations Assessment, Development, and Evaluation (GRADE) approach.

Results: We included 19 RCTs, enrolling 8526 participants. The risk of bias for most of the RCTs ranged from some concerns to high risk. The most frequent interventions addressed were scaling

and root planing (SRP) with oral hygiene instructions (OHI, 10 RCTs), and SRP with OHI and chlorhexidine mouthwash (6 RCTs). Meta-analysis found low-quality evidence suggesting that dental treatment results in a 22% relative risk reduction of preterm birth (RR 0.78; 95% CI 0.63-0.95) when compared to placebo or control, which was usually minimal dental treatment or oral examination only (absolute difference 29 fewer preterm births per 1000 individuals; 95% CI from 48 fewer to 6 fewer).

Conclusion: This systematic review suggests that treating dental disease during pregnancy reduces the risk of preterm birth. The main limitations of the evidence are risk of bias and inconsistency. Additional well-powered RCTs at low risk of bias are necessary to increase the certainty about the effect of dental disease treatments during pregnancy on reduction of preterm births.

Figure 1: Meta-analysis of pooled risk ratio of effect of dental treatments on preterm birth (<37 weeks' gestation) and risk of bias

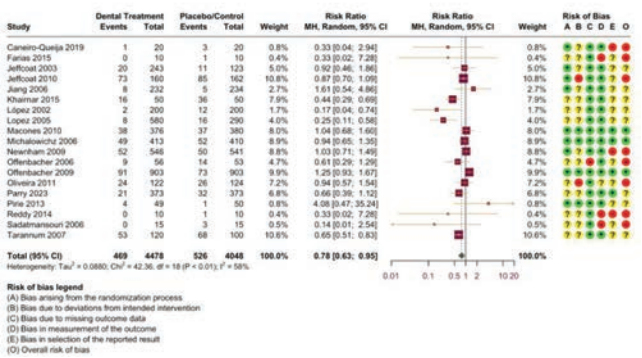

Figure 2: GRADE evidence profile of dental treatments on preterm birth (<37 weeks' gestation)

718 | Perinatal Outcomes of Resolved Fetal Cystic Hygromas

Carmen MA Santoli[1]; Emma EH Peek[2]; Lucas C. Collins[3]; Teresa N. Sparks[4]; Jeffrey A. Kuller[3]; Sarah K. Dotters-Katz[3]

[1]University Of California San Francisco, San Francisco, CA; [2]University of Colorado, Aurora, CO; [3]Duke University School of Medicine, Durham, NC; [4]Center for Maternal-Fetal Precision Medicine, University of California San Francisco, San Francisco, CA

10:30 AM - 12:30 PM

Objective: We described the perinatal phenotype of pregnancies with resolved fetal cystic hygroma and compared outcomes among fetuses with and without genetic abnormalities.

Study Design: A retrospective cohort study (2013-2023) at a single tertiary center identified fetuses with cystic hygroma in the first or second trimester that resolved on subsequent ultrasound imaging. Pregnancies resulting in live birth with prenatal and delivery data were included. We describe perinatal characteristics, delivery outcomes, and genetic diagnoses. Bivariate statistics compared outcomes among fetuses with and without genetic abnormalities. A p-value < 0.05 was considered statistically significant.

Results: Of 297 fetal cystic hygromas, we identified 59(20%) fetuses with cystic hygromas that resolved on subsequent imaging and resulted in live birth. Of these, 46 pursued prenatal and/or postnatal genetic diagnosis; 31(67%) had normal results and 15(33%) had a genetic abnormality, such as aneuploidy(n = 10), copy number variant(n = 2), or single-gene disorder(n = 3).(Figure) Compared to fetuses with normal genetic testing, fetuses with genetic abnormalities were more likely to have a later gestational age at cystic hygroma diagnosis(12.3 vs 11.6 weeks, p = 0.007) and resolution(20.1 vs 17.3 weeks p = 0.006).(Table) Compared to fetuses with normal genetic evaluations, fetuses with genetic abnormalities were more likely to have additional structural anomalies on ultrasound(67% vs 13%,p = 0.001). The most common ultrasound findings were cardiac anomalies, followed by abdominal and renal abnormalities. Fetuses with resolved cystic hygromas and genetic abnormalities were more likely to have growth restriction, an earlier delivery, longer length of neonatal stay, and neonatal complications.

Conclusion: Fetuses with resolved cystic hygromas and genetic abnormalities were more likely to have other structural anomalies and obstetric complications when compared to those with normal results of genetic testing. These data are important for framing expectations and counseling of patients who experience resolution of fetal cystic hygroma.

Table. Pregnancy characteristics of resolved fetal cystic hygromas with abnormal prenatal or postnatal genetic diagnosis (N=15) compared to those with normal genetic results (N=31).

719 | Antenatal Characteristics Predict Need for Dental Referral Using the ACOG-Recommended Oral Health Screening Tool

Carolina Martinez-King; Charlie Rose; Annika Sahota; Krystle M. Perez; Tommy J. Yang; Shruti Kulkarni; Sophia Tibayan; Kanika Nallaseth; Abdul Hameed; Kathryn J. Gray; Tommy Wood; Gregory C. Valentine
University of Washington, Seattle, WA

10:30 AM - 12:30 PM

Objective: The American College of Obstetricians and Gynecologists (ACOG) recommends screening pregnant patients with a 3-question survey at their first prenatal visit for oral health. We sought to evaluate which characteristics are associated with an overall positive screen (defined as a positive response on any of the three questions) or with positive screen for each specific question.

Study Design: We screened pregnant individuals at a university-based prenatal clinic using the 3-question ACOG screening tool (Figure 1). We performed generalized linear models with stepwise forward AIC regression to evaluate antenatal characteristics (Table 1) with a positive overall screen and each specific question including adjusted odds ratios per included variable. Missing data for binary risk factors was imputed assuming the predictor was unknown. The dataset was divided 80:20 for model development and validation, respectively.

Results: Among 817 patients that completed the ACOG screen, 44.9% screened positive (367/817) with 14.9% (122/817) screening positive on question 1, 37.1% (303/817) on question 2, and 5.8% (48/817) on question 3. The models predicted 89.5%, 78.0%, and 93.2% accuracy with a positive screen for questions 1, 2, or 3, respectively. The model also predicted a positive overall screen with 66.7% accuracy. Antenatal factors with >1.5-fold increased odds of a positive overall screen (Figure 1A) and symptomatic oral disease (Figure 1B) were Medicaid insurance, self-identifying as Hispanic, having COVID, or having substance abuse during pregnancy.

Conclusion: Our models using antenatal characteristics can accurately (≥89%) predict symptomatic oral disease in pregnancy. Medicaid insurance, self-identifying as Hispanic, having COVID or substance abuse during pregnancy were strongly associated with increased odds of having symptomatic oral disease or needing referral to a dentist underscoring that health disparities are present related to oral care in pregnancy. Antenatal efforts improving access to oral health in pregnancy are needed to reduce health disparities.

Figure 1: Forest plots demonstrating the generalized linear models after stepwise forward AIC antenatally known characteristics. The ACOG 3-question screening tool includes three questions: (1) Do you have any swollen or bleeding gums, a toothache, problems eating or chewing food, or other problems in your mouth? (2) Has it been more than 6 months since you last saw a dentist? (3) Do you need help finding a dentist? (A) Model A demonstrates the antenatal characteristics associated with an overall positive screen, defined as a positive answer to any of the 3 ACOG-recommended questions. (B) Model B demonstrates the antenatal characteristics associated with a positive answer to the first of the 3 ACOG-recommended questions focusing on symptomatic oral disease. (C) Model C demonstrates the antenatal characteristics associated with a positive answer to the second of the 3 ACOG-recommended questions focusing on time since last dental visit. (D) Model D demonstrates the antenatal characteristics associated with a positive answer to the final of the 3 ACOG-recommended questions focusing on needing assistance finding a dentist. aOR = adjusted odds ratio. All aORs are written as point estimates with 95% confidence intervals (CI).

Table 1 – Table Representing Antenatal Characteristics of All Screened Pregnant Individuals Evaluating Those with a Positive Overall ACOG Screen Compared to Those with a Negative Overall Screen

	Screen Positive (n=367)	Screen Negative (n=450)	p-value
Age (years), median (IQR)	33.0 (28-36)	34.0 (30.3-37)	**<0.01**[c]

Creanga[9]
[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [2]Mercy Medical Center, Baltimore, MD; [3]Luminis Health Anne Arundel Medical Center, Annapolis, MD; [4]Johns Hopkins Howard County Medical Center, Columbia, MD; [5]Sinai Hospital of Baltimore, Baltimore, MD; [6]Johns Hopkins School of Medicine, Baltimore, MD; [7]Sinai Hospital of Baltimore, Sinai Hospital of

Baltimore, MD; [8]Sinai Hospital of Baltimore, Baltiomre, MD; [9]Johns Hopkins University, Baltimore, MD

10:30 AM - 12:30 PM

Objective: Maryland implemented facility-based severe maternal morbidity (SMM) surveillance and review in 2020 following AGOG/SMFM guidance. This study aims to analyze trends in primary cause of SMM, preventability and contributing factors. We also examine policy and practice changes that have resulted from the program.

Study Design: Data are from SMM surveillance for 2021-2023 among the 5 hospitals that participated over the full period (level III & IV birthing facilities in rural and urban settings). Using X^2 tests, we analyzed changes in primary cause of SMM, patient characteristics, and contributing factors. We further examined policy and practice changes that resulted from SMM reviews.

Results: Of 428 SMM events identified and reviewed, 80%, 78%, and 86% of patients had preexisting comorbidities in 2021, 2022, and 2023, respectively ($p = 0.24$). A growing proportion of patients did not receive prenatal care (1.6% in 2021, 5.4% in 2022, and 8.7% in 2023; $p = 0.035$). Obstetric hemorrhage was the leading cause (>50%) of SMM across all 3 years; however, the distribution of other causes varied (Table 1). COVID-19 was the second primary cause of SMM in 2021 (18%), but resulted in only 3 SMM events in 2022-23. Over the 3-year period, review committees determined that 37% (increasing from 34% to 40% between 2021 and 2023) of SMM events were preventable with changes to one or more provider, system, or patient factor. System and patient factors were identified in a larger percentage of preventable SMM events in 2023 than 2021-2022, while the contribution of provider factors did not change significantly (Table 2). In response to SMM reviews, all participating hospitals made specific policy and practice changes to address factors that contributed to leading causes of preventable SMM.

Conclusion: 40% of SMM events were deemed preventable by review committees in 2023. With hemorrhage being the leading cause of SMM, participating hospitals introduced policy and practice changes targeting hemorrhage and implementation of AIM's Obstetric Hemorrhage bundle is underway in Maryland.

Table 1. Primary Cause of SMM Surveillance & Review, Maryland 2021-2023

	2021 (N=125)		2022 (N=130)		2023 (N=173)		Overall	
	N	%	N	%	N	%	N	%

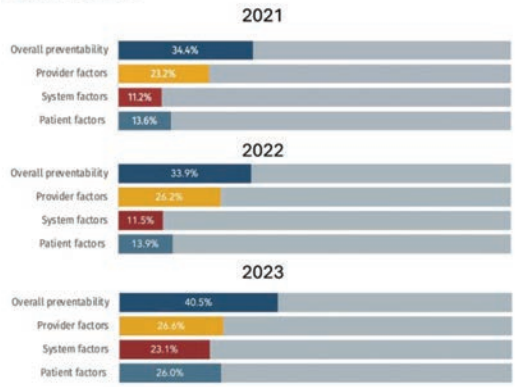
Other	0	0.0	3	2.3	2	1.2	5	1.2

Note: Pearson X^2=86.4, p<0.001.
In line with ACOG/SMFM guidance for facility-based surveillance for SMM, Maryland's SMM surveillance definition includes patients during pregnancy or within 42 days postpartum who are: a) admitted to an intensive care or critical care unit, and/or b) receive transfusion of 4 or more units of blood products.

Figure 1. Preventability and Types of Factors That Could Have Altered the SMM Outcome, Maryland 2021-2023



Note: Percent preventable assessed among all SMM events identified each year (2021, N=125 2022, N=130; 2023, N=173). Pearson X^2 for overall preventability=1.79, p=0.41; provider factors=0.49, p=0.78; system factors= 10.53, p=0.005; patient factors=10.24, p=0.006.

721 | Urine Culture Speciation During Pregnancy and Association with Maternal Attributes and Neonatal Outcomes

Chaarushi Ahuja[1]; Lisbet S. Lundsberg[2]; Jennifer F. Culhane[2]; Caitlin Partridge[2]; Mert Ozan Bahtiyar[3]; Katherine Kohari[2]
[1]Yale New Haven Hospital, New Haven, CT; [2]Yale School of Medicine, New Haven, CT; [3]Yale University, New Haven, CT

10:30 AM - 12:30 PM

Objective: Urine culture(UC) is commonly ordered during pregnancy for urinary tract infection(UTI) symptoms or abdominopelvic pain. Little is known about the positivity rate of UC during pregnancy or associated maternal and neonatal outcomes. We aimed to assess the rate of positivity of UCs, and to assess maternal attributes and neonatal outcomes associated with different speciations.

Study Design: This is a retrospective study of pregnant patients who had a UC performed in our hospital system in non-ambulatory settings from 2013-2022. Patients with UCs were classified as 1) always negative (< 10k colony forming units-CFU), 2) ever positive for GBS (>10k CFU) or UTI-causing microbes (>100k CFU) or 3) ever positive for non-UTI microbes (>100k CFU). Maternal characteristics of age, insurance, race, parity, language, BMI, chronic hypertension(cHTN), hypertensive disorders of pregnancy(HDP), gestational diabetes(GDM), and pregestational diabetes were compared between the 3 groups using chi-square or ANOVA. Pregnancy outcomes of preterm birth(PTB), small for gestational age(SGA), mode of delivery, and neonatal intensive care unit(NICU) admission were also compared.

Results: 19,698 patients had a UC performed. The ever positive rate for GBS/UTI was 3.3% in patients with 1 UC, increasing to 18% among patients with ≥7 UC(Fig 1). Statistically significant differences across groups were noted in age, insurance, race, parity, language, BMI, and smoking(Table 1). There were also significant differences for cHTN, HDP, pregestational diabetes, PTB, NICU admission and SGA (Table 1). There was no statistical difference between groups for mode of delivery.

Conclusion: This is one of the first studies to classify rate of positivity by UC speciation during pregnancy. Maternal attributes were significantly different between groups, suggesting a need for further exploration of the basis of these differences. Surprisingly,

PTB was more common in the always negative UC group compared to the positive UC groups. Thus, more studies are needed to understand relationships between positive UC, sociodemographics, and obstetric outcomes.

722 | Progesterone Supplementation in Preeclamptic Women Reduces Blood Pressure and Inflammatory Mediators of Hypertension During Pregnancy

Charles H. Brewerton; Christy Chambers; Richard Rein; Nathan Campbell; Baoying Zheng; Ty Turner; Montianah Roseburgh; Babbette LaMarca; Sheila Belk; Cameronne Dodd; Lorena M. Amaral
University of Mississippi Medical Center, Jackson, MS

10:30 AM - 12:30 PM

Objective: **Introduction**: Preeclampsia (PE), new onset hypertension after 20 weeks of gestation, is associated with lower progesterone, increased CD4+T cells, inflammatory cytokines, and autoantibodies to angiotensin II type 1 receptor (AT1-AA). We have previously shown that placental PE CD4+ T cells cause a PE phenotype in athymic nude rats. Moreover, we have shown that 17-hydroxyprogesterone caproate (17-OHPC), lowers blood pressure in PE patients, however, it is unclear if this was mediated via a T cell effect.

Objective: Determine if placental CD4+ T cells from 17-OHPC treated PE women increase blood pressure in athymic nude recipient rats.

Study Design: PE women received 17-OHPC (250 mg, I.M.) with blood draws before and after injection. One million placental CD4+ T cells from normal pregnant (NP) or PE participants were isolated by magnetic beads and injected I.P. into pregnant nude athymic rats on gestational day (GD) 12. On GD18, carotid catheters were inserted. On GD19, mean arterial blood pressure (MAP), blood and tissues were collected. One-way ANOVA was used for statistical analysis.

Results: Participants had matched GA. Maternal blood pressure was 116 +/-4 mmHg in NP women (n = 8), 147 +/- 4 mmHg in PE women (n = 19) and reduced to 136 +/- 3 mmHg in PE+17-OHPC women (n = 14, $p < 0.05$). AT1-AAs were 23 +/- 5 beats per minute in PE (n = 4) and 10 +/-2 in PE+17-OHPC (n = 8; student t-test, $p < 0.05$). Placental CD4+T cells were 2+/- 1% gate in NP, 6 +/- 1 in PE, and 3 +/-1 % gate in PE+17-OHPC (n = 4-5). Circulating TNF-α was 21 +/- 4 pg/mL in NP, 41 +/-8 in PE ($p < 0.05$), 21+/-5 pg/ml in PE+17-OHPC (n = 6-8, $p < 0.05$). In pregnant nude recipient rats, MAP was 98 +/- 2 mmHg with NP CD4+ T cells (n = 5), 122 +/-7 (n = 7, $p < 0.05$) with PE CD4+ T cells (n = 7) and 102+/- 5 with PE+17-OHPC CD4+ T cells (n = 7, $p < 0.05$).

Conclusion: 17-OHPC in PE women reduces blood pressure and inflammatory mediators of hypertension during pregnancy. Moreover, PE CD4+ T cells treated with 17-OHPC do not mediate a PE phenotype in recipient pregnant rats.

723 | Delivery and Neonatal Outcomes of Resolved Vasa Previa Cases

Chiara Corbetta-Rastelli[1]; Molly Zeme[1]; Rachel Mundaden[1]; Mary E. Norton[2]; Kate Swanson[3]
[1]University of California San Francisco, San Francisco, CA; [2]Center for Maternal-Fetal Precision Medicine, University of California San Francisco, San Francisco, CA; [3]University of California, San Francisco, San Francisco, CA

10:30 AM - 12:30 PM

Objective: Recent expert opinion has questioned the definition of vasa previa. We examined delivery and neonatal outcomes in cases of resolved vasa previa, comparing fetal vessels 2-5cm from the cervical os versus >5cm away from the os.

Study Design: Retrospective cohort study of patients diagnosed with vasa previa at a single academic urban institution between 2004 to 2024. We conducted an electronic chart review, including ultrasound images, to obtain variables at diagnosis and throughout pregnancy, along with delivery and neonatal outcomes. We used descriptive and chi-square statistics.

Results: We identified 112 pregnancies with vasa previa, of which 31 (28%) resolved on a subsequent ultrasound. Of the 31 resolved vasa previa cases, 20 were 2-5cm from the os and 11 were >5cm. Of those with vessels 2-5cm from the cervical os, 9 (45%) delivered by scheduled cesarean and 11 (55%) had a trial of labor (TOL). Of those that had a TOL, five (45%) delivered vaginally and six (55%) had a cesarean delivery due to PPROM (n = 2), fetal intolerance of labor (n = 1), arrest of descent (n = 1), unstable lie (n = 1) and worsening pre-eclampsia (n = 1). Of those with vessels >5cm from the os, one (9%) delivered by scheduled cesarean and 10 (91%) had a TOL, of which 8 (80%) delivered vaginally. The only emergent cesarean delivery and neonatal blood transfusion occurred in a patient with fetal vessels >5cm from the os; the suspected etiology was placental abruption. There were no statistically significant differences in neonatal APGAR scores, umbilical artery pH and intensive care nursery admissions between groups. There were no perinatal deaths.

Conclusion: The majority of resolved vasa previa cases with vessels 2-5cm from the cervical os delivered by cesarean. While many were scheduled, there were urgent cesareans for PPROM, unstable lie, arrest of descent, worsening pre-eclampsia and fetal intolerance. Most cases with vessels >5cm from the os delivered vaginally. Larger studies are needed to further assess delivery and neonatal outcomes of resolved vasa previa.

724 | Metabolic Recovery at 12 Months Postpartum Among Individuals with Glucose Intolerance in Pregnancy

Christina M. Scifres[1]; Arunabh Sinha[1]; Kaleab Abebe[2]; Christina Lalama[2]; Tina Costacou[2]; Steve Orris[2]; Patrick Catalano[3]; Esa Davis[4]

[1]Indiana University School of Medicine, Indianapolis, IN; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA; [3]Tufts University, Tufts University/Boston, MA; [4]University of Maryland School of Medicine, Baltimore, MD

10:30 AM - 12:30 PM

Objective: Glucose intolerance in pregnancy is associated with long-term risk for type 2 diabetes (T2D). We evaluated metabolic characteristics and β-cell function during pregnancy and at 12 months postpartum among varying levels of glucose intolerance in pregnancy.

Study Design: This is a planned follow-up to the Gestational Diabetes Diagnostic Methods (GDM2) trial, which randomized pregnant individuals to either a 75-gram oral glucose tolerance test (OGTT) with GDM diagnosed using the IADPSG criteria, or a 100g OGTT with GDM diagnosed by the Carpenter-Coustan (CC) criteria. All participants with treated GDM (diagnosed by either CC or IADPSG), those with untreated mild glucose intolerance (MGI, one abnormal value on CC criteria), and half of the participants with normal glucose tolerance were invited for a 75g OGTT at 12 months postpartum. Measures assessed at the time of GDM screening and at follow-up included metabolic characteristics, Stumvoll and Matsuda Indices to evaluate insulin sensitivity and resistance, and the Disposition Index (DI), which integrates insulin sensitivity and response.

Results: Of the 407 individuals seen at 12 months, 49 (12%) had MGI and 53 (13%) had treated GDM (CC and IADPSG). MGI was associated with lower insulin sensitivity, lower beta cell function, dyslipidemia, and alterations in leptin and adiponectin similar to those individuals with treated GDM (Table). Measures of metabolic function, insulin sensitivity and β-cell function demonstrated similar rates of change from pregnancy to postpartum after adjusting for maternal age, BMI, and history of GDM.

Conclusion: Patients with MGI have impaired β-cell function and significant metabolic abnormalities at 12 months postpartum similar to individuals with treated GDM and require ongoing follow-up for progression to T2D. The similar rate of change from pregnancy to postpartum in insulin sensitivity, β-cell function, and metabolic assessments among groups indicates that individuals were returning to their baseline levels of glucose tolerance rather than recovering from pregnancy-induced glucose intolerance.

TABLE: Maternal Metabolic Outcomes at 24-28 Weeks' Gestation and 12 Months Postpartum

Characteristic	No GDM (n=305)	Mild Glucose Intolerance (n=49)	Treated GDM (n=53)	P-value
Pregnancy				
Stumvoll Index	1,470.5 (±607.6)	1,465.5 (±750.9)	1,755.6 (±848.3)	0.037
Matsuda Index (n=402)	23.5 (±18.3)	13.3 (±8.1)	9.4 (±8.4)	<0.001
Disposition Index (n=402)	27,937 (±14,892)	15,359 (±5,479)	12,519 (±5,222)	<0.001
Triglycerides (mg/dL)	160.3 (±57.3)	200.4 (±73.5)	203.8 (±71.7)	<0.001
Cholesterol (mg/dL)	235.7 (±43.2)	231.4 (±46.8)	233.0 (±50.7)	0.75

725 | Symptoms of Post Traumatic Stress Disorder Among Placenta Accreta Spectrum Providers

Christina M. Duzyj[1]; Alireza A. Shamshirsaz[2]; Daniela A. Carusi[3]

[1]Massachusetts General Hospital, Boston, MA; [2]Fetal Surgeon Chief, Division of Fetal Medicine and Surgery Director of the

Maternal Fetal Care Center Director of the Perinatal Surgery Fellowship Professor of Surgery, Boston Children's Hospital Harvard Medical School, Boston, MA; [3]Brigham and Women's Hospital, Boston, MA

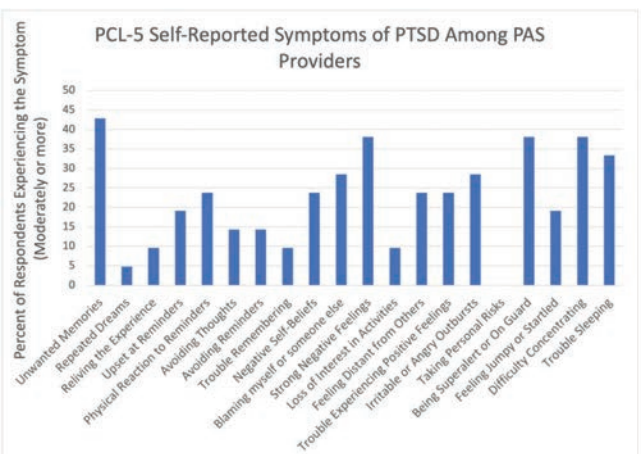
10:30 AM - 12:30 PM

Objective: Physicians as a second victim have been increasingly recognized since the COVID-19 pandemic. However, physician post-traumatic stress disorder (PTSD) is less frequently recognized. We sought to evaluate for symptoms of PTSD among physicians caring for women with placenta accreta spectrum (PAS), a medical condition with known high acuity and high mortality.

Study Design: This is a cross-sectional study consisting of a quantitative survey distributed via email to physicians who either are members of the Pan-American Society for Placenta Accreta Spectrum, or who attended a PAS Post-Graduate Course or Scientific Session at the SMFM Annual Meeting in 2024. The survey included the PTSD Checklist for DSM-5 (PCL-5), as well as demographic questions, and open ended questions regarding institutional support after severe cases of PAS. Scoring was performed as recommended by the National Center for PTSD.

Results: The email containing the survey was opened by 71 individuals, and the survey completed by 21 (30%). All responders cared for women with PAS, the majority for 3-5 years (38.1%) although 28.6% reported greater than 10 years experience in caring for PAS, and 38.1% reported caring for a women who died of PAS. Most (71.4%) reported perceiving personal psychologic impact occasionally from severe PAS cases, with only one respondent never impacted. 66.6% of the cohort met diagnostic criteria for PTSD (PCL-5 >30), with highest responses being for unwanted memories (42.9%), strong negative feelings, feeling superalert or onguard, and difficulty concentrating (38.1% each). 28.6% reported that their institution provided no psychological support after difficult cases.

Conclusion: This preliminary study demonstrates that physicians caring for the obstetric patients at highest risk for mortality are themselves at high risk for post-traumatic stress disorder. Although our results are likely biased towards respondents experiencing the outcome of interest, we demonstrate that institutions must build capacity for supporting their physicians when adverse obstetric outcomes occur, particularly among patients with PAS.



726 | Placenta Accreta Spectrum is Associated with Lower Rates of Hypertensive Disorders of Pregnancy

Colleen Sinnott[1]; Olga Grechukhina[2]; Jennifer F. Culhane[2]; Sonya Abdel-Razeq[2]; Khadija Alshowaikh[2]; Viktoriia Kolesnyk[2]; Yang Yang-Hartwich[2]; Mert Ozan Bahtiyar[1]; Kevin Dysart[3]
[1]Yale University, New Haven, CT; [2]Yale School of Medicine, New Haven, CT; [3]Nemours Children's Hospital, Wilmington, DE

10:30 AM - 12:30 PM

Objective: Placenta accreta spectrum (PAS) arises from over-invasion of the placenta, while hypertensive disorders of pregnancy (HDP) are thought to arise from trophoblast under-invasion; these may represent two ends of a spectrum of disordered placentation. In a single-institution study, we previously demonstrated clinical evidence suggesting PAS is protective against HDP. Here, we validated this finding in a larger patient cohort.

Study Design: This retrospective study utilizes Epic Systems' Cosmos research platform, an electronic health record database with de-identified patient-level data. PAS, HDP (gestational hypertension, preeclampsia, eclampsia, and HELLP) and other clinical and sociodemographic characteristics were extracted from the database for all deliveries from 2017-2023. Patients with and without HDP were compared across a range of maternal attributes. To account for scheduled preterm deliveries for PAS, such that some patients with PAS deliver before HDP is clinically diagnosed, these comparisons were repeated with cohorts stratified by gestational age (GA) at delivery (< 34 weeks and ≥ 34 weeks). For all cohorts, the crude and adjusted odds of HDP by PAS diagnosis was calculated using logistic regression. All covariates in the bivariate tests of association were included in the multivariable regression models.

Results: A total of 4,287,549 delivery encounters were included. Of those, 8,979 (0.21%) had PAS, 869,759 (20.3%) had HDP, and 125,332 deliveries (2.9%) occurred < 34 weeks. In the total cohort, after adjusting for GA at delivery and maternal factors, patients with PAS were half as likely to be diagnosed with HDP (aOR 0.55 [0.51, 0.59]). In both GA-stratified cohorts, < 34 weeks and ≥34 weeks, this effect remained stable with aOR 0.54 [0.47, 0.62] and aOR 0.42 [0.38, 0.45], respectively.

Conclusion: Patients with PAS develop HDP at half the rates seen in those without PAS after controlling for GA at delivery and patient factors. These two seemingly unrelated conditions may result from abnormalities of the same biologic mechanisms and may benefit from future tandem investigation.

727 | Correlation Between Blood Pressures and Markers of Inflammation in the Maternal Circulation in Pregnancy

Corrine K. Nelson[1]; Kylie Cooper[1]; Sylvie Girard[1]; Anna Borchers[1]; Elsa Bernier[2]; Marie-Eve Brien[3]
[1]Mayo Clinic, Rochester, MN; [2]Montreal University, Montreal, PQ; [3]Sainte-Justine Hospital Research Center, Montreal, PQ

10:30 AM - 12:30 PM

Objective: Hypertensive diagnostic criteria from the American Heart Association has been revised in non-pregnant individuals. However, in pregnancy the diagnosis of chronic hypertension, defined as blood pressure >/ = 140/90 prior to pregnancy or 20 weeks gestation, has remained consistent. It is unclear if changes in blood pressure, such as in elevated and stage 1 hypertension, are associated with inflammatory markers. Therefore, we determine if levels of markers of inflammation were associated with blood pressure in a cohort of uncomplicated pregnancies and as compared to patients with gestational hypertension (gHTN).

Study Design: Maternal blood samples were obtained in the third trimester close to delivery in a cohort of pregnant patients with uncomplicated pregnancies (n = 96) or with gHTN (n = 36), and plasma isolated for multiplex analysis of inflammatory mediators. In-depth review of the medical record was performed.

Results: Circulating levels of several mediators were significantly associated with increased blood pressure. Of interest, the pro-inflammatory chemokine MCP-1 was positively correlated with blood pressure (r = 0.47, p< 0.001) whilst CXCL10 was negatively correlated (r = -0.36, p< 0.01). In addition, pro-inflammatory cytokines IL-5 and TNFa presented trending positive correlation with blood pressure (IL-5: r = 0.22, p = 0.072; TNFa: r = 0.024, p = 0.055). Surprisingly, the anti-inflammatory cytokine IL-4 was also positively correlated with blood pressure (r = 0.24, p< 0.05). Of note, MCP-1 and CXCL10 were both significantly elevated in gHTN while IL-5 and TNFa were unchanged.

Conclusion: Our data suggest that specific inflammatory markers, including MCP-1–responsible for monocyte recruitment, IL-5 and TNFa are correlated with increased blood pressure in a cohort of uncomplicated pregnancies. While MCP-1 was also significantly elevated in gHTN, this was not the case for the other cytokines. Further analysis will ascertain the role of pre-pregnancy body mass index in the level of these markers. In addition, a larger cohort is needed to have better understanding of the clinical significance of this work.

728 | Should Transvaginal Cervical Length Surveillance be Conducted After Cerclage Placement to Predict Spontaneous Preterm Birth?

Dahiana M. Gallo[1]; Rupsa C. Boelig[2]; Julio Mateus Nino[3]; Vincenzo Berghella[4]; Leonardo Pereira[5]; Catalina M. Valencia[6]; Joanne N. Quiñones[7]; Richard M. Burwick[8]; Joseph Bell[9]; Luisa López-Torres[10]; Adam Taylor[11]; Luis Alvarado[12]; Jorge E. Tolosa[13]

10:30 AM - 12:30 PM

Objective: Transvaginal cervical length (CL) surveillance after cerclage placement is not universally performed and recommended. The objective of our study was to assess whether a cervical length < 25 mm after cerclage placement affects the risk of spontaneous preterm birth (sPTB).

Study Design: Retrospective cohort of the International Collaborative for Cerclage Longitudinal Evaluation and Research (IC-CLEAR) study included singleton pregnancies managed with cerclage for history, ultrasound, or physical exam indications between June 2016 and August 2020 at 8 sites across the United States (6) and Colombia (2). Exclusion criteria were patients without CL measurement post cerclage and iatrogenic preterm birth < 37 weeks. The exposure of interest was cervical length after cerclage < 25 mm. Statistical analysis included univariable and multivariable models. Each model was adjusted for the use of vaginal progesterone after cerclage.

Results: Of 839 patients managed with cerclage, 408 (49.39%) had a CL measurement after cerclage, but only 219 patients met the criteria. Patients with a CL < 25mm post-cerclage did not have a significantly increased risk of sPTB < 37 weeks or < 34 weeks (76% vs 73%, p 0.680, 52 vs 42%, p 0.140 respectively) compared to those whose cervix returned to a normal length of >25 mm; however, a CL < 20mm was associated with an increased risk of spontaneous

preterm birth < 34 weeks (59% vs 43% p 0.039). After adjusting for the use of vaginal progesterone, there was a reduction in the risk of sPTB before 34 weeks (RR 1.49,95% CI 0.88 -2.54, p 0.131).

Conclusion: The results indicate that if the cervical length after cerclage is less than 20 mm, there remains an elevated risk of preterm birth before 34 weeks. Monitoring the cervical length following cerclage placement could be beneficial. In these instances, additional treatments such as progesterone might be considered when counseling patients to help lower the rate of early spontaneous preterm birth.

Table 1. Demographics and patient characteristics of pregnancies who had cervical length measurement after cerclage and spontaneous preterm birth (sPTB) before 37 weeks.

729 | An Updated Rapid Review of Pain Management Following Cesarean Birth

Dana Feldman[1]; Bryan L. Aaron[2]; Faith Gacheru[2]; Holli Sharples[2]; Michelle Moniz[2]; Jennifer Waljee[2]; Mark Bicket[2]; Lisa Kane Low[2]; LaTeesa James[2]; Alex Peahl[3]
[1]Wake Forest University, Winston-Salem, NC; [2]University of Michigan, Ann Arbor, MI; [3]Michigan Medicine, Ann Arbor, MI

10:30 AM - 12:30 PM

Objective: To update our rapid review assessing the evidence for key aspects of pain management following cesarean birth, to inform new clinical practice guidelines.

Study Design: We used Ovid MEDLINE, Elsevier's Scopus, Elsevier's Embase, Google Scholar, PubMed, and Web of Science to perform a narrative synthesis of studies that assessed opioid use, analgesia effects, patient-centered outcomes, and disparities in the general population, patients with opioid use disorder (OUD), chronic pain, and psychiatric conditions. Articles were screened and abstracted by two reviewers. Quality was assessed using the RAND/UCLA Appropriateness Methodology approach.

Results: Of 2753 studies screened, 106 were included: 24 RCTs, 5 non-RCTs, and 77 observational studies (7 with very high/critical, 28 with high/serious, 25 with moderate/some concerns for, and 17 with low risk of bias). Following cesarean birth, multimodal, non-opioid interventions (e.g. scheduled ibuprofen and acetaminophen) consistently reduced opioid consumption and/or prescribing without increasing pain. discharge prescribing studies showed variability and racial/ethnic disparities following cesarean births. Patients with chronic pain and psychiatric conditions had increased opioid exposure and persistent use. Non-pharmacologic strategies had limited evidence for pain reduction but high satisfaction. Tailored prescribing reduced outpatient opioid use without worsening pain control. Higher inpatient use, discharge prescription size, and substance abuse history were associated with new persistent opioid use. Patients with chronic pain and psychiatric conditions had increased opioid exposure and persistent use.

Conclusion: Multimodal opioid-sparing strategies provide adequate pain control while limiting opioid use after cesarean birth. Non-pharmacologic methods may provide low-risk enhancement in pain management. There are significant evidence gaps for postpartum pain management in patients with OUD, chronic pain, and psychiatric conditions.

730 | Non-Hormonal Treatments for Vasomotor Sequelae in Patients with Postpartum Hemorrhage Requiring Peripartum Hysterectomy

Daniel J. Martingano[1]; Amanda F. Francis Oladipo[2]; Marwah Al-Dulaimi[3]; Sandra Kumwong[4]; Andrea Ouyang[5]; Lauren Cue[6]; Ashley Nguyen[3]; Francis X. Martingano[7]; Shailini Singh[8]; Mark Rebolos[3]; Kristin Cohen[9]; Alexander Ulfers[10]; Donald Morrish[3]; Iffath A. Hoskins[11]
[1]St. John's Episcopal Hospital-South Shore and William Carey University College of Osteopathic Medicine, Far Rockaway, NY; [2]Hackensack University Medical Center, Hackensack, NJ; [3]St. John's Episcopal Hospital-South Shore, Far Rockaway, NY; [4]Touro College of Osteopathic Medicine-Harlem Campus, New York, NY; [5]William Carey University, Hattiesburg, MS; [6]Rutgers University and the Jersey City Medical Center, Jersey City, NJ; [7]NYU Grossman School of Medicine - NYU Brooklyn, New York, NY; [8]AtlantiCare Regional Medical Center, Pamona, NJ; [9]RWJBarnabas Health - Trinitas Regional Medical Center, Elizabeth, NJ; [10]Walter Reed National Military Medical Center, Bethesda, MD; [11]Albert Einstein College of Medicine - Montefiore Medical Center, New York, NY

10:30 AM - 12:30 PM

Objective: Emergent peripartum hysterectomy may be required as a lifesaving procedure for sever postpartum hemorrhage (SPPH). SPHH requiring hysterectomy can rarely be associated with severe complications such as unintended oophorectomy or

Sheehan syndrome, which respectively can lead to vasomotor sequelae. This study sought to evaluate the effectiveness of non-hormonal treatment regimens for vasomotor sequelae in patients with pregnancies complicated by SPHH requiring peripartum hysterectomy.

Study Design: We conducted a multi-center, prospective observational study from 7/2019 to 7/2024 comparing all pregnant patients requiring a peripartum hysterectomy due to SPHH and endorsed vasomotor symptoms up to 6-months postpartum. Monotherapy clonidine 24-hour patch, paroxetine, gabapentin, black cohosh, sertraline, and fluoxetine were included as covariates. Patients less than 34 0/7 weeks gestation, with prior endocrine or rheumatology disorders, or allergies to or prior use of any of the covariates were excluded. The primary outcomes included patient-reported resolution of daytime and/or nighttime symptoms confirmed by provider assessment and the need to switch medication, as discrete events.

Results: The study included 27 patients who reported vasomotor symptoms following SPHH requiring hysterectomy. Study groups' demographics were not significantly different. 16 (59.3%) patients had complications of unintended oophorectomy, 20 (74.1%) were diagnosed with Sheehan Syndrome, and 9 (33.3%) were diagnosed with both conditions. Patients using the clonidine 24-hour patch were more likely to achieve daytime vasomotor symptom resolution (92.6% v. 18.5%, p = 0.030) and were less likely to switch medications (85.2% v. 22.2%, p = 0.004). Patients using paroxetine at doses of 10mg or greater were more likely to achieve resolution of both nighttime vasomotor and insomnia symptoms compared to non-use (88.9% v. 11.1%, p = 0.021).

Conclusion: Clonidine and paroxetine are reasonable nonhormonal treatment therapies for vasomotor sequelae in patients with pregnancies complicated by SPHH requiring peripartum hysterectomy.

731 | Effect of Oral Magnesium Supplementation as Adjunctive Treatment in Pregnancies Complicated by Chronic Hypertension

Daniel J. Martingano[1]; Amanda F. Francis Oladipo[2]; Marwah Al-Dulaimi[3]; Sandra Kumwong[4]; Andrea Ouyang[5]; Lauren Cue[6]; Ashley Nguyen[3]; Francis X. Martingano[7]; Shailini Singh[8]; Alexander Ulfers[9]; Mark Rebolos[3]; Kristin Cohen[10]; Donald Morrish[3]; Iffath A. Hoskins[11]

[1]St. John's Episcopal Hospital-South Shore and William Carey University College of Osteopathic Medicine, Far Rockaway, NY; [2]Hackensack University Medical Center, Hackensack, NJ; [3]St. John's Episcopal Hospital-South Shore, Far Rockaway, NY; [4]Touro College of Osteopathic Medicine-Harlem Campus, New York, NY; [5]William Carey University, Hattiesburg, MS; [6]Rutgers University and the Jersey City Medical Center, Jersey City, NJ; [7]NYU Grossman School of Medicine - NYU Brooklyn, New York, NY; [8]AtlantiCare Regional Medical Center, Pamona, NJ; [9]Walter Reed National Military Medical Center, Bethesda, MD; [10]RWJBarnabas Health - Trinitas Regional Medical Center, Elizabeth, NJ; [11]Albert Einstein College of Medicine - Montefiore Medical Center, New York, NY

10:30 AM - 12:30 PM

Objective: Intravenous magnesium sulfate remains an essential medication for seizure prophylaxis in the context of severe preeclampsia (SPEC), with oral formulations reserved for non-severe comorbid conditions with inconsistent results. This study sought to determine the effect of oral magnesium supplementation as adjunctive treatment in pregnancies complicated by chronic hypertension (CHTN).

Study Design: We conducted a multi-center, prospective observational study from 7/2022 to 7/2024 and included all pregnant women diagnosed with chronic hypertension requiring antihypertensive medication with gestational ages ranging from 24 0/7 through 38 0/7 weeks-gestation. All patients were prescribed low-dose aspirin prophylaxis. Monotherapy magnesium oxide and magnesium citrate were included as covariates. The primary outcomes included diagnosis of superimposed SPEC, new-onset headache (NOH) not relieved by acetaminophen monotherapy, and worsening hypertension requiring additional or initiation of antihypertensive medications, as discrete events. Patients with preexisting neurological or cardiac disorders or allergies to any included medications were excluded. Medication choice was determined by physician clinical assessment.

Results: The study included 693 patients diagnosed with CHTN. 351 patients were given magnesium oxide and 342 patients were given magnesium citrate. Baseline demographic factors were not significantly different. Patients who received magnesium oxide were less likely to develop SPEC (30.1% v. 69.9% p = 0.001) or NOH (14.1% v. 73.1%, p< 0.001) with a 14% (RR = 0.86, 95% CI 0.68-0.93, p = 0.004) and 33% (RR = 0.67, 95% CI 0.41-0.82, p = 0.002) decreased risk in adjusted models, respectively. In stratified analysis, patients with BMI < 30 kg/m2 who received magnesium oxide were less likely to require addition or initiation of antihypertensive medications (54.8% v. 22.9%, $p = < 0.001$). None of the primary outcomes were significant for patients receiving magnesium citrate.

Conclusion: Magnesium oxide supplementation may be beneficial for patients with pregnancies complicated by CHTN.

732 | Twin Pregnancy is a Significant Risk Factor for Delivery within 24 hours in P-PROM

Daniel Gabbai[1]; Itamar Gilboa[1]; Anat Lavie[2]; Yariv Yogev[3]; Emmanuel Attali[1]

[1]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel-Aviv, Tel Aviv; [2]Tel Aviv Sourasky Medical Center, Tel Aviv Sourasky Medical Center, Tel Aviv; [3]Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv University, Tel Aviv Sourasky Medical Center, Tel Aviv

10:30 AM - 12:30 PM

Objective: To assess the likelihood of delivery within 24 hours after preterm premature rupture of membranes (P-PROM) in twin pregnancies in comparison to singleton pregnancies.

Study Design: We conducted a retrospective cohort study in a tertiary university-affiliated medical center with approximately 12,500 deliveries annually (2012-2023). Data collected encompassed demographic and obstetrics characteristics including maternal age, gestational age at delivery, body mass index, parity, mode of delivery, and delivery outcomes. A comparison was made between twin (study group) and singleton (control group) pregnancies with P-PROM (gestational age 24+0-36+6). Statistical analyses, including Cox regression and multivariate

logistic regression, were performed to evaluate the impact of twin pregnancies on the likelihood of delivery within 24 hours.

Results: 1) During the study period, 145,883 women delivered in our center. Of them, 1,498 [1%] women were admitted with P-PROM, of whom 297 (19.9%) with twin pregnancies.

2) The characteristics of the two groups differ regarding gestational age at delivery, parity, previous cesarean deliveries, and mode of conception [Table 1].

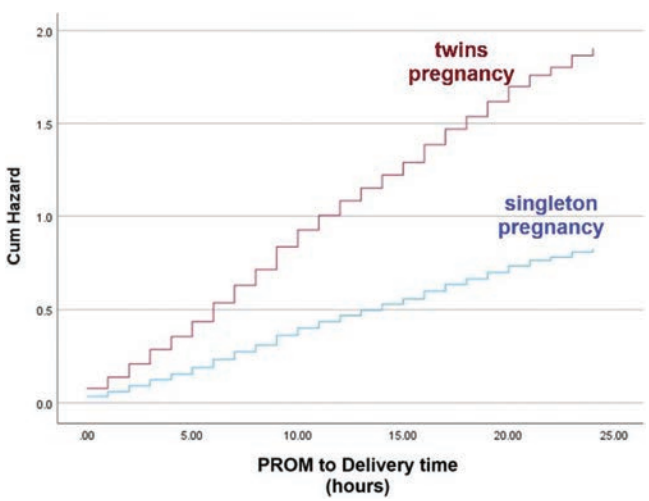
3) In the study group, 234 women (78.8%) delivered within 24 hours, while 697 women (58.3%) in singleton pregnancies (p-value< 0.001).

4) Using a Cox regression and multivariate logistic regression, twin pregnancy was identified as a significant factor for delivery within 24 hours: HR 2.3 (95%CI 1.9-2.7, p< 0.001) [Table 2].

Conclusion: Twin pregnancy was found to be the most significant risk factor for delivery within 24 hours in women with P-PROM.

Table 1: Cox regression for delivery within 24 hours

	HR (95%CI)	p-value
Multiple pregnancies	**2.3 (1.9-2.7)**	**<0.001**
Gestational week < 34	**0.7 (0.6-0.87)**	**<0.001**
Assisted Reproductive Technology	0.9 (0.8 -1.17)	0.805
Nulliparity	1.12 (0.9-1.3)	0.135
Antibiotics during labor	**0.6 (0.5 – 0.73)**	**<0.001**
Previous Cesarean Delivery	1.12 (0.8-1.5)	0.4
Spontaneous delivery	**1.6 (1.4-1.8)**	**<0.001**



733 | The 5-Year Results of an Institutional Shadowing Program Aiming to Train New Senior "Obstetricians On-Call"

Daniel Tairy[1]; Eran Weiner[2]; Anat Engel[3]; Yael Ganor Paz[1]

[1]Edith Wolfson Medical Center, Holon, HaMerkaz; [2]Wolfson Medical Center, Wolfson Medical Center, Tel Aviv; [3]Edith Wolfson Medical Center, holon, HaMerkaz

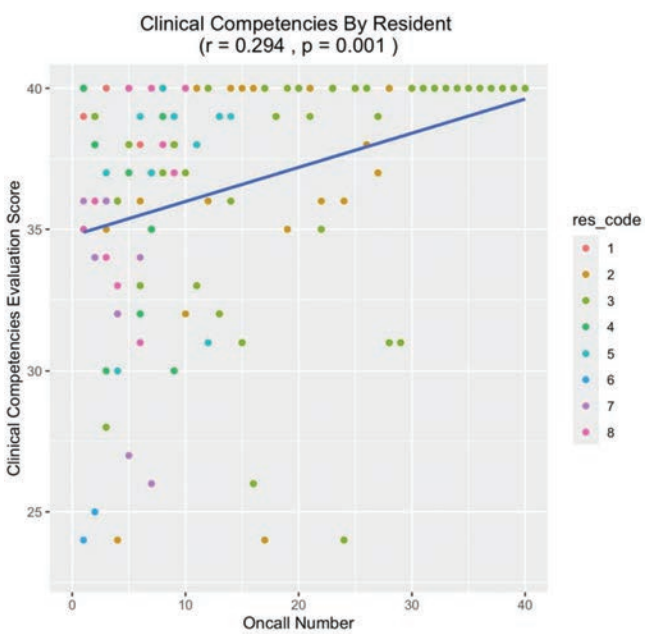
10:30 AM - 12:30 PM

Objective: On-call night and weekend shifts are pivotal components of the clinical activity of any obstetric unit. Worldwide, these teams are usually led by a senior in-house "obstetrician on call" (OOC). This study presents the effects of a structured institutional shadowing program to train future OOCs (fOOC) on their clinical competencies and on obstetric adverse outcomes.

Study Design: In August 2022 we implemented a training program where senior residents (fOOCs) improve complex obstetric and leadership competencies by performing repeated 24h calls shadowed by an experienced obstetrician. After each 24h call the fOOC received a structured oral and written feedback scoring their competencies. Additionally, the fOOC's self-assessed their respective competencies upon entering and completing the program using structured questionnaires. Lastly, we compared the occurrence of major maternal and neonatal adverse outcomes before (January 2019 to July 2022 = P1) vs. after (August 2022 to July 2024 = P2) the program implementation.

Results: As of August 2024 we performed 151 shadowed 24h shifts, performed by 8 fOOCs trained by 15 obstetricians. The fOOC's skills were evaluated with a higher performance degree when compared between upon entering vs. completing the program as assessed by the fOOCs as well as by the senior obstetricians (p< 0.05 to all). Figure 1 describes an example for the improvement of the clinical competencies as were assessed by the senior obstetricians for the cohort of fOOCs during the program. Additionally, when comparing the 13336 on-call deliveries in P1 to the 8718 on-call deliveries in P2, P2 was characterized by lower rates of maternal bleeding and transfusion (p< 0.001), shoulder dystocia (p = 0.04), neonatal Apgar score< 7 (p = 0.009), respiratory morbidity (p = 0.02), Erb's palsy (p = 0.03), and neonatal death (p = 0.05)- table 1.

Conclusion: The implementation of a shadowing training program to fOOC was associated with a higher reported perception of clinical competencies, and the 2-year period post implementation was associated with institutional lower rates of important obstetric adverse outcomes.



Table– Selected outcomes compared between the time periods

	P1 n=13336 deliveries	P2 n=8718 deliveries	*p* value
Selected obstetric outcomes			
Perineal tear grade 3/4	50 (0.4)	37 (0.4)	0.56
Shoulder dystocia during labor	112 (0.8)	52 (0.6)	**0.04**
Bleeding necessitating blood transfusion	283 (2.1)	77 (0.9)	**<0.001**
Selected neonatal outcomes			
NICU admission	2519 (19.9)	1766 (20.9)	0.06
Umbilical Ph< 7.1	92 (0.7)	56 (0.7)	0.59
5 minute Apgar score< 7	223 (1.8)	110 (1.3)	**0.009**
Respiratory morbidity*	40 (0.3)	13 (0.2)	**0.02**
Cerebral morbidity**	3 (0.02)	4 (0.04)	0.35
Sepsis	2 (0.002)	1 (0.001)	0.81
Transfusion	4 (0.003)	0 (0)	0.1
Erb's palsy	18 (0.1)	4 (0.04)	**0.03**
Clavicular fracture	21 (0.1)	14 (0.2)	0.99
Neonatal death	17 (0.1)	4 (0.04)	**0.05**

All data are shown as number (%). Values in bold are statistically significant (p<0.05).

NICU- neonatal intensive care unit; *Respiratory morbidity include- respiratory distress syndrome or mechanical ventilation; **Cerebral morbidity include- intra ventricular hemorrhage, seizures or hypoxic-ischemic encephalopathy

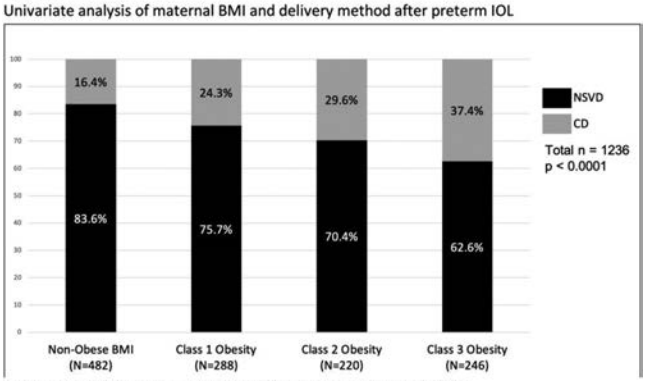
734 | Preterm Medically Indicated Labor Induction and Mode of Delivery in Patients with Obesity

Daniella Rogerson[1]; Madison Kent[2]; Minhazur R Sarker[1]; Alice Sutton[1]; Elizabeth Nicole Teal[3]; Cynthia Gyamfi-Bannerman[3]
[1]University of California San Diego Health, San Diego, CA; [2]University of California San Diego, San Diego, CA; [3]University of California, San Diego, San Diego, CA

10:30 AM - 12:30 PM

Objective: Maternal obesity is associated with cesarean delivery (CD) during induction of labor (IOL) at term; whether the same is true for patients with obesity undergoing preterm IOL is unknown. We sought to evaluate CD rates for patients with and without obese BMI undergoing medically indicated preterm IOL.
Study Design: This is a secondary analysis of a multicenter, randomized trial of singleton pregnancies at risk for preterm delivery. Participants with body mass index (BMI) >18.5 who underwent IOL for any indication were included. Planned CD and spontaneous labor were excluded. We compared delivery mode among participants undergoing preterm IOL by body mass index (BMI) at delivery: non-obese 18.5-29.9, class 1 30-34.9, class 2 35-39.9, class 3 > 40. The primary outcome was incidence of CD by BMI class. Chi-square, ANOVA and multivariable regression tests determined the strength of association.
Results: Of 1236 included participants, 482 had non-obese BMI (39%); 288 (23%), 220 (18%) and 246 (20%) had class 1-3 obesity. Pregnancies with class 1-3 obesity were more likely to be of Black race (20% for non-obese; 27%, 29% and 37% for class 1-3) or have hypertension (HTN) (6% non-obese; 13%, 21%, 33% class 1-3) or gestational diabetes (GDM) (6% non-obese; 13%, 18%, 21% class 1-3) (p values < .0001). In a univariate analysis, those with obesity were more likely to undergo unplanned CD than their non-obese counterparts (p< .0001). In a multivariable analysis adjusted for nulliparity, advanced maternal age, HTN, GDM, and treatment group, participants with class 1-3 obesity were more likely to undergo CD than their non-obese counterparts (class 1 aOR 1.62, 95% CI 1.12-2.36, class 2 aOR 2.30, 95% CI 1.55-3.41, class 3 aOR 2.96, 95% CI 2.02-4.33).
Conclusion: These novel findings suggest that while participants with obesity are more likely to undergo CD during medically indicated pre-term IOL, the majority still deliver vaginally. This data may aid in counseling patients undergoing medically indicated pre-term delivery who have obese BMI.

Figure 1
Univariate analysis of maternal BMI and delivery method after preterm IOL



NSVD – normal spontaneous vaginal delivery. CD – cesarean delivery.

Table 2

Multivariate logistic regression of maternal BMI and delivery method after preterm IOL* *Adjusted for nulliparity, AMA, HTN, GDM, and treatment group.				
	Non-Obese BMI (N=482)	Class 1 Obesity (N=288)	Class 2 Obesity (N=220)	Class 3 Obesity (N=246)
Adjusted OR (95% CI)	ref	**1.62 (1.12-2.36)**	**2.30 (1.55-3.41)**	**2.96 (2.02-4.33)**

AMA – advanced maternal age, HTN – hypertension, GDM – gestational diabetes mellitus. Treatment group per the original trial was betamethasone administration versus placebo.

735 | Nicu Admission for Neonatal Hypoglycemia and Impact on Breastfeeding Outcomes Among Gravidas with Diabetes

Daniella Rogerson[1]; Marni B. Jacobs[2]; Minhazur R. Sarker[3]; Kim Boggess[4]; Ashley N. Battarbee[5]; Gladys (Sandy) A. Ramos[3]; On behalf of the MOMPOD Study Consortium
[1]University of California San Diego Health, San Diego, CA; [2]University of California, San Diego Health, San Diego, CA; [3]University of California, San Diego, San Diego, CA; [4]University of North Carolina at Chapel HIll, Chapel Hill, NC; [5]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL

10:30 AM - 12:30 PM

Objective: Neonatal hypoglycemia (NH) is common in pregnancies with diabetes mellitus (DM) and can lead to neonatal intensive care unit (NICU) admission, a known barrier to breastfeeding (BF). We hypothesized that BF rates are lower after NICU admission among infants with NH compared to NICU admission without NH. This study compares BF rates among gravidas with DM with neonatal NICU admission.
Study Design: This is a secondary analysis of the MOMPOD randomized controlled trial of metformin versus placebo in insulin treated DM. Participants with live births and intention to BF were included. NH was defined as glucose < 40mg/dL or requiring IV glucose within 72 hours. A BF questionnaire was collected

30 days postpartum. Primary outcome was exclusive and partial BF among participants with neonatal NICU admission with NH versus other indications. Secondary outcomes were time and reasons for BF cessation. Characteristics were compared with Chi-square and t-tests or Wilcoxon; multivariable regression tests were performed.

Results: Of 468 participants who completed a BF survey, 378 were included. 142 neonates were admitted to the NICU: 102 with NH and 40 without. Neonates admitted to the NICU with NH were more often born by cesarean and had higher birthweight than those without ($p < 0.05$, Table 1). No BF, exclusive BF, and partial BF did not differ between groups; this remained true when adjusting for birthweight and mode of delivery (aOR 0.62, 95% CI 0.25–1.51, aOR 2.72, 95% CI 0.54 –13.60, aOR 1.10, 95% CI 0.44–2.70, Table 2). Participants who stopped BF did so at an average of 2.8 weeks for both groups ($p = 0.91$) and for similar reasons (trouble latching, pain, poor weight gain, low supply, $p > 0.05$, data not shown).

Conclusion: Among pregnancies complicated by DM, NICU admission with NH did not pose additional barriers to BF compared with NICU admission in general, although analysis is limited by sample size. Future studies examining specific reasons for BF cessation pertinent to NH are needed to understand which factors affect BF in this population.

Table 1

Baseline demographics for infants with NICU admission among participants intending to breastfeed

Demographic	Neonatal Hypoglycemia (n = 102)	No Hypoglycemia (n = 40)	p-value
Maternal age, mean years (SD)	32.1 (6.2)	33.9 (5.5)	0.11

736 | The Rate of Weight Gain During Pregnancy and Newborn Head Circumference

Danruo Zhong; Grace Liu; Khadija R. Jones; Elizabeth Werner; Catherine E. Monk

Columbia University Irving Medical Center, New York, NY

10:30 AM - 12:30 PM

Objective: Weight during pregnancy, a marker of gestational biology and maternal health, has been related to neonatal outcomes. However, no study has examined the effects of the *rate of weight gain* during pregnancy on newborn head circumference, an early indicator of children's neurodevelopment (e.g., autism spectrum disorder). In this study, we aim to examine the association between the initial level and the rate of body mass index (BMI) change during pregnancy and newborn head circumference.

Study Design: This is a secondary data analysis from the Prenatal Stress: The Epigenetic Basis of Maternal and Perinatal Effects Study. From n = 187 pregnant participants ($M_{Age} = 29.64$; $SD_{Age} = 6.24$), BMI in pregnancy was collected three times at gestational week 15, 25, and 35, respectively. Newborn head circumference, gestational age at birth, and sex were abstracted from the medical record. We hypothesized that BMI intercept (from 15 weeks) and slope would be positively associated with newborn head circumference.

A latent growth curve model (LGCM) was used to delineate the trajectories of mothers' BMI across three assessments, treating the intercept (BMI at 15 weeks) and the slope (rate of BMI change) as two latent variables. Additionally, a structural equation model (SEM) was built, predicting newborn head circumference from the intercept and the slope of BMI while controlling for mother's age, newborn gestational age at birth and sex.

Results: Sample characteristics are shown in Table 1. Pregnant individuals' BMI intercept (B = 1.27, $p < .05$) and slope across three assessments (B = 1.19, $p < .05$) were positively associated with newborn head circumference (Figure 1).

Conclusion: Individuals' BMI at the start of the 2nd trimester and its rate of change throughout the 2nd and 3rd trimesters were positively associated with newborn head circumference. These findings suggested that the *rate* of gestational weight gain, in addition to weight status, may play an important role in influencing infant growth and future health.

Table 1

Characteristics of Participants (n=187)

Participant Characteristics	Mean (SD)
Mother	
Age at the first assessment (in years)	29.64 (6.24)
Race

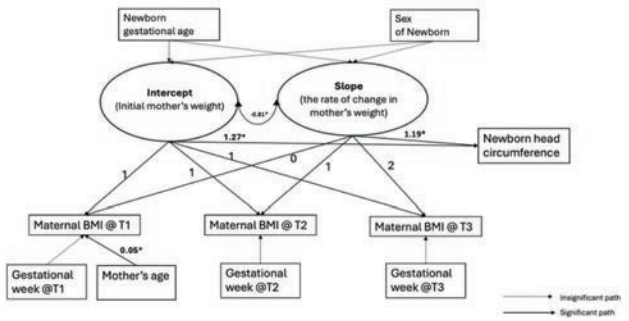
Head circumference (in cm)	34.36 (1.55)

Note. Participants who are Latinx identified themselves as American Indians in our study.

Figure 1. The Intercept and Slope of BMI in Pregnancy are Associated with Newborn Head Circumference.



Note. Fit statistics indicated an acceptable fit of the final model (CFI =0.98, RMSEA=0.07, SRMR=0.06, NNFI=0.97, χ^2 with 21 df = 28.55, p = 0.13). The intercept and the slope of maternal BMI across three assessments during pregnancy (from the beginning of the 2nd trimester to the end of the 3rd) were positively associated with newborn head circumference. T1 (time 1), gestational week 15; T2 (time 2), gestational week 25; T3 (time 3), gestational week 35. *p <0.05; **p <0.01; ***p <0. 001. All estimates shown are standardized.

737 | Risk Factors for Preeclampsia Following Early Onset Fetal Growth Restriction

David Nadav Sabag[1]; Ronen Fluss[2]; Rakefet Yoeli-Ullman[3]; Abraham Tsur[4]

[1]Sheba Medical Center, Ramat Gan, Tel Hashomer, Israel, Givatayim, HaMerkaz; [2]Gertner Institute, Ramat Gan, HaMerkaz; [3]Sheba Medical Center, Ramat Gan, HaMerkaz; [4]Sheba Medical Center, Ramat Gan, Tel Hashomer, Israel, Ramat Gan, HaMerkaz

10:30 AM - 12:30 PM

Objective: Early onset fetal growth restriction (FGR) may precede the development of preeclampsia (PE). The aim of this study was to evaluate risk factors associated with the development of PE in individuals with early onset FGR.

Study Design: The study included all consecutive individuals admitted to the antepartum unit of a tertiary university affiliated medical center between 2011-2024 for the diagnosis of early onset FGR. Maternal and pregnancy characteristics were recorded, including: maternal age, BMI, smoking, parity, gestational age (GA) at diagnosis, chronic hypertension, maternal cardiac disease, pre- or gestational diabetes, thrombophilia, chronic renal disease, history of major pregnancy complications, mode of conception, number of fetuses, premature contractions, ultrasound (US) measured abdominal circumference (AC), US measured estimated fetal weight (EFW), umbilical artery doppler PI (UAPI) and middle cerebral artery doppler PI (MCAPI).

AC and EFW were classified as < 5% and < %3 respectively based on local population growth charts. UAPI and MCAPI percentiles calculated per specific gestational age.

We investigated the association of these variables with development of PE using univariate and multivariable logistic regression.

Results: During the study period 774 pregnant individuals were admitted for early-onset FGR, while 79 of them (10.2%) subsequently developed PE. Table 1 presents maternal and pregnancy characteristics according to the development of PE. Using multivariate analysis (Table 2) GA 24-28 weeks at diagnosis (OR 2.54, CI 1.20-5.36, p = 0.01), AC below the 5th percentile (OR 2.31, CI 1.10-4.86, P = 0.02), and UAPI above the 95th percentile (OR 3.35, CI 1.55-7.20, P< 0.01) were significantly associated with the subsequent development of PE.

Conclusion: Early GA at diagnosis of FGR, AC below the 5th percentile and UAPI >95th percentile are significantly associated with the development of PE in pregnancies complicated by early-onset FGR.

738 | Severe Maternal Morbidity In Urban vs Rural Populations Following Patient Safety Bundle Implementation in Hawaii

Deepraj K. Pawar[1]; Mary Tschann[2]; Julie Kathman[3]; Rebecca Delafield[4]; Pai-Jong Stacy Tsai[2]
[1]University of Hawaii, Honolulu, HI; [2]University of Hawaii, John Burns School of Medicine, Honolulu, HI; [3]Health Association of Hawaii, Honolulu, HI; [4]University of Hawaii, Manoa, Honolulu, HI

10:30 AM - 12:30 PM

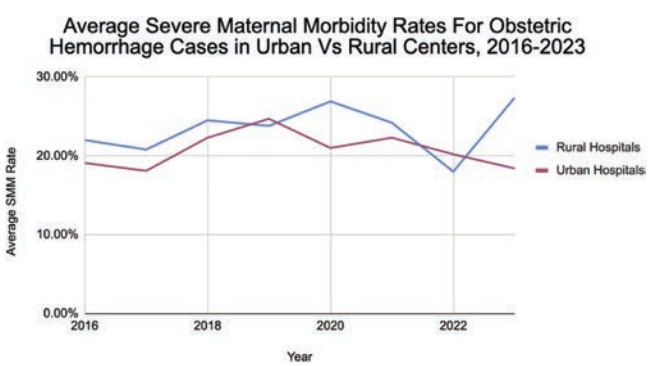
Objective: The Alliance for Innovation on Maternal Health (AIM) has developed evidence-based patient safety bundles (PSB) to decrease severe maternal morbidity (SMM) for several obstetric outcomes including hemorrhage. In 2021, 10/12 hospitals with birthing facilities in Hawaii adopted AIM safety bundles.

Hawaii faces challenges in implementing such interventions given its unique geography. Hawaii has 5 urban birthing facilities, all located on the island of Oahu, and 7 rural facilities, located on neighbor islands. Resources, such as blood products, are limited on neighbor islands and transfer to higher level tertiary urban facilities requires air transportation. Our goal was to explore how SMM rates in the setting of obstetric (OB) hemorrhage differ between rural vs urban centers in Hawaii, particularly since AIM PSB implementation.

Study Design: We abstracted data from the AIM Data Center, which provided aggregated SMM rates among OB hemorrhage cases (excluding ectopic pregnancy and spontaneous abortion) for 4 urban and 6 rural birthing facilities in the state of Hawaii, and stratified by year from 2016 to 2023.

Results: A total of 9,527 births were included. Average SMM rates in OB hemorrhage at rural centers ranged from 18.0% to 27.4% over the course of the 2016 to 2023 study period (Figure 1). At the time of implementation of AIM PSB in 2021, SMM rate was 24.2%, fluctuating to 18.0% and 27.4% in 2022 and 2023 respectively. In Hawaii's urban centers, SMM fluctuated between 18.1% to 24.7% during the study period, with a rate of 22.3% in 2021, decreased to 18.4% by 2023.

Conclusion: Our analysis showed that Hawaii's rural centers often have a higher rate of SMM than Hawaii's urban centers. Our analysis also revealed that urban populations did have a reduction in SMM rates among OB hemorrhage after the implementation of AIM PSB in 2021; rural populations did not see a similar decrease. This data supports previous known association between rural residence and increased SMM. Further studies are warranted to identify specific trends and interventions for the unique challenges rural Hawaiian communities face.



739 | Risk Factors Associated with Uterine Rupture in Stillbirth Pregnancies with Prior Cesarean

Dharani Ramaiah[1]; Ashley Boerrigter[2]; Emily A. DeFranco[3]
[1]University of Kentucky College of Medicine, Lexington, KY; [2]University of Kentucky, Lexington, KY; [3]Department of Obstetrics and Gynecology, University of Kentucky, Lexington, KY

10:30 AM - 12:30 PM

Objective: The risk-benefit ratio of trial of labor after cesarean differs when fetal risk is absent, as in pregnancies complicated by stillbirth. We aimed to quantify risk factors associated with uterine rupture in mothers with stillbirth and prior cesarean to help inform counseling regarding mode of delivery and risk.

Study Design: Case-control study using US vital statistics fetal death data from all stillbirths in the US, 2005-2021. Study population was limited to patients with prior cesarean and birth at ≥ 20 weeks gestation. The case and controls were deliveries with and without uterine rupture, respectively. Logistic regression estimated the risk of various factors and uterine rupture while adjusting for coexisting risks.

Results: There were 422,963 stillbirths during the study period. 15,132(3.6%) were ≥ 20wks and had prior cesarean. 332 (2.2%) cases had uterine rupture and 14,800 (97.8%) controls did not. Hispanic ethnicity was associated with lower odds of rupture, whereas no prenatal care, two or more prior cesareans, preterm delivery < 28 weeks, and TOLAC were associated with higher odds of rupture, even after adjusted analyses. The most significant association was trial of labor after cesarean (TOLAC) being nearly 4.5 times more likely to result in uterine rupture (OR = 4.48 [3.28-6.13], p< 0.001). The rate of uterine rupture among those undergoing TOLAC with 1, 2 and 3 or greater cesareans was 8.9%, 22.9%, and 19.7%, respectively.

Conclusion: Sociodemographic, medical, and obstetric factors influence the risk of uterine rupture among pregnancies complicated by stillbirth and prior cesarean. The highest risk for uterine rupture was observed with no prenatal care, early preterm delivery, higher number of prior cesareans and TOLAC attempt. These data may be useful in counseling regarding mode of delivery and anticipated risks when managing delivery in cases of stillbirth.

740 | The Association Between Maternal Preeclampsia and the Risk for Offspring Endocrine Morbidity– Sibling Matched Analysis

Dor Marciano[1]; Eyal Sheiner[2]; Tamar Wainstock[2]
[1]*Soroka university medical center, Soroka, HaDarom;*
[2]*Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom*

10:30 AM - 12:30 PM

Objective: Emerging research suggests maternal preeclampsia may be linked to long-term endocrine morbidities in offspring, but these studies may be biased due to uncontrolled confounding variables. This sibling-matched study investigates the association between maternal preeclampsia during pregnancy and long-term endocrine hospitalizations in offspring, rigorously controlling for potential confounders.

Study Design: A retrospective population-based cohort study was conducted with parous women diagnosed with preeclampsia in one pregnancy. A sibling-matched analysis compared siblings where one was prenatally exposed to maternal preeclampsia, and the other was not. The incidence of hospitalization for endocrine morbidities, including diabetes mellitus, thyroid disorders, and obesity, was compared between siblings, as well as the time to first hospitalization. Multivariable generalized estimation equation (GEE) analysis adjusted for confounding variables.

Results: Among 8544 siblings, with half born after a preeclamptic pregnancy, the Kaplan-Meier survival curve showed no higher cumulative endocrine-related hospitalization rates in the preeclampsia group (log-rank P = 0.363). The crude rates of total endocrine hospitalizations were comparable between the preeclampsia and non-preeclampsia groups (0.6% vs. 0.5%; OR = 0.994; 95% CI 0.992-0.997 P = 1.0). After adjusting for confounders such as maternal age, gestational age, and induction of labor, the adjusted hazard ratio from the GEE model was not significant (adjusted HR = 1.112; 95% CI 0.598-2.068 P = 0.737).

Conclusion: This sibling-controlled cohort study found no significant association between maternal preeclampsia and long-term endocrine-related hospitalization in offspring after adjusting for potential confounders. These findings suggest that prior associations may have been influenced by unmeasured confounding variables. Further research is needed to validate these results and continue exploring the long-term endocrine implications of maternal preeclampsia.

10:30 AM - 12:30 PM

Objective: It has been well described that pregnancies in women who are ≥ age 35 carry an increased risk of adverse maternal

and neonatal outcomes. The age at which patients are becoming pregnant through reproductive technology has steadily been increasing to age 50 and beyond, potentially pushing the boundaries of what may be considered a safe age for pregnancy. Because pregnancies in this age range are not well studied, our objective was to describe the rates of adverse pregnancy outcomes of patients age 50 and older and compare them to previously reported rates of outcomes in advanced maternal age (AMA) patients age ≥ 35 and < 50 years.

Study Design: This is a retrospective observation study describing maternal and neonatal outcomes of pregnancy ≥ age 50 from 2019–2024 at our institution. The rates of adverse pregnancy outcomes were compared to previously reported outcome data from large meta-analyses of AMA pregnancy ≥ 35 and < 50 years. Demographic factors, pregnancy and neonatal outcomes were obtained from medical records.

Results: 15 patients were included with a total of 14 live births. Median gestational age at conception was 51 years old, with an age range from 51-65 years. Compared to previously reported outcome data of pregnancies in patients ≥ 35 and < 50 years, there was a statistically significant increase in the rate of hypertensive disorders of pregnancy (26.7% vs. 3.1%; p-value < 0.001) and cesarean delivery (73.3% vs 28.7%; p-value < 0.001). Rates of NICU admission and preterm birth were also increased, but not significantly different among the two groups.

Conclusion: There was an increased risk of some adverse pregnancy in patients age 50 or above compared to AMA patients younger than 50. Due to the rarity of these pregnancies, evidenced-based protocols to optimize pregnancy outcomes in postmenopausal patients have not yet been developed. Patients planning pregnancy at age 50 or later should be strongly cautioned about the increased risk of adverse outcomes, and alternative options should be considered.

Outcome	Age ≥35 and < 50 (proportions based on meta-analyses outcome data)	Age ≥ 50	p-value
Cesarean delivery	0.28	0.73	<0.001
IUFD	0.005	0.133	<0.001

742 | Utility of Prenatal Nutrition Consult in Achieving Recommended Weight Gain in Diamniotic Twin Pregnancies

Elena Lands[1]; Andrea Pelletier[2]; Rachel L. Wood[3]; Carolina Bibbo[4]

[1]University of Pittsburgh Medical Center Magee-Womens Hospital, Pittsburgh, PA; [2]Brigham & Women's Hospital, Boston, MA; [3]Duke University, Durham, NC; [4]Brigham and Women's Hospital, Boston, MA

10:30 AM - 12:30 PM

Objective: To determine if prenatal nutrition counseling affected maternal weight gain and birth outcomes in diamniotic pregnancies

Study Design: A retrospective cohort of diamniotic twin pregnancies cared for by maternal-fetal medicine specialists at one academic institution from January 2021 to December 2022 was collected. Patients were grouped based on whether they received a nutrition consult or not. Institute of Medicine (IOM) goals for twin pregnancies were used to determine appropriate weight gain based on pre-gravid BMI. Comparisons were performed with Chi-square, t-tests, and multivariable logistic regression adjusted for characteristics that were significantly associated with the outcome.

Results: Our cohort included 109 patients with and 70 without a nutrition consult. The rate of monochorionicity was significantly higher in the nutrition group at 49 versus 13% (p< 0.001). The mean pre-gravid BMI was significantly lower in the nutrition group (26 vs. 28.9, p = 0.006). The groups were otherwise similar (Table 1).

Nutrition consult was associated with a significantly higher mean total weight gain (17.9 vs. 13.4 kg, p< 0.001) and a significantly higher rate of meeting IOM goals (59 vs. 29%, p = 0.003). Mean gestational age at delivery was 5.6 days later in the nutrition group (p = 0.04). When adjusted for age, race, parity, marital status, pregravid BMI, and chorionicity, those who did not receive a nutrition consult had over doubled odds of delivery < 34 weeks (aOR 2.65, 95% CI 1.12-6.23) and of a very low birthweight neonate (aOR 2.34, 95% CI 1.19-4.62) (Table 2).

Conclusion: Prenatal nutrition consult in diamniotic twin pregnancies resulted in a significantly higher proportion of patients meeting IOM weight gain goals, later gestational age at delivery with significantly fewer births before 34 weeks, and lower risk of very low birthweight neonates. This supports the importance of prenatal nutrition consult for twin pregnancies.

743 | Association Between Adverse Pregnancy Outcomes and Awareness of Cardiovascular Risk Factors: a Numom2b-HHS Secondary Analysis

Elizabeth Wendl[1]; Lauren H. Theilen[2]; Amanda A. Allshouse[2]; Philip Greenland[3]; Lisa D. Levine[4]; William A. Grobman[5]; Natalie A. Cameron[3]; George R. Saade[6]; On behalf of the NuMoM2b-HHS Network
[1]University of Utah, North Salt Lake City, UT; [2]University of Utah, Salt Lake City, UT; [3]Northwestern, Northwestern/Chicago, IL; [4]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [5]The Ohio State University, Columbus, OH; [6]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA

10:30 AM - 12:30 PM

Objective: Adverse pregnancy outcomes (APOs) complicate up to 20% of pregnancies and are associated with increased risk of subsequent cardiovascular (CV) disease. We aimed to determine whether having had an APO is associated with greater patient awareness of their own CV risk factors 2-7 years postpartum.
Study Design: This is a secondary analysis of the NuMoM2b-HHS study. We included participants with a CV risk factor (hypertension [HTN], diabetes/prediabetes [DM], and/or dyslipidemia) identified 2-7 years after index pregnancy (Table 1). We excluded patients with a CV risk factor during the index pregnancy; a subsequent pregnancy; and patients who did not fast for their blood draw. Exposure was an APO in the index pregnancy: hypertensive disorders of pregnancy, gestational DM, preterm delivery, small-for-gestational age, and stillbirth. The primary outcome is a composite of self-awareness of HTN, DM, or dyslipidemia diagnoses after the index pregnancy utilizing patient questionnaire data. Using logistic regression, we estimated the association between exposure and outcome using three models (unadjusted, fully adjusted, and parsimonious).
Results: Among 980 included participants with CV risk factors identified 2-7 years after the index pregnancy, 77% had only one risk factor with the most common being HTN (34%). APO was present in 35% of patients with the most common being hypertensive disorders of pregnancy. The primary outcome (awareness of a CV risk factor) was present in 22% of women (220/980) - 26% of women with an APO versus 20% without. Prior to adjustment, odds ratio (OR) of APO history and awareness of later CV risk factors was 1.379 (95% CI 1.013-1.877). After full adjustment and the use of a parsimonious model, there was no significant association between APO history and awareness of later CV risk factors with an OR of 1.346 (95% CI 0.974-1.859) and 1.313 (95% CI of 0.960-1.797), respectively (Figure 1).
Conclusion: History of APO was not associated with awareness of CV risk factors 2-7 years later. Women with CV risk factors were infrequently aware of their diagnosis (22%).

Table 1. Comparisons at the time of HHS visit 1 (2-7 years postpartum)

Model 2: Adjusted for: insurance, age at visit 5, BMI at visit 5, education at visit 5, postpartum weight retention, time from index pregnancy to HHS visit, and if they were seen by a 'general doctor who treats a variety of illnesses'
Model 3: Parsimonious model via backwards selection (APO history forced to remain in) adjusted for age at visit 2-7 years after index pregnancy and seen by a 'general doctor who treats a variety of illnesses'

744 | Can Doulas Help Improve Equity in the Operating Room?: Clinician Perspectives

Elizabeth Bloom[1]; Caroline Goldfarb[2]; Nicole A. Smith[3]; Alexandria Williams[4]; Rasheca Logendran[2]; Kathleen Clarke[5]; Christina Gebel[6]; Chloe Zera[5]; Elysia Larson[7]
[1]Beth Israel Deaconess Medical Center, BOSTON, MA; [2]Harvard Medical School, Boston, MA; [3]Brigham and Women's Hospital, Boston, MA; [4]Brigham and Women's Hopsital, Boston, MA; [5]Beth Israel Deaconess Medical Center, Boston, MA; [6]Accompany Doula

Care, Boston, MA; [7]Department of Obstetrics and Gynecology, Beth Israel Deaconess Medical Center, Boston, MA

10:30 AM - 12:30 PM

Objective: We aimed to describe obstetric clinical care team members' perspectives on doulas' impact on equity for birthing persons in the operating room.

Study Design: We used in-depth, semi-structured interviews with questions based on the Consolidated Framework for Implementation Research. Using criterion-I and stratified random sampling, OB/GYNs, labor and delivery nurses, and anesthesiologists were recruited via fliers and emails. Rapid Qualitative Analysis was used for data coding and analysis.

Results: Twenty-seven clinicians were interviewed: seven anesthesiologists, ten OB/GYNs, and ten labor and delivery nurses. Of these, three quarters expressed a positive view on the impact of doulas on equity, describing benefit from an additional voice advocating for the patient and their goals. Many saw particular benefit for non-English speaking patients, for whom a language-concordant doula may significantly improve communication and trust. Participants also often mentioned benefits for their patients of color, who they noted sometimes have distrust in the medical system or may not see themselves reflected in their care team. Participants also observed that doulas improved equity by "translating" across levels of health literacy to help patients understand and accept recommendations, such as the need for cesarean delivery. Clinicians who were uncertain about doulas' effect on equity cited concerns about possible inequities in the implementation of doula support (cost of doula care, variation in doula experience), while the two clinicians who endorsed a negative view expressed doubt that doulas improve equity, one of whom specifically expressed skepticism about the benefit of a race-concordant doula.

Conclusion: Most clinicians view doulas as beneficial in improving equity for patients undergoing cesarean delivery. These benefits mirror those of prior qualitative work exploring general benefits of doulas for equity, specifically aligning with themes of patient agency, knowledge, connectedness, and respect. Further work should examine impact of doulas on equitable experiences and outcomes in cesarean deliveries.

Overall View	Theme	Example Quote(s)
Positive	Language Concordance	"When people speak different languages, I do see a change, whether it be conversations that are happening behind the curtain, whether it be the noise level in an operating room or even a delivery room, whether it be the care provided... [So when patients have a doula who speaks their language], they're their support, they're this interpreter, they're helping us out and they're providing excellent care for that patient"
	Racial/Ethnic Concordance	"Especially patients of color, are in an environment where they don't see anyone that looks like them, so having a concordant doula can help." "[There are things with] concordance and race that I think [are] really empowering... [the doula's] physical presence can be symbolic to the patient in a really special way, and I think that just gets amplified in the OR."
	Advocacy and Translation	A doula "can be a facilitator...explaining to the patient what it is what I'm asking and then advocating for the patient." "I think it's important...having somebody to advocate for them and possibly either kind of translate down to their health literacy level or advocate for the provider to do so." "Doulas can be extremely helpful in advocating for the patient in some situations. Especially patients who don't feel like they can advocate for themselves."
Neutral	Implementation of Doula Support	"I don't really know the finances of hiring a doula...if there are any racial or ethnic disparities in terms of utilization of doulas... but improving access to anyone who wants a doula, I think, can ultimately improve... people's birth experiences." "I sometimes have a hard time with the way we like operationalize it right now, because I've seen plenty of white patients who have doulas... they paid for them privately and sometimes they're there for longer...it's just a very different experience than the patients who…are getting a volunteer doula who doesn't know them [and] was often... less well-trained."
Negative	Racial/Ethnic Concordance	"Some would say that a Black patient may feel better with a Black doula. I [would] personally not necessarily agree with that..."

745 | Peripartum Hysterectomy: evolving trends over 50 years in a single European city

Elizabeth Tunney[1]; Karen Flood[2]; Ronan Daly[1]; Shahad Al-Tikriti[3]; Carmen Regan[1]; Declan Keane[4]; Mike P. Geary[5]; Fergal D. Malone[6]

[1]Royal College of Surgeons in Ireland, Dublin, Dublin; [2]Royal College of Surgeons in Ireland, Dublin, DE; [3]The National Maternity Hospital, Dublin, Ireland., Dublin, Dublin; [4]Royal College of Surgeons in Ireland., Dublin, Dublin; [5]Rotunda Hospital, Dublin, Ireland., Dublin, Dublin; [6]Royal College of Surgeons in Ireland, Dubiln, Dublin

10:30 AM - 12:30 PM

Objective: The objective of this study was to determine trends in incidence of, and indications for, peripartum hysterectomy (PH) over 50 years at a single European city.

Study Design: A retrospective cohort study was performed between 1966 and 2022 of PH cases performed in the three large tertiary obstetric hospitals of a single European city. After identifying all cases, data were collected from the published clinical reports of all three hospitals.

Results: During the 56 years, there were 1,332,115 deliveries, with 596 PH performed (0.5/1,000 deliveries). When comparing study periods, PH incidence in the most recent seven year period 2016-2022 (0.74/1,000 deliveries) has returned to 1966-1975 levels (0.85/1,000 deliveries) despite transient reduced incidence between 1986-2006 (0.2/1,000 deliveries). The indications for PH have changed significantly over the years. While uterine rupture was the main indication for PH in early years, it is now rare decreasing from 41% to 1% ($p< 0.001$). Placenta accreta spectrum (PAS) has significantly overtaken other indications for PH from 5% to 32% ($p< 0.001$). The focus towards antenatal diagnosis of PAS and optimizing surgical management is reflected in our study, with a notable increase in rates of elective PH from 14% to 26% ($p< 0.001$). A strong correlation was observed between the cesarean delivery rate (6% - 37%) and the prevalence of peripartum hysterectomy in this large obstetric population ($p< 0.001$).

Conclusion: The influence of increased cesarean deliveries internationally is reflected in the increasing incidence of PH, largely for PAS cases and the increased role of elective PH. Our data serve to inform how emergency obstetric practice has evolved over five decades and in turn may be helpful in the focus on training required for PH in the future.

Table 1 Incidence of Peripartum Hysterectomy

Years Analyzed	Total Deliveries	Peripartum Hysterectomy performed	Incidence rate
1966-1975	193,413	n=165	0.85/1000
1976-1985	232,325	n=104	0.44/1000
1986-1995	209,969	n = 40	0.20/1000
1996-2005	272,468	n = 49	0.20/1000
2006-2015	257,188	n =115	0.44/1000
2016-2022	166,752	n =123	0.74/1000
1966 - 2022	1,332,115	n=596	0.50/1000

Table 2 Known Indications for Peripartum Hysterectomy (PH)

Indications for Peripartum Hysterectomy	Cases of PH with known indication	Uterine Rupture (%)	Major Obstetric Hemorrage (%)	Placenta Accreta (%)	Elective (%)	Malignancy (%)	Placenta Praevia (%)
1966-1975	148	61 (41)	36 (24)	8 (5)	21 (14)	2 (1)	9 (6)
1976-1985	98	25 (26)	47 (48)	8 (8)	4 (4)	1 (1)	6 (6)
1986-1995	31	1 (3)	13 (42)	7 (23)	0	5 (16)	4 (13)

746 | Optimal Aspirin Dose in Preeclampsia Prevention: A Retrospective Comparison of 81 mg and 162 mg

Ellen M. Murrin[1]; Scott Sullivan[2]; Garima Sharma[3]; Olayinka Agboola[2]; G. Larry Maxwell[2]; George R. Saade[4]; Antonio F. Saad[5]

[1]Inova Fairfax Medical Campus, Falls Church, VA; [2]Inova Fairfax Medical Campus, Fairfax, VA; [3]Inova Heatlh, Norfolk, VA; [4]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [5]Inova Health, Falls Church, VA

10:30 AM - 12:30 PM

Objective: There is a lack of consensus regarding the optimal dosing for aspirin (ASA) in preeclampsia prevention, with recommendations ranging from 75 to 162 mg daily. This practice reflects evidence suggesting that dosages above 100 mg are most effective at reducing preeclampsia risk. Our objective was to compare the incidence of preeclampsia in patients taking 81 mg versus 162 mg ASA daily using national data.

Study Design: A retrospective cohort study was conducted using the Cosmos Epic database. Data from pregnancies between June 2021 and July 2024 in which ASA was prescribed were pooled based on ICD-10 codes. Baseline clinical characteristics and risk factors were compared between groups. Two-sided chi-square tests and odds ratios were used for statistical analysis.

Results: A total of 328,310 pregnant patients taking ASA were identified—81.2% in the 81 mg group and 18.8% in the 162 mg group. The 162 mg ASA group had significantly higher rates of BMI ≥30, multiple gestation, pre-gestational diabetes, antiphospholipid syndrome, chronic kidney disease, and chronic hypertension (Table 1). Obstetric outcomes were poorer in this group, with increased rates of cesarean delivery and birth weight < 2500 g. More patients in the 162 mg group developed preeclampsia compared with the 81 mg group (OR 1.31, 95% CI 1.29-1.35). This difference remained significant despite accounting for the above-mentioned confounding variables (aOR 1.11, 95% CI 1.11-1.13; Table 2).

Conclusion: In this national dataset, a higher daily dose of aspirin (162 mg) was not more effective than a lower dose (81 mg) in reducing the risk of preeclampsia, despite correcting for differences in risk factors that may have prompted clinicians to use a higher dose. More research is needed to confirm these findings and optimize aspirin dosing guidelines for preeclampsia prevention.

Table 1: Baseline Characteristics

Characteristics	Aspirin 81 mg	Aspirin 162 mg	p-value	OR	95% CI
Advanced maternal age (AMA)	74151/264637 (28.0%)	16073/61034 (26.3%)	<0.0001	0.92	0.90-0.94
BMI >30	115945/210820 (55.0%)	32775/56027 (58.5%)	<0.0001	1.15	1.13-1.18
In vitro fertilization (IVF)	6156/266727 (2.3%)	1540/61583 (2.5%)	0.004	1.09	1.03-1.15

747 | Impact of Early Zygosity Determination via NIPT on Maternal and Neonatal Outcomes in Twin Pregnancies

Ellen M. Murrin[1]; Elizabeth Levit-Smith[2]; Helen Havens Howell[3]; Alyssa Savelli Binsted[4]; Peyton Kalan[2]; Emma Cherayil[2]; Tetsuya Kawakita[4]; George R. Saade[4]; Antonio F. Saad[5]

[1]Inova Fairfax Medical Campus, Falls Church, VA; [2]Inova Fairfax Medical Campus, Fairfax, VA; [3]University of Virginia College of Medicine, Charlottesville, VA; [4]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [5]Inova Health, Falls Church, VA

10:30 AM - 12:30 PM

Objective: Monochorionic (MC) twins have significant morbidity compared with dichorionic twins (DC) due to their risk for unequal placental sharing. Non-invasive prenatal testing (NIPT) can now determine zygosity, which often informs chorionicity. This study examines pregnancy outcomes in monozygous (MZ) and dizygous (DZ) pregnancies and the correlation between zygosity and chorionicity.

Study Design: A retrospective cohort study of twin pregnancies with NIPT zygosity results at two tertiary care centers from January 2020 to 2024 was conducted. Demographics, pregnancy complications, NIPT results, fetal fractions, placental pathology, and delivery outcomes were collected. DZ twins were classified

as DC while chorionicity within the MZ group was determined by placental pathology. Statistical tests such as Chi-square, Fisher exact, Wilcoxon rank sum test, or logistical regression were used as appropriate.

Results: In 177 twin pregnancies with NIPT zygosity testing, 66.3% were DZ and 33.7% MZ. Baseline characteristics did not differ among groups except for race and gestational age. After adjusting for these variables, a subgroup analysis was performed to compare MZ DC and MZ MC to DC subtypes. Within the MZ group, 8 (17%) were DC and 38 (82.6%) were MC. MZ MC twins were significantly more likely to experience neonatal morbidities such as hypoglycemia and hyperbilirubinemia requiring phototherapy, NICU admission, and additional respiratory support (Figure & Table). The MZ DC group was not more likely to experience these outcomes. Composite neonatal morbidity was also more common in the MZ MC group (aOR 6.01 [1.89-10.12], p = 0.002). Maternal outcomes did not differ between groups.

Conclusion: The early differentiation of chorionicity and zygosity allows for the implementation of tailored care strategies to enhance outcomes. Our study shows that MZ MC twins have significantly higher neonatal morbidity, thus underscoring the necessity for vigilant monitoring and intervention.

Outcome	Dizygotic (N=116)	Monozygotic					
		Dichorionic (N=8)			Monochorionic (N=38)

748 | The Effect of Glucose Challenge and Oral Glucose Tolerance Tests Timing on Tests' Results

Enav Yefet[1]; Zohar Nachum[2]
[1]Tzafon Medical Center, Poriya, HaZafon; [2]Emak Medical Center, Afula, HaZafon

10:30 AM - 12:30 PM

Objective: The usual time for performing glucose challenge test (GCT) and oral glucose tolerance test (OGTT) is between 24-28 gestational weeks. After which, it is not known whether GCT or OGTT act in the same manner.

In the present study we compared the results of GCT and OGTT when the tests were done between 24-28 gestational weeks or later.

Study Design: A population-based retrospective cohort study of women who performed GCT between June 2013 and December 2021. In our institution GCT is recommended even after 28.6 weeks to women who did not perform it before. Women with large for gestational age fetus or polyhydramnios were excluded, since OGTT is performed in those cases. The rates of abnormal GCT (≥140 mg%) and gestational diabetes mellitus (GDM) were compared. GDM was defined as GCT≥200 mg% or at least 2 abnormal OGTT values according to the Carpenter and Coustan criteria.

Results: Data were collected for 20,485 women with GCT between 24-28.6 weeks and 1,806 with GCT thereafter. GCT results for every gestational week are presented in the figure. The rate of abnormal GCT and GDM were similar between the groups (abnormal GCT: 3797 (18.5%) versus 323 (17.9%), respectively; P = 0.49, and GDM: 1063 (5.2%) versus 86 (4.8%), respectively; P = 0.43)

Conclusion: In low risk women, GCT values and the rate of GDM are similar from 24 weeks and thereafter.

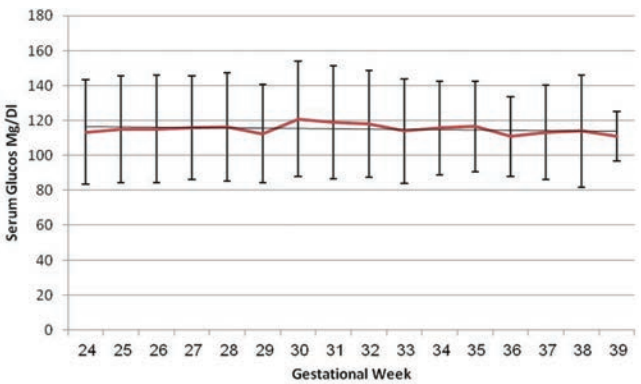

Figure. Mean serum glucose ± SD following GCT from 24 gestational weeks and thereafter

749 | Time from Decision to Execution of Manual Exploration of the Uterus and Postpartum Hemoglobin Drop

Enav Yefet[1]; Dana Segal[2]; Omri Zarka[2]; Zohar Nachum[3]
[1]Tzafon Medical Center, Poriya, HaZafon; [2]Emek medical center, Afula, HaZafon; [3]Emak Medical Center, Afula, HaZafon

10:30 AM - 12:30 PM

Objective: Manual exploration of the uterus is performed in women with postpartum hemorrhage to remove blood clots, retained placenta and to repair obstetrical tears. There is very limited data to evaluate the time from when the decision of conducting the manual exploration is made to the actual procedure to avoid complications.

Study Design: A retrospective cohort study conducted between 2013 and 2019. The data was collected from women in the maternity ward who underwent a manual exploration of the uterus after a vaginal birth. A comparison was made between women in whom the time from making the decision of performing manual exploration to the time of the procedure was more than 20 minutes (>20 minutes cohort) versus up to 20 minutes (≤20 minutes cohort). The primary outcome was the rate of women with hemoglobin (Hb) decrease of at least 3 g/dL after delivery.

Results: Among 696 women who were analyzed, 224 and 472 women underwent manual exploration >20 minutes and ≤20 minutes, respectively. Characteristics and outcomes are presented in tables 1 and 2. Mean time from decision to performing manual exploration was 45±54.8 and 9.5±5.6 minutes in the >20 minutes and ≤20 minutes cohorts, respectively (P< .0001). Mean Hb

decrease was greater in the >20 minutes cohort versus ≤20 minutes cohort (3.4 ±1.7 gr\dl versus 1.8±3.0 gr\dl, respectively; P = 0.02). The rate of Hb decrease≥3 g/dL was 59% and 50% in the >20 minutes and ≤20 minutes cohorts, respectively (P = 0.06). No other significant differences were observed. The cutoff for performing manual exploration to predict Hb decrease of at least 3 g/dL was 19 minutes (47% sensitivity, 54% specificity)

Conclusion: While it seems that the medical staff is skilled in managing the optimal time to perform manual exploration of the uterus, the time from decision to procedure should be up to 20 minutes in order to avoid excessive blood loss.

Table 1. Patients' characteristics

	20 minutes or less from decision to manual exploration of the uterus N=472	more than 20 minutes from decision to to manual exploration of the uterus N=224	P-value
Age	28.3 (5.3) [27,24-32]	29.2 (5.4) [28,25-33]	0.09

750 | Gestational Diabetes Mellitus in Pregnancies with Suspected Growth Restriction: Blessing or Curse?

Misgav Rottenstreich[1]; Sahra Nathoo[1]; Bryon DeFrance[2]; Jon F. Barrett[2]; Eran Ashwal[2]
[1]McMaster University, Hamilton, ON; [2]McMaster university, Hamilton, ON

10:30 AM - 12:30 PM

Objective: Fetal growth restriction (FGR) is a condition that occurs when a fetus fails to achieve its growth potential. Gestational diabetes mellitus (GDM) is another common complication during pregnancy associated with accelerated fetal growth. This study aims to evaluate the impact of GDM on perinatal outcomes in pregnancies with suspected fetal growth impermanent.

Study Design: This retrospective cohort study enrolled singleton pregnancies without fetal genetic or structural abnormalities and EFW and/or AC below the 10th centile for gestational age on the last sonographic assessment within 14 days from delivery. The study compared pregnancies with GDM to those without GDM. The primary outcome of interest was the o ccurrence of composite adverse perinatal outcomes. Multivariable logistic regressions were performed, adjusting for relevant covariates.

Results: A total of 1,583 patients were included in the study, with 234 (14.8%) diagnosed with GDM, while 1,349 (85.2%) did not . Patients with GDM were found to be older, had a higher body weight, and had higher rates of hypertensive disorders compared to those without GDM. Patients with GDM experienced longer pregnancies, with a difference of approximately one week, but there were no significant differences in the rates o f preterm labor (< 37 weeks). The rates of labor induction and mode of delivery were comparable between the GDM and non-GDM groups. Neonates born to mothers with GDM had higher birthweight and lower adverse perinatal outcome rates than neonates of normoglycemic pregnancies (45.2% vs. 52.2%; p = 0.04). In the multivariate analysis, which controlled for maternal age, parity, oligohydramnios, hypertensive disorders of pregnancy, gestational age at delivery, and birthweight, it was found that GDM was significantly and independently associated with lower adverse perinatal outcome (adjusted odds ratio = 0.65, 95% confidence interval 0.47-0.9) (Table).

Conclusion: GDM significantly impacts perinatal outcomes in pregnancies with suspected fetal growth impairment and can potentially improve the overall outcome in such cases.

Association between GDM in pregnancies with suspected fetal growth impairment and adverse perinatal outcomes – a multivariate analysis.

	Crude odds ratio (95% CI)	Adjusted odds ratio (95% CI) *
Composite adverse outcome	0.75 (0.57-1)	0.65 (0.47-0.9)
Antepartum fetal death	N/A	N/A
Cesarean delivery for fetal distress	1.18 (0.83-1.68)	1.17 (0.8-1.71)
5-minute Apgar < 7	0.59 (0.35-1.01)	0.67 (0.36-1.24)
Arterial cord pH < 7.1	0.98 (0.51-1.9)	0.66 (0.31-1.42)
Need for ventilation	1.08 (0.8-1.46)	1.1 (0.77-1.56)
Respiratory distress syndrome	0.8 (0.53-1.19)	0.75 (0.38-1.46)
Necrotizing enterocolitis	1.26 (0.27-5.86)	2.03 (0.38-10.69)
Sepsis	0.35 (0.11-1.14)	0.27 (0.06-1.17)
Intracranial hemorrhage	N/A	N/A
Prolong length of stay at NICU	0.78 (0.58-1.06)	0.65 (0.45-0.94)
Neonatal Death	N/A	N/A

*Adjusted for maternal age, parity, oligohydramnios, hypertensive disorders of pregnancy, gestational age at delivery, and birthweight.
AC – abdominal circumference; EFW – estimated fetal weight; PI – pulsatility index; UA – umbilical artery; NICU – neonatal intensive care unit

751 | Addressing Medical Mistrust Among Black Birthing People Through Community-Based Doulas

Erica Marion[1]; Katherine Quinn[1]; Jessica Olson[1]; Dalvery Blackwell[2]; Joni Williams[1]; Anna Palatnik[1]
[1]Medical College of Wisconsin, Milwaukee, WI; [2]African American Breastfeeding Network Inc., Milwaukee, WI

10:30 AM - 12:30 PM

Objective: Structural and systematic barriers within healthcare systems are associated with medical mistrust between Black birthing people and healthcare providers. This study explored how partnership with community-based doulas can address medical mistrust between Black birthing people and obstetric healthcare teams.

Study Design: A prospective qualitative study that included focus groups and in-depth interviews using a semi-structured interview guide with OBGYNs (n = 7), Maternal-Fetal Medicine

specialists (n = 2), certified nurse midwives (n = 2), a perinatal psychologist (n = 1), a prenatal care coordinator (n = 1), clinical and inpatient nurse supervisors (n = 3), birth center nurses (n = 2), an OB-Anesthesiologist (n = 1), and community-based doulas (n = 11). Interviews and focus groups were recorded, transcribed verbatim, coded using MAXQDA software, and analyzed using thematic content analysis to understand how community-based doulas can contribute to improving patient-clinician relationships specifically for Black birthing people.

Results: Analysis yielded the following themes: 1) Doulas have a unique opportunity to sustain patient trust through continuous social support and continuity of care; 2) Doulas serve as liaisons and advocates between Black birthing people and healthcare teams to assist with navigating conflict and facilitating communication; and 3) Doulas of color provide a unique perspective and shared experience that can foster trust and understanding for both patients and healthcare teams. As a result, patient-clinician communication can be improved by community-based doulas facilitating bidirectional understanding to reduce healthcare mistrust.

Conclusion: Our results highlight the vital role of community-based doulas in mitigating medical mistrust between healthcare professionals and Black birthing people. Data obtained from this qualitative analysis will inform the design of a collaborative community-based doula-clinician model focused on improved communication and meaningful engagement to foster trust.

752 | Pregnancy Health Information-Seeking Behaviors and Knowledge of Pregnancy Risks among Male Partners of Pregnant Patients

Erin Kim[1]; Joshua Bellisario[2]; Fanglong Dong[3]; Kristina Galyon[4]; Hindi Stohl, JD[4]
[1]Western University of Health Sciences COMP Pomona, Los Angeles, CA; [2]Harbor-UCLA Medical Center, Los Angeles, CA; [3]Western University of Health Sciences, Los Angeles, CA; [4]UCLA David Geffen School of Medicine Harbor-UCLA Medical Center, Los Angeles, CA

10:30 AM - 12:30 PM

Objective: Partners play an active role in supporting pregnant patients with prenatal and perinatal decisions, yet there are few studies on this population. This study examines the information seeking behavior and pregnancy risk knowledge of male partners of pregnant patients.

Study Design: An IRB-approved 45-question survey was administered in 2017 to male partners of pregnant patients at Harbor-UCLA Medical Center prenatal clinics. Men were interviewed one-on-one in private areas of the clinic. Statistical significance was determined using a chi-squared test with $p < 0.05$.

Results: 127 male partners completed the survey. 86.4% of male partners could not name one of the major pregnancy-related health risks in an open-ended question format. When asked about seven specific pregnancy-related health risks from a multiple-choice list, only 5.6% of male partners were able to identify all of them correctly. Noticeably, 41.6% were able to correctly identify the increased risk of the two most common complications: diabetes and hypertension. These findings were not associated with higher education ($P = 0.5055$) or fathering a prior pregnancy ($P = 0.4831$). When asked whether they would like more education about pregnancy, 82.1% responded yes, 40.2% of whom wanted the information from their partner's healthcare provider. Male partners who were not interested in learning more about pregnancy had a significantly lower score of correctly reporting the seven specific pregnancy risks ($P = 0.0003$).

Conclusion: Our study highlights that a large percentage of male partners of pregnant women are unaware of the health risks associated with pregnancy. Additionally, male partners who are less information-seeking about pregnancy also have lower knowledge levels of pregnancy risks, underscoring the need for improved pregnancy education.

753 | Conversion to Telehealth During COVID-19 and Depression Symptom Response in a Perinatal Collaborative Care Model

Esther Y. Son[1]; Mayán Alvarado-Goldberg[2]; Allie Sakowicz[3]; Siyuan Dong[1]; Emily S. Miller[4]; Dorothy Sit[1]; LaTasha Nelson[1]; Michelle A. Kominiarek[1]
[1]Northwestern Feinberg School of Medicine, Northwestern Feinberg School of Medicine/ Chicago, IL; [2]Northwestern University, Northwestern University/ Evanston, IL; [3]Wake Forest University School of Medicine, Winston-Salem, NC; [4]Women & Infants Hospital of Rhode Island and Alpert Medical School of Brown University, Providence, RI

10:30 AM - 12:30 PM

Objective: We aimed to assess the association between conversion to telehealth and depression symptom response in a perinatal collaborative care model-based treatment (PCCM).

Study Design: This was a retrospective study of pregnant and postpartum people from 2017-2022 who engaged in a PCCM for perinatal mental health care. Outcomes were analyzed by epoch, defined as pre-telehealth (preT) (2017-2020) and post-telehealth (postT) (2020-2022) cohorts, based on when PCCM converted to telehealth as a result of the COVID-19 pandemic. Sociodemographic (age, race/ethnicity, parity, substance use) and perinatal data (gestational age at delivery, delivery route) and all PHQ-9 scores were abstracted from the EHR. Bivariate and multivariate analyses were performed to compare depressive symptom response over time between preT and postT cohorts in three ways: change in PHQ-9 score from initial to final, dichotomized PHQ-9 score improvement from initial to final, and as a linear mixed effects model to analyze trajectories of PHQ-9 scores adjusting for random effects within each person.

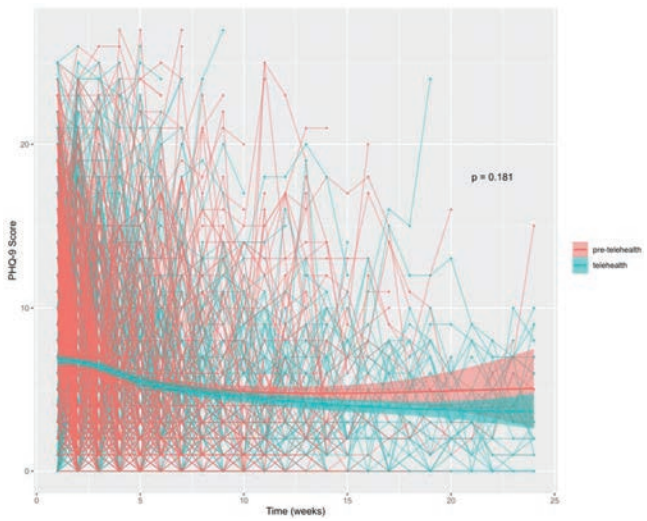
Results: Of 1422 people who met eligibility criteria, 679 (48%) engaged in PCCM postT. There were no differences in age, race/ethnicity, parity, tobacco use, gestational age at delivery, and delivery route between cohorts. People in preT were less likely to have prior substance use, but more likely to have medical comorbidities and prior mental health diagnoses compared to postT. Both groups had decreases in PHQ-9 scores, consistent with improvement in depressive symptoms, but preT had greater mean decreases and were more likely to have an improvement in scores than postT, after adjusting for potential confounders (Table). There was no difference in PHQ-9 trajectories between the cohorts (Figure).

Conclusion: Overall, we observed improvements in depression symptoms in PCCM with greater improvements in mean PHQ-9 scores in preT compared to postT, but no differences in scores

when accounting for random effects in each person, suggesting that mental health services via telehealth offers similar outcomes compared to in-person visits.

	Pre-Telehealth n=743	Post-Telehealth n=679	p-value	aβ / aOR	CI
Prior substance use	36 (4.85%)	53 (7.9%)	**0.018**		
Medical comorbidities (n,%)	374 (50.34%)	299 (44.23%)	**0.021**		
Prior mental health diagnoses (n,%)	494 (66.49%)	306 (45.54%)	**<0.001**		
Change in PHQ-9 score	-4.28 (6.1)	-0.39 (6.0)	**<0.001**	-2.30[a]	-2.8 - -1.8
Improved PHQ-9 (n,%)	552 (74.3%)	350 (51.6%)	**<0.001**	1.94[b]	1.5 - 2.5

Data presented as n (%) or mean (standard deviation)
[a]Adjusted for covariates (i.e. age, initial PHQ-9 score, and time interval between initial and final PHQ-9 scores)
[b]Adjusted for covariates (i.e. initial PHQ-9 score and time interval between initial and final PHQ-9 scores)



754 | Pregnancy During Wartime is Associated with Increased Preterm Rupture of Membranes

Esther Maor-Sagie[1]; Coral Danenberg[2]; Dima Shabita[3]; Amir Naeh[4]; Rinat Gabbay-Benziv[3]
[1]Hille Yaffe medical center, Hillel Yaffe medical canter, Hefa; [2]Ariel University, The Adelson school of Medicine Ariel University, Yerushalayim; [3]Hillel Yaffe Medical Center, Hillel Yaffe medical center, Hefa; [4]Hillel Yaffe Medical Center, Hillel Yaffe Medical Center, HaMerkaz

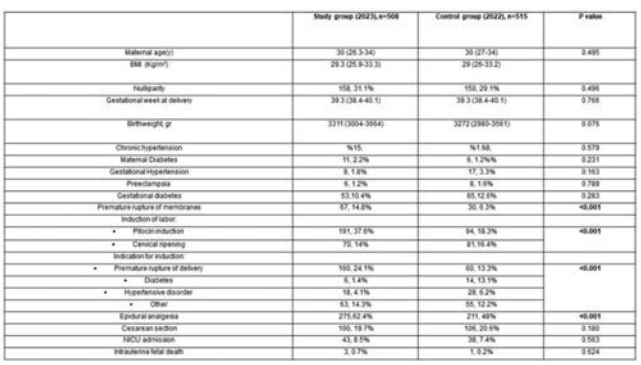
10:30 AM - 12:30 PM

Objective: Anxiety, depression, and stress during pregnancy negatively impact birth outcomes, including infant weight, head circumference, and APGAR scores. These effects are linked to physiological changes like catecholamine and cortisol secretion, leading to high blood pressure, maternal tachycardia, and increased risk of fetal growth restriction and preterm birth. The Iron Sword war, declared by Israel against Hamas, following the October 7, 2023 attack, has created tremendous psychological stress in the Israeli population. This study aims to assess the consequences of the Iron Sword war on obstetric outcomes related to stress and psychological distress, including preterm labor, premature rupture of membranes, preeclampsia, and preterm births.

Study Design: A retrospective cohort analysis was conducted at a single university-affiliated medical center in Israel. The study included deliveries from October 7, 2023, to November 19, 2023, compared to deliveries during the same period in 2022. Univariate and regression analyses were used to adjust for confounders. Categorical variables were compared using χ^2 tests, and continuous variables were analyzed with the Mann-Whitney test. Significance was set at $p< 0.05$.

Results: Overall, 508 women in the study group were compared to 515 women in the control group. There was no difference in gestational age at delivery or neonatal birth weight. Women who delivered during the Iron Sword war experienced a nearly threefold increase in preterm rupture of membranes and 1.5 times more labor inductions, mainly due to rupture of membranes (14.8% vs. 6.3% and 51.4% vs. 34%, respectively, $p< 0.001$ for both). Women during the war used more epidural anesthesia (62.4% vs. 48%, $p< 0.001$) . Results remained significant after adjusting for maternal age, BMI, nulliparity, and fetus number. No other differences were noted in delivery mode or other perinatal outcomes.

Conclusion: The prevalence of premature rupture of membranes increased significantly during the Iron Sword War, potentially linked to maternal stress and anxiety. Further studies are needed to evaluate these outcomes better.



755 | Evaluating the Association Between Eczema in Pregnancy and Maternal and Fetal Outcomes

Ethan Bendayan[1]; Andrea R. Spence[2]; Haim A. Abenhaim[3]
[1]McGill University, Montreal, PQ; [2]Jewish General Hospital, Montreal, PQ; [3]Jewish General Hospital, McGill University, Montreal, PQ

10:30 AM - 12:30 PM

Objective: Eczema is a common skin condition on which little literature exists regarding its association in pregnancy and pregnancy-related outcomes. Our study served to evaluate the association between various obstetric and newborn outcomes and pregnancies affected by eczema.

Study Design: Using the Nationwide Inpatient Sample's 2016-2021 records, a population-based retrospective cohort study was conducted. To extract pregnancy and delivery records, both affected by eczema and unaffected, ICD-10 codes were used. ICD-10 codes were also used to identify baseline characteristics, obstetric outcomes and neonatal outcomes. Adjusting for age and race, multivariate logistic regression models were performed in order to compute odds ratios and p-values.

Results: The sample contained 8634 deliveries affected by eczema and 4,337,612 total deliveries, for an overall prevalence of 199 cases per 100,000 deliveries. Eczema was associated with adverse maternal outcomes, such as sepsis, OR 2.5 (95% CI 2.1-3.1); need for blood transfusions, 1.8 (1.5-2.0); pulmonary

embolism, 3.2 (1.04-10.08); length of stay greater than 3 days, 3.0 (2.9-3.1); preeclampsia, 1.6 (1.4-1.7); gestational diabetes, 1.1 (1.02-1.18); anemia, 1.6 (1.5-1.7); placental abruption, 1.6 (1.4-1.9); placenta previa, 1.5 (1.2-1.9); preterm premature rupture of membranes, 1.4 (1.3-1.5); preterm labor, 1.3 (1.2-1.4); chorioamnionitis, 2.1 (1.9-2.3); spontaneous vaginal delivery, 0.53 (0.51-0.55); caesarean section, 2.1 (2.0-2.2); instrumental vaginal delivery, 0.69 (0.60-0.78); and disseminated intravascular coagulation, 3.3 (1.6-6.5). In newborns, eczema was associated with congenital abnormalities, 2.3 (2.0-2.7); and intrauterine growth restriction, 1.3 (1.2-1.5).

Conclusion: Pregnancies affected by eczema appear to be at higher risk for various obstetric and neonatal outcomes. Consideration should be given to monitor and manage pregnancies with eczema. Additional research should be conducted on the topic and on potential management.

756 | Evaluating the Incidence and Risk Factors of Melanoma and History of Melanoma in Pregnancy

Ethan Bendayan[1]; Andrea R. Spence[2]; Haim A. Abenhaim[3]
[1]McGill University, Montreal, PQ; [2]Jewish General Hospital, Montreal, PQ; [3]Jewish General Hospital, McGill University, Montreal, PQ

10:30 AM - 12:30 PM

Objective: Melanoma is a common form of skin cancer, the incidence of which is uncertain in pregnancy. Previous reports estimated melanoma to be one of the most prevalent cancers in pregnancy. We sought to find the incidence of melanoma or a history of melanoma in pregnancy in a population-based study.

Study Design: The Nationwide Inpatient Sample's 2016-2021 records were used in order to conduct a retrospective cohort study. To identify pregnancy and delivery records, both affected by melanoma or a history of melanoma and unaffected, ICD-10 codes were used. ICD-10 codes were used to isolate the baseline characteristics, as well.

Results: The cohort contained 213 admissions with melanoma or a history of it, out of 4,337,612 total delivery admissions. The incidence was calculated to be 4.9 cases per 100,000 deliveries. Of the records with melanoma or history of melanoma, 64% were between 25 and 35 years old and 74% were at, or past, the 50th income percentile.

Conclusion: The results suggest that the incidence of melanoma or history of melanoma in pregnancy is extremely low and, unlike previously reported, melanoma is likely one of the least prevalent cancers in pregnancy. Age and income appear to be risk factors for developing melanoma, or having a history of melanoma, in pregnancy. Larger scale studies should be conducted in order to verify the degree of association.

757 | The Correlation Between Extent of Invasion in Placenta Accreta Spectrum and Units of Blood Transfused

Eva Hoffmann; Brian Z. Druyan; Carolyn Wheeler; Anna K. Sfakianaki; Paloma Toledo; Michael J. Paidas; Rodrigo Ruano; Pouya Abhari
University of Miami, Miami, FL

10:30 AM - 12:30 PM

Objective: The primary objective of this study is to determine if there is an association between the extent of invasion in Placenta Accreta Spectrum (PAS) as identified on pre-operative imaging and transfusion of packed red blood cells (pRBCs). By establishing this correlation, the study aims to enhance preoperative preparation for patients with PAS and reduce the waste of healthcare resources by avoiding the preparation of unnecessary blood products.

Study Design: This was a retrospective cohort study, approved by the Institutional Review Board. The study was conducted at a single accreta center of excellence from April 1, 2010 through January 9, 2023. All patients diagnosed pre-operatively with PAS via ultrasound were included. We excluded patients who did not have clear ultrasound diagnosis of PAS with extent of invasion documented. Data was collected from electronic medical records, including maternal demographics, pre-operative ultrasound findings, pre-operative hemoglobin level, blood loss and pRBCs.

Descriptive statistics were used to summarize maternal demographics and clinical outcomes as well as parametric and non-parametric statistics to compare groups. Data analysis was performed using SPSS version 29.0.2.0. P-values < 0.05 was statistically significant.

Results: Prenatal ultrasound was used to identify 160 patients with PAS with extent of invasion identified as focal accreta (N = 9), accreta (N = 97), increta (N = 29), and percreta (N = 25). There were no differences across demographic, age, race, BMI, number of prior cesarean deliveries and preoperative hemoglobin. There were no differences found in units of pRBCs between groups or estimated blood loss.

Conclusion: In conclusion we found no differences in units of pRBCs transfused and blood loss despite differences in preoperative diagnosis. This may be related to overall increased preparedness at a placenta accreta center of excellence with multi-disciplinary care. This study supports standard protocols and uniformity in available blood despite differences in preoperative diagnosis.

Table 1: Patient Demographics

	Preoperative Diagnosis Based on Ultrasound				
	Focal Accreta N= 9	Accreta N= 97	Increta N= 29	Percreta N=25	p-valve
Age, y	36.78± 4.41	33.74± 5.29	33.69± 3.97	33.24± 4.59	0.31
BMI, m/kg2	34.78± 6.91	30.36± 5.49	31.39± 5.76	32.96± 7.80	0.07
Hemoglobin on admission	10.48± 1.8	10.98± 1.21	11.09± 1.57	10.82± 1.09	0.61
Gestational age at delivery, weeks	34.97± 1.50	33.10± 4.22	33.8± 1.79	31.97± 4.58	0.09

758 | Changes in Fetal Heart Rate Baseline For Deliveries 22 to 31.6 Weeks and Adverse Outcomes

Fabrizio Zullo[1]; Roby Lauren[2]; Cassidy A. O'Sullivan[2]; Ha L. Tran[3]; Giuseppe Rizzo[4]; Kelley Kovatis[2]; Matthew K. Hoffman[2]; Anthony C. Sciscione[2]; Suneet P. Chauhan[5]
[1]University of Rome La Sapienza, Rome, Lazio; [2]Christiana Care Health System, Newark, DE; [3]Nemours Children's Hospital, Wilmington, DE; [4]Sapienza Università di Roma (ROMA), Rome, Lazio; [5]Delaware Center of Maternal-Fetal Medicine at Christiana Care, Delaware, DE

10:30 AM - 12:30 PM

Objective: The significance of a change in baseline fetal heart rate tracing (FHRT) is unclear. We aim to estimate the incidence of change in FHR baseline in deliveries at 22.0 to 31.6 weeks gestational age (wga) and associated neonatal morbidity or mortality.

Study Design: A retrospective review of all deliveries from Jan to Dec 2023 at a tertiary care referral hospital. The inclusion criteria included delivery at 22-31 wga, of a non-anomalous singleton, where at least 40 minutes of a FHRT was available, and neonatal resuscitation was initiated. A physician—blinded to maternal characteristics and peripartum outcomes—reviewed the FHRT (0-120 min proximal to delivery, at 20 min epochs). FHR baseline variation was assessed by calculating a delta (D) between the last and the first epoch. Neonatal outcomes were abstracted. The primary outcome was long term neonatal morbidity or mortality (LTNMM); the secondary outcomes were Apgar score of 4-6 at 5-min and short-term neonatal morbidity or mortality (STNMM). Descriptive statistics with 95% confidence intervals (CI) were calculated, and non-overlapping CI was considered significant.

Results: Among the 6,521 deliveries, 169 (2%) occurred at 22-31.6 wga, of which 97 (57%) met the inclusion criteria. Magnesium sulfate was administered in 97% of the newborns and antenatal corticosteroids in 98%. A positive variation (+ D) in baseline occurred in 26/97 (26%) patients, and the likelihood of LTNMM in this cohort was 9/26 (34%; 95% CI 18.4-55.3). A negative variation (-D) in baseline occurred in 29/97 patients (29%), and the likelihood of LTNMM in this cohort was 11/29 (37%; 95% CI 21-57).

A neutral variation (D = 0) occurred in 42/97 (43.3%) of cases with a LTNM rate of 18/42 (42%; 95% CI 2858. Each analyzed cohort, even when stratified for discreet changes, had overlapping CI for all outcomes examined (Table 1).

Conclusion: Among newborns delivered at 22.0 to 31.6 weeks, change in baseline was noted in the majority and, irrespective of direction, it was not associated with adverse fetal outcome.

Table 1. Change in fetal heart rate tracing baseline within 2 hours of delivery of newborns at 22.0 to 31.6 weeks

		Apgar 4-6 at 5 min			Short Term Neonatal Outcome*			Long Term Neonatal Outcome**

759 | Income-Level and Regional Variations and the Impact of Cesarean Delivery Rates on Maternal Mortality

Fabrizio Zullo[1]; Roby Lauren[2]; Teresa C. Logue[2]; Daniele Di Mascio[3]; Sara Sorrenti[3]; Antonella Giancotti[3]; Giuseppe Rizzo[3]; Suneet P. Chauhan[4]
[1]University of Rome La Sapienza, Rome, Lazio; [2]Christiana Care Health System, Newark, DE; [3]Sapienza Università di Roma (ROMA), Rome, Lazio; [4]Delaware Center of Maternal-Fetal Medicine at Christiana Care, Delaware, DE

10:30 AM - 12:30 PM

Objective: To investigate the relationship between cesarean delivery (CD) and maternal mortality ratio (MMR) across different income levels and UNICEF regions.

Study Design: We conducted a cross-sectional analysis from 157 countries pooled from UNICEF database. To analyze interactions, we utilized a linear regression model. The model was built to account for variations due to income classifications by including dummy variables for each income level -Low Income (LI), Lower Middle Income (LMI), Upper Middle Income (UMI), and High Income (HI) as defined by the World Bank. We controlled for the impact of income on MMR while isolating the effect of CD rates. Descriptive statistics and correlation analysis were used.

Results: Most UNICEF regions exhibit a negative correlation between CD rates and MMR, with the strongest correlations in Sub-Saharan Africa (-0.84) and South Asia (-0.68). In contrast, Eastern Europe and Central Asia show a weak positive correlation (0.43), indicating a slight increase in MMR with higher CD rates. When stratified for income group, CD rates were negatively correlated with MMR across all income groups but HI. The strongest negative correlation (-0.61) in LI countries indicates a significant decrease in MMR with higher CD rates. HI countries show a weak positive correlation (0.14), suggesting a slight increase in MMR with higher CD rates (Table 1). The regression analysis revealed that each % increase in CD rates corresponds to a reduction of approximately 4.4 units in MMR ($p < 0.001$). MMR was significantly higher in LI countries (coefficient: 370.18, $p < 0.001$) and LMI countries (coefficient: 159.06, $p < 0.001$) compared to HI countries. UMI countries had a coefficient of 61.84 with a p-value of 0.079, indicating no clear association with MMR (Table 2).

Conclusion: Increasing the rate of CD was associated with a significant reduction in MMR in LI countries. In HI countries the correlation is weakly positive. This suggests that in LI countries an increase in CD rate may lower MMR; conversely in HI

countries an increase in CD may be associated with increased MMR.

Table 1: Descriptive Statistics and Correlation Analysis

UNICEF REGION	N of countries	Maternal Mortality Ratio[1]		Cesarean Delivery		r *
		Median	IQR (5th-95th pc)	Median	IQR (5th-95th pc)	
East Asia and Pacific	22	90	10-243	15.3	3.5-34.5	**-0.57**
Eastern Europe and Central Asia	20	14	2-40	24.4	6.5-40	0.43

760 | Perioperative Risk Factors for Amniotic Band Sequence Following Fetoscopic Laser Photocoagulation for Twin-Twin Transfusion Syndrome

Felicia V. LeMoine[1]; Sami Backley[1]; Gustavo Vilchez[2]; Jimmy Espinoza[1]; Anthony Johnson[3]; Ramesha Papanna[4]; Eric P. Bergh[5]

[1]Division of Fetal Intervention, Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern Medical School at UTHealth Houston, Houston, TX; [2]UTHealth Houston, Houston, TX; [3]McGovern Medical School University of Texas Health Science Center at Houston (UThealth), Houston, TX; [4]McGovern Medical School at UTHealth Houston, Houston, TX; [5]UT Health, Houston, TX

10:30 AM - 12:30 PM

Objective: Observational studies have suggested associations between perioperative characteristics such as gestational age (GA) at fetoscopic laser photocoagulation FLP, chorioamnion separation (CAS), and iatrogenic septostomy (IS) and amniotic band sequence (ABS) after FLP for twin-twin transfusion syndrome (TTTS). We aim to evaluate the relationship between perioperative factors and ABS in monochorionic, diamniotic (MCDA) twins undergoing FLP for TTTS treatment.

Study Design: A secondary analysis of a prospective cohort study involving 816 cases of FLP (2011-2024) was conducted. Detailed ultrasound evaluation before FLP showed absence of ABS for all cases. ABS was either identified by post-FLP imaging and confirmed postnatally or identified on postnatal exam. Perioperative factors were compared using t-test, $\chi 2$ test, and Fisher's exact test, where applicable. Multivariate logistic regression was performed to adjust for the following covariates: intertwin discordance, GA at FLP, CAS diagnosed on post-op day 1 scan, amnioinfusion, and trocar size.

Results: 11 cases (1.3%) were complicated by ABS. Prenatal suspicion of ABS prompted prenatal lysis without amputation in 3/11 cases (27.3%; Table 1). Digital amputation occurred in 3/11 cases (27.3%). There was no difference in maternal characteristics. Significant differences in intertwin weight discordance prior to FLP (12.9% ± 8.7% versus 23.2% ± 13%, $p < 0.05$), GA at FLP (17.9 ± 1.1 weeks versus 20.6 ± 2.8 weeks, $p < 0.05$), CAS (63.6% (7/11) versus 10.6% (85/805), $p < 0.05$), and trocar size ($p = 0.04$) were demonstrated between cases with and without ABS (Table 2). Amnioinfusion (aOR 0.17, 95% CI 0.02-0.76, $p = 0.04$), smaller intertwin weight discordance (aOR 0.90, 95% 0.83-0.96), and earlier GA at FLP (aOR 0.56, 95% CI 0.34-0.82) decreased the risk of ABS. Conversely, CAS increased the risk of ABS (aOR 11.90, 95% CI 3.15-52.30, $p < 0.05$).

Conclusion: ABS is a rare complication post-FLP for TTTS, yet, is associated with significant neonatal sequelae. Perioperative factors, particularly CAS, should prompt detailed post-FLP evaluation for development of ABS.

10:30 AM - 12:30 PM

Objective: Preterm delivery (PTD) is a persistent complication of in-utero spina bifida repair despite the transition to a minimally-invasive, fetoscopic approach. We aimed to evaluate the relationship between maternal and perioperative characteristics and PTD < 34 weeks gestation among pregnancies that underwent fetoscopic spina bifida repair.

Study Design: A secondary analysis of a prospective cohort study was conducted of 79 completed cases of fetoscopic spina bifida repair between 2020 and 2024 [NCT#04243889 & #06042140]. Maternal and perioperative factors were compared between cases with delivery at < 34 and ≥ 34 weeks' gestation using the Wilcoxon rank sum test, Welch's *t*-test, χ^2 test, and Fisher's exact test, where applicable. Multiple logistic regression was performed to adjust for maternal and perioperative factors. Sub-group univariate analysis of maternal and perioperative factors between cases with and without placental abruption (PA) were compared using the appropriate comparative statistics.

Results: Twenty-five (31.6%) cases resulted in delivery at < 34 weeks. Maternal age was greater in cases that resulted in delivery < 34 weeks (Table 1). Maternal and perioperative characteristics were, otherwise, similar between the groups. PPROM and placental abruption occurred more frequently among cases with delivery < 34 weeks (Table 1). Multiple logistic regression demonstrated that event of delivering at < 34 weeks was significantly associated with lesion surface area, PPROM, and placental abruption (Table 2). Sub-group univariate analysis comparing cases with and without PA demonstrated only a smaller lateral ventricular size among cases with PA (10.3 ± 2.8mm) versus cases without PA (12.76 ± 3.8mm, $p = 0.035$).

Conclusion: PPROM and placental abruption are significant predictors of PTD before 34 weeks. Further research is needed to elucidate the relationship between PPROM and placental abruption in the context of fetoscopic intervention.

Table 1. Univariate analysis comparing maternal and perioperative characteristics between pregnancies with delivery < 34 weeks' and ≥ 34 weeks' gestation.

Variable	GA at Delivery		*p* value[2]
	< 34 weeks, N = 25[1]	≥ 34 weeks, N = 54[1]

762 | TTTS on Tiktok: News Or Noise?

Gabriela F. Tessler; Noelle Breslin; Russell S. Miller
Columbia University Medical Center, New York, NY

10:30 AM - 12:30 PM

Objective: Patients are increasingly looking to TikTok for health information. We evaluated content and quality of TikTok videos related to twin-twin transfusion syndrome (TTTS) and fetoscopic laser surgery (FLS).

Study Design: The top 50 TikTok videos (TikToks) related to TTTS were identified using search terms "TTTS", "twin-twin transfusion", and "fetal laser surgery". Data were gathered on video metrics. Three independent reviewers evaluated videos using three standardized quality scales: a modified 5-point DISCERN scale, the Patient Education Maternal Assessment Tool for Audiovisual Materials (PEMAT A/V), and a 5-point Likert Global Quality Scale (GQS). TikToks were also graded on creator type, content, tone, and outcomes. Exclusion criteria included non-English, unrelated, or duplicate videos.

Results: 50 TikToks created by 42 users were evaluated. Total views for all TikToks were 63.3 million. The most viewed TikTok had 2.5 million views, the most liked had 537,000 likes, and the most shared had 22,100 shares. 66% of content was created by patients and 14% was created by medical professionals. 26% of videos contained educational content. 34% of videos reported a good fetal outcome and 8% noted a complication or poor outcome. The mean mDISCERN score was 0.8 (SD 0.7). The mean PEMAT A/V understandability score was 56.3% (SD 28.9%), and the mean actionability score was 2.4% (SD 7.5%). The median GQS was 1 [IQR 1- 1.6]. TikToks posted by medical professionals had higher quality scores ($p< 0.001$). Of the 10 videos with highest GQS, 6 were posted by medical professionals. Of the 10 most-liked videos, 3 were posted by medical professionals.

Conclusion: TikToks related to TTTS and FLS are highly viewed, liked, and shared, yet of overall poor quality. A majority of content was posted by patients and related to individual pregnancy experiences, and was more likely to detail good outcomes than poor outcomes. Medical professionals posted higher-quality content, much of which was highly viewed and liked. These data support a need and demand for more high-quality content related to TTTS and FLS on TikTok.

Table 1: Metrics for selected TikTok videos

Video metrics (n=50)	Average
Length (seconds), median [IQR]	33 [13; 90]
Views, median [IQR]	15,050 [2380; 419,975]
Likes, median [IQR]	517 [97; 6351]
Comments, median [IQR]	13 [2; 63]
Saves, median [IQR]	21 [4; 181]
Shares, median [IQR]	8 [1; 118]

Table 2: Evaluation data for selected TikTok videos

Global Quality Scale score (1-5), median [IQR] §	1 [1; 1.6]

* Modified DISCERN (mDISCERN): Assesses aims, sources, bias, resources, and uncertainty. Scale 0-5, with 5 the highest rating
†PEMAT A/V score: Assesses understandability of content in terms of language, narration, readability, as well as actionability. For each score, scale 0-100%, with 100% the highest rating
§ Global Quality Scale score (GQS): Assesses overall quality of content and usefulness to patients. Scale 1-5, with 5 the highest rating

763 | Implementation of a New Rolling Circle Replication Assay for Universal Non-Invasive Prenatal Screening

Gayathri D. Vadlamudi[1]; Kristen Warncke[2]; Jessica E. Pruszynski[3]; Patricia Santiago-Munoz[1]; Elaine L. Duryea[2]
[1]UT Southwestern Medical Center, Dallas, TX; [2]University of Texas Southwestern Medical Center, Dallas, TX; [3]University of Texas Southwestern, Dallas, TX

10:30 AM - 12:30 PM

Objective: To evaluate the uptake and performance of non-invasive prenatal aneuploidy screening (NIPS) using a new rolling circle replication assay.

Study Design: We conducted a prospective observational study of patients receiving prenatal care at a large county hospital. Patients with singleton pregnancies ≥ 10 weeks gestation were offered NIPS for trisomy 13, 18, and 21 using a non-sequencing based rolling circle replication assay (Vanadis system, PerkinElmer, Waltham, MA, USA) with analysis performed on-site. Individuals with abnormal screening results were offered diagnostic testing. We recorded results of invasive diagnostic testing and postnatal genetic testing if performed. Samples with diagnostic confirmation available were used to calculate predictive values.

Results: Among 14,127 patients who received prenatal care at our institution between August 2023 to July 2024, 11,631 (82.3%) elected NIPS. The mean BMI in this population was 29.5 ± 6.6 kg/m^2. There were 106 (0.9%) positive screening results, of which 46 had increased risk for trisomy 21, 32 for trisomy 18, and 28 for trisomy 13. There were 18 no-call results, with a no-call rate of 0.15%. Of patients with diagnostic results available, abnormal screening results were confirmed in 16/19 (84.2%) patients who screened positive for T21, in 11/15 (73.3%) patients who screened positive for T18, and in 2/8 (25.0%) patients screened positive for T13. There were no false negative screens identified for any of these three aneuploidies.

Conclusion: Non-invasive prenatal screening using a rolling circle replication assay offers high sensitivity and specificity for aneuploidy screening with a low rate of no-call results. Positive predictive values for trisomy 21 and trisomy 18 far exceeded that for trisomy 13 screening.

Table 1: Outcomes of the rolling circle replication non-invasive prenatal screening assay

	Number of positive screens*	Prevalence	Sensitivity	Specificity	Positive predictive value	Negative predictive value
Trisomy 21	46	0.1%	100%	99.97%	84.2%	100%
Trisomy 18	32	0.02%	100%	99.97%	73.3%	100%
Trisomy 13	28	0.01%	100%	99.95%	25%	100%

*Number of positive screens out of n = 11,631 screening assays performed during the study period.

764 | Assessing Prioritized Groups Referenced in 2019-2024 Maternal Mortality Review Committees' Summaries

Genevieve Kitts[1]; John J. Byrne[2]; Brenda Berumen-Flucker[3]
[1]Texas State University, Texas State University, TX; [2]University of Texas Health San Antonio, San Antonio, TX; [3]Texas State University, Houston, TX

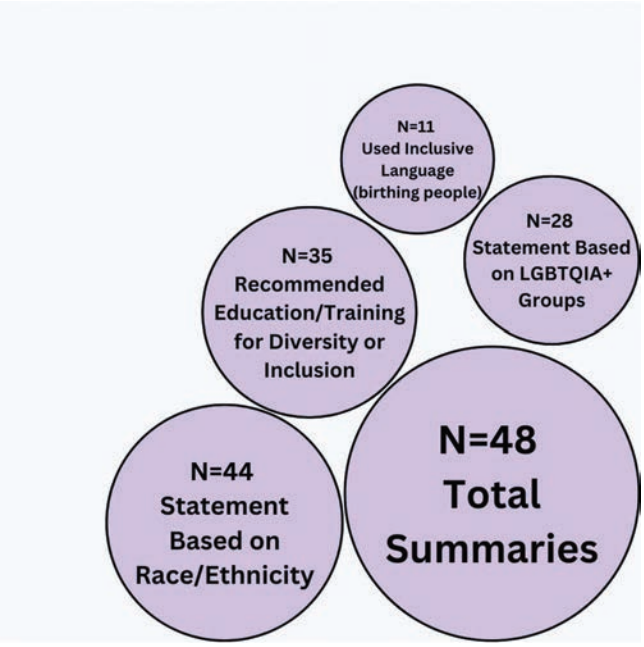
10:30 AM - 12:30 PM

Objective: Maternal mortality review committees are encouraged to define populations at risk of maternal morbidity and mortality. Summaries should work to include the most recent data among racial/ethnic, socioeconomic, rural, and LGBTQIA+ groups. We investigated states' most recent summaries to identify which disproportionately affected groups they prioritized.

Study Design: We utilized publicly available data from maternal mortality review committees or similar organizations' summaries online in June 2024. Using Prisma 2020, we established inclusion and exclusion criteria. We compared their priority populations to the CDC's 2022 data set for maternal mortality. We evaluated the utilization of inclusive and gender-neutral language for LGBTQIA+ individuals. Commonly used phrases within the summaries were birthing people, persons, or individuals.

Results: Of the 48 summaries that met inclusion criteria, 91.7% included an excerpt of their priority population based on race or ethnicity. Black, Hispanic, and Native American groups were the most commonly reported minority groups prioritized. Recommendations for diversity training or education were included for 72.9% of reviews, 25.0% did not, and 2.0% were unclear. Evaluating use of inclusive language, 58.3% of summaries explicitly stated intentions to include sexual minority groups using gender-neutral language; 22.9% were unclear but used terms birthing people or individuals.

Conclusion: As of 2024, there continues to be a lack of focus on high-risk groups within the MMRC reports. This study supports the need for health practitioners to focus on improving inclusive language within MMRC reports. Without acknowledging the groups most in need, providers and community health workers will fail to address maternal morbidity and mortality adequately.



765 | Maternal History of Recurrent Pregnancy Loss and the Risk for Offspring Inflammatory Bowel Disease

Gil Gutvirtz[1]; Gali Pariente[2]; Tamar Wainstock[2]; Eyal Sheiner[2]
[1]Soroka University Medical Center, Metar, HaDarom; [2]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom

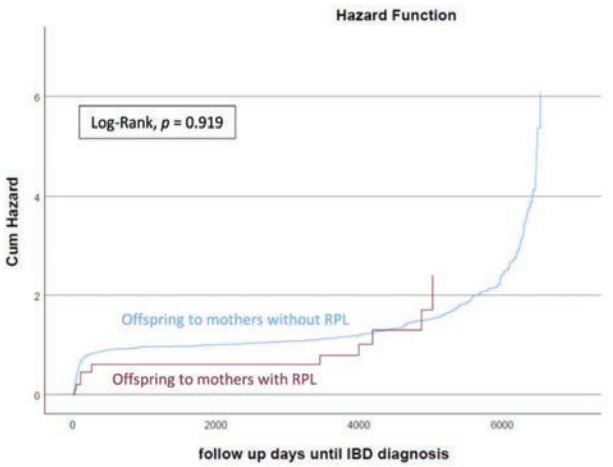
10:30 AM - 12:30 PM

Objective: Women with a history of recurrent pregnancy loss (RPL) may harbor a genetic disposition for inflammatory responses causing pregnancy losses. As altered immune response has been implicated in the pathogenesis of inflammatory bowel disease (IBD), we sought to investigate whether offspring of women with RPL are at an increased risk to develop IBD.
Study Design: A population-based cohort study of singleton deliveries was conducted to evaluate the risk for IBD in children (up to the age of 18 years) born to mothers with and without a history of RPL. Data for the diagnosis of IBD of the offspring were extracted from community-based clinics and hospitalization records. Kaplan-Meier survival curve was used to compare the cumulative incidence of IBD between the study groups. A cox proportional hazards model was used to control for confounders.
Results: During the study period (1991-2021), 356,356 singleton deliveries were included in the study, of them, 14,235 (4%) deliveries were in women with a history of RPL. Comparable rates of IBD were documented in children born to mothers with and without a history of RPL (0.1% vs. 0.1%, $p = 0.104$, **Figure**). The Kaplan-Meier survival curve demonstrated a comparable incidence of IBD in offspring of both groups (Log Rank, $p = 0.919$, **Figure**). Likewise, using a Cox proportional hazards model, adjusted for maternal age and gestational age at birth, maternal history of RPL was not associated with IBD of the offspring (adjusted hazard ratio (HR) = 1.11, 95%CI 0.60-2.05, $p = 0.731$).
Conclusion: Maternal history of recurrent pregnancy loss is not a risk factor for IBD in the offspring.

Figure. The association between RPL and IBD of the offspring: Univariate analysis, Kaplan Meier survival curve and results from a Cox proportional hazards model

	History of RPL (n=14,235)	No RPL (n=342,121)	Odds Ratio (95% CI)	Adjusted* HR (95% CI)
Inflammatory bowel disease	11 (0.1%)	432 (0.1%)	0.61 (0.33 – 1.11)	1.11 (0.60 – 2.05)

* Adjusted for maternal age and gestational age at birth



766 | Maternal Age at First Delivery and Long-term Ophthalmic Morbidity of the Mother

Gil Gutvirtz[1]; Eyal Sheiner[2]; Tamar Wainstock[2]; Ruslan Sergienko[3]; Erez Tsumi[4]; Roy Kessous[4]
[1]Soroka University Medical Center, Metar, HaDarom; [2]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom; [3]Ben-Gurion University of the Negev, Beer Sheva, HaDarom; [4]Soroka, Beer-Sheva, HaDarom

10:30 AM - 12:30 PM

Objective: Advanced maternal age has been associated with adverse pregnancy outcomes. Complications such as hypertensive disorders, preterm delivery and low birthweight suggest that maternal age is a crucial determinant of vascular adaptation to pregnancy. Few studies have examined these associations with mothers long-term outcome. We investigated the impact of maternal age at first delivery on long-term ophthalmic morbidity
Study Design: A population-based retrospective cohort study of women who delivered between the years 1991-2021 at a tertiary center was conducted. Maternal age at first delivery was divided into 4 categories (< 30 years, between 30-35, 35-40 and >40 at first delivery). The long-term ophthalmic morbidity was compared based on data from both community and hospitalization records involving an ophthalmic morbidity. A Kaplan–Meier survival curve was used to compare the cumulative incidence of ophthalmic morbidity and a Cox regression model was constructed to control for confounders, comparing the groups of maternal age over 30 to a reference group of women under 30
Results: A total of 76,131 women were included in the study. 69,530 (91.3%) were under 30 years in their first delivery, 5,066 (6.7%) were between 30-35, 1,231 (1.6%) were between 35-40 and 304 (0.4%) were over 40 years old. The cumulative incidence of ophthalmic morbidity over time was higher as maternal age was older in the first delivery (**Figure**). A trend of increased

ophthalmic morbidity was noted as maternal age was older but it did not reach a statistical significance (3.7%, 3.6%, 4.1% and 6.3%, $p = 0.08$). The Cox regression model, controlling for fertility treatments and ethnicity, found a dose dependent effect as maternal age in the first delivery was an independent risk factor for long-term ophthalmic morbidity of the mother as compared with women under 30 years old (**Table**)

Conclusion: Advanced maternal age at first delivery is an independent risk factor for long-term ophthalmic morbidity of the mother. The risk tends to increase in a dose-response manner over age 30, and specifically for patients over 40 in their first delivery

Figure. Kaplan-Meier survival curve demonstrating the cumulative incidence of ophthalmic morbidity among study groups divided by maternal age in the first pregnancy

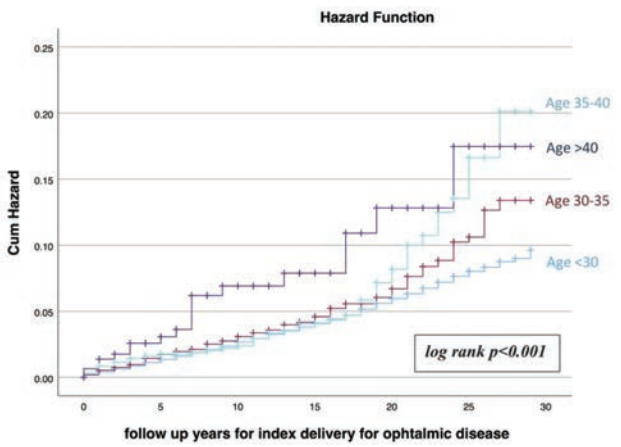


Table. Cox regression model for the association between maternal age in the first pregnancy and the mother's long-term ophthalmic morbidity

	aHR	95%CI	p value
Maternal age < 30 years	1 (reference)		
30-35 vs. under 30	1.21	1.03 – 1.41	0.016
35-40 vs. under 30	1.37	1.04 – 1.82	0.027

767 | Normotension is not Predictive of Duration of Expectant Management of Preterm Preeclampsia with Severe Features

Gillian Piltch[1]; Burton Rochelson[2]; Matthew J. Blitz[2]; Evelina Grayver[2]; Alejandro D. Alvarez[2]; Caroline Pessel[2]

[1]Northwell, Astoria, NY; [2]Northwell, New Hyde Park, NY

10:30 AM - 12:30 PM

Objective: To identify the optimal blood pressure range during expectant management of preterm preeclampsia with severe features.

Study Design: Multicenter retrospective cohort study of pregnant people with preterm (< 34 weeks gestation) preeclampsia with severe features by severe hypertension criteria who underwent a period of expectant management >48 hours from 2017-2022. People were excluded if they had chronic hypertension, fetal anomaly, or underwent pregnancy termination. Primary outcomes were completed percentage of maximum potential duration of expectant management until goal of 34 weeks and attainment of 34 weeks gestation. ANOVA, Kruskal-Wallis test, t-test, Wilcoxon rank-sum test, and multivariate regression were performed with $p < 0.05$ considered statistically significant.

Results: 186 people met inclusion criteria. Antepartum blood pressures were normal (< 140/90) 0-33% of measurements in 36 people (19.4%), 34-66% in 94 people (50.5%), and 67-100% in 56 people (30.1%). Percentage of normal blood pressures was not associated with completed percentage of maximum potential duration of expectant management (Figure 1), but increasing percentage of blood pressures in the severe range was associated with lower completed percentage of maximum potential duration of expectant management (Figure 2). Multivariate analysis demonstrated that percentage of blood pressures in the severe range (OR 0.91, CI 0.86-0.96) and diagnosis of fetal growth restriction (OR 0.41, CI 0.23-0.74) were associated with a lower completed percentage of maximum potential duration of expectant management while maintenance antihypertensive medication (OR 2.45, CI 1.06-5.67) was associated with a higher completed percentage. Neither the percentage of normal blood pressures ($p = 0.7$) nor the percentage of blood pressures in the severe range ($p = 0.9$) were associated with attaining 34 weeks gestation.

Conclusion: Percentage of normal as opposed to elevated blood pressures was not predictive of the duration of expectant management of preterm preeclampsia with severe features.

768 | Neonatal outcomes following rescue Antenatal Corticosteroids given after 34 weeks of gestation

Hadel Watad[1]; Keren Ofir[2]; Michal Fishel Bartal[3]; Rakefet Yoeli-Ullman[2]; Shali Mazaki-Tovi[4]
[1]Sheba Medical Center, Jatt Village, HaZafon; [2]Sheba Medical Center, Ramat Gan, HaMerkaz; [3]UTH Houston & Sheba Medical Center Israel, Houston, TX; [4]Department of Obstetrics and Gynecology, Sheba Medical Center, Tel HaShomer, Ramat Gan, HaMerkaz

10:30 AM - 12:30 PM

Objective: We aimed to determine neonatal outcomes following administration of rescue antenatal corticosteroid (ACS) at late preterm (>34 weeks) after completion of initial cycle of ACS during early preterm period.

Study Design: A retrospective cohort study including all pregnant individuals who delivered singleton late preterm infants and received first dose of ACS before 34 weeks of gestation. Individuals were divided to two groups:1. study group: Received rescue ACS >34 weeks and 2. control group: no rescue ACS after 34 weeks. Data were collected from medical records. Parametric and non-parametric statistical methods were used for analysis.

Results: A total of 757 pregnant individuals met the inclusion criteria. Among them, 21.3% (n = 161) received rescue ACS after 34 weeks of gestation, while 78.7 % (n = 596) did not. Individuals who received rescue ACS had a higher median maternal age, gravidity and parity and received first course earlier during pregnancy compared to individuals without rescue dose (table 1). Neonates born to individuals who received rescue ACS had a significantly lower rates of composite neonatal outcomes compared to those who did not receive ACS (27.6% vs. 39.9%, p = 0.05), lower rates of NICU admission (26.9% vs. 39.7%, P = 0.003), and higher rates of neonatal fever (3.2% vs. 0.7%, P = 0.027). However, rates of RDS (1.3% vs. 3.2 %, P = 0.274) and composite respiratory adverse outcomes (10.3% vs. 13.8%, P = 0.298) were comparable between the groups. Additionally, rates of neonatal hypoglycemia were comparable (11.8% vs. 17.4%, p = 0.085 respectively). Following logistic regression and adjustment for gestational age at first ACS course, maternal age, and gravidity; those not receiving rescue ACS at late preterm had a higher rate of adverse composite neonatal outcomes [aOR 1.13, 95% CI 1.044-1.186].

Conclusion: Rescue ACS administration in late preterm was associated with reduced composite neonatal outcomes and NICU admission. However, it was not associated with a reduced rates of RDS or composite respiratory outcomes. Importantly, there was no significant difference in the prevalence of hypoglycemia.

Table 1. Demographic and baseline characteristics of pregnant individuals who received Antenatal Corticosteroids

Variable	Rescue dose at late preterm (N=161)	Without rescue dose (N=596)	P value

Arterial pH <=7.1	1 (0.9)	7 (2)	0.688
Composite neonatal outcome	43 (27.6)	223 (39.9)	**0.005**

Data are presented as median (interquartile range) and n (%)
Composite respiratory outcome includes: RDS, Mechanical Ventilation, non-invasive ventilation, Oxygen supplement, Apnea, Pneumonia, TTN and neonatal resuscitation.
Composite neonatal outcome includes: NICU admission, hypoglycemia, IVH, NEC, neonatal Fever, Neonatal sepsis, hyperbilirubinemia, RDS, Mechanical Ventilation, non-invasive ventilation, Oxygen supplement, Apnea, Pneumonia, TTN and neonatal resuscitation.
RDS- Respiratory Distress Syndrome, TTN- Transient Tachypnea of the Newborn, IVH-intraventricular Hemorrhage, NICU- Neonatal Intensive Care Unit

769 | Did Increasing Postpartum Oxytocin Infusion to 30 Units Decrease Postpartum Hemorrhage(PPH) at a University Hospital?

Hadley K. Ross[1]; Alixandria F. Pfeiffer[2]; Camille B. Marquez[3]; Nora M. Doyle[4]; Michael Gardner[5]
[1]Univeristy of Texas Health San Antonio, San Antonio, TX; [2]University of Texas Health Science Center at San Antonio, San Antonio, TX; [3]University Health System, San Antonio, TX; [4]University of Texas Health San Antonio, San Antonio, TX; [5]University Health Women and Childrens Hospital, San Antonio, TX

10:30 AM - 12:30 PM

Objective: Postpartum hemorrhage is a common occurrence affecting approximately 5% of all pregnancies and 11% of all pregnancy associated mortalities in the U.S. In January of 2024 we changed our institutional protocol to increase the routine use of Oxytocin from 10 units to 30 units immediately after delivery. The primary aim of our study was to see if this protocol decreased PPH at a university hospital. Our secondary aim was to determine if PPH was associated with population characteristics such as BMI.

Study Design: We performed a retrospective cohort study of PPH before and after the implementation of the new Oxytocin protocol on 1/16/2024. We initially implemented the change in vaginal deliveries only, but on 5/22/2024 we instituted the

higher oxytocin dose at all deliveries. Secondary analysis involved patient demographics such as BMI.

Results: The patient demographics were similar between groups with high rates of obesity, cesarean sections, multiparity, and hypertension. The rate of PPH was the same at 14% both before and after the increase in oxytocin postpartum.

Conclusion: In an attempt to decrease the high rate of PPH at our institution we implemented a protocol to increase the postpartum dose of Oxytocin to 30 units. We did not find any change in the rate of PPH. Of note, our rate of PPH of 14% both before and after the change is higher than the national reported average of 5%. This may be because of our tertiary care center, our high rate of obesity, or that we routinely use quantitative measurement of postpartum blood loss. Further interventions are needed to address the high rate of PPH seen at our university hospital.

770 | The Efficacy of Deep Learning Based Automated Cervical Length Measurement for Predicting Preterm Birth

Hayan Kwon; Ju-hee yoon; Yun Ji Jung; Ja-Young Kwon; Suhra Kim
Yonsei University College of Medicine, Seoul, Seoul-t'ukpyolsi

10:30 AM - 12:30 PM

Objective: Cervical length measurement of less than 2.5 cm in pregnant women between 16 weeks 0 days and 24 weeks 6 days is commonly used to predict preterm labor. However, conventional measurements are highly operator-dependent and often underestimate actual cervical length, which can lead to overtreatment. This study aimed to compare conventional cervical length measurement with deep learning-based automated measurement to determine any differences in preterm prediction.

Study Design: The study included 197 women out of 1270 who received antenatal care and delivery at Severance Hospital from 2019 to 2023. Participants had cervical lengths measured conventionally as 2.5 cm or less within the specified gestational period. Those with preterm labor, multiple pregnancies, or who underwent cerclage were excluded. Cervical length was measured using traditional and deep learning methods. Deep learning program utilized a semantic image decomposition network to divide images into pre-cervix, cervix, and post-cervix regions for cervical canal identification. The canal was assessed at six points for distance calculation. Participants were divided into Group A (cervical length of 2.5 cm or less by both methods) and Group B (less than 2.5 cm by conventional but more than 2.5 cm by deep learning). The primary endpoint was preterm birth, defined as delivery before 37 weeks.

Results: Group A had an average cervical length of 2.32 cm (+-0.159), while Group B's average was 2.73 cm (+-0.317). The preterm birth rate was 16.2% (9/152) in Group A and 4.8% (21/197) in Group B. Group B had a significantly lower preterm birth rate ($P < 0.05$), suggesting that cervical tracing provides longer cervical length measurements, improving preterm birth prediction accuracy.

Conclusion: Cervical length measurement through tracing offers more accurate preterm birth predictions than conventional methods. Deep learning for CL measurement can also reduce patient discomfort, shorten examination times, and provide operator independence. Integrating deep learning AI for cervical length measurement has important implications for future practices.

Chart 1- Incidence of Cerclage Placement by Race and Ethnicity Groups, Language, Insurance and Cervical Length <10mm

771 | Outcomes in Vaginal versus Cesarean Periviable Breech Delivery: A 5-year, Propensity Score–Matched Study

Helen B. Gomez Slagle[1]; Yongmei Huang[2]; Cande V. Ananth[3]; Uma M. Reddy[4]; Alexander M. Friedman[1]
[1]Columbia University Irving Medical Center, New York, NY; [2]Department of Obstetrics and Gynecology, Columbia University Irving Medical Center, New York, NY; [3]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; [4]Columbia University, New York, NY

10:30 AM - 12:30 PM

Objective: To determine maternal and neonatal outcomes associated with vaginal versus cesarean breech delivery at periviability.

Study Design: This study analyzed non-anomalous, singleton, breech live births at 22w0d to 25w6d gestational age identified in the CDC Linked Birth/Infant Death Records data from 2016 to

2021. Multiple imputation was used to account for missing data. A propensity score (PS) analysis was conducted to establish pseudo-randomization based on the mode of delivery matching vaginal to cesarean deliveries at a ratio of 1:2 using greedy nearest-neighbor matching. The balance diagnostic was measured using standardized mean difference. In the outcome model, we estimated the risk difference (RD) and risk ratios (RR) and associated 95% CIs based on generalized estimation equation framework, using log-linear models with binomial distribution and a log/ identity link, respectively, after re-adjusting for gestational age (GA).

Results: Of 21,461 periviable breech singleton births, 34% (N = 7,289) delivered vaginally. Vaginal delivery was more common in earlier GA. After PS matching, the distributions of baseline factors were balanced between the delivery arms. A composite of adverse neonatal outcomes occurred among 99.0% (N = 7,213) of vaginal and 96.8% (N = 13,716) of cesarean breech births (RD 1.85, 95% CI -1.77 to 5.46; RR 1.02, 95% CI 0.98 to 1.06). Neonatal mortality was significantly higher for vaginal than cesarean breech births (73% versus 36%; RD 28.29 95% CI 25.50 to 31.07; RR 1.70, 95% CI 1.61 to 1.79). A composite of adverse maternal outcomes occurred in 1.6% of vaginal breech and 3.1% of cesarean births (RD -1.58, 95% CI -2.20 to -0.96, RR 0.48, 95% CI 0.36 to 0.65).

Conclusion: Vaginal breech birth between 22w0d and 25w6d gestation is associated with lower risk of adverse maternal outcomes but higher risk of neonatal mortality.

Risks of Adverse Maternal and Neonatal Outcomes by Mode of Delivery in Periviable Breech Presentation: Singleton Live Births in the United States, 2016-2021

	Vaginal delivery Number (%) (N=7,289)	Cesarean delivery Number (%) (N=14,172)	Adjusted risk difference (95% confidence interval)*	Adjusted Risk Ratio (RR) (95% confidence interval)*
Adverse neonatal outcomes				
Composite	7213 (99.0)	13716 (96.8)	1.85 (-1.77, 5.46)	1.02 (0.98, 1.06)
Neonatal mortality	5294 (72.6)	5128 (36.2)	28.29 (25.50, 31.07)	1.70 (1.61, 1.79)
5-min Apgar score <4	5615 (77.0)	3554 (25.1)	40.92 (38.15, 43.69)	2.43 (2.29, 2.57)
Neonatal intensive care unit admission	2739 (37.6)	12587 (88.8)	-41.06 (-44.00, -38.11)	0.53 (0.51, 0.56)
Assisted ventilation >6 hours	1081 (14.8)	5790 (40.9)	-20.13 (-22.13, -18.14)	0.49 (0.46, 0.53)
Adverse maternal outcomes				
Composite	115 (1.6)	440 (3.1)	-1.58 (-2.20, -0.96)	0.48 (0.36, 0.65)
Uterine rupture^	4 (0.1)	24 (0.2)	-0.15 (-0.29, -0.01)	0.36 (0.12, 1.09)
Maternal transfusion	78 (1.1)	237 (1.7)	-0.81 (-1.27, -0.35)	0.57 (0.40, 0.82)
Intensive care admission	29 (0.4)	206 (1.5)	-0.91 (-1.27, -0.56)	0.29 (0.16, 0.51)
Unplanned hysterectomy^	6 (0.1)	20 (0.1)	-2.01 (-19.30, 15.28)	0.33 (0.04, 2.68)
			1.85 (-1.77, 5.46)	1.02 (0.98, 1.06)

Parameter estimates were derived from 25 multiply-imputed datasets after propensity score matching. The propensity score calculation included year of delivery, maternal age, liveborn parity, marital status, maternal education, smoking before/during pregnancy, race/ethnicity, insurance status, attendant at delivery, pre-pregnancy body mass index, hypertensive disorders, diabetes mellitus, gestational age, induction of labor, and trial of labor attempted. The outcome model was re-adjusted for gestational age, using it as a categorical variable with 22 weeks of gestation as the reference group for all the outcomes, except for uterine rupture and unplanned hysterectomy. For these two outcomes, gestational age was re-adjusted as a continuous variable for better model fitting.

772 | Gestational Diabetes Mellitus in the 3RD Trimester After Diagnosing Large for Gestational Age And/Or Polyhydramnios

Henry Lesser; A. Dhanya Mackeen; David Chromey, II; Amanda J. Young; Celia Gray; Michael J. Paglia
Geisinger Medical Center, Danville, PA

10:30 AM - 12:30 PM

Objective: To evaluate outcomes of patients who rescreen for gestational diabetes mellitus (GDM) in the 3rd trimester based on a diagnosis of large for gestational age (LGA) and/or polyhydramnios.

Study Design: This is a retrospective cohort study from 1/1/11-3/1/24 of term, singleton pregnancies who were rescreened for GDM after being diagnosed with LGA and/or polyhydramnios. Patients with fetal growth restriction, or fetal anomalies were excluded. We compared outcomes in those that passed and failed rescreening using a logistic regression model where birthweight was adjusted for gestational age. Odds ratios and respective 95% confidence intervals and p-values are reported.

Results: We identified 348 pregnancies that completed GDM rescreening: 48 (13.8%) were diagnosed with GDM of which 10 (20.8%) required medication (A2GDM). When comparing patients that passed vs. failed rescreening, there were no statistically significant differences for birthweight (BW), BW ≥4000g, shoulder dystocia, preeclampsia or cesarean delivery. Patients that failed rescreen were more likely to have a newborn with neonatal hypoglycemia (7.0% vs. 22.9%, p< 0.01) and develop GDM in future pregnancies (1.3% vs. 10.4%, < 0.01).

Conclusion: The rate of diagnosis of GDM in the 3rd trimester after rescreening is low at only 14%, and similarly the rate of A2GDM is exceedingly low at 3% of all patients that were rescreened. Except for neonatal hypoglycemia, outcomes for patients diagnosed with GDM did not differ from those that passed rescreening. Despite making the diagnosis of GDM, there does not appear to be utility in rescreening due to the lack of improvement in perinatal outcomes.

Table: Maternal and neonatal outcomes for all patients who completed rescreening by results (pass/fail)

	Results of Completed Rescreen		Odds Ratio[1] (95% CI)	P-value[1]
	Pass (N=300)	Fail (N=48)

773 | Clinical Utility of Various Growth Factors in Preeclampsia

Ho Yeon Kim[1]; Gwan Heup Song[2]
[1]Korea University School of Medicine, Danwongu AnsanSi, Kyonggi-do; [2]Korea University School of Medicine, Danwongu/Ansan City, Kyonggi-do

10:30 AM - 12:30 PM

Objective: This study aimed to compare the levels of various growth factors in maternal serum and umbilical vein serum between individuals with preeclampsia (PE) and those with normotensive pregnancies.

Study Design: One hundred eight pregnant women were enrolled in this prospective study. 67 serum samples of preeclampsia and 41 normotensive mothers were collected. Umbilical

vein serum samples of 27 PE and 38 normotensive pregnancies were collected. Serum levels of BDNF, EGF, FGF-2, HGF, LIF, NGF-beta, PDGF-BB, PlGF-1, SCF, and VEGF-A and D were measured.

Results: EGF, HGF, LIF, PDGF-BB and SCF levels were significantly higher in PE compared to normotensive group. After adjustment for gestational age, EGF, HGF, LIF and SCF remained significantly high in PE. There were no differences in growth factors in umbilical vein serum between two groups. EGF, NGF-beta and SCF were associated with the elevation of systolic and diastolic blood pressure, while EGF was negatively correlated with birthweight and positively with protein/creatinine ratio. SCF showed a positive correlation with ALT and creatinine and a decreasing trend as gestational age advances.

Conclusion: Circulating growth factors in PE, especially elevated levels of EGF, HGF, LIF, and SCF, may be responsible for the development or consequences associated with the pathogenesis of PE, with evidence demonstrating an association with severe features. These hormones in placenta appear to have different patterns compared to those in the maternal blood, suggesting that the placenta may regulate these factors to prevent them from reaching the fetus. Further experiments are need to explain this phenomenon.

	Maternal blood serum (pg/mL)				Umbilical vein serum (pg/mL)

774 | Sonographic Features of Placenta Accreta Spectrum with and Without Placenta Previa

Hope Y. Yu[1]; Rishi B. Chopra[2]; Kris Ann Botka[2]; Daniela A. Carusi[2]; Thomas D. Shipp[2]

[1]Brigham and Women's Hospital / Harvard Medical School, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA

10:30 AM - 12:30 PM

Objective: To evaluate sonographic features of placenta accreta spectrum (PAS) with placenta previa compared to those without placenta previa.

Study Design: Prospective, single referral center study of pregnancies undergoing a standardized, ultrasound protocol for PAS risk assessment in the second and third trimesters. Protocol was applied to pregnancies with placenta previa or request of the obstetric provider based on risk factors. Transvaginal ultrasound was performed if placenta previa was present. Loss of hypoechoic zone (LHZ), retroplacental myometrial thinning (RMT), placental lacunae (PL), placental extension (PE), hypervascularity (HV) and overall PAS risk were assessed. Delivery at $\geq$23 weeks gestation from 1/1/2023 to 7/15/2024 with clinical and/or histologic PAS were included. PAS with placenta previa (PAS-PP) included those with placenta covering the cervical os at the time of delivery. PAS without placenta previa (PAS-NP) excluded those with low-lying placenta even if they resolved.

Results: Two hundred nineteen patients underwent the PAS ultrasound protocol and 37 diagnosed with PAS, 24 PAS-PP and 13 PAS-NP. PAS-NP was more likely than PAS-PP to have history of PAS (38% vs 0%, $p < 0.01$) and less likely to have LHZ, RMT, and HV. There was also a difference in number and size of PL. PAS-PP was more likely to have sonographic suspicion for PAS (78% vs 33%, $p = 0.02$) with a PPV and NPV of 76% and 82%, respectively. Among PAS-NP, PPV and NPV was 44% and 81%, respectively. Twenty-three cases were non-invasive, 10 PAS-PP (42%) and 13 PAS-NP (100%). Sonographic suspicion for PAS was noted in 60% PAS-PP and 33% PAS-NP in the non-invasive subgroup, however, we were not powered to detect a difference ($p = 0.39$).

Conclusion: Standard ultrasonographic signs of PAS are less likely to be present in PAS without placenta previa resulting in lower detection rates. Larger studies are needed to determine whether these differences persist in non-invasive PAS. Alternative PAS risk assessment tools should be investigated in non-previa PAS to improve antenatal detection.

Table 1. Sonographic features of PAS with and without placenta previa

(N=37)	PAS with previa (n=24)	PAS without previa (n=13)	p-value[#]
Loss of hypoechoic zone (LHZ)	17 (71%)	3 (23%)	<0.01
Retroplacental myometrial thinning (RMT)	16 (67%)	3 (23%)	0.02

Clinical Epidemiology Unit, Bordeaux University Hospital, Aquitaine; [3]Public Health Department, Clinical Epidemiology Unit, Bordeaux University Hospital, Bordeaux, France, Public Health Department, Clinical Epidemiology Unit, Bordeaux University Hospital, Bordeaux, Aquitaine; [4]Université Paris Cité, CRESS U1153, Obstetrical, Perinatal and Pediatric Epidemiology Research Team, EPOPé, INSERM, INRAE, Paris, France, Paris, Ile-de-France; [5]Department of Obstetrics and Gynecology, Bordeaux University Hospital, Bordeaux, France, Department of Obstetrics and Gynecology, Bordeaux University Hospital,, Aquitaine

10:30 AM - 12:30 PM

Objective: Prophylactic tranexamic acid has been shown to reduce postpartum blood loss in cesarean deliveries, but its effectiveness may vary based on individual factors and cesarean management. Identifying the women who would benefit most could optimize treatment and minimize unnecessary exposure.
We reanalyzed data from the TRAAP2 trial to determine if the effect of tranexamic acid on postpartum hemorrhage (PPH) varies with women and management of the cesareans' characteristics.
Study Design: We included all women in the modified intention-to-treat population of TRAAP2 who received tranexamic acid or placebo. The primary outcome was PPH, defined as blood loss over 1000 ml or a red-cell transfusion within two days post-delivery. Predictors for PPH included baseline characteristics and cesarean management details. Both logistic regression with lasso penalization (LRL) and random forest (RF) were used to estimate associations between PPH and predictors. Prediction accuracy was assessed using the area under the ROC curve (AUROC) and the precision-recall curve (AUPRC).
Results: The study included 4,367 women (2,190 in the tranexamic acid group and 2,177 in the placebo group). Lasso logistic regression outperformed random forest, with an AUROC of 0.72 (95% CI: 0.70-0.74) (Figure 1). The most important predictors of PPH were multiple pregnancy, number of cesareans, body mass index at the end of pregnancy, hemoglobin within 7 days before delivery, gestational age at delivery and cesarean during labor because of protracted labor. Model had poor calibration for benefit of tranexamic acid with an observed benefit almost constant across the quintile of predicted benefit with a discrimination for benefit of 0.04 (95%CI: -0.07; 0.15) (Figure 2).
Conclusion: Although tranexamic acid is effective for the prevention of calculated blood loss at population level, its individual efficacy is difficult to forecast accurately. This suggests that a targeted prophylactic approach, rather than universal use, may not be appropriate for preventing blood loss in cesarean deliveries.

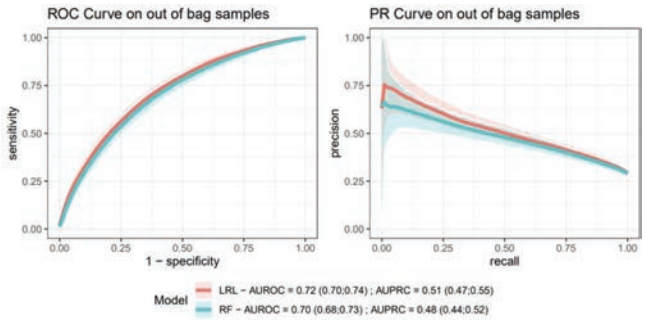

Figure 1: Receiving Operator Curve (ROC) and Precision Recall (PR) curve of models to predict PPH. Area under both ROC (AUROC) and PR (AUPRC) curves are presented with bootstrapped 95% confidence intervals.

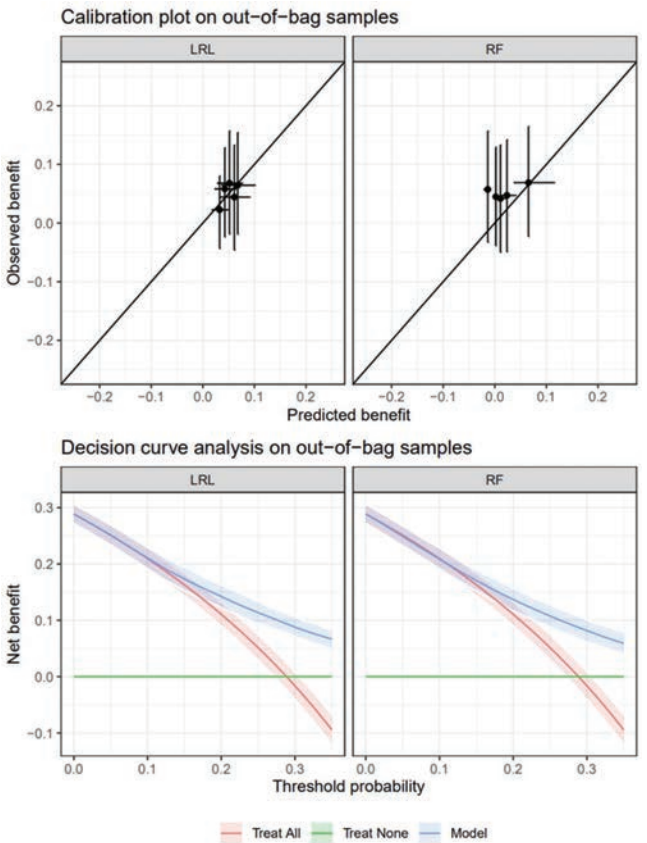

Figure 2: Calibration plot of the predicted benefit compared to the observed benefit and decision curve analysis.

776 | Assessment of the Impact of Hemodynamic-aligned Antihypertensive Therapy in Postpartum Management of Preeclampsia

Ifeoma M. Ogamba-Alphonso[1]; Erin Miller[2]; Tudi-Max Brown-Thomas[2]; Ioanna Katehis[2]; Saige Gitlin[2]; Delphina Maldonado[2]; Gabriella Fernandez De Salvo[2]; Tony Asfour[2]; Keya Shah[2]; Mehak Kapoor[2]; George Gubernikoff[2]; Wendy Kinzler[2]; Martin Chavez[3]; Hye Heo[2]; Patricia Rekawek[2]
[1]NYU Langone Hospital - Long Island, Island Park, NY; [2]NYU Langone Hospital, Long Island, NY; [3]NYU Langone Hospital, New York, NY

10:30 AM - 12:30 PM

Objective: Labetalol and nifedipine are first line antihypertensive agents for hypertensive disorders of pregnancy. There's limited research on selecting medication based on hemodynamic profiles in preeclampsia (PEC), such as high cardiac output (CO) and high systemic vascular resistance (SVR). Our objective was to assess if concordance of antihypertensive treatment with the hemodynamic status on echocardiography (echo) optimizes blood pressure (BP) control in PEC patients.

Study Design: This is a retrospective cohort study of patients with PEC with severe features who delivered at our institution and received a postpartum echo, excluding patients with cardiomyopathy. Antihypertensive choice and decision to order echo were provider dependent. CO and SVR were calculated retrospectively from the echo in collaboration with cardiology. Concordance was defined as patients with high CO (>6L/min) initiated on labetalol and high SVR (>1200 dyn.s.cm^5) initiated on nifedipine. Patients initiated on the opposite medication were grouped as discordant. The primary outcome was time to optimal BP control, defined as the period from the start of BP medication to when no titration was needed. Chi-squared & Fisher's exact tests were used for categorical variables, and Mann-Whitney U test for continuous variables.

Results: Of the 145 patients, 83 (58%) received concordant therapy. Maternal demographics were similar between groups (Table 1). No patients were on magnesium sulfate during the echo. Most patients had high SVR (74%) vs high CO (26%). Of those with high SVR, 56% were on nifedipine. Overall, 51% of patients received Labetalol and 48% received Nifedipine. There was no difference in the median time to optimal BP control (2 days for both groups, p = 0.4). The median postpartum length of stay was 3 days for both groups (p >0.9) (Table 2).

Conclusion: Our study revealed majority of patients with PEC had high SVR, with Nifedipine initiation aligning with most hemodynamic profiles. Although time to optimal BP control did not differ, prospective studies are needed to explore the benefits of hemodynamic aligned therapy in PEC.

Table 1 - Baseline Characteristics of the Patients

777 | Effect of Social Drivers of Health on Screening for Type 2 Diabetes During Delivery Hospitalization

Ingmar N. Bastian; Manisha Gandhi; Mark A. Turrentine
Baylor College of Medicine, Houston, TX

10:30 AM - 12:30 PM

Objective: To estimate the effect of social and structural drivers of health on completion of screening for type 2 diabetes during the delivery hospitalization in patients with gestational diabetes mellitus (GDM).

Study Design: The American College of Obstetricians and Gynecologists updated guidance in May 2024 to offer a 2-hour oral glucose tolerance test (OGTT) in patients with GDM during the immediate delivery hospitalization. Subsequently, our institution began to offer all patients with GDM this option. Patients with recent (7 days) administration of antenatal corticosteroids and those with out of state follow-up were excluded. Demographic, social and structural drivers of health were prospectively collected on all patients with GDM. A comparison of variables was performed between those who did versus those who did not complete the OGTT in the immediate delivery hospitalization. P < 0.05 was considered statistically significant.

Results: From June 24 through August 1, 2024, 694 deliveries occurred with 40 (5.8%) patients having GDM. 38 patients were offered inpatient OGTT, 1 was not eligible, and 1 was excluded from analysis. 53.8 % (21/39) completed and 46.2% (18/39) did not complete screening (Figure 1). 84.6% (11/13) with medication controlled GDM (A2GDM) and 38.5% (10/26) with diet controlled GDM (A1GDM) completed screening; (OR = 8.8, 95% CI: 1.87-65.09). Social and structural drivers of health were similar between the two groups (Table 1).

Conclusion: A greater proportion of patients with GDM accept screening for type 2 diabetes via the OGTT during delivery hospitalization compared to traditional rates reported at 4 to 12 weeks postpartum (< 30% receive recommended screening with OGTT). Patients with A2GDM were more likely to complete inpatient screening than those with A1GDM. Social and structural drivers of health were similar between groups. Further studies will be needed to identify variables that may increase screening uptake for type 2 diabetes in patients with GDM in the immediate postpartum delivery hospitalization.

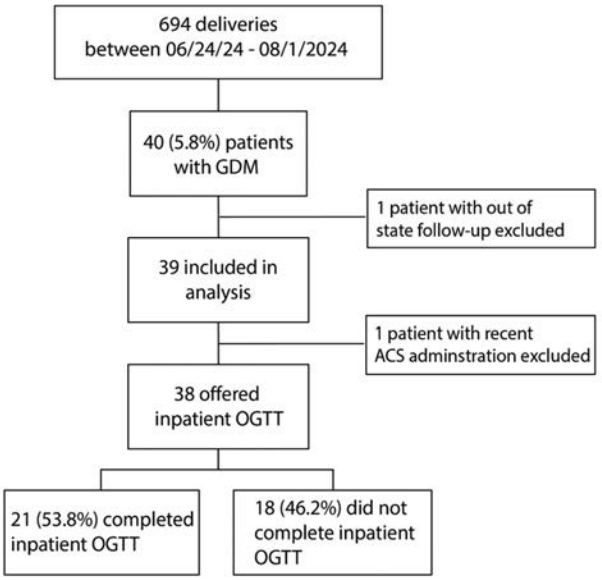

Figure 1: Schematic of prospective review of patients with GDM and completion of OGTT

Distance from hospital (miles)	18.7 ± 25.3	15.7 ± 7.9	0.61
Mean Income	$115,695	$117,356	0.93
Median Income	$90,671	$96,226	0.77

Race and ethnic group were reported by patient electronic health records.
Data are presented as mean ± SD (range) and number (percent) where applicable.
The body-mass index is the weight in kilograms divided by the square of the height in meters.
Independent t-test or Mann Whitney U test were used for continuous variables and Fisher Exact test for binomial variables. Linear regression analysis was used for analysis of GDM types.
SVI (social vulnerability index) and income are based on 2022 Census Tract Data from the CDC.

778 | Which Cutoff of the 50-Gram Gct Has a Higher Predictive Value for Gestational Diabetes Mellitus?

Israel Yoles[1]; Tuvia Baevsky[2]
[1]*Clalit Health Services, THe Central District, Beit Gamliel, HaMerkaz;* [2]*Clalit Health Services, THe Central District, Rishon Le Tzion, HaMerkaz*

10:30 AM - 12:30 PM

Objective: The 50-gram glucose challenge test (GCT) is used as the initial step in screening for gestational diabetes mellitus (GDM). If the GCT result exceeds the institutional threshold, a 100-gram oral glucose tolerance test (OGTT) is performed. The objective of this study was to determine which GCT result is high enough to predict a diagnosis of GDM

Study Design: The study included all pregnant women who underwent a GCT in in a large Health Maintenance Organization. The study included all pregnant women who underwent a GCT between July 2002 and July 2024. We analyzed various GCT values to determine the percentage of women with at least one abnormal value in the subsequent OGTT. GCT was performed if the value was 140 mg/dL or higher. Normal results for OGTT were defined as follows: fasting < 95 mg/dL, 60 minutes < 180 mg/dL, 120 minutes < 155 mg/dL, and 180 minutes < 140 mg/dL

Results: During the study period, 95,562 GCTs were performed, of which 20,797 (21.7%) resulted in a value of 140 mg/dL or higher. Overall, 3,068 women (15%) exhibited at least one abnormal value in the OGTT. The incidence of women with abnormal OGTT results for each GCT group ranged from 24% to 80% (Table 1). The incidence of abnormal OGTT results in each GCT group increased with age, with older women having a higher incidence of these results (Table 2)

Conclusion: In this large cohort, even significantly elevated GCT values could be followed by normal OGTT results, especially in young pregnant women. Therefore, it is recommended to perform an OGTT for every GCT result above the institutional cutoff

Table 1

GCT Result (mg/dL)	Percent of Women with Abnormal OGTT
140-149	24%
150-159	31%
160-169	43%
170-179	59%
180-189	63%
Above 190	80%

Percent of women with a pathological value in OGTT, by GCT results

Table 2

Age / GCT	20-29 y	30-39y	40-49 y
140-149	21%	25%	%36
150-159	27%	34%	%39

779 | Clinical Chorioamnionitis is a Major Risk Factor for Failed Vacuum-Assisted Deliveries

Itamar Gilboa[1]; Daniel Gabbai[1]; Anat Lavie[2]; Yariv Yogev[3]; Emmanuel Attali[1]
[1]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel-Aviv, Tel Aviv; [2]Tel Aviv Sourasky Medical Center, Tel Aviv Sourasky Medical Center, Tel Aviv; [3]Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv University, Tel Aviv Sourasky Medical Center, Tel Aviv

10:30 AM - 12:30 PM

Objective: We aimed to determine the impact of clinical chorioamnionitis during labor and the risk of failed vacuum-assisted delivery (VAD).

Study Design: A retrospective cohort study at a single university-affiliated tertiary medical center with approximately 12,000 deliveries annually from 2011-2023. The study group included singleton pregnancies at ≥36 weeks' gestation undergoing a trial of vacuum delivery. The study group, comprising cases of failed vacuum extraction (defined by extraction duration over 20 minutes, more than two cup detachments, or the operator's decision to switch to urgent cesarean delivery), and the control group, consisting of successful vacuum extractions. Clinical chorioamnionitis was diagnosed with an intrapartum fever of ≥38°C and the presence of either a white blood cell count ≥15,000 or documentation of a commonly used broad-spectrum antibiotic regimen for clinical chorioamnionitis.

Results:

1. Vacuum extraction was attempted in 9,402 out of 111,878 vaginal deliveries (8.4%).
2. The rate of failed VAD was 197/9402 deliveries (2.1%).
3. Multivariate logistic regression analysis identified clinical chorioamnionitis as the major independent risk factor for failed VAD (OR = 3.65, 95% CI 2.3-5.8, p < 0.001).
4. Additional risk factors for failed VAD included: Occiput posterior position (OR = 2.45, 95% CI 1.6-3.7, p < 0.001); Fetal head station less than 2 cm below the ischial spine (OR = 1.92, 95% CI 1.4-2.7, p < 0.001); duration of the second stage of delivery > 3.5 hours (OR = 1.92, 95% CI 1.4-2.7, p < 0.001); birth weight > 3,500 grams (OR = 1.77, 95% CI 1.3-2.5, p < 0.001); induction of labor (OR = 1.95, 95% CI 1.4-2.7, p < 0.001); meconium stained amniotic fluid (OR = 1.52, 95% CI 1.1-2.2, p = 0.018); Male gender (OR = 1.18, 95% CI 1.0-2.0, p = 0.042).

Conclusion: In addition to well-known risk factors for failed VAD, clinical chorioamnionitis was found to be the main factor associated with an increased risk of vacuum failure.

TABLE 1. Obstetrical & Labor characteristics of the study population during labor

Characteristic	Study group (n=169)	Control group (n=9208)	*P*-value

780 | is Prenatal Bisphenol and Phthalate Exposure Associated with Fetoplacental Ratio?

Ayushi Bommireddipalli[1]; Jacqueline A. Erler[2]; Whitney Cowell[1]; Kurunthachalam Kannan[3]; Leonardo Trasande[1]; Linda G. Kahn[1]; Shilpi S. Mehta-Lee[4]
[1]NYU Grossman School of Medicine, New York, NY; [2]Rutgers Robert Wood Johnson Medical School, NJ; [3]NY State Department of Health, Wadsworth Center, Albany, NY; [4]NYU Langone Health, Brooklyn, NY

10:30 AM - 12:30 PM

Objective: Fetoplacental ratio (FPR), the ratio of birthweight (BW) to placental weight (PW), is a well-described indicator of placental efficiency that is linked to future health risks. Bisphenols (BPs) and phthalates are endocrine-disrupting chemicals found in plastics, household products, and vinyl medical tubing. There is no strong evidence that prenatal exposure to BPs or phthalates is associated with neonatal BW, and yet studies show associations with pregnancy complications and adverse child health outcomes. We analyzed prenatal exposure to BPs and phthalates in relation to FPR, BW, and PW as a possible novel explanation.

Study Design: 401 participants in the [institution redacted] Children's Health and Environment Study with data on prenatal chemical exposure, BW, and PW from singleton births were included. Chemical concentrations were log-transformed and adjusted for creatinine. Molar sums of metabolites represented exposure to low and high molecular weight (LMW, HMW) phthalates, diethylhexyl phthalate (DEHP), antiandrogenic phthalates, and BPs; trimester concentrations were averaged. Linear regression models were adjusted for gestational age, fetal sex, maternal demographics, and chemical batch (Table 1). Analyses were stratified by fetal sex.

Results: We found no significant associations between chemical exposure and FPR in the combined sample. Among female fetuses, BPs and HMW phthalates were linked with higher FPR, the former association driven by BPS and the latter driven by DEHP. In models with BW and PW as outcomes, we observed no association with BW in combined or stratified models. We found significant negative associations for the same chemical groups and PW among female infants.

Conclusion: Among female fetuses, exposures to HMW phthalates and BPs are significantly associated with higher FPR due to reduced PW. The BP findings were driven by exposure to BPS, a recent BPA substitute in many consumer products. Our results suggest that BPs and phthalates may affect placental efficiency, with potential implications for pregnancy complications and child health outcomes.

781 | a Just Start: a Mixed-Methods Analysis of Obstetric Health-Harming Legal Needs Among Low-Income Pregnant People

Jecca R. Steinberg[1]; Hebron Kelecha[1]; Madeline F. Perry[1]; Nivedita Potapragada[1]; Allie Valenzuela[1]; Erica O'Neill[2]; Ashish Premkumar[3]; Lynn M. Yee[1]

[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Stroger Hospital Cook County, Chicago, IL; [3]Pritzker School of Medicine, University of Chicago, Chicago, IL

10:30 AM - 12:30 PM

Objective: Health-harming legal needs (HHLN) comprise social barriers to health best addressed through medical-legal collaboration. The objective of this analysis was to understand patient perspectives and experiences with HHLN in pregnancy and postpartum.

Study Design: In this mixed-methods study, we conducted validated surveys and semi-structured interviews in English or Spanish with obstetric patients in a public hospital in Chicago, Illinois. Surveys included the Medical-Legal Partnership Legal Needs Screening Tool and a demographic survey. We applied community-engaged strategies to collaborate with patients, advocates, physicians, nurses, and social workers to design obstetric HHLN interviews. Interviews focused on four HHLN domains: employment, public benefits, housing, and safety. We applied iterative transcript-based coding to develop and refine a codebook, assess interrater reliability (Cohen's kappa >0.85), and analyze themes.

Results: Forty-eight obstetric patients (94% pregnant, 6% postpartum), aged 19-39 years, participated. Twenty participants (42%) identified as Black, 26 as Latine (54%), and 2 as white (4%). All but two participants had public insurance (67%) or were uninsured (27%). In interviews, when asked generally, 92% of participants denied having HHLN. However, 70% of all participants screened positive in the HHLN survey, and when queried about HHLN domains, 95% described obstetric-specific HHLN (Figure). The majority of participants (77%) experienced two or more HHLN, while few faced only an isolated HHLN or none (Figure). The most prevalent obstetric HHLN related to employment (e.g. pregnancy-related workplace discrimination), poor access to public benefits, or substandard housing (Table). Participants described limited options for recourse when HHLN negatively affected their pregnancies (Table).

Conclusion: HHLN burdened nearly all low-income obstetric patients in this study, but most did not realize they had unmet legal needs. Evidence-based interventions are needed to increase awareness of obstetric HHLN and protect pregnant people from the obstetric consequences of HHLN.

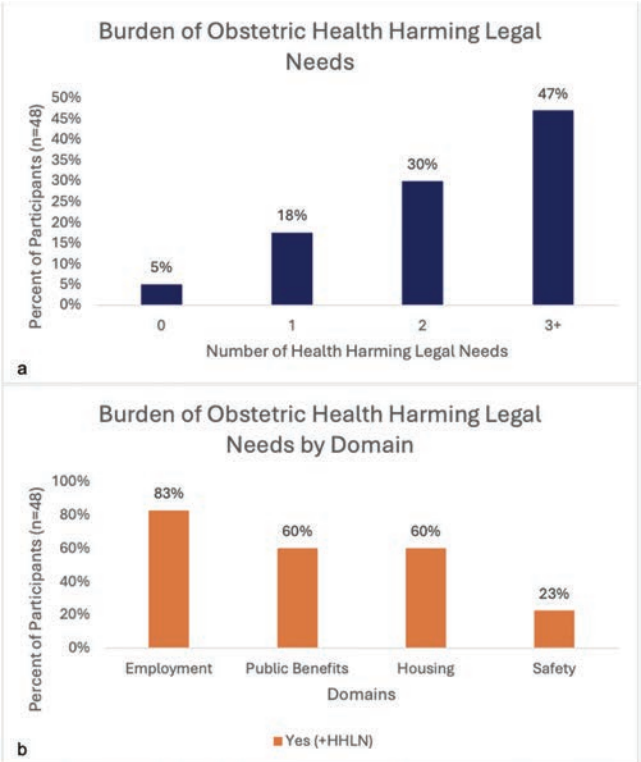

Figure. Obstetric health harming legal needs (HHLN) in pregnancy and postpartum.

Table. Obstetric health harming legal needs: themes and representative quotations
Employment
Unjustified pregnancy-related job terminations "I was feeling very lightheaded. I felt like throwing up, and the employer said they couldn't keep me on." *Difficulty finding work due to pregnancy* "It's difficult because employers are reluctant to hire me because I'm pregnant, and it's very noticeable. They fear taking the risk something might happen to me, that's why." *Lack of accommodations* "I have epilepsy, and I also had frequent seizures during pregnancy…My employer was supportive by allowing me to work for as long as I wanted...I had to resign because the high-risk pregnancy became overwhelming…The employer never offered or spoke to me about any benefits I could get [during pregnancy]."
Public Benefits
"They try to say, 'Get into programs,' but it's hard to get into certain programs or it's hard for other programs to call you back because there's so many people that need help. So you have to wait. And by the time you get help, it's a little bit too late."
Housing
"[The landlord] doesn't keep up the maintenance of the building…It's molding or open spaces … it's rodents and stuff throughout the building… There's been a couple of times the heat went off throughout the whole building for a month or so... Our wall that's half missing or not all the way done…I've sent letters to her, have mentioned to her plenty of times about the maintenance."
Safety
"Safety over there because the vehicle I have, they stole the vehicle before, but not from that location particularly. So I know it's dangerous over there. Then it's right there in the city and the area will mow a lot of shooters and stuff going there. But I don't be outside. And since I just moved out, I don't try to be nobody by the window."

782 | Transcerebellar Diameter in Fetal Growth Restriction - Does Concordance with Estimated Fetal Weight Matter?

Jenna S. Silverstein[1]; Emily Schneider[2]; Meralis V. Lantigua-Martinez[3]; Gabrielle K. Concepcion-Taveras[3]; Young Mi Lee[4]; Martin Chavez[5]; Ashley S. Roman[4]; Justin S. Brandt[4]; Erinn M. Hade[3]; Steven Friedman[3]; Christina A. Penfield[4]

10:30 AM - 12:30 PM

Objective: Fetal growth restriction (FGR) is a significant risk factor for perinatal morbidity and mortality. Differentiating pathologic FGR due to placental insufficiency from a benign constitutionally small fetus remains challenging. We evaluated whether discordance between transcerebellar diameter (TCD) and estimated fetal weight (EFW) was associated with signs of pathologic FGR.

Study Design: We conducted a multi-center prospective study of singleton pregnancies with FGR (EFW < 10th%) diagnosed between 16 and 37.6 weeks gestation. We excluded those without confirmed first trimester dating, or with identifiable anatomic, genetic, or infectious etiologies of FGR. Cerebellum measurement was planned at each growth scan. Concordance between measures was defined as TCD < 25th% and EFW < 10th% and discordance TCD ≥ 25th% and EFW < 10th%. The primary outcome was a composite of signs of placental insufficiency (abnormal umbilical artery Dopplers, oligohydramnios, and/or abnormal antepartum testing). Secondary outcomes included gestational age (GA) at delivery, FGR resolution prior to delivery, neonatal outcomes, and hypertensive disorders of pregnancy (HDP). Associations between discordance and outcomes was estimated by the adjusted relative risk (95% confidence interval) through modified Poisson regression.

Results: Of the 128 participants enrolled, 68 had complete data on cerebellar measurements. Pregnancies with discordant measures were more likely to have signs of placental insufficiency compared to those with concordant measures (41.8% vs. 23.1%; aRR 1.63 (95% CI [0.57, 4.69])). Concordant pregnancies were diagnosed with FGR earlier and were more likely to resolve prior to delivery. Groups did not differ in GA at delivery, birthweight, rates of medically-indicated preterm birth, rates of SGA, other neonatal outcomes, and HDP.

Conclusion: FGR pregnancies with discordant TCD and EFW may be associated with signs of placental insufficiency, but due to high variability in the association, further confirmation of these findings is warranted. TCD discordance may be a tool for differentiating pathologic from benign FGR.

783 | Delayed Oral Misoprostol Dosing for Cervical Ripening: association with perinatal outcomes

Suna Njie[1]; Fei Xu[2]; Jennifer M. Baker[2]; Michael W. Kuzniewicz[3]; Monique Hedderson[2]; Mara Greenberg[4]
[1]Kaiser Permanente Northern California, Oakland, CA; [2]Kaiser Permanente Northern California, Pleasanton, CA; [3]Kaiser Permanente Northern California, Kaiser Permanente Northern California, CA; [4]Kaiser-Permanente Northern California, Oakland, CA

10:30 AM - 12:30 PM

Objective: To examine dosing characteristics for misoprostol used as a cervical ripening agent in a large integrated health care system and evaluate association between dosing delay and perinatal outcomes.

Study Design: Retrospective study of all deliveries without prior cesarean that underwent induction of labor (IOL) from 2011-2023 at Kaiser Permanente Northern California. For the proportion of patients undergoing IOL who received misoprostol for cervical ripening, dosing characteristics were examined. Delayed dosing among patients who received >1 misoprostol dose was defined as >4.5 hours between doses. Associations between delay characteristics and outcomes including cesarean delivery, chorioamnionitis, postpartum hemorrhage, time to vaginal delivery, and length of stay were examined in unadjusted and multivariable analyses.

Results: Among 126,864 induced labors without prior cesareans, 91,776 (72%) received misoprostol and of those 53,734 (58.6%) received >1 dose. Most misoprostol was dosed orally (96.7%) starting with an initial dose of 50mcg (98.8%), and subsequent doses of 100mcg (95%). Delayed dosing was present in 55.6% (29,863), and of those with delays 41% were delayed within 1 hour, 19% from 1-2 hours and 40% >2 hours. Delay in misoprostol dosing was associated in a dose response manner with perinatal outcomes (Figure 1), with higher degrees of delay associated with higher rates of cesarean delivery, chorioamnionitis, and postpartum hemorrhage, lower rate of achieving vaginal delivery within 24 hours, and longer length of stay. In multivariable analysis, presence and degree of dosing delays were associated with increased adjusted risks of all adverse outcomes examined (Table 1).

Conclusion: Delayed oral misoprostol dosing was common in a large diverse cohort of induced labors. Frequency and degree of dosing delay was associated with adverse perinatal outcomes. This presents a potential opportunity to improve quality of intrapartum care and outcomes of labor.

784 | The Impact of Pregnancy and Obesity on Glucose Metabolism in Mouse Skeletal Muscle

Jenny B. Koenig[1]; Ella Rust[1]; Liam S. Fitzgerald[1]; Simon Schenk[1]; Lindsey A. Burnett[2]
[1]UC San Diego, La Jolla, CA; [2]UC San Diego Medical Center, La Jolla, CA

10:30 AM - 12:30 PM

Objective: Obesity affects over 40% of reproductive-aged women in the United States. This study aimed to examine the interactive effects of diet-induced obesity and pregnancy on oral glucose tolerance and skeletal muscle insulin-stimulated glucose uptake in a mouse model of diet-induced obesity.
Study Design: C57/BL6/NJ mice (4 weeks old) were fed a low-fat diet (LFD; 10% of calories from fat) or high-fat diet (HFD; 60% of calories from fat) for 6 weeks before mating. An oral glucose tolerance test (OGTT; 2 g/kg) was conducted in late pregnancy (LP, E12.5-17.5) or in age-matched non-pregnant (NP) mice. Skeletal muscle glucose uptake was assessed using a radiolabeled 2-deoxyglucose (2DG) approach in paired soleus muscle, with and without a physiological insulin concentration (60 μU/mL). Statistical analysis was performed using 2-way ANOVA with appropriate post-hoc analysis and significance of $P < 0.05$.
Results: NP HFD-fed mice weighed significantly more than LFD-fed controls (30.20 vs. 19.97 g, $P < 0.0001$). Oral glucose tolerance as measured by area under the curve (AUC) was significantly different between LFD-fed and HFD-fed animals (NP: LFD 18,055 vs. HFD 24,089 mg · min/dL, $P < 0.01$) but was not between NP and LP within each diet (LFD: NP 18,055 vs. LP 16,074 mg · min/dL, $P = 0.66$; HFD: NP 24,089 vs. LP 21,311 mg · min/dL, $P = 0.32$). Specific to skeletal muscle, insulin-stimulated glucose uptake (insulin 2DG uptake minus basal 2DG uptake) was decreased by HFD-feeding (NP: LFD 0.69 vs. HFD 0.29 μmol/20 min/g, $P = 0.09$; LP: LFD 0.98 vs. HFD 0.19 μmol/20 min/g, $P < 0.001$), but not by pregnancy (LFD: NP vs. LP, $P = 0.28$; HFD: NP vs. LP, $P = 0.90$).
Conclusion: Diet-induced obesity, but not pregnancy, significantly impairs oral glucose tolerance and insulin-stimulated glucose uptake in skeletal muscle. This study provides valuable insights into the interactive effects of pregnancy and obesity on glycemia and skeletal muscle insulin resistance.

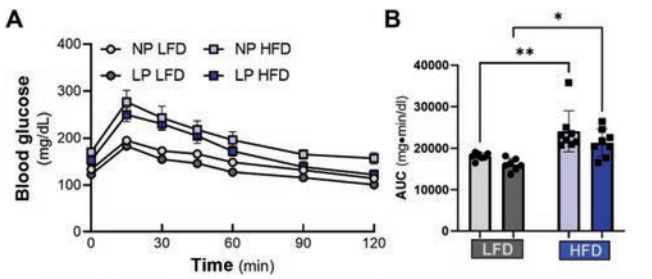

Figure 1. A. Blood glucose concentrations during an oral glucose tolerance test (2 g/kg dextrose load) for non-pregnant low-fat diet fed (NP LFD, n=7), late pregnant low-fat diet fed (LP LFD, n=7), non-pregnant high-fat diet fed (NP HFD, n=8), and late pregnant high-fat diet fed (LP HFD, n=8) animals and B. area under the curve (AUC) during OGTT. 2-way ANOVA with Tukey's multiple comparisons test. *P<0.05, **P<0.01.

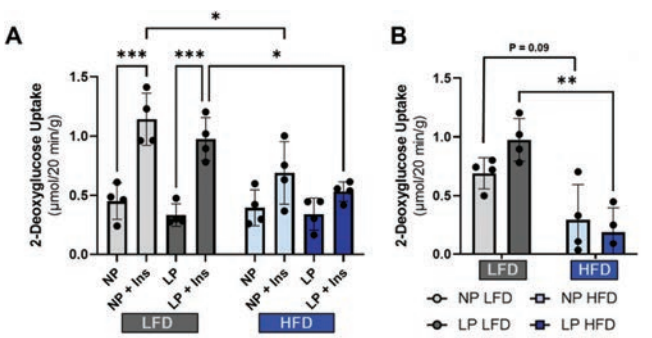

Figure 2. A. 2-deoxyglucose uptake in the presence (+Ins, 60 μU/mL) or absence of insulin and B. insulin-stimulated glucose uptake (calculated as +Ins 2-deoxyglucose uptake minus basal 2-deoxyglucose uptake) in mouse soleus muscle, n=4 for all groups. 2-way ANOVA with Tukey's multiple comparisons test. *P<0.05, **P<0.01, ***P<0.005.

785 | Influence of Group Prenatal Care Participation on Attendance at the Postpartum Visit

Kate Tolleson[1]; Jessica Britt[2]; Moonseong Heo[3]; Amy Crockett[4]
[1]NYU Grossman School of Medicine, New York, NY; [2]Prisma Health, Prisma Health, SC; [3]Clemson University, Clemson, SC; [4]Prisma Health and University of South Carolina School of Medicine, Greenville, SC

10:30 AM - 12:30 PM

Objective: The 6 week postpartum visit (PPV) is an opportunity for family planning, evaluation of physical and mental health, and a link to follow-up for chronic health conditions. Many patients miss this visit, with attendance averaging 61%. Participation in group prenatal care (GPNC) encourages patient engagement dur-

ing pregnancy and may improve PPV attendance. We compared rates of PPV attendance between GPNC and individual prenatal care (IPNC).

Study Design: Secondary analysis of a prospective clinical trial comparing GPNC vs IPNC on birth outcomes. The primary outcome variable was PPV attendance. Comparisons were made using 3 analytic approaches: intent-to-treat (ITT) including all randomized participants, modified ITT (mITT) including participants attending ≥1 visit in the assigned study arm, and a per compliance (PC) including those receiving ≥5 visits in the assigned study arm. Comparisons with χ-square and t-test were performed for mITT and PC groups and logistic regression was used to control for differences between groups.

Results: 2348 participants were enrolled with 1175 in GPNC and 1173 in IPNC. Participants were 40% Black, 36% White, and 21% Hispanic. Compared with IPNC, GPNC did not have higher rates of PPV attendance in ITT (61% GPNC vs 61% IPNC, RR 1.01, 95% CI 0.942-1.07). However, with increasing participation, GPNC had significantly higher PPV attendance in mITT (70% vs 64%, RR 1.10, 95% CI 1.03-1.17) and PC (76% vs 66%, RR 1.14,95% CI 1.07-1.21). Adequacy of Prenatal Care Utilization Index ≥ 3 was associated with PPV attendance (RR 2.52,95% CI 2.16-2.94) regardless of prenatal care type. Participants with 1+ living children had significantly less PPV attendance compared to participants with no living children (58% vs 65%, RR 0.892, 95% CI 0.84-0.95).

Conclusion: There were no significant differences in PPV attendance between GPNC and IPNC in ITT, but increased participation in GPNC was associated with increased PPV attendance. Efforts to improve adequacy of prenatal care will be beneficial to all patients. Innovation in prenatal care delivery is needed to improve overall PPV attendance.

Table 1. PPV follow up based on prenatal care participation and maternal factors: Relative Risk (95% CI)

	PPV Follow Up		
	GPNC Number/Total (%)	**IPNC Number/Total (%)**	**RR (95% CI)**

786 | Interdisciplinary Pregnancy Hypertension Alert System to Reduce Morbidity Associated with Hypertensive Disorders of Pregnancy (HDP)

Jessica O. Amoako[1]; Aliah L. Fonteh[1]; Jeanie Haggan[1]; Cori VanHouten[1]; Theresa Hyland[1]; Christine Coffey[1]; Rohit Sangal[2]; Katherine Campbell[2]

[1]Yale New Haven Hospital, New Haven, CT; [2]Yale School of Medicine, New Haven, CT

10:30 AM - 12:30 PM

Objective: To create a Pregnancy-Related Hypertension Alert to trigger a timely assessment, diagnosis, and management of hypertensive disorders of pregnancy (HDP) in the Emergency Department (ED).

Study Design: Emergency Medicine (EM) and Obstetrics (OB) teams collaborated to develop and implement the Pregnancy-Related Hypertension Alert. Patients with an elevated blood pressure (BP) defined as a systolic BP of ≥ 150 mmHg and or a diastolic of ≥ 100 mmHg at ≥ 20 weeks gestational age or within 6-weeks postpartum met criteria for the alert. When triggered, an OB resident, OB nurse and EM team immediately evaluated patient using a standardized HDP care pathway. Treatment according to the pathway includes the use of oral IR nifedipine, IV labetalol, IV hydralazine, and patients with mild elevated BP received oral antihypertensive.

Results: 80 patients (17 pre-alert; 63 post-alert) were included in the study. BP recheck within 15 minutes was noted in 41% of patients' pre-alert and increased to 86% post-alert. Median time for patients to receive antihypertensives was 72 minutes [IQR 37.5-195.5] in the pre-alert period and improved to 23.5 minutes [IQR 15- 67 minutes] with the alert . Pre-alert the ED median length of stay was 219 minutes [IQR 182-297 minutes] and reduced to 147 minutes [IQR 73-231 minutes] with the alert. Patient disposition was to Inpatient Obstetrics Unit (pre-alert: 41%; post-alert: 52%), IR/SICU (pre alert: 0%; post alert: 3%), Labor & Birth/Triage (pre alert: 6%; post-alert:13%), transfer from satellite ED to main ED for additional management (5%), home (pre-alert: 53%; post-alert: 25%), other (2%).

Conclusion: After alert implementation, more patients achieved guideline recommended care including BP check and delivery of antihypertensives. Future directions include ongoing optimization of the HDP alert and expanding coverage of the program across the health care system.

Table 1: Demographics of Target Patient Population (with pre- alert data included)

787 | The Association Between Maternal Immune Thrombocytopenia Purpura (ITP) and Adverse Perinatal Outcomes

Jill K. Kumasaka; Ava D. Mandelbaum; Bharti Garg; Aaron B. Caughey

Oregon Health & Science University, Portland, OR

10:30 AM - 12:30 PM

Objective: Immune thrombocytopenia purpura (ITP) is a common cause of thrombocytopenia in pregnancy, however, limited data exist on perinatal complications associated with maternal ITP. This study aimed to evaluate the impact of maternal ITP on adverse perinatal outcomes.

Study Design: This is a retrospective cohort study of linked vital statistics and hospital discharge data among singleton, non-anomalous births delivered between 23-42 weeks in California (2008-2020). Patients were stratified by diagnosis of ITP. Maternal outcomes included gestational hypertension, preeclampsia, gestational diabetes (GDM), preterm delivery < 37 weeks, postpartum hemorrhage, and severe maternal morbidity (SMM). Neonatal outcomes included cephalohematoma, intraventricular hemorrhage, and congenital thrombocytopenia. We utilized chi-squared tests for univariate analyses and multivariable logistic regression analyses to evaluate the association of ITP with outcomes.

Results: Among 5,061,386 patients in our final sample, 4,346 (90 cases per 1000 deliveries) had a diagnosis of ITP. Compared to patients without ITP, individuals with ITP had increased rates of gestational hypertension (4.21% vs 3.44%, aOR = 1.18, 95% CI: 1.02-1.37), preeclampsia (7.23% vs 3.80%, aOR = 1.74, 95% CI: 1.56-1.95), GDM (11.99% vs 9.58%, aOR = 1.98, 95% CI: 1.10-1.31), preterm delivery < 37 weeks (10.47% vs 6.39%, aOR = 1.69, 95% CI: 1.54-1.86), postpartum hemorrhage (9.27% vs 3.37%, aOR = 2.63, 95% CI: 2.38-2.91), and SMM (11.64% vs 1.18%, aOR = 9.21, 95% CI: 8.42-10.07) (Table 1). Neonates born to mothers with ITP had higher rates of intraventricular hemorrhage and congenital thrombocytopenia, compared to those without ITP. These associations remained in sub-analyses of vaginal versus cesarean deliveries only (Table 2).

Conclusion: Maternal ITP was associated with increased rates of gestational hypertension, preeclampsia, GDM, preterm delivery < 37 weeks, postpartum hemorrhage, and SMM. Further research to elucidate specific aspects of patients with ITP and perinatal complications will be important to identify those that may benefit from more aggressive interventions.

788 | Elevated Middle Cerebral Artery Peak Systolic Velocity and Donor Twin Demise in Twin-Twin Transfusion Syndrome

Jimmy Espinoza[1]; Ramesha Papanna[2]; Anthony Johnson[3]; Eric P. Bergh[4]; Gustavo Vilchez[5]; Edgar A. Hernandez-Andrade[2]; Sami Backley[1]; Felicia V. LeMoine[1]; Sen Zhu[6]; Arlyn Llanes[7]; Ramen H. Chmait[7]

[1]Division of Fetal Intervention, Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern Medical School at UTHealth Houston, Houston, TX; [2]McGovern Medical School at UTHealth Houston, Houston, TX; [3]McGovern Medical School University of Texas Health Science Center at Houston (UThealth), Houston, TX; [4]UT Health, Houston, TX; [5]UTHealth Houston, Houston, TX; [6]McGovern Medical School at the University of Texas, Houston, TX; [7]Keck School of Medicine, University of Southern California, Los Angeles, CA

10:30 AM - 12:30 PM

Objective: To determine the association of elevated donor middle cerebral artery peak systolic velocity (MCA-PSV) without twin anemia polycythemia sequence (TAPS) and fetal demise among pregnancies complicated by twin-to-twin transfusion syndrome (TTTS).

Study Design: This prospective cohort study included TTTS cases that underwent laser surgery between 2006 and 2023 at two referral centers. The study was designed to: 1) explore the association of elevated donor MCA-PSV (>1.5 multiples of the median) without TAPS with fetal demise of the donor twin; 2) to evaluate if donor or recipient MCA-PSV is associated with an increased risk for their corresponding fetal death using receiving operator characteristic curve analysis. TAPS was defined as donor MCA-PSV >1.5 MoM and recipient MCA-PSV < 1.0 MoM or inter-twin MCA PSV difference >0.5. Uni- and multivariable as well as Poisson (Zou's method) regression models were used to estimate odd ratios and relative risks (RR) of elevated donor MCA-PSV without TAPS for donor demise, adjusted for TAPS, TTTS stage, intertwin size discordance >25%, low donor MCA pulsatility index, gestational age at surgery, and other confounders.

Results: Of 1,602 TTTS cases, 3.3% (n = 53) had elevated donor MCA-PSV without TAPS and comprised our cases, which were compared to the other 1,549 cases (controls). Clinical characteristics are shown in Table 1; donor demise rate was higher among cases than controls [45.3% (23/53) vs. 13.2% (205/1549), p< 0.001]. 1) Elevated donor MCA-PSV without TAPS was an independent risk factor for donor fetal demise (RR: 2.86; 95 % CI: 1.78-4.59; p< 0.001), and conferred the highest relative risk for demise of the

donor twin (Table 2). 2) Donor MCA-PSV was associated with donor fetal demise (AUC: 0.61; p< 0.001), but recipient MCA-PSV was not associated with recipient fetal demise (AUC: 0.54; p = 0.2).

Conclusion: 1) Isolated elevated donor MCA-PSV prior to laser is an important risk factor for donor fetal demise, adjusted for confounders including TAPS; 2) The association of TAPS with fetal death may be driven by elevated donor MCA-PSV, not by recipient twin MCA-PSV.

Table 1. Clinical characteristics of the study population according to elevation of donor twin MCA-PSV without TAPS (cases)

789 | Does Premature Rupture of Membranes Affect Adverse Health Outcomes in Second Trimester Medical Abortion

Jocelyn Wascher[1]; Neha Reddy[1]; Camille Johnson[1]; Eryn Wanyonyi[1]; Taytum Kahl[2]; Vanya Manthena[3]; Lahari Vuppaladhadiam[2]; Julie Chor[1]; Beth Plunkett[4]; Isa Ryan[5]; Olivert Mbah[5]; Jungeun Lee[6]; Emily Barker[7]; Laura Laursen[8]; Leanne McCloskey[9]; Sloane York[8]; Ashish Premkumar[3]
[1]University of Chicago Medicine, Chicago, IL; [2]University of Chicago, Chicago, IL; [3]Pritzker School of Medicine, University of Chicago, Chicago, IL; [4]Northshore Endeavor Health, Chicago, IL; [5]NorthShore Health, Chicago, IL; [6]Endeavor Health, Evanston, IL; [7]Washington University in St Louis, St. Louis, MO; [8]Rush University, Chicago, IL; [9]Northwestern Medicine, Chicago, IL

10:30 AM - 12:30 PM

Objective: Previable and peri-viable preterm rupture of membranes are frequently managed with medication abortion (MAB). Little is known about how ruptured membranes affect labor duration or maternal or health outcomes in MAB when compared to intact membranes.

Study Design: This retrospective cohort study examined patients undergoing second-trimester (2T) MAB of a singleton pregnancy at 4 academic health centers from 2009-2019. Patients who received a diagnosis of preterm labor or advanced cervical exam prior to MAB were excluded. The primary exposure was rupture of membranes (ROM) or intact membranes (IM) prior to MAB. Patients with infection diagnosed at the start of induction were included. The primary outcome was duration of labor in hours. Secondary outcomes were composite morbidity (uterine rupture, blood transfusion, intensive care unit admission, or readmission) and its components, estimated blood loss (EBL) ^{3}500 mL and clinical chorioamnionitis (CC) Bivariate analyses were performed for composite morbidity and its components due to low frequency of outcome occurrence. Multivariate analyses were performed for EBL >500ml and CC. For the primary outcome, a survival analysis, censoring at the time of delivery, was performed.

Results: 1,341 patients were included, 344 (25.7%) with ROM and 997 (74.3%) with IM. On bivariate analyses, there were significant differences in baseline characteristics between groups (Table1). ROM was associated with decreased labor duration compared to IM (HR 2.5, 95% CI 2.1-2.9); this was significant after adjusting for age, race, body mass index, parity and site of delivery (aHR 2.4, 95% CI 2.1-2.8), (Figure1). There were no significant differences in secondary outcomes, with the exception of a higher likelihood of EBL ^{3}500 (aRR 1.54, 95% CI 1.1-2.2) and CC (aRR 1.9, 95% CI 1.3-2.7).

Conclusion: ROM prior to 2T MAB is associated with shorter labor duration labor than IM. There was an increased likelihood of CC and higher blood loss without need for blood transfusion among people with ROM. These findings can be used in counseling patients undergoing 2T MAB.

Table 1. Demographic and Outcome Data of Patients Undergoing Second Trimester Medication Abortion by Membrane Status

	Ruptured Membranes (n=344)	*Intact Membranes (n=997)*	*p-value[a]*

790 | Can We Train A.I. Chatbots to Replace Physicians for Counseling on Soft Markers?

Keren Khromchenko[1]; Joseph Canterino[1]; Jonathan D. Baum[1]; Karen Koscica[1]; Sheveta Jain[1]; Jennifer E. Powel[2]; Valeria Distefano[1]; Maria Martins[1]; Jonathan Faro[3]

[1]Hackensack Meridian Health - Jersey Shore University Medical Center, Neptune, NJ; [2]Hackensack Meridian Jersey Shore University Medical Center, Neptune, NJ; [3]Jersey Shore University Medical Center / Hackensack Meridian School of Medicine, Marlboro, NJ

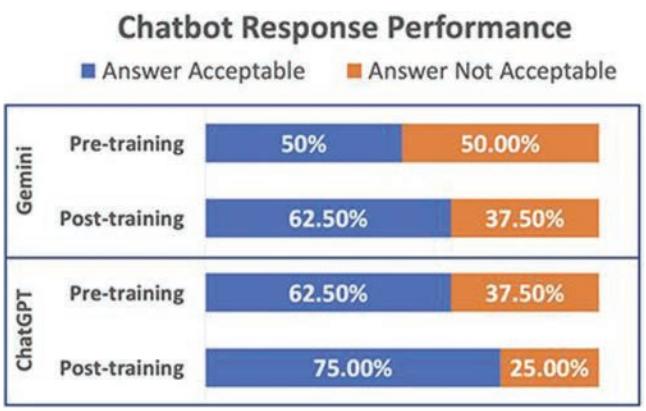
10:30 AM - 12:30 PM

Objective: Chatbots offer a user-friendly source of information. Recent studies have raised concerns about their accuracy. The World Health Organization (WHO) has warned that untested AI systems could harm patients and erode trust. The detection of soft markers for aneuploidy on ultrasound can cause significant anxiety. The accuracy and completeness of chatbot responses regarding soft markers are unknown. We sought out to evaluate chatbot performance on answering questions regarding soft markers for aneuploidy and whether training improves performance.

Study Design: A qualitative analysis was performed. ChatGPT Version 4o and Google Gemini 1.5 pro were queried on 8 isolated soft markers both prior to and after training using Society for Maternal-Fetal Medicine (SMFM) Consult Series #57: evaluation and management of isolated soft ultrasound markers for aneuploidy in the second trimester. Queries were conducted in July of 2024. Query responses were graded as "acceptable" or "not acceptable" based on accuracy and completeness. Grading of responses were performed by the MFM co-authors individually and then as a group to formulate a consensus.

Results: Pre-training, 37.5% of ChatGPT responses and 50% of Gemini responses were graded as 'not acceptable.' For ChatGPT, all 'not acceptable' responses (3/3) were incomplete, with none incorrect. For Gemini, all 'not acceptable' responses (4/4) were incomplete, with one response also being incorrect. Post-training, 25% of ChatGPT responses and 37.5% of Gemini responses were graded as 'not acceptable.' For ChatGPT, all 'not acceptable' responses (2/2) were incomplete, with none incorrect. For Gemini, all 'not acceptable' responses (3/3) were incomplete, with none incorrect.

Conclusion: While generative AI chatbots like ChatGPT and Google Gemini show potential as supplementary information sources on soft markers for aneuploidy, their responses often lack completeness, which limits their effectiveness. Training with specific medical publications improves performance, but these chatbots should not replace physician counseling.



791 | Alternative Payment Models for Pregnancy Care: a Difference-In-Difference Analysis Among State Medicaid Programs

Jordan S. Stone[1]; Arina Chesnokova[1]; Allison Schachter[2]; Sindhu K. Srinivas[3]; Sunni Mumford[3]
[1]Hospital of the University of Pennsylvania, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA; [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA

10:30 AM - 12:30 PM

Objective: There is growing interest in using payment model design to improve pregnancy care delivery and reduce morbidity and mortality, particularly within Medicaid. Despite this, data on alternative payment models (i.e., those that establish a budget for a care episode, coupled with quality incentives) in pregnancy are sparse. The objective of this study is to evaluate whether the introduction of a mandatory Medicaid bundled payment program for pregnancy care was associated with changes in antenatal care delivery and maternal morbidity.

Study Design: This is a quasi-experimental difference-in-difference (DiD) analysis comparing two states that implemented mandatory Medicaid bundled payment programs for pregnancy care (TN in 2011 and OH in 2014) to control states (GA, KS, KY, OK). Demographic variables and pregnancy outcomes were collected from birth certificate records between 2009 and 2019. Inclusion criteria were births reimbursed by Medicaid in intervention or control states with concordance between state of residence and state of birth. A DiD analysis was conducted for co-primary outcomes—gestational age at entry into prenatal care and maternal transfusion at time of delivery. These were chosen as proxies for modifiable aspects of pregnancy care within the domains of antenatal care delivery and maternal morbidity. The extended two-way fixed effects estimator was used with the heterogenous DiD regression to account for staggered rollout in the intervention group.

Results: Between 2009 and 2019, we identified 2,227,136 births that met inclusion criteria. 55% were in the control group and 45% were in the intervention group. The pre-intervention parallel trends assumption was satisfied between groups. In the heterogenous DiD regression model, no significant difference-in-differences were identified for the specified outcomes between the two groups (see table).

Conclusion: Mandatory Medicaid bundled payment programs did not have a significant effect on gestational age at entry into prenatal care or maternal transfusion rates. Additional studies are needed to further evaluate the impact of these models.

Hetergenous difference-in-difference for primary outcomes, intervention states vs. controls

Outcome	Difference in average treatment effect on treated (95% confidence interval)	p-value
GA at entry into prenatal care*	-0.010 (0.07 -0.05)	0.665
Maternal transfusion	0.001 (-0.002 - 0.004)	0.636

*Binary, first trimester versus other

792 | Missed Connections: Exploring the Gap in Patient Awareness of Hypertensive Disorders of Pregnancy Diagnoses

Julia Thelen; Alyssa M. Hernandez; Eleanor Saffian; Anna Palatnik
Medical College of Wisconsin, Milwaukee, WI

10:30 AM - 12:30 PM

Objective: To evaluate patients' awareness of a hypertensive disorder of pregnancy (HDP) diagnosis following their most recent pregnancy.

Study Design: A 24-question survey was given to patients with a recent HDP diagnosis who delivered at a tertiary care center in 2022-2024. HDP was defined as gestational hypertension or preeclampsia. Descriptive statistics and bivariate analyses compared demographics, clinical characteristics, and survey responses stratified by ability to recall an HDP diagnosis.

Results: Of the 1,072 survey recipients, 355 (33.1%) responded and were included in analysis. The mean interval between childbirth and survey distribution was 11.2 months (±7.7m) and was not significantly different between study groups ($p = 0.29$). Among respondents, 87 (24.5%) were unaware of or could not recall their HDP diagnosis. 96.1% of patients who recalled their diagnosis recalled discussing blood pressure during their birth admission compared to only 71.6% of patients who did not recall their diagnosis. Patients who were less likely to be aware or were unable to recall a diagnosis of HDP were more likely to be Hispanic ($p = 0.02$), not college educated ($p = 0.01$), publicly insured ($p = 0.02$), WIC-eligible ($p = 0.05$), diagnosed during the intra- or postpartum period ($p = 0.001$), and deliver at full term ($p < 0.001$). Patients with gestational hypertension were less likely to recall their diagnosis compared to those diagnosed with preeclampsia with severe features ($p < 0.001$).

Conclusion: Awareness and recall of a prior HDP diagnosis was influenced by demographic factors and clinical characteristics indicative of disease severity. Since history of HDP is a significant risk factor for future pregnancies and lifelong cardiovascular health, further research exploring this gap in awareness is needed to optimize patient education during the index pregnancy.

793 | Evaluating the Potential Relationship between sFlt-1:PIGF and Hypertension Across Pregnancy and early Postpartum

Julia L. Berkowitz[1]; Stephen Juraschek[2]; Lara Kovell[3]
[1]UMass Medical Center, UMass Medical Center, MA; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]UMass Memorial Health, Worcester, MA

10:30 AM - 12:30 PM

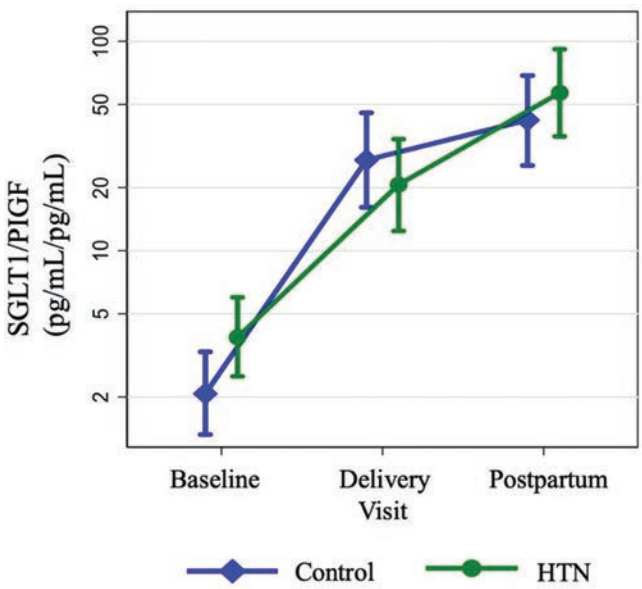
Objective: Hypertensive disorders of pregnancy are major contributors to adverse maternal outcomes including stroke, cardiovascular disease, and death. Vascular biomarkers, including the ratio of soluble fms-like tyrosine kinase 1 and placental growth factor (Sflt-1: PIGF) are independent predictors of gestational hypertension and preeclampsia. The aim of this study is to examine the trend in Sflt-1: PIGF in pregnancy and post-partum in women with and without hypertension (HTN).

Study Design: In a prospective, 1:1 case-control design, we enrolled pregnant women with HTN and without HTN (control group) between 24-32 weeks gestation from 2019-2022. HTN was defined by a clinical diagnosis or baseline blood pressure (BP) ≥140/90 mm Hg. The control group had a systolic BP < 120 mm Hg and no HTN diagnosis. Serum was collected at baseline, at delivery admission, and postpartum day 1. Mixed effects tobit models were used to compare Sflt-1:PIGF across HTN groups and over time, adjusted for age and BMI.

Results: At baseline, the HTN group had higher sFLT-1(pg/mL): PIGF (pg/mL) (mean (SD): 3.9 (0.9)) versus the control group (2.1 (0.5)). Both groups had a significant increase in mean sFLT-1:PIGF at the delivery admission (HTN: 20.7 (5.3); Control: 27.0 (7.2)) and postpartum (HTN: 56.7 (13.9); Control: 42.0 (10.6)); however, no significant difference was seen between these groups (see Figure 1). Across pregnancy and the early postpartum period, there was no significant difference in the mean sFLT-1: PIGF ratio between the HTN and control groups (HTN: 13.06 (2.73); Control: 10.44 (2.24)).

Conclusion: While women with HTN had greater baseline sFLt-1: PIGF than controls, no significant differences were found during delivery admission or postpartum. All women demonstrated a significant increase in sFLt-1:PIGF during pregnancy with elevations continuing postpartum.

Future studies examining the impacts of HTN on subclinical cardiovascular injury and long-term maternal outcomes are needed.



794 | The Screening Accuracy of Betke-Kleihauer Test for Fetal-Maternal Hemorrhage in the Antepartum and Postpartum Period

Juliana Poli[1]; Yulia Hin[1]; Heather VanderMeulen[1]; Nir Melamed[2]
[1]University of Toronto, Toronto, ON; [2]Division of Maternal Fetal Medicine, Department of Obstetrics and Gynecology, Sunnybrook Health Sciences Centre, Toronto, ON

10:30 AM - 12:30 PM

Objective: Accurate detection of fetomaternal hemorrhage (FMH) is important both antenatally (e.g., cases of abdominal trauma) and postpartum (to guide the RhIg dosage in RhD-negative patients). Betke-Kleihauer (BK) is the most commonly used quantitative screening test for FMH, but data on its screening accuracy in specific circumstances and the optimal screening threshold are conflicting. The current study aimed to estimate the screening accuracy of the BK test for large FMH and identify the optimal screening threshold in the antepartum and postpartum periods.

Study Design: A retrospective cohort study of patients who had a BK test at a single center (2014-2022). The definitive diagnosis of large FMH (≥ 15 mL) was done by flow cytometry that was sent in cases of a positive BK test (≥ 2 mL). The screening accuracy

of the BK test for large FMH was described using the area under the ROC curve (AUC), detection rate (DR), and false-positive rate (FPR), and was stratified by the timing of testing (antepartum vs. postpartum).

Results: A total of 4,628 patients underwent BK testing during the study period, 2217 (47.9%) antenatally and 2,411 (52.1%) postpartum. The incidence of a positive BK was 9.1%. The discriminative accuracy of the BK for large FMH was high in the entire cohort (AUC 0.97 [95%-CI 0.94-0.99]) but was lower during the antepartum vs. postpartum period (0.88 [0.80-0.96] vs. 0.997 [0.94-1.00], p = 0.02). The highest BK threshold providing a DR of 100% for large FMH was 2.0 mL (FPR of 67% [58%-76%]). A higher BK threshold of 7.5 mL was associated with a reduced DR (81% [85%-97%) and lower FPR (9% [3%-15%]). This threshold (7.5 mL) maintained a DR of 100% in the postpartum period (DR 100%, FPR 8% [3%-14%]) but performed poorly antepartum (DR 57% [47%-67%], FPR 14% [7%-20%]).

Conclusion: The BK test is associated with a high FPR when using a conservative threshold of 2 mL that provides a 100% DR. Its screening accuracy is higher during the postpartum period, where a less strict threshold of 7.5 mL maintains the same DR of 100% with a lower FPR.

795 | Association of Body Mass Index with Adverse Pregnancy Outcomes When Stratified by Cardiovascular Health

Karen J. Gibbins; Nicole E. Marshall; Amy M. Valent
Oregon Health & Science University, Portland, OR

10:30 AM - 12:30 PM

Objective: High body mass index (BMI) is associated with adverse pregnancy outcomes, but it is not a direct measure of cardiovascular health (CVH) and misclassifies many. We aimed to evaluate the association between BMI≥30 and adverse pregnancy outcomes stratified by CVH.

Study Design: Secondary analysis of nuMoM2b multicenter cohort of nulliparas, excluding pregestational diabetes and chronic hypertension. We used American Heart Association's Life's Simple 7 to assess CVH. Metrics included smoking, physical activity, healthy diet pattern, total cholesterol, and blood pressure. We omitted BMI given our objective, and we added triglycerides as these are a marker of CVH in pregnancy. We assigned 0 points for Poor category, 1 for Intermediate, and 2 for Ideal for each metric, with maximum total score of 14. Total score was categorized as Poor (1-7), Intermediate (8-11), or Ideal (12-14). Outcomes included adverse perinatal outcomes previously linked to BMI (Table 1). Association between exposures and outcomes were calculated via logistic regression.

Results: 2462 participants were included. 473 had BMI≥30, 134 (5.4%) had Poor CVH, 1740 (70.7%) had Intermediate CVH, and 517 (21.0%) had Ideal CVH. Overall, BMI≥30 was associated with increased HDP (38.7 vs 19.6%, OR 2.6, 95% CI 2.1-3.2), severe preeclampsia (8.3 vs 3.1%, OR 2.8, 95% CI 1.9-4.3), LGA (10.6 vs 4.3%, OR 2.6, 95% CI 1.8-3.8), GDM (7.4% vs 2.6%, OR 3.0, 95% CI 1.9-4.6), and CB (37.0 vs 22.4%, OR 2.0, 95% CI 1.6-2.5). However, when stratified by CVH category, these associations were altered. In the Ideal CVH category, BMI≥30 was only associated with LGA and GDM (Table 1). For some outcomes, like HDP, OR was higher in those with poor CVH and low BMI than those with Ideal CVH and high BMI (Figure 1).

Conclusion: Relying on BMI alone to assess pregnancy risk appears to overestimate risk of BMI≥30 in those with otherwise Ideal CVH and underestimate in those with BMI 18.5-29.9 but Poor CVH. More comprehensive assessment of CVH could result in more accurate risk stratification.

Table 1. Association of BMI ≥30 and adverse pregnancy outcomes stratified by cardiovascular health (CVH).

Adverse Pregnancy Outcome	Poor CVH Score (1-7)		Intermediate CVH Score (8-11)		Ideal CVH Score (12-14	
	BMI 18.5-29.9 N (%) OR N=70	BMI ≥30 N (%) OR N=64	BMI 18.5-29.9 N (%) OR N=1,374	BMI ≥30 N (%) OR N=366	BMI 18.5-29.9 N (%) OR N=472	BMI ≥30 N (%) OR N=45

796 | Impact of Fetal Head Station on Maternal and Neonatal Outcomes in Second-Stage Cesarean Delivery

Karolin Sokolik[1]; Asaf Romano[2]; Adi Litmanovich[3]; Ran Matot[2]; Natav Hendin[4]; Eran Hadar[4]; Ohad Houri[4]; Yossi Geron[4]
[1]Helen Schneider Hospital for Women, Rabin Medical Center, Petach-Tikva, Petach-Tikva, HaMerkaz; [2]Rabin Medical Center, Tel Aviv, HaMerkaz; [3]Rabin Medical Center, Tel Aviv, Tel Aviv; [4]Rabin Medical Center, Petach Tikva, HaMerkaz

10:30 AM - 12:30 PM

Objective: We hypothesized that second-stage cesarean delivery with fetal head station below the ischial spine increases adverse maternal and neonatal outcomes.

Study Design: A retrospective cohort study of term pregnant women who underwent cesarean delivery at full cervical dilatation was assessed for adverse maternal and neonatal outcomes. The study was conducted in a tertiary medical center between 2012-2023. Patients were categorized based on fetal head station in a manual examination: at or above ischial spines and below ischial spines. Maternal outcomes analyzed included cesarean section duration, need for push assistance, uterine extension, postpartum fever, hemoglobin drop, postpartum hemorrhage, blood transfusion, puerperal endometritis, and rehospitalization. Neonatal outcomes evaluated were 5-minute APGAR scores, arterial pH levels, and NICU admissions.

Results: Of the 418 patients studied, fetal head station was at or above ischial spines in 276 patients and below spines in 142 patients. The below ischial spines group had a higher incidence of failed vacuum attempts (50.7% vs. 13.0%, P< 0.001) and required more blood transfusions (16.2% vs. 7.6%, P = 0.011). Additionally, neonatal arterial pH levels < 7.2 were significantly more common in the below ischial spines group (21.8% vs. 13.0%, P = 0.013). The composite neonatal outcomes were more common in the below ischial spines group (16.9% vs. 9.8%, P = 0.041, Table 1). However, in a subgroup analysis excluding cases with failed vacuum attempts, no significant differences in maternal and neonatal adverse outcomes were found, except for differences in surgery duration (Table 2).

Conclusion: Fetal head station per se is not associated with adverse maternal and neonatal outcomes in second-stage cesarean delivery.

797 | Genome Sequencing Versus Exome Sequencing for Fetal Anomalies

Kate Swanson[1]; Teresa N. Sparks[2]; Nuriye Sahin-Hodoglugil[1]; Billie R. Lianoglou[2]; Katie Tick[1]; Patrick Devine[3]; Mary E. Norton[2]

[1]University of California, San Francisco, San Francisco, CA; [2]Center for Maternal-Fetal Precision Medicine, University of California San Francisco, San Francisco, CA; [3]Genomic Medicine Laboratory, University of California, San Francisco, San Francisco, CA

10:30 AM - 12:30 PM

Objective: Genomic sequencing is increasingly recommended when fetal anomalies are detected. Exome (ES) and genome sequencing (GS) are both options; there are limited data comparing the two technologies. Our laboratory transitioned from ES to GS in July 2023; our objective was to compare ES versus GS in the setting of fetal anomalies.

Study Design: Prospective study of pregnancies with fetal anomalies undergoing ES or GS after non-diagnostic microarray. ES was performed in our laboratory from 1/2018 to 7/2023, and GS from 7/2023 to 7/2024. Rapid testing was performed in ongoing pregnancies to prioritize turnaround time (TAT) when management might be impacted. The primary outcome was diagnostic yield, defined as a pathogenic or likely pathogenic variant consistent with the presentation. Secondary outcomes were TAT, diagnostic yield in cases of multiple vs single anomalies, and frequency of variants of uncertain significance (VUS) and secondary findings.

Results: A total of 384 patients underwent fetal sequencing, 54 with multiple anomalies and 330 with a single anomaly. In all, 294 had ES and 90 had GS. Patients undergoing ES were more likely to undergo trio sequencing (69% vs 42%; p< 0.01). Multiple anomalies were present in 15% undergoing ES and 10% of GS cases (p = 0.21). Diagnostic yield was higher with multiple versus a single anomaly (31% vs 12%; p< 0.01) but did not differ by sequencing approach (14% for trio, 15% for duo or proband first; p = 0.7). The diagnostic yield was 16% with ES versus 10% with GS (p = 0.16). TAT with rapid sequencing was 30 days for ES vs 13 days for GS and was 51 vs 25 days for ES vs GS with routine (p< 0.01). The detection rate of VUS and secondary findings did not differ (Table).

Conclusion: GS for fetal anomalies was not associated with higher diagnostic yield or more VUS results when compared to ES, but was associated with shorter TAT. When decision making and care plans may be impacted by results, GS may be preferred for this reason.

Table. Exome versus genome sequencing

798 | Severe Maternal Ehlers-Danlos Diagnoses Among Patients Referred for Hypermobility

Kate Swanson[1]; Mary E. Norton[2]; Teresa N. Sparks[2]
[1]*University of California, San Francisco, San Francisco, CA;*
[2]*Center for Maternal-Fetal Precision Medicine, University of California San Francisco, San Francisco, CA*

10:30 AM - 12:30 PM

Objective: Joint hypermobility may indicate multiple conditions, including hypermobile, vascular, and classic Ehlers Danlos syndromes (hEDS, vEDS, cEDS). While hEDS is associated with generally low risks and good pregnancy outcomes, vEDS carries a 5% risk of maternal mortality and cEDS an increased risk of spontaneous preterm birth. Our objective was to describe the prevalence of vEDS and cEDS in a cohort of preconception and pregnant individuals with hypermobility.

Study Design: Retrospective cohort study of individuals presenting for maternal genetic evaluation for hypermobility between 2023-2024. Individuals were offered gene panel testing that includes the genes associated with vEDS and cEDS (COL3A1, COL5A1, COL5A2). A diagnosis of hEDS or hypermobility spectrum disorder (HSD) was made clinically as the genes associated with this condition are poorly understood. Primary outcome was genetic diagnosis of vEDS or cEDS. Secondary outcomes were clinical features with each of these diagnoses.

Results: 26 individuals were evaluated for hypermobility. Genetic testing was pursued in 19 patients; an additional 2 patients had already undergone testing with nondiagnostic results and a clinical history consistent with hEDS. Among those tested, 2/19 (11%) were identified to have pathogenic or likely pathogenic variants in COL3A1 consistent with a diagnosis of vEDS, and were managed with cardiac surveillance and cesarean section. One of these two individuals had previously been diagnosed with hEDS by a primary care physician. No individuals were clearly identified with cEDS, though one patient had a variant of uncertain significance in COL5A2. The remaining individuals were clinically diagnosed with hEDS or HSD and had routine obstetric management (Figure). The Table shows clinical features across diagnoses.

Conclusion: vEDS was diagnosed in 11% of individuals tested after referral for hypermobility. Genetic evaluation should be considered in individuals with hypermobility due to overlapping features across disorders, as well as significant implications for clinical management of when vEDS or cEDS are identified.

10:30 AM - 12:30 PM

Objective: The current obesity epidemic is a major public health concern; from 2016-2019, there was an 11% increase in women entering pregnancy with obesity. Maternal obesity is associated with fetal overgrowth as assessed by two-dimensional (2D) ultrasonography. However, 3D ultrasonography can characterize fetal lean and fat tissue and organ volumes, which may provide additional insight into fetal metabolic programming than 2D. Therefore, we evaluated fetal 3D measures across pregnancy by maternal pre-pregnancy BMI.

Study Design: In the NICHD Fetal 3D Study (2015-2019), fetal body composition and organ volumes were measured at up to five ultrasound scans from 15-40 weeks by certified sonographers. BMI (kg/m^2), based on self-reported pre-pregnancy weight and height, were categorized as normal (18-< 25; n = 1567), overweight (25-< 30; n = 767), or obese (≥30; n = 468). Trajectories of fetal 3D measurements were modeled using linear mixed effect models. Overall and weekly mean differences in fetal growth were tested by BMI group, adjusted for covariates.

Results: Fetuses of women with overweight or obesity, compared to women with normal BMI, had significantly larger fractional arm and thigh volumes, starting at 25-26 weeks and continuing through gestation. Proportional to fractional limb volume, fetuses of women with obesity had significantly smaller lean but larger fat limb volumes. Additionally, for overweight and obese groups, fetuses had significantly larger abdominal area and maximum abdominal subcutaneous tissue thickness (SCTT) from 29 weeks onward. Fetuses of women with overweight BMI had significantly larger lung volume from 22-31 weeks, while those with obesity had significantly smaller lung volume from 17-20 weeks, compared to those with normal BMI. No overall differences were observed among limb SCTT or other organs.

Conclusion: Fetuses of mothers with obesity had relatively smaller lean tissue but greater fat tissue accumulation throughout gestation, compared to normal BMI. Future research should examine whether fetal soft tissue differences may relate to metabolic dysfunction across the life course.

Table. Summary of overall and weekly comparisons of fetal 3D body composition and organ volumes across maternal pre-pregnancy BMI; NICHD Fetal 3D Study, 2015-2019.

	Global Comparison	Weekly Comparisons			
		Overweight vs. Normal		Obese vs. Normal

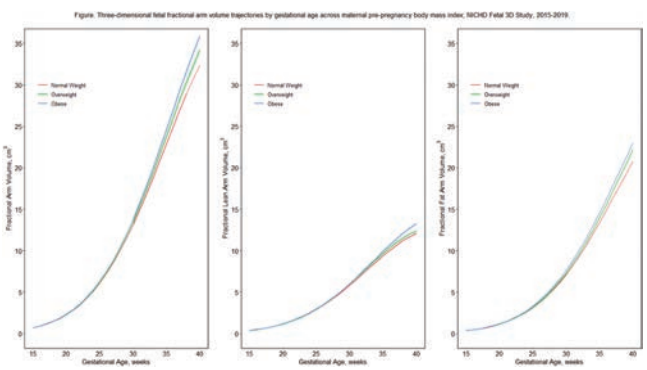
Liver volume, cm³	0.06	37-40	Larger	30-36	Larger
Average kidney volume, cm³	0.35	15-18	Larger	-	-

Linear mixed models were adjusted for: maternal age, race/ethnicity, parity, education, full-time employment status, marital status, insurance, and infant sex.
Dashes indicate no gestational age for which weekly pairwise comparisons were different.



800 | Prenatal Clinic Management of High-Risk Pregnant Patients

Kenechukwu Odenigbo[1]; Harini Pennathur[2]; Rachel A. Clark[1]; Jourdan E. Triebwasser[3]; Shayla Parthasarathy[1]; Michelle Moniz[3]; Lisa Kane Low[3]; Alex Peahl[4]

[1]University of Michigan Medical School, Ann Arbor, MI; [2]Texas A&M University School of Engineering Medicine; [3]University of Michigan, Ann Arbor, MI; [4]Michigan Medicine, Ann Arbor, MI

10:30 AM - 12:30 PM

Objective: To describe how prenatal clinics in the state of Michigan manage patients with high-risk conditions in pregnancy.

Study Design: Prenatal care providers were identified and recruited through a systematic web search and snowball sampling. Semi-structured surveys assessed prenatal care practices for birthing people with high-risk conditions (e.g. pre-existing diabetes, chronic hypertension). Clinics reported whether they managed, co-managed, or referred patients. We assessed differences in practice by clinic type: Federally Qualified Health Centers, outpatient clinics linked to hospitals, and private practices using basic tests of comparison. Qualitative content analysis was used to summarize free-response answers about additional services offered to medically complex patients. Funding provided by Blue Cross Blue Shield of Michigan.

Results: In total, 19 clinics representing 8/10 regions, with an average of 408 (range 20-1700) patients per site, were included.

Of the 19 clinics, 9/19 (47.4%) manage, 6/19 (31.6%) co-manage, and 4/19 (21.1%) refer pregnant patients with pre-existing type 2 diabetes. More outpatient clinics linked to hospitals managed patients with pre-existing type 2 diabetes. For patients with chronic hypertension, 11/19 (57.9%) clinics manage, 6/19 (31.6%) co-manage, and 2/10 (10.5%) refer patients. Management practices for chronic hypertension did not differ by clinic type. Additional services offered to medically complex patients included nurse navigators; care coordination by nurses, faculty, and trainees; support from social workers, therapists, doulas, or community health workers; and access to maternal fetal medicine physicians.

Conclusion: Many patients with type 2 diabetes or chronic hypertension require referrals or management from multiple providers. Future work is needed to understand the effects of varying management practices for chronic conditions on care access and outcomes, and the effects of additional services such as care coordination.

Table 1. Management of Pregnant Patients with Type 2 Diabetes by Clinic Type

Clinic Type	Pregnant Patients with Type 2 Diabetes			p value*
	Manage	Co-Manage	Refer	
Federally Qualified Health Center (n = 9)	3	5	1	p = 0.023
Outpatient Clinic linked to Hospital (n = 7)	6	0	1

801 | Adjunctive Quadratus Lumborum Block to Reduce Opioid Use after Cesarean Delivery

Kevin S. Shrestha[1]; Yumo Xue[2]; Victoria C. Jauk[1]; Hanna Hussey[1]; Ayamo Oben[3]; Annalese Neuenschwander[1]; Michelle Tubinis[1]; Jeff M. Szychowski[4]; Mark Powell[1]; Alan T. Tita[1]; Casey Brian[5]; Ayodeji Sanusi[2]

[1]University of Alabama at Birmingham, Birmingham, AL; [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL; [3]Maternal Fetal Consultants of Houston, Houston, TX; [4]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL; [5]West Virginia University, Morgantown, WV

10:30 AM - 12:30 PM

Objective: Peripheral nerve blockade in addition to neuraxial morphine (NM) and enhanced recovery protocols may improve analgesia following cesarean delivery (CD). We assessed if adjunctive quadratus lumborum (QL) block will reduce the oral morphine equivalent (OME) consumption for the first 24 and 48 hours after CD.

Study Design: Retrospective cohort comprising patients enrolled in a single tertiary center RCT of reduced NM dose (50mcg NM+QL block vs 150mcg NM+QL block) aimed at minimizing OME use and NM adverse effects after scheduled CD; and a historical cohort who received 150mcg of NM without a QL block. Patients in the RCT were excluded for preeclampsia, insulin-treated diabetes, placental abnormalities or history of opioid use disorder. Intervention groups were 50mcg NM+QL, 150mcg NM+QL, and 150mcg NM without QL block. Comparison groups were 150mcg NM+QL vs. 150mcg NM without QL and 50mcg NM+QL vs. 150mcg NM without QL. Primary outcomes were total OME on postoperative days 1 and 2 and opioid use 24hr prior to discharge. Secondary outcomes included total OME, opioid adverse effects, and pain scores. Linear regression and log-binomial models were used to calculate risk differences and 95% confidence intervals between groups.

Results: Of 243 patients were included, 43 were in the 50mcg NM+QL arm, 42 in the 150mcg NM+QL arm, and 158 in the 150mcg NM without QL arm. Patients in the 150mcg NM without QL arm delivered earlier and had higher rates of preeclampsia, pregestational diabetes and ASA class. There were no significant differences in the primary outcomes between all comparison groups. QL block was associated with lower parenteral opioid use and lower pain scores in the first 6 hours after surgery for patients receiving 150mg NM. There were no other significant differences in secondary outcomes.

Conclusion: Routine QL block in addition to multimodal pain management and NM did not significantly reduce total OMEs after scheduled CD however, it reduces parenteral opioid use and improve pain control in the immediate post cesarean period. Larger studies may be needed to confirm.

Table: Outcomes for Participants in the Reduced Neuraxial Dose Morphine Randomized Trial and a Historical Institutional Cohort

	50mcg NM + QL (n=43)	150mcg NM + QL (n=42)	150mcg NM + no QL (n=158)	50mcg NM + QL vs 150mcg NM + no QL RD (95% CI)	150mcg NM+ QL vs 150mcg NM + no QL RD (95% CI)

802 | Cost Effectiveness Analysis of Outpatient Versus Inpatient Antibiotic Treatment for Syphilis in Pregnancy

Kevin S. Shrestha[1]; Theodoros Giannouchos[1]; Jeff M. Szychowski[2]; Ashley N. Battarbee[3]; Akila Subramaniam[3]; Alan T. Tita[1]; Ayodeji Sanusi[3]

[1]University of Alabama at Birmingham, Birmingham, AL; [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL; [3]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL

10:30 AM - 12:30 PM

Objective: Inadequate treatment and inequitable access to care contribute to the rising incidence of congenital syphilis in the US. In pregnancy, inpatient treatment is offered due to increased risk of Jarisch-Herxheimer reaction (JHR) and other adverse outcomes. Our objective is to determine the cost-effectiveness of admissions averted by comparing inpatient versus outpatient treatment for initial antibiotic dose in pregnant patients with syphilis.

Study Design: We performed a cost effectiveness analysis using a decision tree, for viable (≥23 weeks), pregnancies with syphilis, to compare initial treatment in two settings: (1) inpatient and (2) outpatient. Input parameters included the probability of JHR resulting in a 3-day admission to the hospital among outpatient treatment, the total cost of treatment in each setting, and the total cost of subsequent admissions. Costs were estimated using a cost-to-charge ratio obtained from charges at a US, tertiary, academic hospital in 2024 USD, while the probability of admission was equated to the JHR incidence obtained from the literature (1.72%). An incremental cost-effectiveness ratio (ICER) was calculated using the ratio of differential total costs and admission probabilities between the two settings from a healthcare system perspective. A probabilistic sensitivity analysis using 100 Monte Carlo simulations was conducted to assess parameter uncertainty.

Results: The average treatment cost of pregnant women with syphilis was estimated at $2,720 and $170 in an inpatient and outpatient setting respectively, while the cost of a 3-day admission following JHR in the outpatient settings was around $9,000. The ICER was estimated at $134,463 (95% Confidence Interval: $121,874-$149,052) per admission averted.

Conclusion: Initial antibiotic treatment in an outpatient setting for syphilis in pregnancy is cost-effective compared to patient treatment in terms of admissions averted. Future work should explore whether the costs of treating women with syphilis in an inpatient setting are justified by exploring birth-related health outcomes (e.g. still-births averted).

Notes: Red point indicates average ICER estimate; blue points indicate estimates from the Monte Carlo simulations

803 | Impact of Iron Deficiency in Pregnancy on Childhood Neurodevelopmental Outcomes

Kimberly Ryan; Lucy Ward; Joseph Shatzel; Libby Nousen; Jamie O. Lo; Hanna Goustafsson; Ashley E. Benson; Elinor Sullivan

Oregon Health & Science University, Portland, OR

10:30 AM - 12:30 PM

Objective: Iron deficiency in pregnancy is common and associated with perinatal morbidity. Retrospective studies suggest an association between prenatal iron deficiency and worsened long term childhood neurodevelopmental outcomes. The objective of this study was to evaluate childhood neurodevelopment from infancy to two years of age and perinatal outcomes associated with iron deficiency in pregnancy.

Study Design: Prespecified secondary analysis of a prospective cohort study evaluating the influence of prenatal exposures on child neurodevelopmental outcomes. Patients were recruited prior to 24 weeks gestation. Pregnancy and health information was extracted from medical health records. Prenatal iron deficiency was defined as serum ferritin <30ng/mL. Childhood neurodevelopment was assessed through the Ages and Stages Questionnaire (ASQ) at 1, 6, 12,18 and 24 months of age. Mean ASQ subscale scores and their 95% confidence intervals were graphed across 1-24 months.

Results: A total of 147 maternal-child dyads met inclusion criteria; 104 (70.7%) had prenatally diagnosed iron deficiency, 43 (29.3%) did not have iron deficiency. These groups had similar baseline characteristics (Table 1). The mean ferritin in pregnancy in the iron deficient group was 23.8 ng/mL, compared to 64.9 ng/mL in those without iron deficiency. There was a trend towards lower ASQ fine motor skills, persisting from 1 to 18 months of age, in children with maternal prenatal iron deficiency as compared to those without, however, this did not achieve significance (Figure 1). Otherwise, other ASQ scores were similar across the timepoints.

Conclusion: Although prenatal iron deficiency was not associated with significant differences in childhood neurodevelopmental outcomes via the ASQ, larger studies are warranted to evaluate the relationship between iron deficiency and diminished motor skills as this trend has been previously described in retrospective studies.

10:30 AM - 12:30 PM

Objective: Up to 40% of obstetric patients do not attend postpartum visits. Birthing parents of preterm infants are often sicker than those of full-term infants. Yet parents of preterm infants may forgo postpartum visits to be present in the neonatal intensive care unit (NICU). We evaluated whether parents of preterm infants were less likely to receive postpartum care than parents of full-term infants.

Study Design: Retrospective cohort study of births in Epic Systems' Cosmos research platform (2018-2023), a US-based electronic health record database with anonymized, de-identified, patient-level data. We explored bivariate associations of infant gestational age with postpartum visits. Logistic regression models estimated the odds of missing postpartum visits among parents of infants of varying gestational ages compared to parents of full-term infants (39-40 weeks). Models first adjusted for patient characteristics (age, parity, body mass index, race and ethnicity, insurance, smoking, year, and CDC Social Vulnerability Index), and then adjusted for morbidities (diabetes, hypertension, and cesarean birth) (Table 1).

Results: In bivariate analyses, parents of infants < 24 weeks' gestation missed postpartum visits significantly more often than parents of full-term infants (37% vs. 32%, respectively, OR 1.26 [1.13–1.40]) (Table 2). Adjustment for patient characteristics did not meaningfully change estimates. However, with adjustment for morbidities, parents of preterm infants in every gestational age category had significantly higher odds of missing postpartum visits compared to parents of full-term infants; adjusted odds ratios ranged from 1.11 (1.06–1.17) to 1.20 (1.08–1.33) among parents of infants 24-27 and < 24 weeks' gestation, respectively.

Conclusion: Parents of preterm infants are at higher risk for not receiving postpartum healthcare than parents of full-term infants.

Interdisciplinary, innovative approaches to deliver care to this high-risk group, potentially in the NICU, are needed.

805 | Maternal Fetal Medicine Fellow Experience with Placenta Accreta Spectrum Care

Kristen L. Moriarty[1]; Andrea D. Shields[2]; Nicole R. Gavin[3]
[1]UCONN Health, Farmington, CT; [2]University of Connecticut Health, Avon, CT; [3]University of Connecticut, Farmington, CT

10:30 AM - 12:30 PM

Objective: Evaluate MFM fellows' experience with PAS management and their desire to perform PAS surgeries post-fellowship.

Study Design: A 43 question IRB approved survey regarding PAS exposure was validated with experts and novice learners. The survey was distributed via REDCap to fellowship program directors for dissemination from June-July 2024. Baseline demographics: fellowship year, region, number of fellows in the program, and if home program was a PAS center of excellence. Primary outcome: fellows' desire to participate in PAS post-fellowship. Secondary outcomes: various aspects of PAS participation. Chi square and pearson's t-test analyzed outcome variables.

Results: 42 MFM fellows responded, distributed evenly by year (PGY5-7+: 33.3%, 28.6%, 38.1%) and region (Northeast 38.1%, South 31%, Midwest 19%, West 11.9%). Most programs (52.4%) had 5+ fellows, and 64.3% identified as PAS center. Prior to fellowship, 90.5% of fellows participated in some aspect of PAS care, with 52% performing 1-5 cases. 60% of fellows previously in OBGYN practice had performed PAS cases as primary surgeons. 64.3% of fellows reported training in a PAS program influenced their fellowship ranking. During fellowship, all respondents participated in ultrasound and intrapartum PAS management, with 95.2% involved in surgical management. Over one-third (35.7%) performed 1-5 PAS cases during fellowship and there was no difference in the number of hysterectomies performed per fellowship year ($p = 0.916$). Two-thirds (66.7%) expressed a desire to perform PAS cases post-training and those who desired felt more confident managing the entire surgery for PAS ($p = < 0.001$) as well as managing the routine post-operative care ($p = 0.025$) and showed a trend toward training at a PAS center of excellence ($p = 0.08$).

Conclusion: 2/3 of fellows intend to perform PAS cases post-training and felt confident managing the entire surgery for PAS patients and had a trend to have trained a PAS center of excellence. A solid foundation in PAS identification, management, and care coordination during training is essential for fellows' future participation in PAS care.

806 | MEWS Due to Severe Hypertension Prior to Delivery: Clinical Characteristics and Outcomes

Kristen A. Cagino[1]; Beverly Red[1]; Joe Haydamous[2]; Tala Ghorayeb[3]; Sandra Sadek[4]; Sean C. Blackwell[5]; Baha M. Sibai[5]
[1]UT Houston, Houston, TX; [2]Division of Maternal-Fetal Medicine, Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern Medical School at UTHealth Houston, Houston, TX; [3]McGovern Medical School at UTHealth, Houston, TX; [4]University of Texas Health Science Center in Houston, McGovern Medical School, Houston, TX; [5]McGovern Medical School at UTHealth Houston, Houston, TX

10:30 AM - 12:30 PM

Objective: Maternal early warning systems (MEWS) are used to identify individuals at risk for adverse outcomes related to severe hypertension (HTN). We aimed to describe the frequency, demographics, management, and adverse outcomes of MEWS for severe HTN.

Study Design: A retrospective cohort study on the pragmatic management of MEWS for severe HTN from March to Dec 2022 at a level IV center. Individuals that triggered a MEWS antenatally or intrapartum for systolic BP $\geq$ 160 or diastolic BP $\geq$ 110 mm Hg were included and any subsequent MEWS were collected. Those with MEWS exclusively postpartum were excluded. MEWS were triggered after two sustained severe BPs prompting a provider to bedside within 30 minutes. Composite maternal adverse outcomes (CMAO) included eclampsia, stroke, pulmonary edema, acute kidney injury, myocardial ischemia, placental abruption, or

death. Descriptive statistics were performed using N (%), mean (standard deviation [± SD]) and median (interquartile range [IQR]). 95% confidence intervals (CI) were calculated for CMAO.
Results: There were 3933 deliveries during the study period and 100 individuals (2.5%) who met inclusion criteria with a total of 541 MEWS—a median of 4 (IQR 2-8) per person. 52% were nulliparous, 21% had preeclampsia in a previous pregnancy, and 54% had chronic hypertension. Mean systolic BP and diastolic BP were 172 ± 12 and 98 ± 13 mm Hg, respectively. Symptoms occurred in only 15% of MEWS. The rate of CMAO was 8% (95% CI; 3-15%). In response to MEWS, acute antihypertensives were given in 41%, both acute and oral in 20%, and oral only in 7% of cases. 31% of all MEWS (n = 170) were not treated. When evaluating adverse outcomes, only one (acute kidney injury) occurred after an untreated MEWS.
Conclusion: In our population, the likelihood of developing MEWS for severe HTN before delivery was 2.5% and adverse outcomes occurred in approximately 1 in 10. The majority of cases had no symptoms other than elevated BP. BPs were not treated in 31% of MEWS and only 1 out of 170 were associated with the development of CMAO.

10:30 AM - 12:30 PM
Objective: Our pilot study noted that in our population, understanding of risk factors/complications (RF/C) and management options (MO) for macrosomia (birthweight ≥ 4,000 g) was poor. We hypothesized that a graphics-based education tool (GBET) would improve knowledge about macrosomia.
Study Design: Inclusion criteria for our randomized clinical trial (NCTO6281301) comprised of individuals at 18-55 years, with singleton pregnancy delivering at ≥ 36 weeks. After consent, participants were randomized to either routine care or GBET (Fig 1). To assess the knowledge about macrosomia, a questionnaire consisting of 17 questions relating to the RF/C and MO of suspected macrosomic fetuses was administered to eligible candidates. The primary outcome was the overall score on the questionnaire. Secondary outcomes were individual scores on the RF/C (n = 11) and MO (n = 6). We estimated a priori that 100 participants in each group would provide 90% power to detect a 10% difference in the mean macrosomia questionnaire score (baseline score 56% ± SD of 12, alpha = 0.05). Descriptive statistics were used for baseline characteristics. Chi-squared test was used to compare categorical variables and Student's t-test for continuous variables.
Results: During the study period from Jan to July 2023, 230 eligible individuals were approached and 200 (87%) agreed to participate; of them, 103 received the GBET. Baseline demographics were similar. The majority (42%) of respondents self-identified as Black, 60% were employed, 56% had some level of college education, and 30% lived below the poverty line. There were 41% nulliparous, 67% with a BMI ≥ 30 kg/m^2 and 16% with diabetes. The primary outcome was significantly higher in those who received the GBET (70% versus 63%, $p < 0.01$). The RF/C score was also higher in the GBET group (71% versus 63%, $p = 0.01$); however, the MO score was similar between the groups (64% versus 67%, $p = 0.12$).
Conclusion: In our population, a graphics-based education tool improved patient knowledge on the risk factors / complications for macrosomia, but not their management options.

808 | Effects of Co-Occurring Opioid Use and Mood Disorders on Neonatal Outcomes in Pregnancy

Kristin C. Prewitt; Bharti Garg; Kimberly Ryan; Sarena Hayer; Ashley E. Benson; Aaron B. Caughey; Jamie O. Lo
Oregon Health & Science University, Portland, OR

10:30 AM - 12:30 PM

Objective: Co-occurring prenatal mood disorders and opioid use disorders are the leading cause of pregnant-related mortality, but the combined effect on neonatal morbidity is poorly understood. Thus, the objective of this study is to better understand associations between co-occurring prenatal opioid use and mental health diagnoses on neonatal outcomes.

Study Design: This retrospective cohort study used California linked vital statistics and hospital discharge data (2008-2020). Patients were categorized into opioid-users, mental health disorders, both, or neither. We included singleton gestations delivered between 23-42 weeks and excluded individuals using other substances. Exposure (opioid use and mental health disorders) and outcomes were identified using birth certificate and ICD-9/10 codes. Results were analyzed by chi-square tests and multivariable Poisson regression models. Adjusted risk ratios (aRR) with 95% confidence intervals (CI) were estimated.

Results: A total of 5,423,898 pregnancies were included, and of those,6,285 (0.12%) had opioid-related diagnosis, 165,121 (3.04%) had mental health disorders and 1,599 (0.03%) had a dual diagnosis. The impact of opioid use and mental health disorders (3.4%; aRR = 3.39 (2.59-4.43)) appears to have an additive effect compared to either opioid use (2.3%; aRR = 2.62 (2.21-3.12)) or mental health disorders (1.4%; aRR = 1.48 (1.42-1.54)) on rates of preterm birth < 32 weeks. Compared to no opioid use or mental health disorders, the risk of neonatal respiratory distress syndrome was higher with dual diagnosis (13.8%; aRR = 4.14 (3.65-4.68)), opioid use (9.1%; aRR = 3.13 (2.89-3.39)) and mental health disorders (5.8%; aRR = 1.79 (1.76-1.83)). Similarly, the risk of NICU admissions was significantly higher in individuals with both opioid use and mental health disorders.

Conclusion: Our study suggests that co-occurring psychiatric disorders with opioid use is associated with worse neonatal outcomes. As the opioid epidemic continues, our findings can shape clinical management.

809 | The Fetal Membrane Metabolome: Arachidonic Acid and Sex Steroid Metabolism Perturbations Associated with Preterm Rupture

Emilie M. Stylli[1]; Briana Ferguson[1]; Rita Leite[1]; Rachel Ledyard[2]; Heather Burris[2]; Lauren Anton[1]; Kristin D. Gerson[1]
[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Children's Hospital of Philadelphia, Philadelphia, PA

10:30 AM - 12:30 PM

Objective: Fetal membranes serve critical immune and mechanical functions in pregnancy, as well as provide signals initiating term and preterm labor. Despite these roles, this feto-maternal interface is often overlooked in reproductive research. Metabolomics has emerged as a powerful tool to understand biochemical footprints of cellular function. We sought to identify differences in the fetal membrane metabolome from cases of preterm premature rupture of membranes (PPROM) compared to term controls.

Study Design: Untargeted metabolomics was performed on amnion and chorion from cases of PPROM (n = 25) and term controls (n = 25) matched by race, nulliparity, age, and fetal sex from a prospective pregnancy cohort. Log_2 transformed batch-normalized data were analyzed by two-way ANOVA ($p < 0.05$) with calculation of false discovery rates ($q < 0.1$).

Results: Demographic characteristics were similar between groups (Table 1). Amnion from PPROM had higher abundance of eicosanoid, endocannabinoid, phosphatidylcholine, phosphatidylethanolamine, and fatty acid metabolites compared to term (Table 2). Amnion and chorion from PPROM had lower abundance of sex steroid metabolites, including pregnenolone, progestin, estrogenic, and androgenic metabolites compared to term (Table 2).

Conclusion: Our study is the first to report a fetal membrane metabolome. We detect evidence of increased metabolism in the arachidonic acid/phospholipid pathway and relative sex steroid deficiency in fetal membranes that rupture preterm. Whether differences in sex steroid metabolites are attributable to PPROM pathophysiology versus advancing gestational age warrants future investigation. Hormonal therapeutics, including local progesterone repletion, may carry potential to mitigate inflammation and fortify membrane integrity, thus reducing preterm birth risk. University of Pennsylvania Research Foundation Award (KG)

810 | Vaginal Polyamines Modify Gardnerella Vaginalis-Induced Alterations in the Mucosal Transcriptome

Lauren Anton; Briana Ferguson; Aaron Loder; Kristin D. Gerson
University of Pennsylvania Perelman School of Medicine, Philadelphia, PA

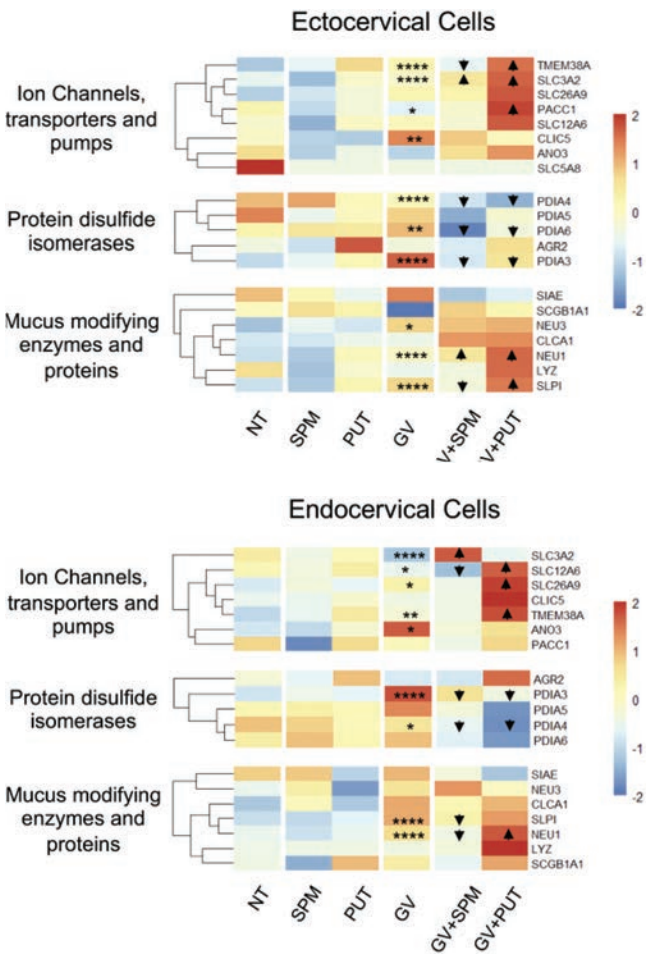
10:30 AM - 12:30 PM

Objective: Anaerobe-dominant cervicovaginal (CV) microbial communities increase risk of preterm birth. Mucus production, a key part of the host defense system, protects the CV epithelial barrier against anaerobes, including *Gardnerella vaginalis*(GV). Vaginal anaerobes modify mucus properties though molecular mechanisms remain unclear. We previously showed that vaginal metabolites, specifically polyamines, regulate GV-induced host immune responses. This study aimed to 1) elucidate effects of GV on genes involved in mucus biosynthesis, and 2) determine whether polyamines modify GV-altered mucosal gene expression.

Study Design: Human ectocervical (Ecto), endocervical (Endo) and vaginal (VK2) epithelial cells were treated for 4h +/- polyamines, spermine (SPM, 400uM) or putrescine (PUT, 4mM) prior to GV (10^7 CFU/well) exposure for 24h (n = 3/treatment). RNA-sequencing was performed. Data were analyzed using DESeq2 to study mucus genes of interest. For genes altered by GV, analysis of polyamine exposure was performed by one-way ANOVA with Tukey's test for multiple comparisons.

Results: Among the 40 mucus-associated genes studied, GV modified expression of 10 genes in Ectos, 13 genes in Endos, and 6 genes in VK2s ($p < 0.05$ for all). Genes clustered into functional pathways including mucins, ion channels, protein disulfide isomerases, glycosyl-transferases, and mucus modifying enzymes (select pathways shown for Ecto in Fig. 1 and Endo in Fig 2.). Among genes altered by GV, SPM partially mitigated these effects in select cells for TMEM38A, SLC12A6, PDIA3, PDIA4, PDIA6, GALNT5, SLPI and NEU1, while PUT potentiated these effects in select cells for TMEM38A, SLC12A6, SLC26A9, PACC1, SLPI, NEU1 ($p < 0.05$ for all).

Conclusion: GV modifies expression of genes in the CV epithelium responsible for increased mucus hydration, formation, and breakdown (sialidases). These alterations in the mucosal transcriptome likely compromise mucus properties, rendering mucus thinner and more penetrable. SPM confers protection against some of these GV-induced effects and may carry potential as a postbiotic therapeutic to restore mucus function.



811 | Association of Prenatal Care Attendance on Perinatal Outcomes with Amphetamine Exposure

Kristin C. Prewitt; Alyssa R. Hersh; Bharti Garg; Bradley M. Buchheit; Ximena A. Levander; Aaron B. Caughey

Oregon Health & Science University, Portland, OR

10:30 AM - 12:30 PM

Objective: Prenatal amphetamine use is known to be associated with increased risk of pregnancy-related morbidity and mortality. Pregnancy can make it difficult to access treatment leading to more limited prenatal care. The purpose of this study is to assess how the number of prenatal care visits impacts perinatal outcomes with amphetamine-related exposure.

Study Design: In this retrospective cohort study of singleton, non-anomalous births between gestational ages 23-42 weeks in California (2008-2020), we assessed the association between amphetamine use identified using ICD-9/10 codes and a variety of perinatal outcomes. We divided patients into two groupings based on WHO recommendations for minimum number of visits to impact perinatal outcomes - 1) more prenatal care ($>= 5$ visits) or 2) less prenatal care (< 5 visits). Chi-squared and multivariable logistic regression were utilized for statistical analyses.

Results: There were 21,827 pregnant persons with an amphetamine-related diagnosis that met our inclusion criteria, with the majority attending more prenatal care (64.2%). Those with less prenatal care were more likely to have placental abruption (3.3% vs 6.5%, aOR 1.32, 95% CI: 1.21-1.44), preterm premature rupture of membranes (4.1% vs 8.3%; aOR 2.08, 95% CI: 1.83-2.37), preterm delivery < 37 weeks (16.8% vs 34.0%; aOR 2.45, 95% CI: 2.28-2.63), and severe maternal morbidity (3.7% vs 7.2%; aOR 1.97, 95% CI: 1.72-2.25). Fewer visits were associated with worse neonatal outcomes, including respiratory distress (2.2% vs 3.8%; aOR 1.82, 95% CI: 1.52-2.17), neonatal withdrawal (2.0% vs 6.43%; aOR 1.85, 95% CI: 1.60-2.14), and NICU admission (24.9% vs 40.4%; aOR 1.89, 95% CI: 1.77-2.02).

Conclusion: Our findings demonstrate an association with adverse perinatal outcomes in individuals with amphetamine-related diagnoses who attend fewer prenatal care visits. Our results call for efforts to improve prenatal care access in individuals with amphetamine use.

812 | Amniotic Fluid Volume and Perinatal Outcomes in Women with Preeclampsia in a Low Resource Country

Kwaku A. Doffour-Dapaah[1]; Alim Swarray-Deen[2]; Alex Boateng[3]; Jeff Osei-Agyapong[1]; Perez Sepenu[4]; Patrick A. Anum[5]; Jerry Coleman[4]
[1]Greater Accra Regional Hospital, Accra, Greater Accra; [2]University of Ghana Medical School, University of Ghana Medical School, Greater Accra; [3]The Trust Hospital, Accra, Greater Accra; [4]Korle Bu Teaching Hospital, Accra, Greater Accra; [5]Korle Bu Teaching Hosptal, Accra, Greater Accra

10:30 AM - 12:30 PM

Objective: To determine:
1. The prevalence of oligohydramnios in women with preeclampsia
2. The adverse perinatal outcomes associated with preeclampsia
3. The association between oligohydramnios and preeclampsia disease severity
4. The association between oligohydramnios and adverse perinatal outcomes in women with preeclampsia

Study Design: A cross-sectional study at the Korle Bu Teaching Hospital which assessed a total of 130 pregnant women from 28 weeks to 42 weeks gestation: 10 had preeclampsia and oligohydraamnios on one arm, and the rest had preeclampsia but no oligohydramnios on the other arm. All participants had their amniotic fluid index assessed by ultrasound. This assessment was repeated weekly and the last measurement taken before delivery was used for the analysis of amniotic fluid volume data. The perinatal outcomes were also recorded.

Results: The prevalence of oligohydramnios in women with preeclampsia was 7.7%. Adverse perinatal outcomes associated with preeclampsia were preterm delivery(50%), stillbirth(10%), poor APGAR scores at one and five minutes (36.1% and 17.7%), low birth weight (46.1%), and NICU admission (40.0%). There was no association between pre-eclampsia disease severity and oligohydramnios in women with preeclampsia and there was no association between oligohydramnios and adverse perinatal outcomes in women with preeclampsia. Male sex ($p = 0.02$), gestational age at delivery ($p = 0.010$) and birth weight ($p = 0.042$) were the factors associated with adverse perinatal outcomes in women with preeclampsia.

Conclusion: Adverse perinatal outcomes associated with preeclampsia were preterm birth, stillbirth, poor APGAR scores, low birth weight and NICU admission. The lack of association between oligohydramnios and adverse perinatal outcomes; as well as the lack of association between oligohydramnios and severe preeclampsia suggests that it may not be beneficial for clinicians in low resource countries to use amniotic fluid volume as a marker for determining when preeclampsia is severe enough to warrant delivery or less severe enough to allow conservative management

Logistic Regression Analysis of Predictors of Adverse Perinatal Outcome in preeclampsia

VARIABLE	AOR	95% C.I. for AOR		P-VALUE

10:30 AM - 12:30 PM

Objective: To compare the incidence of abnormal umbilical artery Doppler (UAD), obstetric and neonatal outcomes in pregnancies affected by fetal growth restriction (FGR) when diagnosed by abdominal circumference (AC) and estimated fetal weight (EFW).

Study Design: This is a retrospective cohort study of patients with a singleton pregnancy with FGR who delivered at a tertiary urban academic center between January 2020 and December 2023.The primary outcome was abnormal UAD. Secondary outcomes were obstetric outcomes and Composite Neonatal Outcomes (CNO) including RDS, IVH, ROP, NEC, HIE, TTN, neonatal seizures, sepsis, hypoglycemia. Fisher's exact, chi square, parametric and non-parametric tests were used.

Results: Among 178 patients, 104 (58%) were diagnosed by AC only (Group 1) and 74 (42%) by EFW (Group 2). Abnormal UAD was more frequent in patients with FGR diagnosed by EFW [3(3%) vs 11(15%) in Groups 1 and 2 respectively, $p = 0.004$]. Gestational age at FGR diagnosis was significantly lower in Group 1 (32w4d vs 35w6d in Groups 1 and 2 respectively, $p = 0.008$). The incidence of cesarean delivery was similar between the groups[47(37%) vs 30(45%) in Groups 1 and 2 respectively, $p = 0.35$]. The median GA at delivery was lower in Group 2 [39w0d in Group 1 vs 38w1d in Group 2, $p< 0.0001$]. Resolution of FGR was more likely when initially diagnosed by AC only [27 (21%) vs 1(1%) in Groups 1 and 2 respectively, $p< 0.0001$]. Neonatal weight was lower in group 2 (median 2705g vs 2405g in Groups 1 and 2 respectively, $p< 0.0001$); and incidence of small for gestational age (SGA) and low birth weight (LBW) were higher in group 2 [SGA: 41(39%) vs 51(69%), $p = 0.0001$; LBW: 27(26%) vs 50(68%), $p< 0.0001$, respectively]. Incidence of CNO was higher in Group 2 [18(17%) vs 23(31%), $p = 0.04$].

Conclusion: Abnormal UAD was rarely seen in FGR fetuses diagnosed by AC and adverse neonatal outcomes were also seen less frequently in this group. FGR fetuses diagnosed by AC should be followed closely, although different surveillance frequency could be considered.

814 | The Association Between Diabetes Mellitus During Pregnancy and Retinopathy of Prematurity

Lara Saaida[1]; Victor Novack[2]; Ahed Imtirat[2]; Eilon shani[2]; Tamar Eshkoli[2]
[1]*Haemek medical center, haemek medical center, HaZafon;* [2]*Soroka University Medical Center, Soroka University Medical Center, HaDarom*

10:30 AM - 12:30 PM

Objective: We aimed to evaluate the association between diabetes mellitus (DM) during pregnancy and retinopathy of prematurity (ROP) in preterm infants younger than 32 gestational weeks or infants with low birthweight (< 1500 grams).

Study Design: We conducted a retrospective nested case-control study of all premature infants who were born alive and survived the post-delivery hospitalization period in Soroka Medical Center, with either gestational age younger than 32 weeks or birthweight less than 1,500 grams, during the years 2013-2021. The infants were divided into two groups according to ROP status. Multivariable logistic regression was used to analyze the association between ROP and DM.

Results: During the study period, there were 881 pairs of women and newborns who met the inclusion criteria. The ROP group included 345 infants (39.1%). 22 (6.4%) of the mothers in the ROP group were diagnosed with DM during pregnancy compared with 52 of 536 (9.7%) in the control group (P = 0.082). ROP was associated with oxygen treatment (OR 1.05; 95% CI, 1.03-1.08; P< .001), birthweight < 1250 g‘ (OR 2.70; 95% CI, 1.93-3.80; P< 0.001) and advanced maternal age (OR 1.03; 95% CI, 1.01-1.06; P = .01). Steroid treatment (OR 0.73; 95% CI, 0.60-0.89; P = .002) and advanced gestational age (OR 0.92; 95% CI, 0.85-1.00; P = 0.05) were found as protective factors for ROP. Using multivariable logistic regression analysis and adjusting for multiple risk factors, it was found that there is no significant association between maternal DM and the development of ROP.

Conclusion: The presence of maternal diabetes mellitus does not increase the likelihood of ROP in pre-term infants.

Chart 1: Exclusion criteria

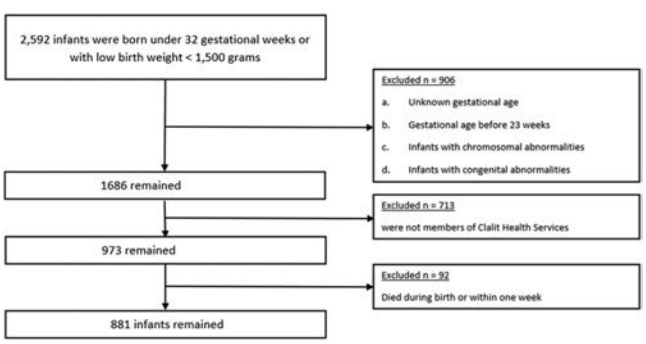

Table 4: Multivariable Logistic Regression (N = 881)

Characteristic	OR[1]	95% CI[1]	p-value
Diabetes	0.59	0.32, 1.05	0.080

815 | Cost-Effectiveness of Atosiban Versus Placebo in the Treatment of Threatened Preterm Birth (APOSTEL 8 TRIAL)

Larissa I. van der Windt[1]; Martijn A. Oudijk[1]; Job Klumper[1]; Ruben G. Duijnhoven[1]; Joris A. M. van der Post[2]; Carolien Roos[1]; Stavros Petrou[3]; Kate F. Walker[4]
[1]*Amsterdam UMC, location University of Amsterdam, Amsterdam, Noord-Holland;* [2]*Amsterdam UMC, location University of Amsterdam, Amsterdam, Noord-Brabant;* [3]*Nuffield Department of Primary Care Health Sciences, University of Oxford, Oxford, England;* [4]*Centre of Perinatal Research University of Nottingham, Queen's Medical Centre, Dublin, England*

10:30 AM - 12:30 PM

Objective: Tocolytics such as atosiban as treatment for threatened preterm birth (PTB) is part of routine care in many countries. However, overall costs and benefits of atosiban compared to placebo have not been evaluated. We assessed the cost-effectiveness of atosiban compared to placebo in improving neonatal outcomes for threatened PTB between 30 and 34 weeks gestation.

Study Design: This was an economic analysis from societal perspective alongside the international randomized placebo controlled APOSTEL 8 study, conducted in 26 hospitals in the Netherlands, England and Ireland. Women with threatened PTB from 30 to 34 weeks of gestation were randomized to atosiban or placebo. We included costs based on data from the case record form (CRF) and additional iMTA questionnaire sent three months after due date. Primary outcome was the difference in total mean costs per child between groups. Health outcome was the prevalence of composite adverse neonatal outcome. Complementary incremental cost-effectiveness ratio (ICERs) was calculated. Analyses were by intention to treat.

Results: In our complete case analysis, we included costs based on the CRFs of 752 mothers with 884 children and 376 completed questionnaires (198 atosiban, 178 placebo). Total mean costs did not significantly differ between groups: €37280 in the atosiban group (449 children) versus €37120 in the placebo group (435 children) (mean difference €160, 95% CI -€3936 to €4257). In pre- and postnatal costs no significant differences were observed. With an estimated difference of 1% in adverse neonatal outcome in favour of atosiban, the ICER was €16783. However, there was high uncertainty as a substantial distribution was located in the top left

quadrant of the ICER plane, indicating scenarios where atosiban is both more expensive and less effective.

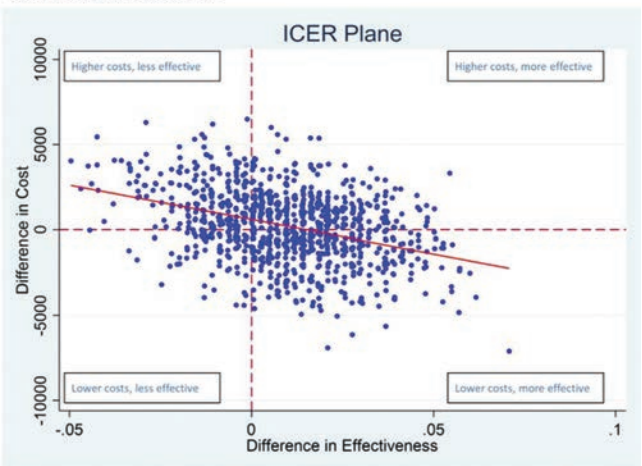
Conclusion: We observed high uncertainty of cost-effectiveness of atosiban compared to placebo as treatment for threatened PTB. As the main trial demonstrated that atosiban is not superior to placebo in improving neonatal outcomes, both clinical and economical findings should be considered in future guidelines.

Table 1. Effect and costs

	Atosiban n=449	Placebo n=435	MD (95% CI)
Composite neonatal outcome	37 (8.2%)	40 (9.2%)	0.90 (0.58 to 1.40)*
Total costs, (mean, SD)	37280 (31725)	37120 (30967)	160 (-3936 to 4256)
Total prenatal costs (mean, SD)	4807 (3594)	4958 (4764)	-150 (-697 to 396)
Total postnatal costs (mean, SD)	32473 (31691)	32162 (31401)	311 (-3857 to 4479)
Total neonatal costs (mean, SD)	27147 (29525)	26801 (30328)	345 (-3625 to 4316)

All costs are in euros. MD, mean difference; CI, confidence interval; SD, standard deviation.
*Risk ratio with 95% CI.

Figure 1. ICER plane of total costs



816 | Mediation of Socioeconomic Disparities and Preterm Birth by Class-Based Discrimination and Financial Strain

Lauren S. Keenan-Devlin[1]; Alexa A. Freedman[2]; Renee Odom-Konja[3]; Tao Jiang[4]; Janedelie Romero[3]; Linda M. Ernst[3]; Greg E. Miller[2]; Ann EB Borders[5]

[1]Endeavor Health/ University of Chicago Pritzker School of Medicine, Endeavor Health, IL; [2]Northwestern University, Chicago, IL; [3]Endeavor Health, Evanston, IL; [4]Northwestern University, Northwestern University / Evanston, IL; [5]Endeavor Health, Evanston Hospital, Evanston, IL

10:30 AM - 12:30 PM

Objective: Various measures of low socioeconomic status (SES) have been associated with elevated preterm birth (PTB) risk. To inform intervention strategies, we sought to identify which SES markers were most predictive of PTB, and identify whether psychosocial factors mediated SES-related PTB disparities.

Study Design: Stress, Pregnancy and Health study participants completed psychosocial and demographic assessments during 2nd and 3rd trimesters. An SES "status" composite was calculated with standardized measures of occupational prestige and highest degree earned in the household; a "financial resources" composite included standardized measures of self-reported household savings relative to cost of living, household income to poverty ratio, and total savings and assets. Psychosocial mediators included lifetime, daily, and perceived class-based discrimination (CBD), and subjective financial strain (SFS). PTB was defined as delivery < 37'0 weeks gestation. Multiple regressions tested the association of PTB with the composites and their individual components, as well as potential mediators. Mediation models estimated the proportion of the association mediated by CBD and SFS. Analyses were adjusted for maternal age, race/ethnicity, and marital status.

Results: Among 599 participants, about half had the highest educational attainment and IPR. 11.5% delivered preterm. Participants with higher status had lower risk of PTB (RR: 0.72, 95%CI 0.54,0.96), whereas self-reported financial resources were not associated with PTB (Table 1). In unadjusted models, higher SFS was associated with PTB risk (RR: 1.38, 95%CI 1.13,1.68), but CBD was not. Approximately 20% of the relationship between status and PTB was mediated by SFS, though this was not statistically significant (p = 0.28).

Conclusion: Status-based SES measures were significantly associated with PTB whereas financial resource-based measures were not. Our results suggest that the experience of being lower SES (i.e. social status/capital and the lived reality that these facilitate) may bear more significantly on pregnancy outcomes than self-identified monetary resources.

Table 1. Associations between Status and Financial Resource composite and PTB. Associations reflect a 1 standard deviation increase (e.g., higher income-to-poverty ratio).

	Unadjusted		Adjusted	
	RR	95% CI	RR	95% CI

*Adjusted models include age, race/ethnicity, and marital status. Models of mediators of interest additionally include the status composite

817 | A Machine Learning Approach to Intrapartum FHRT Analysis To Identify Neonates Requiring Therapeutic Hypothermia

Lauren M. Silva[1]; Jaber Qezelbash-Chamak[2]; Dillon Joiner[1]; Minhee Kim[2]; Karen T. Hicklin[3]; Michael D. Weiss[1]; Marie Berg[1]; Cyndi Garvan[1]; John C. Smulian[1]

[1]University of Florida College of Medicine, Gainesville, FL; [2]University of Florida Herbert Wertheim College of Engineering, Gainesville, FL; [3]Icahn School of Medicine at Mount Sinai, New York, NY

10:30 AM - 12:30 PM

Objective: Examine a "sliding window time frame" as a ML approach to fetal heart rate tracing (FHRT) analysis to identify neonates that developed moderate to severe neonatal encephalopathy (NE) and underwent therapeutic hypothermia.

Study Design: Retrospective observational case-control involving neonates born at a single academic institution and admitted to the NICU with cord pHs ≤ 7.15. The study group included

neonates meeting both physiologic (low cord pH) and neurologic criteria for moderate to severe NE, making them eligible for therapeutic hypothermia. The control group comprised neonates who, despite having low cord pHs, did not show evidence of moderate or severe NE and thus did not undergo therapeutic hypothermia.

The entire intrapartum FHRT for eligible neonates was analyzed to develop a ML-based model incorporating an embedded sliding time window. Isolation Forest was used to identify and cluster windows with unusual patterns as anomalies or typical patterns as normal. A Random Forest classifier was then trained to predict abnormal pattern labels. After the optimal sliding time window size was determined, its impact on the ML model's anomaly detection performance was evaluated by calculating the percentage of anomalous time windows during the entire intrapartum course for both subject groups and compared by student t-test.

Results: There were 22 study and 22 control cases with similar clinical characteristics and cord pH values. Using a 90-minute sliding time window, the ML-based model identified a significant difference in the proportion of windows with abnormal patterns between the control and study cases (4.7 % vs 73.3%, $p < 0.001$). The ML classifier applied to these 90-minute windows achieved 100% accuracy in distinguishing between study and control cases.

Conclusion: The ML-based model incorporating an embedded sliding time window accurately identified neonates with moderate to severe NE. This is a promising approach to intrapartum FHRT assessment with the potential to identify fetuses at risk for neurologic injury and allow for timely intervention.

818 | The Association Between Excessive Gestational Weight Gain in Obese Patients and Intrapartum and Postpartum Outcomes

Lauren M. Silva[1]; Caitlin Rogers[1]; Emily Astarita[1]; Divya Mahesh[1]; Payton Campbell[1]; Danielle Snyder[1]; Nicole Diaz[1]; Aniela Edwards[1]; Caroline Lamoutte[2]; Rebecca Henderson[3]; Khanh Huynh[1]; Thomas Reilly[1]; Matthew Gurka[4]; Tony Wen[1]; Adetola F. Louis-Jacques[5]

[1]University of Florida College of Medicine, Gainesville, FL; [2]St. Louis University School of Medicine, St. Louis, MO; [3]University of Alabama School of Medicine, Gainesville, FL; [4]University of Virginia School of Medicine, Charlottesville, VA; [5]University of Florida, Gainesville, FL

10:30 AM - 12:30 PM

Objective: Obese women have a longer duration of labor, particularly those undergoing induction of labor (IOL), and higher rates of adverse outcomes. This study aimed to determine the length of the latent phase, total induction time, and frequencies of cesarean delivery and adverse outcomes in obese patients with excessive weight gain (EWG) compared to those with appropriate weight gain (AWG) undergoing IOL.

Study Design: Retrospective cohort study including nulliparous patients with a BMI $\geq$ 30 kg/m2 that underwent IOL at a single academic institution between June 2018 and December 2022. Gestational weight gain was calculated based on the difference between pre-pregnancy or first trimester weight and weight at delivery, then categorized as AWG or EWG based on recommendations by the Institute of Medicine. The IOL lengths and frequencies of the outcomes of interest (Table 2) were extracted from the electronic medical record. Chi square, t-test, and Wilcoxon rank sum test were performed where appropriate.

Results: Of 469 obese patients, 105 (22.4%) had AWG and 364 (77.6%) had EWG. The median pregravid BMI for patients with AWG was significantly higher than in those with EWG (38.6 vs 35.5 kg/m2, $p < 0.001$). There were no significant differences in the latent phase lengths, total induction times, or frequencies of cesarean delivery and adverse outcomes.

Conclusion: EWG in obese patients undergoing IOL is not associated with increased latent phase lengths, total induction times, or frequencies of cesarean delivery or adverse outcomes. The significantly higher pregravid BMI in the AWG group may have influenced our findings by diminishing the difference in IOL lengths and frequencies of adverse outcomes when compared to the EWG group. Further investigation is necessary to account

for this difference in pregravid BMIs and to determine whether EWG is independently associated with higher intrapartum and postpartum adverse outcomes in obese patients undergoing induction of labor.

Table 1. Characteristics of the AWG and EWG groups.

Patient Demographics	AWG (n=105)	EWG (n=364)	P value
Maternal age (years)	26 [23,32]	25 [21,30]	0.04

10:30 AM - 12:30 PM

Objective: To assess the tolerance of peripartum prostaglandin use in women with sickle cell disease (SCD).

Study Design: A retrospective cohort study in 10 centers in France. Among all women with SCD (S/S, S/C or S/β-thalassemia), we compared pregnancies with and without exposure to prostaglandins, overall and specifically according to whether prostaglandins were used for labor induction or for post-partum hemorrhage (PPH). The main outcome was the occurrence of acute SCD complications, defined as any vaso-occlusive crisis (VOC) or thromboembolic event, within 7 days after delivery.

Results: Prostaglandins were used in 114/411 pregnancies (27.7%). In 106/411 (25.8%), prostaglandins were used to induce labor, with PGE2 (dinoprostone gel or pessary) for 95 patients and misoprostol for 11 patients. The incidence of PPH was 60/411 (14.6%), and 11 cases required second-line therapy with prostaglandins; sulprostone was used as per French practice guidelines. The incidence of acute complications did not differ between patients exposed and not exposed to prostaglandins (14/114 (12.2%) vs 34/293 (11.6%), respectively, p = 0.87, nor did the incidence of severe VOC (7.0% vs 7.8%, respectively; p = 0.78) or other secondary outcomes. Among patients undergoing labor induction, acute complications occurred in 12/106 (11.6%) exposed to prostaglandins vs 6/77 (7.6%) unexposed (p = 0.46). Among patients with PPH, rates were respectively 2/11 (18.2%) vs 9/49 (18.4%; p = 0.99).

Conclusion: The use of prostaglandins in patients with SCD for labor induction or for PPH appeared safe, within the limitations of a retrospective study.

820 | Associations Between Non-Communicable Diseases and Obstetric Complications at a Tertiary Referral Hospital in Southwestern Uganda

10:30 AM - 12:30 PM

Objective: Non-communicable diseases (NCDs) increasingly contribute to maternal morbidity, accounting for 15% of indirect maternal deaths worldwide. We determined the association between NCDs and obstetric complications at Mbarara Regional Referral Hospital (MRRH) in southwestern Uganda.

Study Design: We conducted a retrospective cross-sectional study, and randomly selected records of women admitted for delivery at MRRH each month from January to December 2022, extracting their socio-demographic and clinical characteristics. We performed multivariable robust Poisson regression analysis to assess the association between NCDs and obstetric complications. Models were adjusted for maternal age, gravidity, referral status, employment status, and HIV serostatus.

Results: We abstracted data for 2,336 women with a mean age of 26±5.9 years. At least one NCD was present in 6.4% (n = 149) including anemia (n = 77, 3.3%), chronic hypertension (n = 35, 1.5%), pre-gestational diabetes (n = 16, 0.7%), asthma (n = 9, 0.4%) and cardiac disease (n = 6, 0.3%). Overall, 542 (23.2%) women had obstetric complications, including pre-eclampsia (n = 265, 11.3%); preterm labor (n = 67, 2.9%); placental abruption (n = 29, 1.2%); PPH (n = 54, 2.3%); and gestational diabetes (n = 5, 0.2%). Women with NCDs had increased likelihood of having an obstetric complication compared to women without (overall proportion 33.6% vs 22.5% respectively; adjusted prevalence ratio (aPR): overall, 1.8, 95% CI: 1.4-2.3; pre-eclampsia (1.8, 95%CI: 1.2-2.8), gestational diabetes (12.0, 95%CI: 2.0-72.7), deep venous thrombosis (6.0, 95%CI: 1.3-27.1), placenta abruption (4.4, 95%CI: 1.5-12.6) and postpartum hemorrhage (4.3, 95%CI: 2.2-8.3).

Conclusion: We found that NCDs were associated with a nearly two-fold increased risk of obstetric complications. Our findings highlight the need for further research to understand the impact of this risk, particularly on maternal and fetal outcomes. Additionally, these findings suggest strengthened NCD surveillance, as means to increased preparedness, and management for potential obstetric complications among pregnant women in Uganda.

821 | a Comparative Study of Stillbirth Classification Schemes

Lena A. Shay; Mohamad Ali Maktabi; April D. Adams
Baylor College of Medicine, Houston, TX

10:30 AM - 12:30 PM

Objective: Stillbirth, defined as fetal death at ≥20 weeks' gestation, complicates ~1 in 160 pregnancies and causes vary widely. The most helpful tests in determining cause of stillbirth are fetal autopsy, placental pathology, and genetic testing, yet uptake is often low or incomplete. Several methodologies exist to classify stillbirth into phenotypic groups based on pathologic and clinical findings, each varying in complexity and ease of use. Our objective was to determine the agreement between three published classification systems (PASS, INCODE, and ReCoDe) using a cohort of patients who had complete diagnostic evaluation after stillbirth.

Study Design: Retrospective cohort study was conducted examining stillbirths occurring at two tertiary care centers from 2016 to 2022 with completed genetic and pathologic evaluation (n = 85). Three independent reviewers examined the cases according to selected classification schemes. Descriptive statistics were calculated and reliability analysis using Fleiss' kappa was performed to determine agreement.

Results: Leading cause of stillbirth among the classification schemes was placental in origin followed by fetal (μ = 48%, μ = 33%) (Table 1). Each scheme had low rate of unclassified cases (μ = 3%). Agreement between the three classification schemes was fair ($\kappa = 0.38$, CI 0.30-0.46; p< 0.001). 26% had positive genetic findings on diagnostic testing. Sub-analysis of cases with a genetic diagnosis did not demonstrate increased agreement ($\kappa = 0.33$, CI 0.14-0.53; p< 0.001).

Conclusion: Findings demonstrate tested classification schemes perform similarly on most stillbirth cases regarding minimization of unclassified diagnoses, but incompletely agree on all classifications. This highlights the diagnostic imprecision of stillbirth. These classification systems are limited by the user's interpretation of findings as well as failure to account for pathophysiologic interactions in cases affected by multiple clinical, genetic, or pathologic factors. Future work should be aimed at using tools such as machine-learning to develop classification algorithms to address these limitations.

Table 1. Comparison of stillbirth classification scheme agreement in determination of primary cause of death.

	PASS (%)	ReCoDe (%)	INCODE (%)	Average (%)
Fetal	33 (0.39)	27 (0.32)	25 (0.29)	28.3 (0.33)
Placenta/Umbilical cord	48 (0.56)	42 (0.49)	33 (0.39)	41(0.48)
Maternal	2 (0.02)	9 (0.11)	16 (0.19)	9 (0.11)
Obstetric	0 (0.0)	0 (0.0)	7 (0.08)	2.3 (0.03)
External	1 (0.01)	1 (0.01)	0 (0.0)	0.6(0.01)
Infection	0 (0.0)	0 (0.0)	3 (0.04)	1 (0.01)
Other	1 (0.01)	6 (0.07)	1 (0.01)	2.6 (0.03)

822 | Evaluating an Artificial Intelligence Platform Answering Common Pregnancy Questions: Satisfactory but Inconsistent

Leonardo F. Antelo[1]; Lois Brustman[2]; Zainab Al-Ibraheemi[2]; Graham Ashmead[3]
[1]*Mount Sinai West Obstetrics and Gynecology, New York, NY;*
[2]*Icahn School of Medicine at Mount Sinai West, New York, NY;*
[3]*Mount Sinai West, New York, NY*

10:30 AM - 12:30 PM

Objective: The availability of artificial intelligence platforms is rapidly increasing. We assessed the platform ChatGPT 3.0 and its ability to answer questions about common pregnancy conditions. This study analyzed the appropriateness of responses, the consistency of responses over multiple iterations, and the presence of misinformation within the responses.

Study Design: Seven questions were generated for each of the following pregnancy conditions to yield a total of 28 questions: Gestational Diabetes, Preeclampsia, Fetal Growth Restriction, and Oligohydramnios. Questions were entered into ChatGPT 3.0 in an identical manner three separate times, generating 84 total responses. Since ChatGPT forms a unique response even when exposed to the same prompt, each set of responses was reviewed by one of three board-certified MFM physicians. The accuracy of responses to each specific question was rated 1) Satisfactory, 2) Incomplete, or 3) Inadequate. ChatGPT responses contain information beyond the scope of the question. This additional information was evaluated for the presence or absence of misinformation by each reviewer.

Results: The responses of 13 out of 28 questions received consistent Satisfactory ratings over the three separate iterations (47%). 26 out of 28 questions had at least one response that was satisfactory (93%). When assessing the total 84 responses for misinformation, 22 out of 84 contained misinformation (27%). 51 out of 84 were rated as both Satisfactory and did not contain

misinformation (61%). Only 7 out of the 28 questions generated consistent answers by the reviewers, receiving both satisfactory ratings and also not containing misinformation (25%).

Conclusion: Our results suggest that Chat GPT 3.0 is able to generate satisfactory responses to common pregnancy questions. However, we found it to be inconsistent over multiple iterations of the same question. This platform should be used with caution, and the presence of misinformation should be noted when counseling patients on the use of AI.

Frequency of ChatGPT 3.0 Response Ratings	Percent (95% Confidence Interval*)
59 of 84 responses rated as Satisfactory**	70.2 (56.5, 81.3)
51 of 84 responses rated as both Satisfactory and Does not contain misinformation+	60.7 (48.4, 71.8)
22 of 84 responses contained misinformation, regardless of rating	26.2 (16.6, 38.7)
7 of 28 questions had consistent Satisfactory responses without misinformation across all three iterations	25.0 (10.7, 44.9)
13 of 28 questions had consistent Satisfactory responses across all three iterations	46.4 (27.5, 66.1)
26 of 28 questions had responses with at least one satisfactory response	92.9 (76.5, 99.1)

* Confidence intervals were computed using the exact binomial method for percentages based on 28 observations and using Generalized Estimating Equations (GEE) for percentages based on 84 observations.
**Satisfactory ratings were based on the ability of the response to comprehensively and accurately answer the specific question being asked
+ Misinformation was based on the entirety of the AI generated response and the presence of misinformation in the additional information

823 | Inflammatory Lesions in Placentas of Endometriosis Patients and Their Relation to Maternal and Neonatal Outcomes

Liat Mor[1]; Roni Goldenberg[2]; Ella Toledano[1]; Ran Keidar[1]; Letizia Schreiber[1]; Eran Weiner[3]; Elad Barber[1]
[1]Edith Wolfson Medical Center, Holon, HaMerkaz; [2]Tel Aviv University, Faculty of Medicine, Tel aviv, Tel Aviv; [3]Wolfson Medical Center, Wolfson Medical Center, Tel Aviv

10:30 AM - 12:30 PM

Objective: This study aimed to investigate the relationship between endometriosis and placental pathology, aiming to elucidate potential mechanisms behind adverse pregnancy outcomes associated with endometriosis.

Study Design: This retrospective cohort study analyzed data of patients with endometriosis who delivered at a single tertiary center between 2008-2023. Inclusion criteria were singleton term deliveries with placentas sent for histopathological examination. Maternal characteristics, pregnancy outcomes, and placental histopathology were compared between patients with endometriosis (n = 50) and a control group without endometriosis (n = 150) matched for maternal and gestational age.

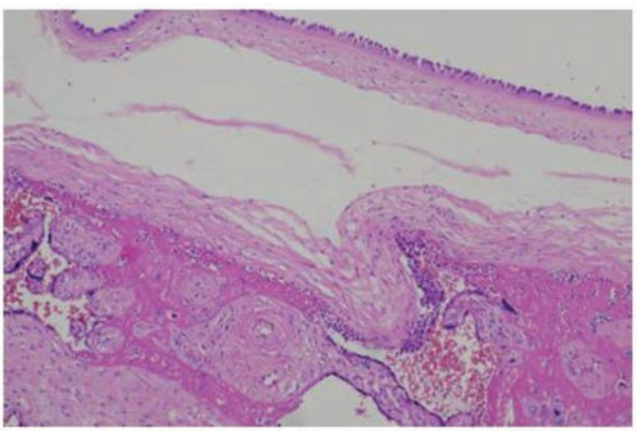
Results: The demographic characteristics and labor outcomes did not differ significantly between the groups. Patients with endometriosis exhibited higher rates of placental lesions, including placental hemorrhage (10% vs. 2.6%, p = 0.045), maternal inflammatory response lesions (16% vs. 6%, p = 0.039), fetal inflammatory response lesions (8% vs. 1.3%, p = 0.035), chronic villitis (8% vs. 1.3%, p = 0.035), and chronic deciduitis (14% vs. 2.6%, p = 0.006). Moreover, composite adverse neonatal outcomes were significantly higher in the endometriosis group (16% vs. 4%, p = 0.007). Multivariable regression analyses confirmed significant associations between endometriosis and all inflammatory placental lesions, both acute and chronic. Additionally, endometriosis was significantly and independently associated with adverse neonatal outcomes.

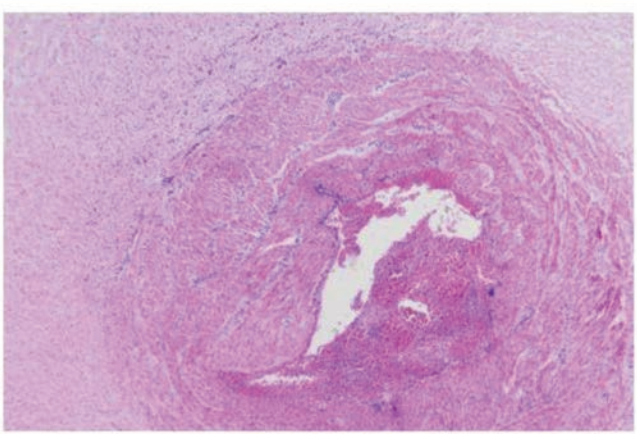
Conclusion: The presence of endometriosis is associated with increased placental pathology and adverse neonatal outcomes. The findings suggest that inflammatory lesions in the placenta may play a significant role in the pregnancy complications observed in women with endometriosis, highlighting the need for targeted monitoring and management strategies in this population.

Logistic regression analyses examining the association between endometriosis, placental inflammatory lesions and adverse neonatal outcomes

	aOR*	95% CI	p-value
Maternal inflammatory response lesions	3.56	1.23-10.33	**0.019**
Fetal inflammatory response lesions	8.45	1.42-50.25	**0.019**
Chronic villitis	9.07	1.50-54.54	**0.016**
Chronic deciduitis	9.01	2.24-36.14	**0.002**
Composite adverse neonatal outcomes	5.66	1.65-19.47	**0.006**

Values reflect the results of multivariate logistic regression analyses adjusted for maternal age, gestational age at birth, smoking, any diabetes during pregnancy, any hypertension during pregnancy, cesarean section and vaginal delivery. aOR- adjusted odds ratio; CI- confidence interval.





824 | Machine Learning-based Pregnancy and Pregnancy Trimesters Prediction Using Electrocardiogram

Lihong Mo[1]; Shantanu Milind Joshi[2]; Sonul Gupta[1]; Vivian Pae[1]; Ijeoma Uche[1]; Hana Shaik[3]; Chen-Nee Chuah[3]; Philip Strong[1];

Uma Srivasta[1]; Imo Ebong[1]; Herman L. Hedriana[1]; Elaine Waetjen[1]
[1]UC Davis Health, Sacramento, CA; [2]Computer Science, UC Davis, Davis, CA; [3]Electrical and Computer Engineering, UC Davis, Davis, CA

10:30 AM - 12:30 PM

Objective: Pregnancy is a physiologic high-volume state. Physiologic electrocardiogram (ECG) changes in pregnancy have been reported but not well characterized. We hypothesize that the physiologic cardiac volume and compliance changes in pregnancy will result in changes in ECG features that can be used to distinguish pregnant from non-pregnant state. The objective of this study is to establish a machine learning (ML) model to predict pregnant from non-pregnant state based on ECG.

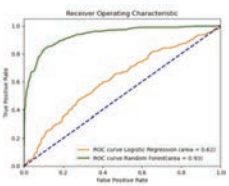
Study Design: This is an analysis of a database that includes 22,034 ECGs on 7,298 individual patients from 18-50 years of age who were pregnant at least once between 2011 to 2024 in a single tertiary medical center. After excluding patients with pre-existing cardiac morbidity, along with those who developed hypertensive disorders of pregnancy, 3,581 ECGs were included (53% negative versus 47% positive label). A supervised ML method (Random Forest) was compared to multiple logistic regression to predict pregnancy state based on four ECG features (QRS interval, QTc interval, PR interval, and heart rate).

Results: Random forest ML model performs better than multivariate logistic regression in the prediction of pregnancy state (Table). From the decision tree display of Random Forest ML model, higher QTc, higher heart rate, and lower QRS duration were associated with the classification of pregnancy state (Figure).

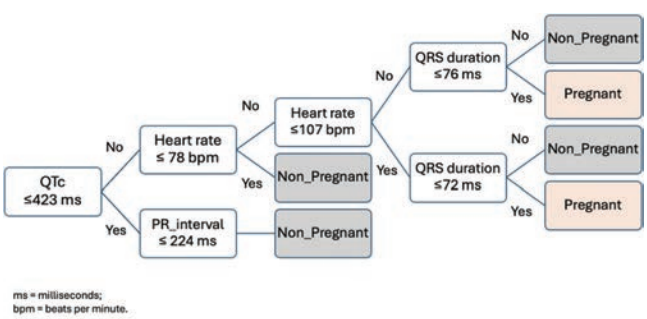
Conclusion: Four features that are commonly reported in clinical assessment of ECG can assist in the prediction of pregnancy state, especially when ML methods are used. By establishing ECG features associated with pregnancy by trimester, we can begin to characterize patterns associated with abnormal pregnancies.

Table. Comparing ML and logistic regression to predict pregnant state from ECG

ML models	Precision	Recall	F1 Score	Accuracy	AUROC
Random Forest	0.87	0.76	0.81	0.87	0.93
Multivariate logistic regression	0.57	0.25	0.35	0.65	0.62



* AUROC = area under the receiver operator curve.



ms = milliseconds;
bpm = beats per minute.

Figure 2. Simplified Decision Tree Diagram from Random Forest ML model.

825 | Using Supervised Machine Learning to Predict Spontaneous Preterm Birth in Patients Presenting with Preterm Contractions

Vivian Pae; Philip Strong; Herman L. Hedriana; Lihong Mo
UC Davis Health, Sacramento, CA

10:30 AM - 12:30 PM

Objective: Threatened preterm labor with the occurrence of preterm contractions is the most common reason for antepartum hospital admission, encompassing between 44–59% of all antenatal hospitalizations. Only half of the women who present with TPTL ultimately experience spontaneous preterm birth (sPTB). The nature of preterm contractions and sPTB relationship is not fully understood. The objective of this study was to understand what contributes to sPTB when patients present with preterm contraction symptoms using machine learning (ML).

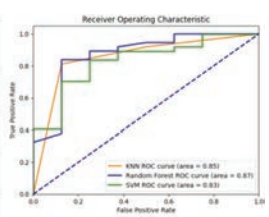
Study Design: A retrospective case-control study of individuals who experienced preterm contractions prior to sPTBs between January 2022 to March 2024 in a single tertiary medical center. A total of 3,245 patients were manually screened. Two hundred twenty-four patients who presented with preterm contractions < 36 weeks were included, with 42 delivering > 37 weeks and 182 delivering < 37 weeks. Three supervised ML methods (Random Forest, Support Vector Machine, and k-Nearest Neighbors) were compared to predict sPTB based on key clinical features (twins versus singleton, gestational age at presentation, body mass index - BMI, smoking history, concurrent PPROM status, history of PTB, and cervical dilation). Missing information in features were imputed from median.

Results: All three ML methods achieved promising AUROC in sPTB prediction (Table 1). The top four features related to the sPTB predictions are cervical dilation (measured in centimeters), BMI, gestational age at presentation, and concurrent PPROM status (Table 2).

Conclusion: Spontaneous PTB can be predicted via clinical information readily available with ML methods. The key clinical features used in the prediction are similar across all three ML methods used. Single center data and rarity of cases were main limitations. A multicenter or state database should be used to further validate findings.

Table 1. Comparing different ML methods in predicting spontaneous preterm birth from clinical features

ML models	Precision	Recall	F1 Score	Accuracy	AUROC
Random Forest	0.86	0.87	0.85	0.87	0.87
SVM	0.86	0.87	0.85	0.87	0.83
kNN	0.79	0.82	0.80	0.82	0.85



ML = machine learning; SVM= Support Vector Machine; kNN = k-nearest neighbors; AUROC= area under the receiver operator curve.

Table 2. Ranking of the feature importance in predicting spontaneous preterm birth in three ML models

Rank	Random Forest		SVM		kNN	
	Features	Importance factor	Features	Importance factor	Features	Importance factor
1	Cervical dilation	0.36	Cervical dilation	0.90	Cervical dilation	0.089
2	BMI	0.25	Concurrent PPROM	0.85	BMI	0.033
3	Gestational age at presentation	0.20	BMI	0.31	Gestational age at presentation	0.022
4	Concurrent PPROM	0.10	Gestational age at presentation	0.17		
5	History of PTB	0.036	History of PTB	0.15		
6	Smoking history	0.034	Smoking history	0.03		
7	Twin versus singleton	0.013	Twin versus singleton	0.03		

ML = machine learning; SVM= Support Vector Machine; kNN = k-nearest neighbors; BMI = body mass index; PTB = preterm birth; PPROM = preterm prelabor rupture of membranes.

826 | Risk Factors for Sexually Transmitted Infection (STI) Partner Management for Pregnant Patients in Southeast Texas

Likhita Nandigam[1]; Sara Vincent[1]; Alison N. Goulding[1]; Irene A. Stafford[2]; Julie Gutierrez[3]; Kaitlyn Stark[4]; Anthony Chartier[5]
[1]Baylor College of Medicine, Houston, TX; [2]McGovern Medical School at UTHealth Houston, Houston, TX; [3]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX; [4]University of Texas Health Science Center at Houston - McGovern Medical School, Houston, TX; [5]Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern Medical School at UTHealth, Houston, TX

10:30 AM - 12:30 PM

Objective: Pregnancy provides an opportunity for routine STI testing. However, partner testing and treatment remain challenging, leading to reinfection cycles. Our study sought to evaluate risk factors for incomplete partner treatment for STIs with and without public health surveillance.

Study Design: We performed a retrospective cohort study of all pregnant women who received care at two safety-net hospitals in Harris County, TX between 2019–2022. Record review was performed for all patients who tested positive for chlamydia, gonorrhea, hepatitis B, and/or syphilis during pregnancy. If any gaps were identified in documentation, patients were contacted for a brief interview about partner(s). Reasons for incomplete partner treatment were stratified into lack of education, lack of contact with patient, financial or other barriers to treatment, tested negative, or treatment status unknown. Partner treatment for hepatitis B and syphilis was confirmed with the regional health department. Differences in categorical variables between groups were examined using chi-square test or Fisher's exact test. $P < 0.05$ was considered statistically significant.

Results: Of 20,108 pregnant patients who received care between 2019-2022, 369 patients met inclusion criteria (Table 1). Partner treatment was most successful for patients with chlamydia (53.6%) and gonorrhea (45.5%), followed by syphilis (43.4%) and hepatitis B (1.2%) (Table 2). Lack of ongoing contact was the most common reason for insufficient partner treatment in patients with chlamydia (43.1%) or gonorrhea (75.0%). For syphilis and hepatitis B, the predominant reason remains unknown (42.9%, 72.5%, respectively).

Conclusion: While reasons for partner treatment are well-documented for clinician-monitored STIs, partner STI status remains relatively unknown for syphilis and hepatitis B. Because these infections are subject to public health surveillance, there may be an overreliance on public health authorities for managing these STIs. Increased education for providers for all STIs should be prioritized, and existing gaps in this area should be addressed.

827 | Anemia Recovery After Pyelonephritis

Lisa R. Thiele[1]; Sara I. Jones[2]; Sainath Kondapaneni[1]; Jessica E. Pruszynski[1]; Elaine L. Duryea[3]; Catherine Y. Spong[3]
[1]University of Texas Southwestern, Dallas, TX; [2]Duke Univeristy, Durham, NC; [3]University of Texas Southwestern Medical Center, Dallas, TX

10:30 AM - 12:30 PM

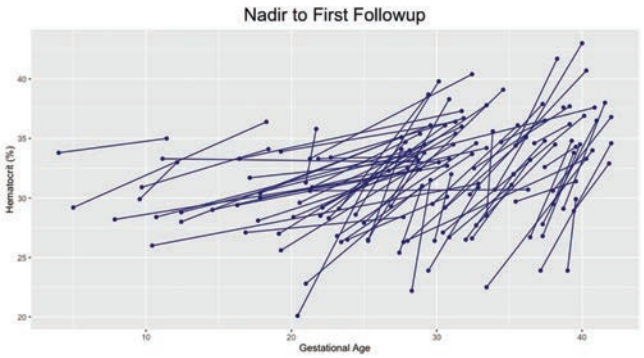
Objective: While pregnant patients with pyelonephritis commonly develop anemia secondary to endotoxin-induced hemolysis, the rate of hematologic recovery is not known. This study aimed to detail the hematologic trajectory during and after antepartum pyelonephritis.

Study Design: Patients with antepartum admissions for pyelonephritis between January 1, 2022 and December 1, 2022 who delivered at our institution at least 7 days following admission for pyelonephritis were included. The primary outcome was change in hematocrit (Hct) from its nadir during admission for pyelonephritis to follow-up. Data collected included hematologic data, patient demographics, medical comorbidities, and characteristics regarding pyelonephritis and delivery admissions. Statistical analysis included t-tests, Kruskal-Wallis, and chi-square tests.

Results: Of 78 patients meeting inclusion criteria, the majority were nulliparous, of Hispanic ethnicity, and had an average age of 25.4. During pyelonephritis admissions, the average admission Hct was 33.2% (32.0-35.2) with an average nadir of 28.8% (26.7-30.6) occurring on hospital day 2 (1-3). 60% of patients had anemia at discharge from pyelonephritis admission. The mean rise in Hct from pyelonephritis admission nadir to first follow-up was 6.0+/-3.3% with an average rise of 1.63+/-2.4% per week (Figure). 6% of patients had anemia at delivery admission, with an average admission Hct of 35.9% (33.8-38.2). Patients with a greater Hct rise were found to have a lower mean nadir, more rapid rise, and

higher Hct at delivery admission ($p < 0.001$), with no difference in initial Hct at pyelonephritis admission.

Conclusion: Following pyelonephritis infection in pregnancy, Hct levels steadily rise by an average of 1.63% per week, resulting in resolution of anemia prior to delivery. Patients with lower Hct during pyelonephritis admission demonstrate faster hematologic recovery and are less likely to be anemic at presentation for delivery.



828 | Postlaser persistent polyhydramnios after resolution of Twin to Twin Transfusion Syndrome

Mackenzie J. Simon-Collins[1]; Camille Shantz[2]; Rachana Tanksali[3]; Maryn Day[3]; Julie Alan[1]; Sarah Millard[1]; Michelle Kush[1]; Jena L. Miller[1]; Ahmet A. Baschat[1]; Mara Rosner[1]
[1]Johns Hopkins Medicine, Baltimore, MD; [2]Johns Hopkins University, Baltmore, MD; [3]Johns Hopkins University, Baltimore, MD

10:30 AM - 12:30 PM

Objective: Fluid abnormalities should resolve after fetoscopic laser surgery (FLS) for Twin to Twin Transfusion Syndrome (TTTS), but polyhydramnios occasionally persists. We sought to compare patients with persistent polyhydramnios (PP) to those with resolved polyhydramnios (RP) after FLS for TTTS.

Study Design: Single-center retrospective review of monochorionic twins who underwent FLS for TTTS from 6/2014 to 1/2024. Patients with PP had a maximum vertical pocket (MVP) > 8 cm in the former TTTS recipient > 14 days after laser. RP patients had resolution of polyhydramnios ≤ 14 days after laser. High order multiples and those with TTTS recurrence were excluded. Pre-treatment characteristics and birth outcomes were compared between PP and RP groups via Pearson or Fischer's Exact Chi Squared and Mann-Whitney U. ROC analysis was performed to explore the relationship between pre-laser MVP and PP.

Results: 377/405 (93%) patients had RP after laser and 28 (7%) patients had PP (Figure 1). PP recipients had higher prelaser MVP (11.3 vs 10.1 cm, $p = 0.013$), higher amnioreduction volumes (1900 vs 1500 cc, $p = 0.034$) and higher post operative day 1 MVPs (7.4 vs 6.0 cc, $p = 0.010$) (Table 1). An ROC analysis demonstrated that a prelaser recipient MVP of 11.0 cm predicted PP with 64% sensitivity and 64% specificity. Model quality Gini Index 0.53, area under the curve 0.64 (95% CI: 0.538-0.753), $p = 0.014$. Remaining pre-treatment and intraoperative findings were not different between groups, though there was a trend towards more pyelectasis in PP recipients (10.7 vs 2.7%, $p = 0.053$). Average time to resolution of polyhydramnios was 35 days in the PP group, versus 3 days in RP ($p < 0.001$), and was documented in 95% of cases. Gestational age at delivery, birth survival, and birthweight discordance were not different between groups.

Conclusion: Persistent polyhydramnios occurred in 7% of patients after laser for TTTS, but ultimately resolved in 95% and was not associated with adverse obstetric outcomes. A trend towards more pyelectasis in PP recipients suggests persistent polyuria as a potential etiology of PP.

Table 1. Persistent polyhydramnios after laser for TTTS

829 | Targeted Regulation of Abortion Providers and Infant Mortality

Madeline F. Perry; Joe M. Feinglass; Lynn M. Yee
Northwestern University Feinberg School of Medicine, Chicago, IL

10:30 AM - 12:30 PM

Objective: Targeted regulation of abortion providers (TRAP laws) are medically unindicated restrictions limiting the provision of abortion, even in states where abortion is legal.

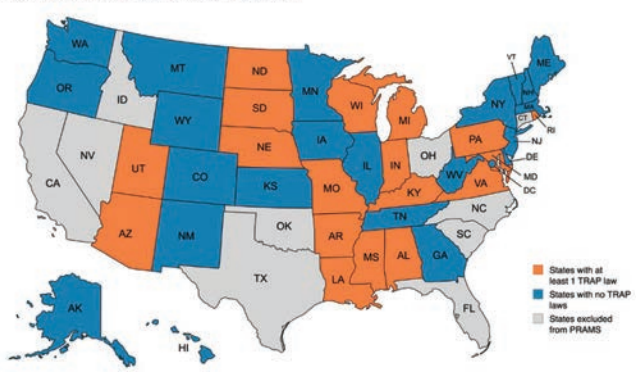
Restrictions on reproductive rights have been associated with adverse maternal and neonatal outcomes. We aimed to evaluate the association of the existence of TRAP laws in a state and state rates of infant mortality.

Study Design: This cross-sectional analysis was performed utilizing 2016-2021 Phase 8 data from the Pregnancy Risk Assessment Monitoring System (PRAMS). PRAMS data were linked with Guttmacher Institute data about state TRAP laws from 2016-2021. Infant death rates were calculated using PRAMS data, which uses respondent self-report. In the PRAMS questionnaire, participants are asked "Is your baby alive now?" If participants answer "no," they are coded as having an infant death. Multivariable Poisson regression testing the association between the existence of TRAP laws in a state and infant mortality was performed, adjusting for individual-level sociodemographic factors from PRAMS.

Results: Among 183,849 participants, representing a weighted population of 9,792,533, 45.2% people lived in states (n = 18) that had at least one TRAP law during the study period (Figure). During the 2016-2021 study period, 0.4% of participants reported an infant death. In adjusted analysis, there was a 29% increased likelihood of infant mortality (aIRR 1.29, 95% CI 1.08, 1.55) in states with TRAP laws in comparison to those without TRAP laws (Table).

Conclusion: TRAP laws are associated with an increased likelihood of infant mortality, even after accounting for individual-level confounders. Restricted access to abortion may result in people with high-risk maternal or fetal health conditions to continue pregnancy rather than receive desired abortion services.

Figure, Map of state TRAP laws from 2016-2021



TRAP, Targeted regulation of abortion providers

TABLE. Poisson regression results for infant mortality by respondent sociodemographic characteristics and state TRAP laws

	Percent reporting infant death (weighted n=9,792,533)	Infant death, aIRR[1]
No TRAP[2] laws	0.33	Reference
At least 1 TRAP law	0.48	1.29 (1.08, 1.55)

TRAP laws, targeted regulation of abortion providers; aIRR, adjusted incident rate ratio; CI, confidence interval; PRAMS, Pregnancy Risk Assessment Monitoring System; BMI, body mass index

PRAMS data is Phase 8 from 2016-2021, states excluded from PRAMS: California, Connecticut, Florida, Idaho, Nevada, North Carolina, Ohio, Oklahoma, South Carolina, Texas. Vermont and Alaska were included in PRAMS but excluded from analysis because of non-reporting of certain sociodemographic data

[1]Percent of PRAMS participants reporting infant death at time of survey completion (generally 2-4 months after delivery) from PRAMS, 183,849 participants representing a weighted population of 9,792,533. Poisson regression, covariates included maternal marital status, maternal age, maternal race and ethnicity, maternal income, year of delivery, Medicaid coverage at time of delivery, preconception uninsurance, neonatal conditions (low birth weight, preterm birth) and maternal conditions (pre-pregnancy diabetes, pre-pregnancy hypertension, diabetes during pregnancy, hypertension during pregnancy, pre-pregnancy BMI)

830 | Targeted Regulation of Abortion Providers and Intimate Partner Violence Before and During Pregnancy

Madeline F. Perry; Joe M. Feinglass; Lynn M. Yee
Northwestern University Feinberg School of Medicine, Chicago, IL

10:30 AM - 12:30 PM

Objective: Targeted regulation of abortion providers (TRAP) laws have been associated with an increased rate of intimate partner violence (IPV)-related homicide. Pregnancy is a uniquely dangerous time for people who experience IPV, yet it is unclear whether abortion restriction on a state level is associated with IPV risk before or during pregnancy. Our objective was to evaluate the association between state-level TRAP laws and IPV before and during pregnancy.

Study Design: We performed a cross-sectional analysis using data from the Pregnancy Risk Assessment Monitoring System (PRAMS) from Phase 8, 2016-2021. PRAMS data were linked to Guttmacher Institute data about TRAP laws from 2016 to 2021. PRAMS asks participants if they were "push[ed], hit, slap[ped], kick[ed], choke[d], or physically hurt in any way?" by their current or ex-partner/husband either in the 12 months before or during pregnancy. IPV before and during pregnancy was defined as answering "yes" to that question. Multivariable Poisson regression analyzing the association between state-level TRAP laws and state percent IPV before and during pregnancy was performed, controlling for individual sociodemographic factors.

Results: In this analysis of 196,451 participants representing a weighted population of 10,267,609 people, 2.5% and 1.7% reported experiencing IPV before and during pregnancy, respectively. Forty-five percent of PRAMS participants lived in states with at

least one TRAP law during the study period (Figure). Multivariable Poisson regression found that participants living in states with TRAP laws had a 14% increased likelihood of IPV before pregnancy and 21% increased likelihood of IPV during pregnancy compared with participants living in states that do not have TRAP laws (aIRR 1.14, 95% CI 1.05, 1.25; aIRR 1.21, 95% CI 1.10, 1.35, respectively; Table).

Conclusion: State restriction to abortion access through TRAP laws is associated with increased rates of reported IPV before and during pregnancy. Further research evaluating how state policies have the potential to both exacerbate and mitigate IPV and maternal health are warranted.

Figure, Map of state TRAP laws from 2016-2021

831 | Quality Improvement Initiative for Respiratory Syncytial Virus Vaccination In Pregnancy- How Can We Do Better?

Madeline Suppiger[1]; Michelle R. Petrich[2]; Miriam Rivkin[3]; Ruizhi Huang[4]; Andrew Storm[5]; Niraj R. Chavan[5]

[1]Saint Louis University School of Medicine, Webster Groves, MO; [2]Saint Louis University School of Medicine, Saint Louis University / St. Louis, MO; [3]St. Louis University, Saint Louis University School of Medicine/ St. Louis, MO; [4]St. Louis University, St. Louis, MO; [5]Saint Louis University School of Medicine, St. Louis, MO

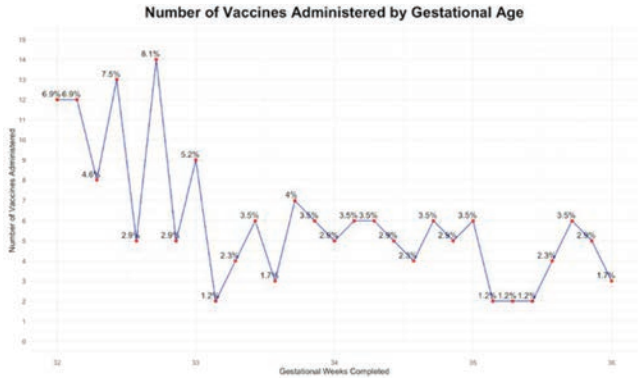
10:30 AM - 12:30 PM

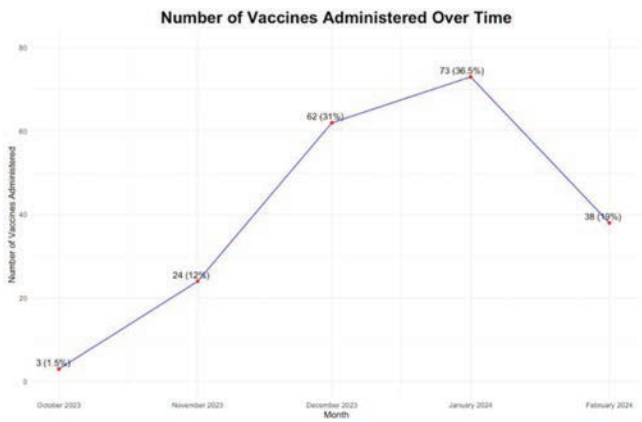
Objective: This study was undertaken to evaluate patterns of perinatal respiratory syncytial virus (RSV) vaccination and to identify strategies to increase vaccine uptake through an institutional quality improvement (QI) initiative.

Study Design: We evaluated rates of perinatal RSV vaccination during the most recent season of vaccine eligibility from October 2023 to February 2024 among patients seeking prenatal care between 32 to 36 weeks gestation at a single academic tertiary medical center. Maternal demographic characteristics, gestational age at vaccination, and number of prenatal visits during eligibility period were abstracted from electronic records and compared across patients who accepted and refused vaccination. Student's t test and chi2 tests were used to compare continuous and categorical data, respectively. We then administered a structured survey at the end of the RSV season among patients who were previously eligible for vaccination to examine reasons for vaccine hesitancy and identify strategies for enhancing vaccine education.

Results: Of 548 eligible patients, 200 (36%) accepted RSV vaccination while 348 (63.5%) did not. Unvaccinated patients were more likely to be Black ($p = .002$), have public insurance ($p = .007$) and attend fewer prenatal visits during eligibility period ($p < .001$). Evaluation of vaccination patterns demonstrated increase in vaccination rates throughout the RSV season with highest rates attained at earlier gestational ages (Figures 1 and 2). Of the 278 patients compliant through postpartum follow up–90 completed the survey (response rate = 32.3%). Primary reasons for vaccine hesitancy were identified as–lack of understanding about vaccine efficacy (40%) and concerns about fetal (30%) and maternal (30%) side effects. Respondents identified handouts (44.1%) and text-based messaging (37.3%) as their preferred approach for receiving vaccine education.

Conclusion: Vaccine education using text-based messaging and handouts with content focused on the clinical benefit and safety of vaccination has the potential to address RSV vaccine hesitancy and enhance perinatal vaccination.





832 | Roll-Over Test as a Screening Tool for Hypertension in Pregnancy - A Prospective Pilot Study

Madhurima K. Keerthy; Vivek Katukuri; Christina Yarrington; Christopher Cox; Conrad Chao; Chloe Fournier-Hall; Mingma Sherpa
University of New Mexico, Albuquerque, NM

10:30 AM - 12:30 PM

Objective: Pre-eclampsia occurs in 3-8% of pregnant patients globally and is more detrimental to rural communities with limited access to care. Early diagnosis and management improve maternal and neonatal outcomes. The screening modalities that are available include mean Blood pressures, uterine artery Dopplers and various angiogenic markers. However, these are not available to rural areas consistently. The aim of our study to evaluate the potential of the low-cost Roll-Over Test to predict hypertensive disease of pregnancies in rural populations.

Study Design: This is a single center pilot prospective cohort study. 56 patients were recruited. Demographic data, Uterine artery Doppler and blood for sflt1/Plgf ratio was obtained between 19wk0d–24w6d. Roll-over Test was conducted by obtaining blood pressures in left lateral and Supine positions, mean change in BP was collected. T-test (continuous) and Chi Square test(categorical) were used for demographic variables.

Receiver Operating Characteristic (ROC) curves generated for ROT change in SBP, DBP and HR for prediction of primary outcome. ROC curves generated for UA PI, First SBP (Initial Systolic BP in pregnancy) and First DBP (Initial Diastolic BP in pregnancy).

Sensitivity and specificity calculated for ROT, Ut PI, First SBP and First DBP.

Results: 14 (26.9%) had primary outcome. 5 (9%) had preeclampsia and 9 (17%) had gestational hypertension. Of the 5, one (1.9%) had HELLP syndrome. A 17-point change in systolic BP on ROT had an optimal sensitivity of 60% and specificity of 80% in diagnosing the primary outcome. A mean diastolic change of 9.6 points was identified to provide a sensitivity of 85% and a specificity of 55%. In this population, Uterine artery Dopplers and angiogenic markers did not perform well in predicting primary outcome.

Conclusion: The low-cost Roll-Over Test is a reasonable screening tool to predict hypertensive disease in pregnancy in rural settings.

833 | Association of Inter-Twin Growth Discordance >25% with Fetosocpic Laser Surgery Outcomes in Twin-Twin Transfusion Syndrome

Manasa G. Rao[1]; Christy Gandhi[1]; Russell S. Miller[1]; Meghan Angley[1]; Rosalie Ingrassia[1]; Lynn L. Simpson[2]; Noelle Breslin[1]
[1]Columbia University Medical Center, New York, NY; [2]Columbia University Irving Medical Center, New York, NY

10:30 AM - 12:30 PM

Objective: Inter-twin growth discordance is associated with adverse pregnancy outcomes in monochrionic-diamniotic (MCDA) twin pregnancies with ≥25% considered a cutoff for pathological discordance. We compared outcomes of fetoscopic

laser surgery (FLS) for twin-twin transfusion syndrome based on presence of absence of discordance ≥25%.

Study Design: Retrospective review of MCDA twins with TTTS that underwent FLS at a single center from 2009-22. Pregnancies with pre-operative inter-twin discordance ≥25% were compared to those < 25%. Primary outcome was donor twin survival at first sonogram after FLS.

Results: 169 MCDA pregnancies underwent FLS and met inclusion criteria. 62 (37%) had discordance ≥25%. Patients with discordance ≥25% were younger (32 ± 5 vs 30 ± 6). GA at TTTS diagnosis and at FLS were similar between groups. Donor twin selective fetal growth restriction (sFGR) was more likely with discordance ≥25% (74.2% vs 23.4%, p< 0.01). Pre-FLS Quintero stage differed between the two groups (p = 0.014), with higher likelihood of stage III and IV in the ≥25% group. Donor twin survival was significantly lower with discordance ≥25% at first post-FLS sonogram (75.8% vs 89.7%, p = 0.02) and at hospital discharge (52.8% vs 73.6%, p = 0.04). After adjusting for age, Quintero stage, and donor FGR, donor twin survival at first sonogram remained lower in patients with discordance ≥25% (p = 0.01). In a subgroup analysis to evaluate discordance in pregnancies with donor sFGR, donor twin survival did not differ at first sonogram post-FLS (78.3% vs 96.0%, p = 0.08) or at hospital discharge (61.5% vs 73.9%, p = 0.3) between the groups. In a subgroup analysis of normally-grown twins, donor twin survival did not differ at first sonogram post-FLS (68.8% vs 87.7%, p = 0.1) but was lower in the ≥25% discordance group at hospital discharge (80.33% vs 45.45%, p = 0.02).

Conclusion: Discordance ≥25% was associated with lower donor twin survival after FLS. While some effect may be attributable to co-existing donor FGR, discordance was associated with survival difference in normally-grown donor twins.

Table 1. Demographics and pregnancy characteristics**

834 | Identifying Optimal Discordance Cutoff for Predicting Donor Survival After Fetosocpic Laser for Twin-Twin Transfusion Syndrome

Manasa G. Rao[1]; Christy Gandhi[1]; Noelle Breslin[1]; Meghan Angley[1]; Rosalie Ingrassia[1]; Lynn L. Simpson[2]; Russell S. Miller[1]
[1]Columbia University Medical Center, New York, NY; [2]Columbia University Irving Medical Center, New York, NY

10:30 AM - 12:30 PM

Objective: An optimal inter-twin discordance cutoff for predicting survival outcomes in monochrionic-diamniotic (MCDA) twin pregnancies is unclear. This study aimed to evaluate the association of inter-twin discordance with donor twin survival after fetosopic laser surgery (FLS) for twin-twin transfusion syndrome (TTTS), and to identify an optimal discordance cutoff.

Study Design: Retrospective review of monochorionic diamniotic (MCDA) twins with TTTS that underwent FLS at a single center from 2009-22. Primary outcome was donor twin survival at first sonogram after FLS. Logistic regression models estimated

association between inter-twin discordance and donor survival at different thresholds. Receiver operating characteristic (ROC) curve analysis was performed to assess predictive accuracy and Youden index was used to determine the optimum cut-point for predictive accuracy.

Results: 169 MCDA pregnancies met inclusion criteria. Discordance cutoffs of ≥25% and ≥30% were significantly associated with donor twin survival at first sonogram post-FLS ($p = 0.03$ and $p < 0.001$, respectively) and this was true after adjusting for donor fetal growth restriction and Quintero stage pre-FLS. In fitting a logistic regression model, discordance as a continuous variable was significantly associated with predicting donor twin survival ($p = 0.02$). The AUC for predicting donor twin survival was 0.63 (95% CI: 0.49, 0.74, $p = 0.060$). Based on the Youden index, the optimum cut point is a discordance of 29%, which has a sensitivity of 0.75, specificity of 0.58, positive predictive value of 0.91 and negative predictive value of 0.29 in predicting donor twin survival.

Conclusion: Inter-twin discordance is a poor predictor of donor twin survival after FLS for TTTS. If it is to be considered in clinical practice, a cutoff value of 29% was most predictive of donor twin survival in this cohort.

Table. Performance of different cut-points of discordance as a predictor of donor twin survival

Discordance	Sensitivity	Specificity	PPV	NPV	LR+	LR-
<20% vs. ≥20%	0.43	0.62	0.86	0.16	1.13	0.92
<25% vs. ≥25%	0.66	0.58	0.90	0.23	1.55	0.59
<30% vs. ≥30%	0.78	0.42	0.88	0.26	1.35	0.53
<35% vs. ≥35%	0.89	0.23	0.86	0.27	1.15	0.48

PPV = Positive predictive value
NPV = Negative predictive value
LR = Likelihood ratio

835 | Health System Level Intervention to Decrease Early Screening Rates for Gestational Diabetes: Associated Perinatal Outcomes

Mara Greenberg[1]; Yeyi Zhu[2]; Jun Shan[2]; Amanda Ngo[2]; Monique Hedderson[3]; Charles Quesenberry[2]; Assiamira Ferrara[2]

[1]Kaiser-Permanente Northern California, Oakland, CA; [2]Kaiser Permanente Northern California, Oakland, CA; [3]Kaiser Permanente Northern California, Pleasanton, CA

10:30 AM - 12:30 PM

Objective: To evaluate a system level intervention intended to decrease rates of gestational diabetes (GDM) screening prior to 24 weeks gestation in relation to perinatal outcomes.

Study Design: Retrospective study of all pregnancies without overt diabetes delivered in Kaiser Permanente Northern California 2018-2022. We performed interrupted time series (ITS) analysis to examine changes in rates of GDM screening and perinatal outcomes in relation to a system-wide intervention to decrease screening < 24 weeks. To reflect the level of exposure to the intervention that started in 4/2020, dates of delivery were categorized in 3 time periods: T1 unexposed (1/2018-3/2020), T2 partially exposed (4/2020-12/2020), and T3 fully exposed (1/2021-12/2022). Primary composite outcome included cesarean delivery, preeclampsia, severe maternal morbidity, large for gestational age neonate, shoulder dystocia, preterm birth, NICU admission, and neonatal hypoglycemia. Patient level factors were examined as potential confounders.

Results: Among 221,068 deliveries, early GDM screening rate decreased from 31.1% in T1, to 20.6% in T2 and 4.3% in T3 (Standardized Mean Difference (SMD) T3 vs T1 -0.75). Patient level characteristics did not vary significantly over time, including measures of social drivers of health and comorbid medical conditions. There was no change in the prevalence of GDM (9.7% in both T1 and T2, 9.0% in T3, SMD T3 vs T1 -0.02). There was no change in the prevalence of the composite primary outcome, which occurred in 43.1% in T1, 44.2% in T2 and 45.2% in T3 (SMD T3 vs T1 0.04). Interrupted time series analysis adjusted for covariates showed no change in risk of the composite outcome during T1 (percent change per 4 weeks [95% CI]): 0.06 [-0.01 to 0.13]), T2 (0.02 [-0.21 to 0.25]), nor T3 (-0.02 [-0.26 to 0.23]). No meaningful changes in prevalence of each individual component of the composite outcome were observed.

Conclusion: A substantial decrease in early GDM screening rate did not impact perinatal outcomes in this large diverse cohort of deliveries within an integrated health care system.

836 | The Illinois Perinatal Syphilis Warmline: A Public Health Initiative to Address the Syphilis Epidemic

Mariana Espinal[1]; Laurie Ayala[2]; Maura Quinlan[3]; Danucha Brikshavana[3]; Irina Tabidze[4]; Helen Cejtin[2]; Nigel Madden[5]; Nkechinyelum Ogu[2]; Stephanie A. Fisher[2]; Lynn M. Yee[2]

[1]for the Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Illinois Department of Public Health, Chicago, IL; [4]Chicago Department of Public Health, Chicago, IL; [5]Beth Israel Deaconess Medical Center, Boston, MA

10:30 AM - 12:30 PM

Objective: In response to the sharp rise in congenital syphilis (CS) cases in the United States and the complexities of perinatal syphilis management, the Illinois Department of Public Health (IDPH) implemented the first statewide perinatal syphilis clinical support warmline to aid CS prevention. We aimed to evaluate the

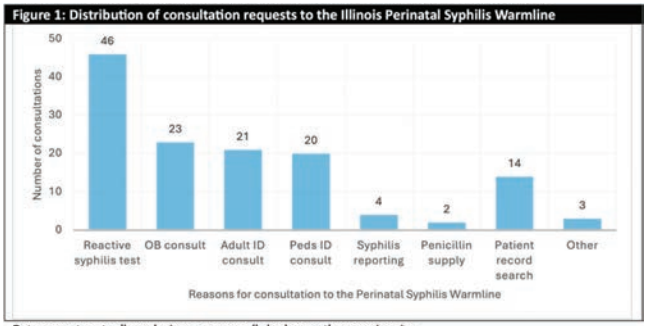
first 9 months of warmline activity and characterize the public health need for perinatal syphilis consultation.

Study Design: The IDPH Perinatal Syphilis Warmline offers remote medical consultation with MFM, adult infectious disease, and pediatric infectious disease experts regarding syphilis diagnosis and treatment during pregnancy and the newborn period, coordinates record searches of prior testing and treatment, and assists in mandatory reporting and linkage to local health department resources. In this prospective cohort study, we performed descriptive analysis of calls to the Warmline from its inception in November 2023 through July 15, 2024.

Results: The Warmline served providers from Chicago (55%), other Illinois areas (40%), and outside Illinois (5%). Of 62 consultations, 53% were from outpatient clinics, 21% from labor and delivery units, and 19% from newborn care units. Consultations were primarily requested by obstetric nurses or nurse practitioners (21%), obstetricians (16%), or pediatricians (16%). Most consultations focused on antepartum (40%) or immediately postpartum (31%) management, mainly due to a reactive syphilis test (Fig. 1). Among 46 consultations for syphilis staging in pregnant or recently postpartum individuals, we identified 2 cases of primary syphilis, 6 early latent, 32 late latent, 4 unknown stage, and 2 false positives (Fig. 2). Among 24 neonatal consultations, by CDC CS surveillance case definitions, 9 were possible CS cases, 8 less likely, 3 unlikely, and 4 unknown (Fig. 2).

Conclusion: This statewide public health initiative has provided critical, timely expertise on diagnosing and managing perinatal syphilis. We offer a blueprint for other public health jurisdictions to adopt this successful model of enhanced public health surveillance and consultation.

Figure 1: Distribution of consultation requests to the Illinois Perinatal Syphilis Warmline



Data are not mutually exclusive, as some calls had more than one inquiry.

Figure 2: Maternal and newborn diagnosis by the Perinatal Syphilis Warmline

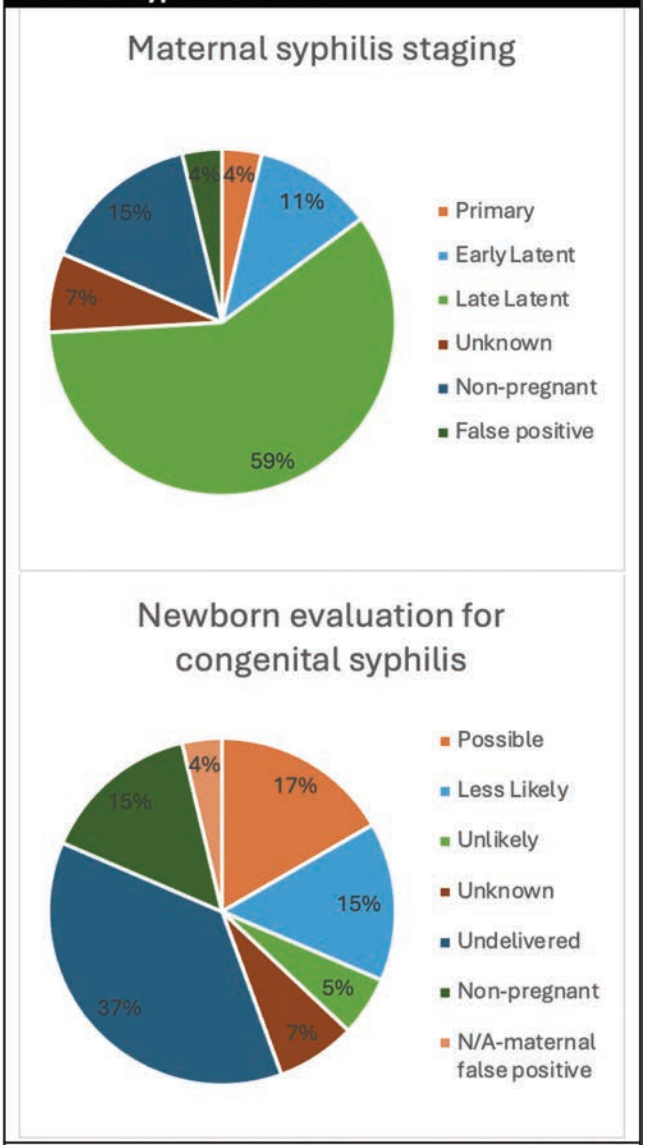


Chart represents 54 consultation requests over a total of 62 calls to the IDPH Perinatal Syphilis Warmline for assistance with maternal syphilis staging and newborn evaluation of CS. Newborn evaluations are described using the Center for Disease Control and Prevention (CDC) Congenital Syphilis scenarios: confirmed proven or highly probable, possible, less likely and unlikely.

837 | Vascular Remodeling of the Maternal Cerebrovascular System

Marie-Laurence Bilodeau; Christine Wilk; Charley Wing; Virginie Gillet; Genevieve Quesnel; Kevin Whittingstall; Annie Ouellet
Université de Sherbrooke, Sherbrooke, PQ

10:30 AM - 12:30 PM

Objective: Pregnancy induces significant changes in the peripheral maternal vasculature, yet whether these changes are also present in the brain is unclear. Magnetic resonance angiography

through Time Of Flight (MRA-TOF) technology allows high-resolution visualization of the cerebral vasculature without the need of contrast agent. The purpose of this study is to investigate maternal intracerebral vessel diameters and intracerebral flow distribution during the third trimester of pregnancy.

Study Design: Five pregnant women experiencing normal pregnancy voluntarily agreed to a MRA-ToF during the third trimester of their pregnancy. The scans took place in 2021 at the Centre Hospitalier Universitaire de Sherbrooke in Fleurimont, Quebec. The images of their main cerebral vasculature were analyzed using an automated software method (eICAB) and compared with 42 non-pregnant women from publicly available database. The mean diameters of each intracerebral vessel forming the Circle of Willis were collected. Statistical standard test was used for comparison.

Results: The mean diameters of the maternal cerebral arteries demonstrated an increase of 23,9% for the internal carotids (4,62 ± 0,2 mm in pregnancy vs 3,73 ± 0,7 mm, p = 0,0001), of 14,8% for the basilar (3,25 ± 0,5 mm vs 2,83 ± 0,6 mm, p = 0,01), of 5,33% for the anterior (2,37 ± 0,1 mm vs 2,25 ± 0,6 mm, p = 0,2) and of 9,4% for the middle cerebral arteries (2,78 ± 0,2 mm vs 2,54 ± 0,7 mm, p = 0,01). However, a decrease of 4,11% was observed in the posterior cerebral artery with diameters of 2,10 ± 0,3 mm vs 2,19 ± 0,4 mm, p = 0,3.

Conclusion: Our preliminary results suggests that most cerebral arteries in the brain slightly dilate during pregnancy. A notable exception is the PCA, which tends to slightly constrict. This may be due to the stimulation of the nervous system in the posterior region, though further study will be needed to confirm these findings.

Overall, these results broaden our understanding of the physiological adaptations of maternal intracerebral vascular flow and distribution during normal pregnancy in the different brain areas.

838 | Financial Benefits of Audacious but Achievable Goals for Improving Maternal and Neonatal Mortality

Mark I. Evans[1]; Gregory F. Ryan[2]; Christian R. Macedonia[3]; David W. Britt[4]; Jaqueline M. Worth[1]; George M. Mussalli[1]; Sean WD Carter[5]; Matthew Kemp[5]; Mahesh A. Choolani[5]; Lawrence D. Devoe[6]

[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Ryan Consulting Services, Burlongton, MA; [3]Lancaster MFM, Lancaster, PA; [4]Fetal Medicine Foundation of America, New York, NY; [5]Yong Loo Lin School of Medicine National University of Singapore, Singapore; [6]Medical College of Georgia at Augusta University, Augusta, GA

10:30 AM - 12:30 PM

Objective: The United States has the highest maternal and neonatal mortality rates (MMR, NMR), of High-Income Countries, disproportionately for people of color. Inadequate prenatal care contributes to these outcomes, producing increased neonatal costs and diminished economic contributions having long-term financial consequences < ![if !supportAnnotations] >[MK1]< ![endif] > (FC). Efforts to improve outcomes and reduce disparities have been hampered by laws requiring most states' require balanced budgets. Unfettered economic arguments are required to justify to gov't agencies the long-term benefits of upfront expenditures for better outcomes for mother and babies and resultant financial benefits for individuals and states. We have introduced a new financial metric (DEVELOP score) measuring long-term FC of governmental (gov't) fiscal policies, including the value of maternal and neonatal lives saved vs typical metrics of costs versus social benefits. Herein, we calculated lives saved and FC of even incremental improvements for every US state by improving its MMR and NMR.

Study Design: Using public, vetted national 2021 databases, we ranked MMR and NMR for all US states and DC from best to worst calculating lives saved and FC (by DEVELOP Score) by modeling better care if every state moved up just 1 spot in the state's ranking (i.e., to next highest ranked state's statistics).

Results: Nationally, moving up just 1 spot on a states' rankings saves 451 neonates and 45 mothers generating an annual increased total FC of $504,313,479 (resultant improved economics of $457,149,465 for neonates and $47,164,015 for mothers. Fig 1).

Conclusion: Mixed financial/social benefit constructs have mostly failed to convince the Federal and State gov'ts to invest sufficiently to substantively improve prenatal and neonatal outcomes. By modeling even modest, reachable gains, our approach provides "cover" for bureaucracies to justify a longer- term vision. Instead of focusing exclusively on curbing expenditures, these monies should be considered as investments which will be considerably profitable in the long run.

State (Rank)	NMR Rate per 100	MMR Rate per 100K	Next Best (Rank)	NMR Rate per 100	MMR Rate per 100K	Total Lives Saved	Total Economic Value Created
MS (51)	9.39	59.73	AR (50)	8.59	58.84	28	$ 15,486,650
NC (40)	6.72	29.88	GA (39)	6.25	29.69	56	$ 55,510,353
TX (20)	5.29	38.81	ID (19)	5.13	36.57	69	$ 79,526,035
NJ (4)	3.57	35.47	MA (3)	3.23	35.18	34	$ 35,239,961
United States	5.44	33.32				496	$ 504,313,480

839 | High Rural Water Per- and Polyfluorinated Alkyl Substances (PFAS) Levels and Preeclampsia

Ellie Baltes[1]; Darrin Thompson[1]; Heath A. Davis[2]; Serena Gumusloglu[1]; Hanna Stevens[1]; David Cwiertny[1]; Donna A. Santillan[1]; Mark K. Santillan[1]

[1]University of Iowa, Iowa City, IA; [2]University of Iowa, Institute for Clinical and Translational Science, Iowa City, IA

10:30 AM - 12:30 PM

Objective: Per- and Polyfluorinated Alkyl Substances (PFAS) are synthetic chemicals used in pesticides. PFAS are found in humans with drinking water as the key route of entry. PFAS exposure in human and preclinical models is associated with preeclampsia (PreE). Yet, adequate control for covariates are limited in previous studies. The objective of this study to estimate the effect of PFAS levels in rural populations on the development of PreE.

Study Design: This retrospective cohort study uses a dataset from the Intergenerational Health Knowledgebase (N = 78,726 pregnancies, IRB#20101369) an integrated datamart of all EHR data of maternal, pediatric, and pregnancy care at the University of Iowa Health Care system. Pregnancies from high PFAS (hiP) areas (N = 1880) were identified by zip codes in which the municipal water tested higher than the maximum contaminant level (MCL) for one PFAS chemical as determined by the Iowa Department of Natural Resources. Low PFAS (loP) pregnancies (N = 1602) were identified by zip codes in which the MCL for any PFAS was not exceeded. Baseline characteristics were compared for both groups (alpha = 0.05). Logistic regression models were

constructed to evaluate the association of municipal water PFOS levels and PreE.

Results: Pregnancies from hiP areas in comparison to loP were significantly more rural by RUCA code (36% vs 3%, p< 0.001), had higher obesity rates (48% vs. 35%, p< 0.001), and higher PreE rates (12% vs. 9%, p = 0.014). Rates of diabetes, racial distribution, and rates of adverse neonatal outcomes were similar between the two groups. After controlling for obesity, race, and diabetes diagnosis, hiP pregnancies were associated with higher odds of developing PreE in comparison to loP pregnancies (aOR = 1.4 [1.1-1.8], p = 0.020).

Conclusion: High rural municipal water PFAS levels are associated with a higher odds of developing PreE even after controlling significant covariates. Future studies should investigate PFAS level exposure at the participant level to determine a more granular association with PFAS levels and PreE development.

840 | Hypertensive Diseases of Pregnancy Are Significantly Associated with Development of Long-Term Neonatal Seizures

Mark K. Santillan[1]; Donna A. Santillan[1]; Serena Gumusoglu[1]; Heath A. Davis[2]; Baojian Xue[1]; Grant Tiarks[1]; Brittany Todd[1]; Angela Wong[1]; Vinit Mahajan[3]; Alan Johnson[1]; Polly Ferguson[1]; Elizabeth Newell[1]; Jason Misurac[1]; Alexander Bassuk[1]
[1]University of Iowa, Iowa City, IA; [2]University of Iowa, Institute for Clinical and Translational Science, Iowa City, IA; [3]Stanford University, Stanford, CA

10:30 AM - 12:30 PM

Objective: Hypertensive Diseases of Pregnancy (HDP) are associated with many long term maternal and child neurologic conditions. While neurodevelopmental and psychiatric conditions and maternal seizures are known to be associated with HDP, the relationship to neonatal seizures (NSz) is not well documented given the overall low rate of NSz. Data suggest common vascular mechanisms in HDP and maternal and offspring neuropathology. The objective of this study is to address the hypothesis that HDP is associated with an increased risk of long-term NSz.

Study Design: This case-control study uses a dataset from the Intergenerational Health Knowledgebase (N = 78,726 pregnancies, IRB#20101369) an integrated datamart of all short-term and long-term EHR data of maternal, pediatric, and pregnancy care at the University of Iowa Healthcare (UIHC) system. A composite case definitions of NSz (G40, R56, P90, R25.9, R40.4) and HDP (O10-11, 13-14, 16, I 10,15) were constructed using ICD-10 codes. Baseline characteristics were compared between cases and controls (alpha = 0.05). Logistic regression models were constructed to evaluate the association between the development of NSz ad HDP.

Results: NSz pregnancies (N = 1370) exhibited significantly higher rates of maternal BMI >40 (16% vs. 12%, p< 0.001), adverse neonatal outcomes (ANO, 59% vs. 35%, p< 0.001), HDP (37% vs. 33%, p< 0.001) in comparison to controls (N = 34297). NSz and control pregnancies had similar gestational ages at delivery (37.7 ± 31.6 vs. 38.1 ± 25.6 weeks, p = 0.571). After controlling for age, gravida, BMI, diabetes in, and race, pregnancies affected by HDP are at higher odds of developing subsequent seizures in the offspring (aOR = 1.132 [1.003-1.278], p = 0.045).

Conclusion: Although overall incidence of NSz is low, our data demonstrate a clear association of a high risk of long-term NSz in neonates born from pregnancies affected by HDP. Further studies should be directed at the human and preclinical shared mechanisms that link hypertensive diseases during pregnancy and neuropathology.

841 | The Association Between Maternal Comorbidity Burden and Severe Neonatal Morbidity

Matthew J. Blitz[1]; Insaf Kouba[2]; Ji Yoon Lee[1]; Annemarie Stroustrup[1]
[1]Northwell, New Hyde Park, NY; [2]Northwell, St. Petersburg, FL

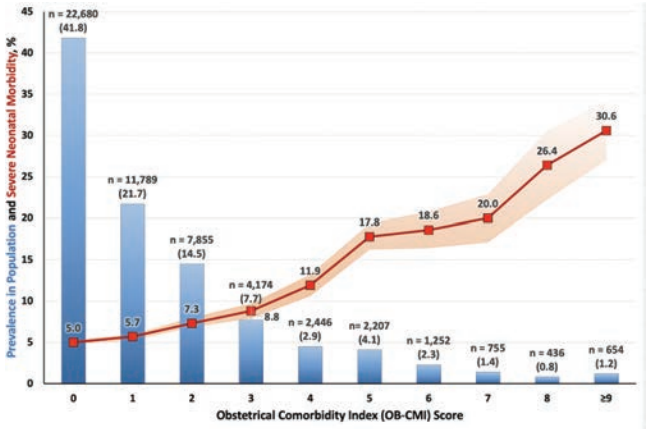
10:30 AM - 12:30 PM

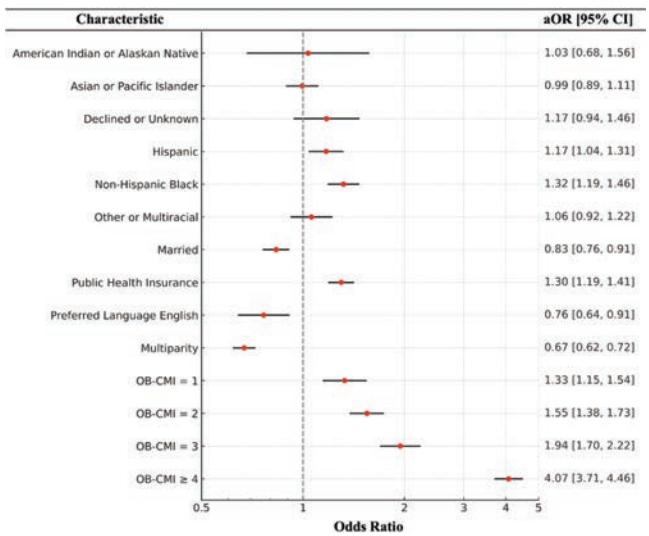
Objective: To determine the association between maternal comorbidity burden and severe neonatal morbidity (SNM), and to evaluate whether racial and ethnic group differences help to explain any disparities in outcomes.

Study Design: This was a retrospective cohort study of all deliveries at ≥23 weeks gestational age at two tertiary hospitals in New York from 2019-2022. Exclusion criteria were fetal demise and multiple gestation. The primary exposure was obstetric comorbidity index (OB-CMI) score, calculated at admission for delivery. This score is based on 24 weighted comorbidity indicators identified by ICD-10 codes and clinical documentation. Covariate factors assessed included race and ethnicity, health insurance, marital status, parity, and preferred language. The primary outcome was SNM, a composite neonatal adverse outcome indicator which includes pre-determined diagnoses and procedures. Multivariable logistic regression was used to model the probability of SNM as a function of OB-CMI score group, while adjusting for covariate factors.

Results: A total of 54,248 patients were included. Non-Hispanic White patients constituted the largest race and ethnicity group (42.8%), followed by Asian or Pacific Islander (18.7%), Non-Hispanic Black (14.5%), and Hispanic (12.2%). The overall SNM rate was 7.6% (n = 4,127). SNM increased from 5% among patients with an OB-CMI score of zero to greater than 30% when OB-CMI scores were 9 or more (Figure 1). Results of regression modeling are presented in Figure 2. Each successive OB-CMI group had an increased odds of SNM, and patients with OB-CMI ≥4 had more than 4 times greater odds of SNM compared to patients with an OB-CMI = 0. Non-Hispanic Black patients and Hispanic patients were at increased risk for SNM compared to non-Hispanic White Patients.

Conclusion: OB-CMI score is positively correlated with SNM. Racial and ethnic disparities in SNM were observed. Future studies should assess if these differences can be better explained by social determinants of health, environmental exposures, genetics, and nutrition.





842 | The use of a Fetal Pillow Device at Full Dilation Cesarean Delivery

Maya Ronen[1]; carmel porat[2]; moshe betser[3]; lee Segev[2]
[1]Shamir Medical Center, Shamir medical Center, HaMerkaz; [2]Shamir Medical Center, Beer Yaacov, HaMerkaz; [3]Shamir Medical Center, beer yaacov, HaMerkaz

10:30 AM - 12:30 PM

Objective: Impacted fetal head at full dilation cesarean delivery (CD) is a major cause of adverse maternal and neonatal outcomes. The Fetal Pillow is a device designed to reduce these complications. Our study aims to evaluate the outcomes of full-dilation CD with and without the use of Fetal Pillow.

Study Design: This retrospective cohort study included full-dilation CDs performed from January 2018 to July 2023, at a single tertiary center. Indications for CDs were arrest of decent, fetal distress and failed vacuum extraction. The study cohort included cases (Fetal Pillow group) matched to controls (without the use of Fetal Pillow) according to the indication to CD, in a 1: 2 ratio. The study evaluated maternal outcomes such as uterine incision extensions, maternal blood loss (ml), maternal postoperative infection and postoperative length of stay (days). Neonatal outcomes included NICU admissions, cord arterial blood pH, Apgar scores, respiratory distress, birth trauma, and encephalopathy.

Results: The study cohort included a total of 138 patients who underwent CD at full dilation. Among them, 46 were in the Fetal Pillow group, and 92 were controls. There were no significant differences between the groups in maternal characteristics such as age, BMI, previous CDs and obstetrics complications. There were also no differences between the groups in the rate of uterine extensions, maternal blood loss, postoperative infection or postoperative length of stay . The fetal pillow group had a lower rate of neonatal NICU admissions compared to the controls (17.3% versus 33.7%, respectively, p = 0.04). There were no differences between the groups in any other fetal outcomes.

Conclusion: The use of Fetal Pillow for impacted fetal head during full dilation CDs was not associated with any maternal complications. The use of Fetal Pillow may reduce NICU admissions.

843 | Chronic Hypertension: Timing of Delivery and Associated Morbidity

Mayra Shafique[1]; Xilin Chen[1]; Molly J. Stout[2]; Lisa Kane Low[1]; Alex Peahl[3]; Michelle Moniz[1]; Jourdan E. Triebwasser[1]
[1]University of Michigan, Ann Arbor, MI; [2]University of Michigan Medical Center, Ann Arbor, MI; [3]Michigan Medicine, Ann Arbor, MI

10:30 AM - 12:30 PM

Objective: The American College of Obstetricians and Gynecologists (ACOG) recommends delivery for uncomplicated chronic hypertension (cHTN) at 37w0d-39w6d. We assessed delivery timing for cHTN and its association with cesarean birth, severe maternal morbidity (SMM), and severe neonatal morbidity (SNM) in a quality collaborative.

Study Design: Retrospective cohort study of nulliparous term singleton vertex births across 71 hospitals using clinically abstracted values from the Obstetrics Initiative, a quality collaborative supported by Blue Cross Blue Shield of Michigan and Blue Care Network. We included births complicated by cHTN from 01/2020 to 12/2023. The exposure was week of delivery and outcomes were cesarean rate, SMM (Centers for Disease Control definition), and SNM (unexpected complications in term newborns, PC-06). Adjusted odds ratios (aOR) were calculated with generalized linear mixed models with hospital random effects (to control for clustering) and adjustment for age, body mass index, diabetes, substance use, and social vulnerability index. A sensitivity analysis excluding 37-week deliveries was performed to assess delivery timing with assumption of better controlled cHTN at later gestational age.

Results: Among 3963 (3.6%) births with cHTN, delivery occurred at 37 (31.1%), 38 (33.8%), 39 (25.4%), and 40+ weeks (9.7%). Compared to 37 weeks, cesarean was lower at 38 (aOR 0.79, 95% CI 0.75-0.84) and higher at 40+ (aOR 1.15, 95% CI 1.10-1.21). SMM and SNM were lower at all gestational weeks compared to 37 weeks (**Table 1**). In the sensitivity analysis SMM was lower (aOR 0.92, 95% CI 0.92-0.93) and SNM was higher (aOR 1.02, 95% CI 1.02-1.02) in births at 39+ weeks versus those at 38 weeks with no difference in cesarean (aOR 0.92, 95% CI 0.82-1.15).

Conclusion: Almost 10% of patients with cHTN delivered at 40+ weeks, outside ACOG recommendations for cHTN. Delivery at 37 weeks is associated with morbidity that is likely related to severity of cHTN or superimposed preeclampsia. If delivery is not

indicated at 37 weeks, there was no clear benefit of delivery at 38 vs. 39 weeks.

Table 1: Risk Adjusted Model Summary Outcome

Gestational weeks	OR	CI	P value
Reference: 37 gestational weeks			
Cesarean			
38	0.79	[0.75, 0.84]	<0.01

844 | Corticosteroid Impact on Umbilical Artery Dopplers in Fetal Growth Restriction Pregnancies: Systematic Review and Meta-Analysis

Meagan Kline[1]; Kendra M. Gray[2]; Rosanne Kho[1]; Sarah Kellerhals[1]; Pamela Garcia-Fillion[3]; N. Brandon Barba[3]
[1]University of Arizona College of Medicine - Phoenix / Banner University Medical Center - Phoenix, Phoenix, AZ; [2]Dignity Health, Phoenix, AZ; [3]University of Arizona College of Medicine - Phoenix, Phoenix, AZ

10:30 AM - 12:30 PM

Objective: Current guidelines recommend the administration of antenatal corticosteroids (ACS) for pregnancies with fetal growth restriction (FGR) and abnormal umbilical artery Doppler (UAD) velocimetry. This systematic review examined the change in UAD after the administration of ACS in pregnancies complicated by FGR and any associations with perinatal outcomes.

Study Design: Seven electronic databases (PubMed, Cochrane Library, OVID Medline, Global Index Medicus, Scopus, Google Scholar and Embase) were searched from 1980 to May 2024 using MESH-terms for studies in English. Eligible studies provided a FGR definition and documentation of UAD prior to and after ACS administration. All studies were independently evaluated following PRISMA guidelines. Risk of bias was assessed via the ROBIN-I tool. Meta-analysis was conducted using the metafor package for R.

Results: A total of 13 studies were included with a total of 585 pregnancies. Six studies reported changes in end-diastolic flow (EDF) while 7 studies reported on pulsatility index (PI). Baseline PI decreased from 2.06 (95% CI, 1.63-2.49) to 1.78 (95% CI, 1.39-2.17) after administration of ACS, but subsequently returned to a baseline PI of 2.00 (95% CI, 1.56-2.43) at time of final Doppler evaluation. In studies evaluating EDF, 44% (95% CI, 33-55%) of patients showed improvement. Patients with improvement in EDF were found to have a lower rate of perinatal mortality compared to persistent absent or reversed EDF (6% vs. 12%).

Conclusion: Evidence suggests that UAD assessment after administration of ACS in fetuses with FGR may result in a transient change in UAD. Improvement of UAD after ACS may prognosticate more favorable perinatal outcomes. This systematic review and meta-analysis did highlight that the studies evaluating UAD changes in pregnancies affected by FGR are inconsistent in the metrics used to evaluate these changes. A set of standardized metrics is necessary for reporting ultrasound changes and perinatal outcomes in studies of Doppler changes following ACS in pregnancies affected by FGR.

Study	Chang 2012	Piazze 2012	Prasannan 2020	Raghuraman 2020	Simchen 2003	Tica 2021	Total

845 | Leveraging Pharmacogenomic Data for Methadone Dosing in Pregnancy

Megan B. Raymond[1]; Dennis Hand[2]; Michael Tarallo[1]; Walter Kraft[3]; Rupsa C. Boelig[4]
[1]Thomas Jefferson University, Philadelphia, PA; [2]Jefferson Center for Maternal Addiction Treatment Education and Research, Philadelphia, PA; [3]Thomas Jefferson University Hospital, Philadelphia, PA; [4]Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA

10:30 AM - 12:30 PM

Objective: Opioid use disorder (OUD) in pregnancy remains a significant cause of maternal/infant morbidity in the United States, making appropriate OUD treatment in pregnancy critical. Pregnancy increases methadone metabolism, and studies in non-pregnant adults demonstrate that CYP2B6 genetic variants are associated with altered methadone metabolism. Current protocols for methadone management in pregnancy do not take into consideration the potential impact of CYP2B6 phenotype, and data on how CYP2B6 phenotype impacts methadone dosing in pregnancy are lacking.

Study Design: This is a prospective study of pregnant patients with OUD admitted for inpatient methadone stabilization. Methadone stabilization followed a standardized protocol involving withdrawal assessments every four hours, as-needed methadone doses based on withdrawal scores, and daily dose increases until stability. Participants underwent sampling for a pharmacologic study, collection of medical history and details of dosing through hospitalization, and CYP2B6 genotyping. CYP2B6 phenotype was characterized as either rapid metabolizer or not (slow, intermediate or normal). Primary outcome was final dose at discharge.

Results: Of N = 40 enrolled, 29 had successful genotyping (Table 1), and 3/29 (10%) were rapid metabolizers. Rapid metabolizers had a higher mean dose at discharge, although this was not statistically significant (177+/-90mg vs 125mg +/-75mg, mean difference 52mg (-43mg to 147mg), p = 0.27). These results were results similar when restricted to participants in the 2nd trimester. Two patients who were rapid metabolizers left against medical advice prior to stable dose. The last dose they received was used for analysis.

Conclusion: Pregnant patients treated for OUD with a CYP2B6 rapid metabolizer phenotype had a trend toward a higher mean dose of methadone than non-rapid metabolizers; although our cohort was underpowered for statistical significance. This may support an impact of CYP2B6 genotype on methadone systemic exposure, which has implications for optimizing dosing protocol in pregnancy.

Table 1. Patient Demographics and Associated Methadone Stable Dose by Metabolizer Status

	Rapid Metabolizer[1] (N=3)	Non-Rapid Metabolizer[2] (N=26)	p-value
Race White Black Asian Other	 2 (57%) 1 (33%) 0 (0%) 0 (0%)	 16 (62%) 7 (27%) 0 (0%) 3 (12%	 0.82
Ethnicity Non-Hispanic Hispanic	 3 (100%) 0 (0%)	 24 (92%) 2 (8%)	 0.62
Trimester at admission 1st 2nd 3rd	 0 (0%) 3 (100%) 0 (0%)	 7 (27%) 12 (46%) 7 (27%)	 0.21
Maternal age	34.0±2.5	32.1±5.5	0.57
Maternal BMI	25.1±1.5	26.5±5.9	0.70
Methadone dose at discharge mean±SD	177±90mg	125mg ±75mg	0.27 MD 52mg (-43mg to 147mg)
Methadone dose at discharge (2nd trimester only) mean±SD	177±90mg	110±85mg (n=12)	0.25 MD 67mg (-52-187)

Data presented as N(%) or mean±standard deviation. MD: mean difference by independent sample t-test

1 Rapid Metabolizer Diplotypes included *1/*4 and *1/*22
2 Non-Rapid Metabolizer Phenotypes included normal metabolizers, poor metabolizers, and intermediate metabolizers

846 | Prolonged Second Stage: How Does Obesity Influence Likelihood of Successful Vaginal Delivery?

Xiang Yu Feng[1]; Christina Frasik[1]; Megan C. Oakes[2]
[1]University of California, Irvine Division of Maternal-Fetal Medicine, University of California, Irvine, CA; [2]MemorialCare Miller Children's and Women's Hospital Long Beach, Miller Children's and Women's Hospital, Long Beach, CA

10:30 AM - 12:30 PM

Objective: In 2024, ACOG revised clinical guidelines supporting the definition of a prolonged second stage labor as ≥ 3 hours. We sought to evaluate the difference in vaginal delivery rate for nulliparous patients with a singleton, term, vertex fetus (NTSV) with prolonged second stage between those with and without obesity.

Study Design: A retrospective cohort study of NTSV patients with a prolonged second stage of labor (≥ 3 hours) delivered at a single tertiary care hospital from 6/1/2023-12/31/2023. Obesity was defined as body mass index (BMI) ≥30 kg/m^2 at delivery. The primary outcome was vaginal delivery and secondary outcomes were select maternal and neonatal morbidities. Categorical variables were compared using Chi square, Fisher's exact and normally distributed continuous variables using Student's T test, as appropriate. Multivariable logistic regression was used to adjust for confounders.

Results: 173 patients with a prolonged second stage were included, 99 (57.2%) without obesity and 74 (42.8%) with obesity. Patients with obesity were more likely to have hypertension (p = 0.04) and hypertensive disorders of pregnancy (p = 0.02), as well as utilize oxytocin in the second stage (p = 0.04). 94 (94.9%) patients without obesity achieved a vaginal delivery compared to 62 (83.8%) with obesity (RR 0.88, 95% CI 0.67-0.98). After adjusting for confounders and compared to patients without obesity, patients with obesity were noted to have an adjusted relative risk of 0.81 (95% CI 0.54-0.96) for vaginal delivery. There was no difference between the groups with regard to operative vaginal delivery and maternal and neonatal morbidities. These findings persisted after adjusting for confounders.

Conclusion: While patients with obesity had a lower likelihood of vaginal delivery after a prolonged second stage compared to patients without obesity, both groups were overall highly successful in delivering vaginally and no differences in likelihood for select maternal or neonatal complications occurred. These findings may aid in counseling patients with a prolonged second stage.

Table 1: Baseline demographics between NTSV patients without obesity and with obesity

	BMI <30 (n=99)	BMI ≥30 (n=74)	P-value

847 | Perinatal Outcomes in Pregnant Patients with a History of Migraine Headaches

Megha Arora; Bharti Garg; Aaron B. Caughey
Oregon Health & Science University, Portland, OR

10:30 AM - 12:30 PM

Objective: To examine maternal and neonatal outcomes among pregnant patients with and without a history of migraine headaches.

Study Design: We conducted a retrospective cohort study of births in the state of California from 2008-2020 to compare perinatal outcomes between those with and without history of migraine headaches. Singleton, non-anomalous deliveries at 23-42 weeks of gestation were used. Outcomes included gestational hypertension, preeclampsia, severe maternal morbidity (SMM), preterm birth (< 37 weeks), NICU admission, and respiratory distress syndrome (RDS). We performed multivariable logistic regression controlling for age, race/ethnicity, education, pre-pregnancy BMI, parity, and insurance status to estimate adjusted odds ratios (aOR) with 95% confidence intervals.

Results: In the cohort of 5,065,732 individuals, there were 48,518 (0.96%) individuals with history of migraines. There were higher rates of migraines among those who were white, highly educated, and privately insured. On multivariable regression, those with migraines had higher odds of gestational hypertension (7.1% vs 3.4%; aOR 1.75, 95% CI 1.69-1.82), preeclampsia (6.7% vs 3.8%; aOR 1.70, 95% CI 1.64-1.76), SMM (2.0% vs 1.2%; aOR 1.71, 95% CI 1.61-1.83), preterm delivery (8.8% vs 6.4%; aOR 1.45, 95% CI 1.40-1.50), and neonatal RDS (4.5% vs 2.3%; aOR 1.75, 95% CI 1.67-1.83).

Conclusion: In this large cohort of pregnant patients, those with a history of migraines were more likely to experience adverse perinatal outcomes, despite the presence of multiple protective social determinants with respect to socioeconomic status and experience of racism. This signals that there may be physiologic or structural vulnerabilities among individuals with migraines contributing to adverse outcomes during pregnancy which require further characterization.

Table 1. Proportions and adjusted odds ratios for adverse outcomes in patients with and without a history of migraines in California (2008-2020)

	No history of migraines	History of migraines	P*	aOR (95% CI)**
Gestational hypertension	3.4%	7.1%	<0.001	1.75 (1.69-1.82)
Preeclampsia	3.8%	6.7%	<0.001	1.70 (1.64-1.76)
Severe maternal morbidity (SMM)	1.2%	2.0%	<0.001	1.84 (1.72-1.96)
Preterm birth <37 weeks	6.4%	8.8%	<0.001	1.45 (1.40-1.50)
Respiratory distress syndrome	2.3%	4.5%	<0.001	1.75 (1.67-1.83)

*Chi-square test
**Adjusted for maternal race and ethnicity, age, education, pre-pregnancy BMI, insurance and parity.

848 | Association of Interpregnancy Interval and Perinatal Outcomes Among Individuals with History of Pprom

Megha Arora; Bharti Garg; Ava D. Mandelbaum; Aaron B. Caughey
Oregon Health & Science University, Portland, OR

10:30 AM - 12:30 PM

Objective: To examine the association of interpregnancy interval with adverse perinatal outcomes among individuals with a history of preterm prelabor rupture of membranes (PPROM).

Study Design: This was a retrospective cohort study of two consecutive births in California between 2008-2020 among patients with a history of PPROM in the index pregnancy. Interpregnancy interval (IPI) was categorized as < 12 months, 12-23 months, 24-35 months, 36-59 months, and ≥60 months. Outcomes included gestational hypertension, preeclampsia, preterm birth (< 37 weeks), severe maternal morbidity (SMM), and primary cesarean delivery. Chi squared and multivariable logistic regression were used for statistical analysis.

Results: In our cohort of 15,271 individuals with a history of PPROM in an index pregnancy, 3,299 (21.6%) had a short IPI (< 12 months) and 1,537 had a long IPI (≥60 months). As compared to IPI of 12-23 months, pregnancies with IPI< 12 months had greater odds of preterm birth (24.10% vs 19.54%; aOR 1.22, 95% CI 1.09-1.37), SMM (1.52% vs 0.86%; aOR 1.58, 95% CI 1.03-2.43), and primary cesarean delivery (11.3% vs 9.26%; aOR 1.28, 95% CI 1.08-1.53). Pregnancies with IPI≥60 months also had increased odds of adverse outcomes including preeclampsia (6.57% vs 3.63%; aOR 1.66, 95% CI 1.28-2.15), preterm birth (24.20% vs 19.54%; aOR 1.22, 95% CI 1.06-1.41), SMM (1.95% vs 0.86%; aOR 1.85, 95% CI 1.12-3.03), and primary cesarean (13.63% vs 9.26%; aOR 1.45, 95% CI 1.17-1.80).

Conclusion: Both short (< 12 months) and long (≥60 months) IPIs were associated with adverse perinatal outcomes among patients with a history of PPROM. These findings highlight the importance of counseling those with PPROM in a prior pregnancy on optimal pregnancy timing to mitigate risks in subsequent pregnancies.

Table 1. Unadjusted rates of perinatal outcomes associated with interpregnancy intervals among pregnant patients with a history of PPROM

	<12 months N=3,299	12-23 months N=4,764	24-35 months N=2,903	36-59 months N=2,768	≥60 months N=1,537	p-value*

849 | Preconception Hormone Levels are Associated with Preterm Birth and Measures of Maternal Stress and Mood

Melissa Scott[1]; Sharon Hunter[2]; M. Camille Hoffman[2]
[1]University of Colorado School of Medicine, Department of Obstetrics & Gynecology, University of Colorado, CO; [2]University of Colorado School of Medicine, Aurora, CO

10:30 AM - 12:30 PM

Objective: Chronic stress during pregnancy has been associated with adverse pregnancy outcomes (APOs) including preterm birth (PTB). In addition, progesterone is crucial in the maintenance of pregnancy and deficiency can increase the risk of miscarriage and PTB. Assessment of hormone levels in human hair provides a stable, non-invasive measurement of chronic hormonal activity. Our objective was to determine the association between preconception maternal hair cortisol and progesterone levels and APOs.

Study Design: Preconception hair hormone levels (HHLs), mood, and APOs were evaluated in participants who were part of a larger prospective cohort study during which maternal hair was cut 3 times during pregnancy: around 16 weeks, 28 weeks, and delivery. As the proximal 1cm of hair from the scalp represents ~one preceding month of hair growth, segments longer than 3 cm at 16 weeks were considered to represent the preconception period. HHLs were analyzed using mass spectrometry. Participant data was collected via chart review and interview. Our primary outcome was the relationship between preconception HHLs and delivery < 37 weeks (PTB). Secondary outcomes included: pre-eclampsia/PIH (PREE) and maternal mood questionnaires including the State-Trait Anxiety Inventory (STAI), Center for Epidemiologic studies-depression scale (CESD). Data were analyzed using Spearman correlations, $p < 0.05$ considered significant.

Results: Of 163 participants, 110 and 34 participants had preconception cortisol and progesterone HHLs available for analysis, respectively. Correlations were noted between cortisol and PTB ($r = 0.20$, $p = 0.04$) and progesterone and STAI and CESD scores ($r = 0.34$, $p = 0.03$ and $r = 0.33$, $p = 0.042$). Additional correlations ($p > 0.05$) included positive relationships between cortisol and: PREE and CESD score at all gestational ages.

Conclusion: Higher preconception cortisol is correlated with higher risk of PTB and higher preconception progesterone correlates with depression and anxiety. These data improve our understanding of the complex relationships between preconception stress, mood, and pregnancy outcomes.

850 | Can Remote Blood Pressure Monitoring Reduce Racial Disparities in Outcomes Among Postpartum Patients with Hypertension?

Shana D. Talbot[1]; Tracy L. Jackson[2]; Scott Machado[2]; Nicole Konecke[2]; William Hunt[2]; Maria Mejia Castillo[2]; Danielle Simmons[2]; Heather A Smith[1]; Nina K. Ayala[1]; William A. Grobman[3]; Adam K. Lewkowitz[2]; Methodius G. Tuuli[1]
[1]Women & Infants Hospital of Rhode Island / Alpert Medical School of Brown University, Providence, RI; [2]Women & Infants Hospital of Rhode Island / Alpert Medical School of Brown University., Providence, RI; [3]The Ohio State University, Columbus, OH

10:30 AM - 12:30 PM

Objective: Remote self-measured blood pressure (SMBP) monitoring programs have been shown to reduce racial inequity in postpartum blood pressure ascertainment. However, their effect on disparities in healthcare utilization and severe maternal morbidity (SMM) is less clear. We aimed to compare outcomes between participants in our remote SMBP program who self-identified as Black versus non-Hispanic White.

Study Design: Postpartum individuals with hypertension (HTN) at our tertiary hospital are offered enrollment in our remote SMBP program. For this analysis, participants who did not self-identify as Black or non-Hispanic White were excluded. The primary outcome was a composite of HTN-related postpartum readmission or ED visit within 30 days of delivery. Secondary outcomes were individual components of the primary composite, HTN-related SMM, and anti-hypertension medication initiation or titration. A log-link binomial generalized linear model was used to estimate relative risks (aRR) adjusting for potential confounders.

Results: Among 2003 participants in the SMBP program from 2022 - 2024, 1363 met inclusion criteria. Of these, 988 (49.3%) self-identified as non-Hispanic White and 375 (18.7%) as Black. Compared to non-Hispanic White participants, Black participants were younger, and more likely to have public insurance and gestational HTN (**Table 1**). After adjusting for these factors, there was no significant difference in the composite of HTN-related postpartum readmission or ED visit between Black and non-Hispanic White participants (19.2% vs 16.7%; aRR 1.29, 95% CI 0.98, 1.69). Risk of HTN-related readmission alone was significantly higher among Black participants (12.2% vs 9.9%; aRR 1.48, 95% CI 1.03, 2.11). There was no significant difference in HTN-related SMM (12.5% vs 11.7%; aRR 1.00, 95% CI 0.72, 1.42). There was also no difference in anti-hypertensive medication initiation or titration (**Table 2**).

Conclusion: Our remote SMBP program for postpartum patients with HTN eliminated racial disparities in overall HTN-related healthcare utilization and HTN-related SMM.

Table 1: Demographics of participants

851 | Should Fasting Blood Glucose Value on the Ogtt be Incorporated Into Initial Gestational Diabetes Counseling?

Mia A. Heiligenstein[1]; Erica Glaser[2]; Elianna Kaplowitz[2]; Guillaume Stoffels[3]; Camila Johanek[3]; Thomas Owens[4]; Olivia Grubman[5]; Xiteng Yan[2]; Sophia Scarpelli-Shchur, RN, CDE[2]; David Cole[2]; Zainab Al-Ibraheemi[4]; Andrei Rebarber[6]; Lois Brustman[4]

[1]Mount Sinai West, Astoria, NY; [2]Mount Sinai West, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Icahn School of Medicine at Mount Sinai West, New York, NY; [5]Westchester Medical Center, Westchester, NY; [6]Icahn School of Medicine at Mount Sinai Hospital, New York, NY

10:30 AM - 12:30 PM

Objective: Hypoglycemic agents are used to optimize glycemic control in the treatment of GDM.The aim of this study was to assess the predictability of the fasting blood glucose value(FBS) on the OGTT in predicting the need for hypoglycemic agents in patients with GDM.

Study Design: This study was a single-center retrospective cohort study of singleton pregnancies with GDM between 2018-2023.Diagnosis was made by Carpenter-Coustan(CC) criteria.Initial management involved dietary and lifestyle modifications, with hypoglycemic agents introduced if blood glucose values were above threshold(FBS > 90mg/dl, 2hpp > 120mg/dl or 1hpp > 140mg/dl).Receiver operating characteristic curves(ROC) were generated to determine predictability of FBS on the OGTT for the need for hypoglycemic agents.Predictability of FBS on OGTT was evaluated using the clinical cut-off values of 81mg/dl(based on the Youden's Index),95mg/dl(based on CC) and 105mg/dl(based on NDDG). Sensitivity, specificity, positive and negative predictive values were calculated.

Results: 1,407 patients diagnosed with GDM, 567(40%) were prescribed hypoglycemic agents. There was a statistically significant difference between patients that required hypoglycemic agents in regards to age, BMI, race, and history of GDM.FBS on OGTT was predictive of need for hypoglycemic agents based on the ROC curve with an AUC of 0.76 (95% CI 0.74-0.79), indicating a 76% chance that FBS on GTT can distinguish between patients who did and did not need hypoglycemic agents(Figure 1). The value with the highest Youden's Index was 81mg/dl.A cut-off value of 95mg/dL had the highest positive predictive value(PPV); of women who had ≥ 95mg/dL FBS on OGTT, 75.25% required hypoglycemic agents, whereas 32.9% of patients with a FBS < 95mg/dl needed hypoglycemic agents(Table 1).

Conclusion: Our data suggests that if a patient has a FBS of ≥ 95mg/dL there is a 75% chance that they will require hypoglycemic agents.This can be used during initial counseling to educate patients diagnosed with GDM on the possibility of the need for hypoglycemic agents and provide reassurance to patient's with FBS < 95mg/dL.

Figure 1: Predicted Probabilities for need for hypoglycemic agents among patients with GDM based on FBS on OGTT

10:30 AM - 12:30 PM

Objective: This study aimed to identify antenatal characteristics that best predict the need for hypoglycemic agents in patients with gestational diabetes (GDM).

Study Design: This study was a single-center retrospective cohort study of patients with singleton pregnancies between 2018-2023, diagnosed with GDM between 24-34 weeks gestation by Carpenter-Coustan criteria on a 3hour OGTT. Hypoglycemic agents were added when optimal control was not achieved as determined by serial finger stick analysis (FBS < 95mg/dl,

postprandial values at 1h 140mg/dl, 2h 120mg/dl).Logistic regression models were developed to determine the need for hypoglycemic agents and included commonly associated predictors of disease severity. Data collected included age, body mass index (BMI), race, gestational age (GA) at diagnosis, history of GDM, and the 1h, 2h, and 3h OGTT values.Model 1 utilized only the fasting OGTT value as the predictor.Model 2 included the aforementioned variables excluding the fasting OGTT value.Model 3 incorporated the fasting OGTT value along with the other predictors from Model 2.

Results: 1,407 patients were diagnosed with GDM;567(40%) were prescribed hypoglycemic agents.

A comparative analysis of the three models was performed to evaluate their predictive performance(Table 1, Figure 1).Model 1, using only the fasting OGTT value, had an area under the curve (AUC) of 0.77.Model 2, which excluded the fasting OGTT value, had an AUC of 0.71.Model 3, incorporating both the fasting OGTT value and the other predictors from Model 2, achieved an AUC of 0.76.This was significantly different from Model 2 ($p < 0.0001$) and Model 1 ($p = 0.0021$) (Table 1).

Conclusion: Our model suggests that the fasting value on the OGTT alone (Model 1) is a significant predictor of the need for hypoglycemic agents when compared to common predictors for disease severity (Model 2). Therefore, the isolated fasting value is a valuable clinical predictor in assessing the risk for hypoglycemic agents and should be used when counseling patients.

Figure 1. Comparison of receiver operating characteristic (ROC) curve for three predictive models

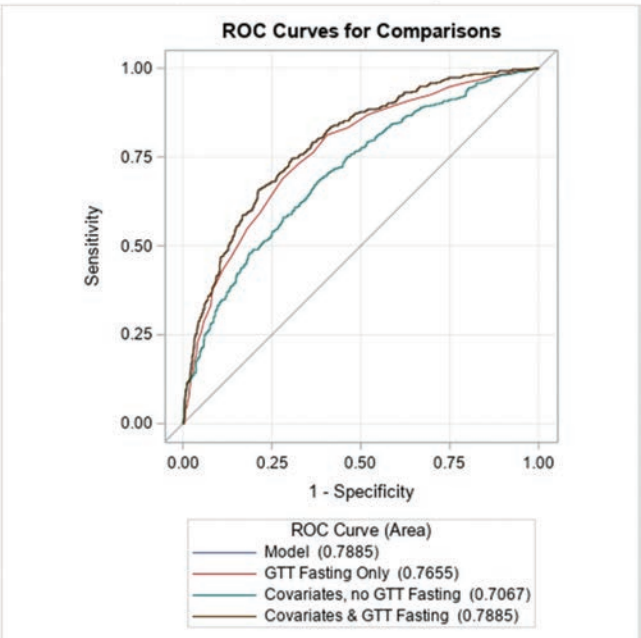

Table 1. Model performance predicting need for hypoglycemic agents among patients with GDM

Predictive model	Selected predictors	AUC	P value M1 vs. M2	P value M2 vs. M3	P value M1 vs. M3
Model 1 (M1)	GTT Fasting	0.77 (0.74, 0.79)	0.0003		
Model 2 (M2)	Age, BMI, race, GA at entry, hx GDM, GTT 1 hr GTT 2 hr, GTT 3 hr	0.71 (0.68, 0.73)		<0.0001	
Model 3 (M3)	GTT Fasting, Age, BMI, race, GA at entry, hx GDM, GTT 1 hr GTT 2 hr, GTT 3 hr	0.79 (0.76, 0.81)			0.0021

§ Multivariable logistic regression models were used and AUCs were compared between models.

853 | Randomized Controlled Trial of Detemir versus NPH in Gestational and Type 2 Diabetes: DETERMINE Study

Michael Richley[1]; Kandace Fung[2]; Megan C Oakes[3]; Ann Nguyen[4]; Aisling M. Murphy[5]; Thalia Mok[5]; Jenny Lester[2]; Lorna Kwan[2]; Maral Demirjian[2]; Rebecca Gerl[2]; Dana Levin-Lopez[2]; Matthew Freeby[2]; Alice Sherman-Brown[4]; Judith H. Chung[6]; Christina S. Han[2]

[1]University of Washington, Seattle, WA; [2]UCLA, Los Angeles, CA; [3]MemorialCare Miller Children's and Women's Hospital, Long Beach, CA; [4]UC Irvine, Orange, CA; [5]University of California, Los Angeles, Los Angeles, CA; [6]University of California- Irvine, Irvine, CA

10:30 AM - 12:30 PM

Objective: Diabetes mellitus (DM) is one of the most common complications in pregnancy. Neonatal hypoglycemia (HG) as a result of DM is associated with NICU admissions and delay to milestones. We hypothesized that the longer-acting insulin detemir may yield lower rates of neonatal HG, compared to intermediate-acting NPH in pregnancies with GDM or T2DM.

Study Design: We conducted a prospective, multi-center, unblinded, randomized-controlled trial. Subjects requiring insulin initiation during pregnancy were randomized 1:1 to detemir or NPH. IRB approval and clinicaltrials.gov registration were obtained. Primary outcomes were rates of neonatal HG (< 45 mg/dl) in the first 24 hours of life, and persistent HG (< 50 mg/dl) beyond 24 hours. Secondary outcomes were rates of maternal, antenatal and neonatal complications. Data were analyzed using Wilcoxon Rank sum, Chi-Square or Fisher's exact tests. Uni- and multivariable logistic regressions were performed. Planned enrollment was 336, but the trial was halted early due to discontinuation of detemir in 2024.

Results: 73 subjects were recruited (NPH: 38, Detemir: 35). Demographic differences were not noted for most categories, but intake A1c (NPH: 5.7%, IQR 5.5-6.0%; Det: 6.8%, IQR 6.0-8.7%; $p = 0.021$) and race (more Asian/Caucasian in NPH versus more Black in detemir) differed, likely due to early termination of study. No differences were noted in rates of HG (44.4 v 36.4%, $p = 0.495$) or persistent HG (5.6 v 6.1%, $p = 1.0$), even after controlling for DM type, preterm birth, BMI and site. No differences were noted for secondary neonatal outcomes (Table 2). Rates of postpartum hemorrhage were higher for NPH (36.8 v 8.8%, $p = 0.005$), but no other differences in maternal outcomes were noted, including mode of delivery, HTN, insulin drip, lacerations, or infection (Table 1).

Conclusion: No difference in rates of neonatal HG were seen between NPH and detemir groups. This study is limited by early termination of the trial due to discontinued production of detemir. Further studies will need to be performed to compare currently available basal insulins in management of DM in pregnancy.

Table 1: Maternal outcomes by type of insulin (N=73)			
	NPH (n=38)	Detemir (n=35)	P-value

854 | Development of a Benchtop Model of Cervical Laceration with Cerclage in Situ

Alyssa L. Trochtenberg[1]; Alexandra Denisevich[2]; Skylar Murphy[2]; Joanna Chase[3]; Mireyda Perez Hernandez[3]; Tim Looney[4]; Walfre Franco[3]; Devon Campbell[5]; Michael House[6]
[1]Tufts University School of Medicine, Tufts University School of Medicine, MA; [2]Cx Therapeutics, Lowell, MA; [3]University of Massachusetts, Lowell, Lowell, MA; [4]Northeast Biomedical, Tyngsboro, MA; [5]Prodct, LLC, Lexington, MA; [6]Tufts Medical Center, Boston, MA

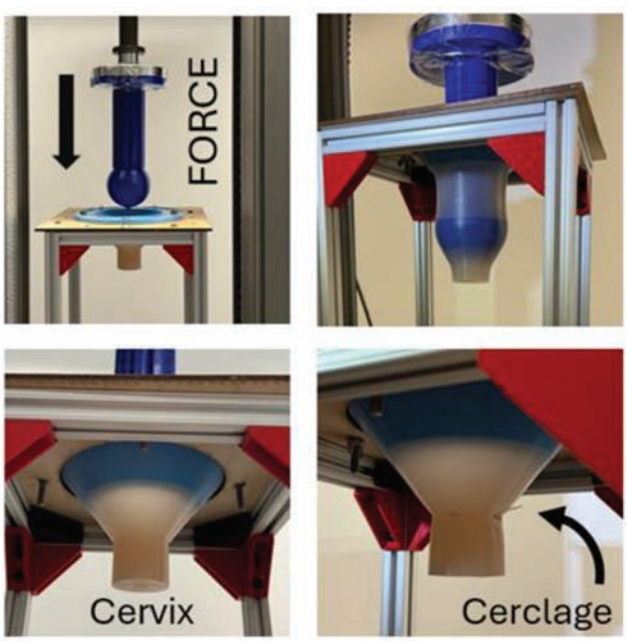
10:30 AM - 12:30 PM

Objective: Our long-term objective is the development of a novel medical device as a cerclage alternative. Cervical laceration is a known complication of cerclage. One goal of the medical device is to reduce the risk of cervical laceration. However, no benchtop model of cervical laceration exists. Thus, we sought to develop a three-dimensional (3D) benchtop model to study cervical laceration using a silicone-based cervix that mimics the stiffness of the human cervix in pregnancy.

Study Design: The silicone cervix model consisted of two parts (see "Cervix" image in Figure). The upper part (blue color) was composed of Smooth-Sil 950 (Smooth-On, Macungie, PA). The lower part (the cervix, tan color) was composed of Ecoflex, a soft silicone (Smooth-On). The silicone cervix formula was selected to match the mechanical properties of human cervical tissue based on pilot studies, as follows: 1-part Ecoflex 00-30 Part A; 1-part Ecoflex Part B; 3-parts SmoothOn silicone thinner . Ecoflex was first poured into the bottom portion of a 3D printed mold and cured to make the silicone cervix. Next, Smooth Sil 950 was added to fill the mold. The stiffness of the silicone cervix was tested with the Pregnolia system (Pregnolia, Switzerland) (N = 9). To assess cervical laceration, the silicone cervix was mounted on a test fixture attached to an Instron machine. A 3D printed fetal head (diameter 8.9 cm) was pushed through the silicone cervix (Figure, top right) (N = 6). Outcomes were compared between silicone cervices with no cerclage and with an O-Vicryl cerclage suture. Silicone tearing was used as an estimate of the risk of cervical laceration

Results: The mean (± SD) stiffness of the silicone cervix was 168 ± 17 millibar, which is similar to the stiffness of the human cervix in previously published studies. Silicone cervices without a cerclage had no tearing. However, tearing occurred in all silicone cervices with a cerclage in place ($P = 0.002$).

Conclusion: We designed a benchtop model that reliably simulates cervical laceration, which can be used to study alternate devices for the treatment of cervical insufficiency.



855 | The Prevalence of Food Insecurity at Time of Delivery and Associated Peripartum Outcomes

Miriam L. Hernandez-Zepeda; Monica Rincon; Amy M. Valent; Bharti Garg
Oregon Health & Science University, Portland, OR

10:30 AM - 12:30 PM

Objective: Food insecurity is the social condition of having limited or uncertain access to adequate food. Nutritional requirements increase in pregnancy, however the impact of food insecurity in pregnancy is not well understood. The objective of this study was to determine the incidence of food insecurity at our institution, and to investigate the relationship between food insecurity and peripartum and neonatal outcomes.

Study Design: Prospective cohort study of all pregnant or postpartum people admitted to Oregon Health and Science University from August 2023 to February 2024 to 1) determine the prevalence of food insecurity and 2) compare perinatal outcomes between those that screened positive for food insecurity to those secure. After informed consent, participants filled out the United States Department of Agriculture (USDA) Six-Item Short Form to screen for food insecurity. Chi-square and t-tests were used for statistical analysis.

Results: Of the 1273 pregnant people admitted during this study period, 232 were screened for food insecurity and 51 screened positive (22%). Of the 51 people who screened positive, 56.9% received a social work consult, 35.3% declined a social work consult, and 27.5% were eligible but not enrolled in food assistance programs. People with food insecurity were younger (28.8 ± 5.7 vs 33.4 ± 5.1 years old, $P < 0.001$), not married (31.4% vs 79.6%, $P < 0.001$), among underrepresented racial/ethnic groups (54.9% vs 28.8%, $P < 0.001$), have government insurance (80.4% vs 21.0%, $P < 0.001$), and have higher prenatal EPDS scores (10.4 vs 4.4, $P < 0.001$). People with food insecurity trended to have higher rates of iron deficiency anemia, higher postpartum EPDS scores, and lower rates of breastfeeding. Neonatal outcomes were similar between both groups.

Conclusion: Food insecurity is an important social driver of health that can affect anyone. Understanding the relationship between food insecurity and peripartum and neonatal outcomes as well as individual perceptions to receiving help is critical to addressing inequities that impact health.

Table 1: Perinatal outcomes in pregnant people who are food insecure compared to food secure.

Perinatal Outcomes	Food Insecure (n=51)	Food Secure (n=181)	P-value
Hypertensive disorders of pregnancy	6 (11.8%)	35 (19.3%)	0.21
Gestational diabetes	6 (11.8%)	37 (20.4%)	0.16
Total gestational weight gain, Median (IQR)	10.4 (5.9-16.4)	12.3 (7.8-16.7)	0.34
Iron deficiency anemia	16 (31.4%)	38 (21.0%)	0.12
Mode of delivery			0.76
Spontaneous vaginal	30 (58.8%)	103 (56.9%)	
Operative vaginal	0 (0.0%)	6 (3.3%)	
Scheduled cesarean	10 (19.6%)	33 (18.2%)	
Unscheduled cesarean	10 (19.6%)	38 (21.0%)	
Estimated or quantitative blood loss	797.6 ± 872.7	658.9 ± 586.5	0.19
Postpartum hemorrhage	2 (3.9%)	3 (1.7%)	0.30
Breastfeeding	40 (78.4%)	161 (89.0%)	0.05
Postpartum EPDS score	8.7 ± 5.3	4.7 ± 4.8	0.02

IQR = interquartile range

856 | Association of Co-Occurring Chronic Hypertension and Oligohydramnios on Neonatal Outcomes

Miriam L. Hernandez-Zepeda; Bharti Garg; Alyssa R. Hersh; Kristin C. Prewitt; Aaron B. Caughey
Oregon Health & Science University, Portland, OR

10:30 AM - 12:30 PM

Objective: Oligohydramnios has been associated with uteroplacental insufficiency and occurs at a higher rate among patients with chronic hypertension. However, the additional risk associated with oligohydramnios and adverse neonatal outcomes has not been well elucidated in this population, which is already at higher risk of adverse outcomes. The objective of this study was to investigate the association between oligohydramnios and chronic hypertension on neonatal outcomes.

Study Design: This is a retrospective cohort study comparing pregnant persons with chronic hypertension who had oligohydramnios versus no oligohydramnios. We used a California cohort of singleton, non-anomalous pregnancies with late preterm or term births (34 to 41 weeks) who delivered between 2008 and 2020. Chi-squared and multivariable logistic regression models were used for statistical analysis with a p-value of 0.05.

Results: Of the 434,362 pregnant persons with chronic hypertension who met inclusion criteria, 14,867 had oligohydramnios (3.4%). Pregnant persons with chronic hypertension with oligohydramnios were significantly different by race/ethnicity, body mass index, and parity compared to those without oligohydramnios. The rate of preexisting diabetes was similar between groups (4.3% vs 4.0%, $P = 0.13$). Oligohydramnios was associated with a higher adjusted odds of preterm birth (aOR 1.58; 1.51-1.65), NICU admission (aOR 1.13; 95% CI 1.07-1.19), small for gestational age (aOR 2.43; 95% CI 2.34-2.53), and stillbirth (aOR 1.81; 95% CI 1.05-3.12).

Conclusion: This study demonstrates that oligohydramnios with chronic hypertension is associated with adverse neonatal outcomes. Our study can enhance patient knowledge and provider counseling to mitigate neonatal impacts of co-occurring diagnoses.

Table 1: Neonatal outcomes among pregnant persons with chronic hypertension oligohydramnios.

Neonatal Outcomes	No oligohydramnios (N = 419,495)	Oligohydramnios (14,867)	Odds Ratio (95% CI)
Preterm birth (<37 weeks)	13.0%	19.1%	1.58 (1.51 - 1.65)
NICU admission	12.1%	15.2%	1.13 (1.07 - 1.19)
Apgar score at 5 minutes (< 7)	1.6%	1.7%	0.93 (0.81 - 1.06)
Small for gestational age	13.4%	28.0%	2.43 (2.34 - 2.53)
Respiratory distress syndrome	1.22%	1.26%	0.83 (0.71 – 0.97)
Neonatal death	0.06%	0.11%	1.62 (0.94 - 2.79)
Infant death	0.16%	0.20%	1.16 (0.78 - 1.73)
Stillbirth	0.13%	0.25%	1.81 (1.05 - 3.12)
Placental abruption	1.44%	1.64%	1.03 (0.90 - 1.18)

Analyses adjusted for race/ethnicity, age, educational attainment, body mass index, insurance type, parity, prenatal care attendance, gestational age, pre-existing diabetes mellitus. Stillbirth was analysis using 2016-2020 data.

857 | Association Between Prenatal Exposure to Environmental Phthalates and Phenols with Adverse Pregnancy Outcomes

Misa Hayasaka[1]; George R. Saade[2]; Tetsuya Kawakita[2]
[1]Department of Obstetrics and Gynecology, Macon and Joan Brock Virginia Health Sciences at ODU, Norfolk, VA; [2]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA

10:30 AM - 12:30 PM

Objective: To evaluate the association between prenatal exposure to phthalates and phenols with adverse pregnancy outcomes.

Study Design: This prospective cohort study used data from the Environmental Influences on Child Health Outcomes (ECHO) consortium, which includes longitudinal data on over 30,000

pregnancies from 69 cohorts across the US. Participants were singleton pregnant individuals with data on urinary chemical concentrations at least one time during pregnancy and pregnancy outcomes. Urinary chemical measurements were performed separately by cohort. Individuals were classified into quartiles of various urinary chemical levels. Outcomes examined included preterm birth (PTB), small for gestational age (SGA), and gestational diabetes mellitus (GDM). Generalized estimating equations models with Poisson distribution and robust variance were used to estimate relative risks (RR) with 95% confidence intervals (95%CI) using the lowest quartile as the reference. All models were adjusted for maternal age, education, race and ethnicity, prepregnancy body mass index, marital status, and study cohorts.

Results: Among the 5,749 participants, 543 (9.4%) had PTB, 335 (5.8%) had SGA, and 401 (7.0%) had GDM. Table 1 presents the urinary levels of the chemicals assayed and the number of samples. Models showed that higher quartiles of phthalates and phenols were associated with an increased risk of PTB and SGA, whereas no significant associations were found for GDM (Table 2). The highest risk of PTB was noted with the 4th quartile of phthalic acid (RR 1.67; 95% CI 1.22-2.28) compared to the 1st quartile. The highest risk for SGA was observed with the 4th quartile of mono-isononyl phthalate (RR 2.37; 95%CI 1.57-3.58).

Conclusion: Pregnancy exposure to phthalates and phenols, ubiquitous environmental chemicals, could be preventable risk factors for PTB and SGA. Further study is needed to confirm these observations and identify the exposure sources.

858 | Association of Postpartum Hemorrhage Management with Risks of Hysterectomy, Icu Admission, and Severe Maternal Morbidity

Moeun Son[1]; Jennifer F. Culhane[2]; Evan Miller[3]; Sara Handley[4]; Heather Burris[5]; Jay Greenspan[3]; Kathryn M. McKenney[6]; Lindsey Knake[7]; Robert Whetsel[8]; Kristie Baisden[8]; Leah Berhane[8]; Kevin Dysart[3]
[1]Weill Cornell Medicine, New York, NY; [2]Yale School of Medicine, New Haven, CT; [3]Nemours Children's Hospital, Wilmington, DE; [4]Children's Hospital of Pennsylvania, Philadelphia, PA; [5]Children's Hospital of Philadelphia, Philadelphia, PA; [6]University of Colorado, Denver, CO; [7]University of Iowa, Iowa City, IA; [8]US Food and Drug Administration, Silver Spring, MD

10:30 AM - 12:30 PM

Objective: To examine if varying management strategies of postpartum hemorrhage (PPH) is associated with hysterectomy, intensive care unit (ICU) admission, and severe maternal morbidity (SMM).

Study Design: This retrospective cross-sectional study utilized Epic Systems' Cosmos research platform, a US-based electronic health record database with de-identified patient-level data. Individuals with an inpatient birth, PPH ICD-10-CM code, and PPH treatment from 1/1/17-12/31/23, without a placenta accreta spectrum ICD-10-CM code were included. Management strategies were categorized into 4 groups: "less aggressive medication use only" (2 types with < 2 doses of either or 1 type with < 3 doses); "more aggressive medication use only" (3 types, 2 types with ≥2 doses of either, or 1 type with ≥3 doses; "less aggressive medication plus procedure(s)"; and "more aggressive medication plus procedure(s)". Medications included carboprost, methylergonovine, and tranexamic acid. Procedures included insertion of intrauterine device, curettage, and uterine artery embolization. Outcomes were hysterectomy, ICU admission, and

SMM with and without transfusion during the birth encounter. Bivariable and multivariable logistic regression analyses were performed.

Results: Of 277,585 patients treated for PPH, 84.9% received less aggressive medication use only (Table). There were 1,951 (7 per 1,000) hysterectomies, 6,383 (2.3%) ICU admissions, and 18,474 (6.7%) SMM cases without and 45,238 (16.3%) with transfusion. Patients with PPH procedures regardless of medication use, were more likely to undergo hysterectomy and experience SMM than those with less aggressive medication use only. Compared to patients with less aggressive medication use only, those with aggressive medication use only were significantly less likely to experience SMM without transfusion.

Conclusion: Higher odds of hysterectomy and morbidity among patients with PPH procedures could represent delay in definitive treatment or confounding by indication (more severe PPH cases). Either way, these procedures are markers of increased risk for hysterectomy, ICU admission, and SMM.

Table. Outcomes associated with type of postpartum hemorrhage (PPH) management among 277,585 patients with PPH

	Hysterectomy		Intensive Care Unit admission		SMM^ without blood transfusion		SMM^ including blood transfusion	
PPH Management	n (%)	aOR (95% CI)*	n (%)	aOR (95% CI)*	n (%)	aOR (95% CI)*	n (%)	aOR (95% CI)*
Less aggressive medication use only (n=235,605, 84.5%)	1,237 (0.5)	Referent	3,892 (1.6)	Referent	14,532 (6.1)	Referent	34,036 (14.0)	Referent
More aggressive medication use only (n=16,576, 6.0%)	92 (0.6)	1.29 (0.99-1.64)	299 (1.8)	1.08 (0.94-1.25)	747 (4.5)	0.70 (0.64-0.77)	2,670 (16.0)	1.25 (1.19-1.31)
Less aggressive medication use + procedure(s) (n=21,065, 7.6%)	541 (2.5)	3.48 (3.06-3.94)	1,815 (8.4)	4.38 (4.07-4.71)	2,671 (12.0)	1.77 (1.68-1.87)	6,934 (32.0)	2.77 (2.67-2.87)
More aggressive medication use + procedure(s) (n=4,339, 1.6%)	81 (1.8)	3.03 (2.27-3.96)	377 (8.5)	4.14 (3.58-4.78)	524 (12.0)	1.68 (1.50-1.88)	1,598 (36.0)	3.59 (3.33-3.87)

SMM=severe maternal morbidity, PPH=postpartum hemorrhage, aOR=adjusted odds ratio, CI=confidence interval
^Severe maternal morbidity (SMM) cases were identified using the United States Centers for Disease Control and Prevention (CDC)'s algorithm based on 21 SMM indicators and corresponding ICD-10 codes

859 | The Association Between Umbilical Artery End Diastolic Flow and Growth Velocity in Growth Restricted Fetuses

Mohammad Salameh[1]; Joshua Brunton[2]; Megan E. Branda[1]; Regan Theiler[1]
[1]Mayo Clinic, Rochester, MN; [2]Virginia Commonwealth University, Richmond, VA

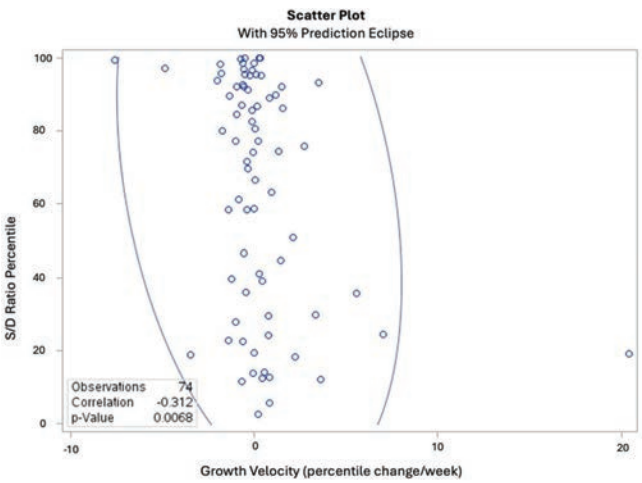
10:30 AM - 12:30 PM

Objective: Growth velocity is receiving increasing attention as a potential marker of fetal wellbeing. We aimed to investigate the relationship between umbilical artery diastolic flow, an established surveillance tool, and growth velocity.

Study Design: We conducted a retrospective cohort analysis of pregnant patients aged 18-45 years old who delivered between 2012 and 2022. Pregnancies with congenital abnormalities or multiple gestations were excluded. Growth velocity was defined as the difference between estimated fetal weight percentiles at 26-32 weeks and at 32-36 weeks divided by the time between ultrasound (percentile change per week). The last systolic to diastolic (S/D) ratio obtained between 32-36 weeks was chosen as the marker of umbilical artery end diastolic flow. A linear correlation model was used to investigate the relationship between S/D ratio percentile and growth velocity.

Results: 324 patients met inclusion criteria, and 74 patients had at least one umbilical artery study between 32-26 weeks. The range of growth velocity was -7.58-20.40/week (mean = 0.31/week). The range of S/D ratio percentiles was 2.46%-99.98% (mean = 63.70%); all patients had forward diastolic flow. There was a negative correlation between S/D ratio percentile and growth velocity with r = -0.31 (p< 0.01). This is shown in Figure 1.

Conclusion: Decreasing umbilical artery diastolic flow correlated with fetal growth deceleration over the weeks preceding the umbilical artery doppler exam. Additional studies are needed to determine whether using growth velocity combined with umbilical artery doppler studies improves prediction of fetal compromise and adverse neonatal outcomes.



860 | Leveraging Deep Neural Networks of Transvaginal Cervical Characteristics to Predict Delivery Timing

Peinan Zhao[1]; Joshua Goyert[2]; Methodius G. Tuuli[3]; Adam K. Lewkowitz[4]; Julie Tumbarello[5]; Emily Dively, BSN[6]; Madeline Felske[5]; Wendy Sparks[5]; Giselle Kolenic[2]; Molly J. Stout[7]
[1]Washington University, St. Louis, MO; [2]University of Michigan, Ann Arbor, MI; [3]Women & Infants Hospital of Rhode Island / Alpert Medical School of Brown University, Providence, RI; [4]Women & Infants Hospital of Rhode Island / Alpert Medical School of Brown University., Providence, RI; [5]University of Michigan Hospital, Ann Arbor, MI; [6]Washington University School of Medicine, St. Louis, MO; [7]University of Michigan Medical Center, Ann Arbor, MI

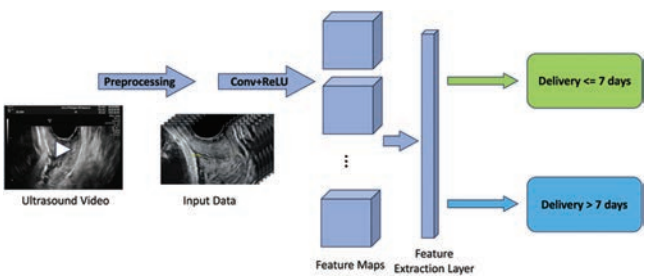
10:30 AM - 12:30 PM

Objective: To utilize deep neural networks of biomechanical characteristics obtained from transvaginal ultrasound videos to predict timing of delivery within 7 days at term.

Study Design: This is a prospective longitudinal cohort of patients who underwent fully quantitative cervical elastography (FQ-CES) starting at 37 weeks and weekly thereafter until delivery. FQ-CES quantifies cervical tissue stiffness utilizing a transvaginal ultrasound probe to quantify both pressure applied and tissue deformation to allow operator independent comparisons. Singleton pregnancies at 37 weeks without delivery planed before 39 weeks were enrolled. FQ-CES and cervical length (CL) were collected weekly until delivery. Patients remained enrolled regardless of their eventual timing or indication for delivery. Transvaginal ultrasound videos from FQ-CES exams were used to build a deep convolutional neural network with *Xception* architecture. The primary outcome is delivery within 7 days.

Results: 118 individuals with 241 FQ-CES ultrasound exams were included. 80% of data was randomly selected as training dataset with a 5-fold cross-validation split. Among 241 FQ-CES exams, 102 (42.3%) delivered ≤7 days and 139 (57.7%) delivered >7 days. Frames from ultrasound videos were treated as individual image inputs. For multiple image predictions inside one FQ-CES exam, majority vote method was applied. The deep convolutional neural network showed high predictive performance including high 92% sensitivity, 90% specificity, and accurate prediction of delivery within 7 days in 91% of the population. In contrast, the network utilizing CL < 2cm showed lower prediction performance (Table)
Conclusion: Deep learning models based on FQ-CES videos have much higher predictive performance for delivery within 7 days. This may be due to the ability to capture characteristics related to anatomy, biomechanical properties, and cervical tissue interaction with surrounding tissues. This technique could be be leveraged to capture intricate cervical characteristics to predict delivery timing.

Prediction Metrics	Cervical length	FQ-CES (Deep learning)
Sensitivity	26.3%	91.7%
Specificity	91.6%	90.3%
Pos. Pred. Value (PPV)	67.4%	86.3%
Neg. Pred. Value (NPV)	65.3%	94.2%
Accuracy	59.0%	91.0%



861 | Vaccine Perceptions Among Hispanic Pregnant and Lactating Individuals During the COVID-19 Vaccine Introduction

Monica Sosa; Mindy Pike; Porshia Underwood; Carolina Martinez-King; Rjika Lottes; Janet A. Englund; Linda Eckert; Alisa B. Kachikis
University of Washington, Seattle, WA

10:30 AM - 12:30 PM
Objective: To investigate vaccine perceptions and hesitancy of Hispanic pregnant and lactating individuals in the setting of the COVID-19 vaccination implementation.
Study Design: An online prospective cohort study of people who were pregnant, lactating, or planning pregnancy launched in January 2021 shortly after approval of the COVID-19 vaccination. Race and ethnicity data were collected using the Centers for Disease Control and Prevention's National Health Interview Survey categories. Participants in this IRB-exempt study completed surveys via REDCap online including one on vaccine perceptions. We performed statistical analysis using Chi-square tests and Fisher's exact tests for categorical variables and t-tests and Wilcoxon rank sum tests for normal and non-normal continuous variables, respectively.
Results: Among the 26,322 participants, 1,618 identified as Hispanic and 24,704 as non-Hispanic. Most participants were well-educated (94.0%) and worked in healthcare (53.0%). Hispanic participants were less likely to gain knowledge about vaccines from physicians compared to non-Hispanic participants (n = 1,190, 73.6%; n = 19,020, 77.0%; p = 0.001) and reported using the internet (n = 266, 16.4%; n = 3,512, 14.2%; p = 0.01), social media (n = 105, 6.5%; n = 1.201, 4.9%; p = 0.003) and radio (n = 65, 4.0%; n = 763, 3.1%; p = 0.04) more than non-Hispanic participants. Compared to non-Hispanics, Hispanics trusted physicians less (p = 600, 37.8%; p = 10,104, 41.6% p = 0.002) and medical literature more (p = 366, 23.0%; p = 4,696, 19.4%; p = 0.002) regarding knowledge on vaccines. On average Hispanic participants reported a lower understanding on which vaccines they and their children should receive (p< 0.001) however no difference noted regarding understanding on how vaccines work or vaccine schedules (p = 0.81 and p = 0.11, respectively) compared to non-Hispanic participants.
Conclusion: When compared to non-Hispanic people, Hispanic participants report a greater use of non-traditional methods to gain vaccines knowledge and report trusting their physicians less and medical literature more on vaccines.

Figure 1.1 Responses to where Hispanic and non-Hispanic patients obtain vaccination knowledge

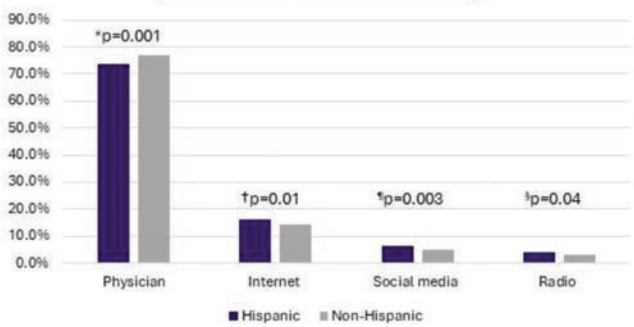


Figure 1.2: The source Hispanic and non-Hispanic patients trust the most for knowledge about vaccinations

862 | The Impact of Antepartum Fibroid Characteristics on Severe Maternal Morbidity

Moti Gulersen[1]; David Krantz[2]; Burton Rochelson[2]; Matthew J. Blitz[2]
[1]*Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA;* [2]*Northwell, New Hyde Park, NY*

10:30 AM - 12:30 PM

Objective: To evaluate the association between uterine fibroids and their characteristics (e.g. number, size) with severe maternal morbidity (SMM).

Study Design: Multicenter retrospective cross-sectional study of all singletons who had a prenatal ultrasound at ≥ 18 weeks and delivered from 2019-2023. Fibroid characteristics were documented when identified on ultrasound. Patients with >1 delivery during the study period had only their first included for analysis. The primary outcomes were SMM, defined based on the Centers for Disease Control and Prevention list of 21 indicators, and non-transfusion SMM. Both were assessed based on the presence of any fibroid, fibroid number (1, 2, ≥3), and size (largest dimension < 5cm, 5-10cm, >10cm), compared to patients with no fibroids. Multivariate logistic regression was performed to adjust for maternal race/ethnicity and obstetric comorbidity index, a validated screening tool used to predict SMM. Data were presented as adjusted odds ratios (aOR) with 95% confidence intervals (CI).

Results: Of the 79,802 patients included, 4,756 (6.0%) had at least one fibroid. The prevalence of SMM and non-transfusion SMM were 4.3% and 1.1%, respectively. Outcomes are displayed in the Table. The presence of any fibroid, regardless of number or size, was associated with an increased risk of SMM. There was no statistically significant association between fibroids and non-transfusion SMM. Patients with more and larger fibroids were at higher risk of SMM compared to those without fibroids. Fibroid number and size did not impact the risk of non-transfusion SMM. After adjusting for fibroid number and size, patients with fibroids in the lower uterine segment or cervix were at higher risk of SMM compared to those without fibroids in that location (aOR 1.48, 95% 1.12-1.96).

Conclusion: The association between fibroids and their characteristics with risk of SMM is likely related to hemorrhage. Providers should consider these risks and interventions to help reduce such risk when caring for patients with fibroids during pregnancy and their delivery.

Table. The association between fibroids and their characteristics with SMM and non-transfusion SMM.

		aOR* (95% CI)	
		SMM	Non-transfusion SMM
Any fibroid	No fibroids	Reference	
	Fibroids	1.34 (1.19-1.51)	1.06 (0.82-1.37)
Number of fibroids	No fibroids	Reference	
	1	1.24 (1.06-1.45)	1.09 (0.79-1.50)
	2	1.28 (1.00-1.65)	0.95 (0.54-1.66)
	≥3	1.69 (1.35-2.13)	1.11 (0.66-1.87)
Fibroid size based on largest dimension	No fibroids	Reference	
	<5cm	1.09 (0.93-1.28)	1.06 (0.77-1.46)
	5-10cm	1.58 (1.31-1.91)	1.16 (0.78-1.75)
	>10cm	2.92 (2.03-4.19)	0.54 (0.13-2.19)

*Models adjusted for maternal race/ethnicity and obstetric comorbidity index (OB-CMI). OB-CMI was entered into the model as a categorical variable.

863 | The Impact of Antenatal Corticosteroids on Severe Neonatal Morbidity in Preterm Births

Moti Gulersen[1]; Frank I. Jackson[2]; Ashley N. Battarbee[3]; Vincenzo Berghella[1]; Matthew J. Blitz[2]
[1]*Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA;* [2]*Northwell, New Hyde Park, NY;* [3]*Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL*

10:30 AM - 12:30 PM

Objective: Studies evaluating the impact of antenatal corticosteroids (ACS) have typically included a wide gestational age (GA) range of preterm births. We aimed to evaluate whether antenatal corticosteroid (ACS) exposure is associated with a decreased risk of severe neonatal morbidity (SNM) in the periviable, early, and late preterm periods.

Study Design: Retrospective cohort study of all singleton preterm births (PTBs) between 22 0/7-36 6/7 weeks' gestation at 2 tertiary academic medical centers from 2019-2022. Patients who had neonates that were not actively resuscitated at birth, intrauterine fetal demise, and missing data were excluded. The primary outcome of SNM, a standardized composite neonatal adverse outcome indicator which includes diagnoses and procedures from the neonatal intensive care unit indicative of severe morbidity, was compared between PTBs exposed to ACS prior to delivery and those unexposed. We compared SNM by ACS exposure stratified by 4 gestational age of delivery groups: 22 0/7-25 6/7, 26 0/7-29 6/7, 30 0/7-33 6/7, and 34 0/7-36 6/7 weeks of gestation. Multivariate logistic regression was performed to adjust for potential confounders. Data were presented as adjusted odds ratios (aOR) with 95% confidence intervals (CI).

Results: Of the 5,070 preterm births included, 2,456 (48.4%) were exposed to ACS prior to delivery. ACS was associated with a lower odds of SNM among PTBs occurring at 22 0/7-25 6/7 weeks of gestation, but the association at 26 0/7-29 6/7 and 30 0/7-33 6/7 weeks was not statistically significant (Table). Among late

PTBs (34 0/7-36 6/7 weeks), ACS exposure was associated with an increased risk of SNM compared to those unexposed (Table).
Conclusion: Our data suggest that the effect of ACS on neonatal outcomes varies by GA at delivery with improved outcomes at periviable GA and worse outcomes in the late preterm period. This differential effect should be considered when counseling patients and deciding if and when to administer ACS.

Table. Severe neonatal morbidity compared between ACS exposed and unexposed preterm births.

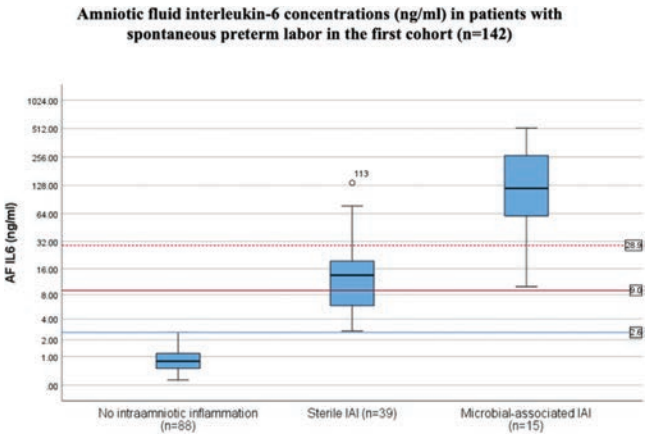
		ACS Exposed	ACS Unexposed	aOR* with 95% CI
Severe neonatal morbidity**	22 0/7-25 6/7 weeks	62/86 (72.1)	36/38 (94.7)	0.13 (0.02-0.50)
	26 0/7-29 6/7 weeks	230/270 (85.2)	57/66 (86.4)	0.87 (0.35-1.97)
	30 0/7-33 6/7 weeks	470/715 (65.7)	140/202 (69.3)	0.79 (0.55-1.12)
	34 0/7-36 6/7 weeks	351/1,385 (25.3)	442/2,308 (19.2)	1.49 (1.25-1.76)

Data are presented as number (percentage).
*Models adjusted for maternal age, body mass index, race/ethnicity, nulliparity, pregestational diabetes, chronic hypertension.
**Composite of ≥ 1 of the following: neonatal resuscitation, continuous positive airway pressure, respiratory distress syndrome, mechanical ventilation, any body cavity surgical procedure, blood transfusion, Intraventricular hemorrhage, sepsis, pneumothorax, chest tube insertion, pneumonia, bronchopulmonary dysplasia, necrotizing enterocolitis, periventricular leukomalacia, hypoxic ischemic encephalopathy, cerebral infarction, exchange transfusion, retinopathy of prematurity, seizures, brachial plexus injury, neonatal death within 28 days of birth or before discharge from hospital.

864 | Preterm Labor with Intact Membranes: the Differential Diagnosis Between Intraamniotic Infection and Sterile Intraamniotic Inflammation

Mousa Eissa[1]; Roberto Romero[2]; David R. Bryant[3]; Fatima Ali[4]; Arun Mezzayhagan[3]; Tinnakorn Chaiworapongsa[3]
[1]Detroit Medical Center, Detroit, MI; [2]Pregnancy Research Branch, Division of Obstetrics and Maternal-Fetal Medicine, Division of Intramural Research, Eunice Kennedy Shriver NICHD, NIH, DHHS, Bethesda, Maryland, USA, Bethesda, MD; [3]Wayne State University School of Medicine, Detroit, MI; [4]Detroit Medical Center/Wayne State University, Detroit, MI

10:30 AM - 12:30 PM
Objective: Preterm labor (PTL) is a syndrome caused by multiple pathologic processes. Intraamniotic inflammation is a major cause of preterm birth and neonatal morbidity/mortality. The two causes of intraamniotic inflammation [intraamniotic infection (IAI) and sterile intraamniotic inflammation (S-IAI)] can be treated in humans. The optimal test to identify intraamniotic inflammation is amniotic fluid (AF) interleukin (IL)-6. This study was designed to determine if AF IL-6 concentration can be used in the differential diagnosis between IAI and S-IAI.
Study Design: The value of AF IL-6 was tested in two independent cohorts of patients with PTL (20–35 weeks of gestation). AF was analyzed for microorganisms using culture and PCR. IL-6 concentration was determined by ELISA. IAI was diagnosed by the combination of bacteria and inflammation (AF IL-6 ≥ 2.6 ng/ml). S-IAI was diagnosed if inflammation was present without microorganisms. ROC analysis was used from the first cohort (n = 142) to identify patients with IAI. The results were tested in a second cohort (n = 166).
Results: 1) Patients with IAI had the highest AF IL-6 concentrations among the groups (Figure); 2) an AF IL-6 ≥ 28.9 ng/ml had a sensitivity of 87% and a specificity of 97% to identify patients with IAI [AUC 0.97 (95% CI, 0.94–1.00)]; 3) an AF IL-6 ≥ 9 ng/ml identified all patients with IAI with a false-positive rate of 19%; 4) all patients with an AF IL-6 concentration between 2.6 and 9 ng/mL were diagnosed with S-IAI, and this IL-6 interval identified 38.5% (15/39) of patients with S-IAI; and 5) results were replicated in the second cohort. AF IL-6 ≥ 28.9 ng/ml had a sensitivity of 83% and a specificity of 83% for IAI. AF IL-6 ≥ 9 ng/ml identified all patients with IAI, and IL-6 between 2.6 and 9 ng/ml identified 39.5% with sterile intraamniotic inflammation.
Conclusion: AF IL-6 concentration can be used for the rapid assessment and diagnosis of IAI and S-IAI.



865 | Placental Pathology in Nulliparas with Gestational Hypertension and Preeclampsia

Nadine Sunji[1]; Melodee Liegl[1]; Amy Y. Pan[1]; Alexa A. Freedman[2]; Linda M. Ernst[3]; Anna Palatnik[1]
[1]Medical College of Wisconsin, Milwaukee, WI; [2]Northwestern University, Chicago, IL; [3]Endeavor Health, Evanston, IL

10:30 AM - 12:30 PM
Objective: To investigate placental pathology patterns in first-time mothers with gestational hypertension and preeclampsia.
Study Design: This was a secondary analysis of the Nulliparous Pregnancy Outcomes Study: Monitoring Mothers-to-be. The present analysis included nulliparous participants with singleton gestations who developed gestational hypertension or preeclampsia and had placental pathology reports available. Placental characteristics and pathologies were described and compared between different types of hypertensive disorders of pregnancy (HDP) and by gestational age at HDP diagnosis using univariate and bivariate analyses.
Results: Of 543 participants who met inclusion criteria, 297 (54.7%) had gestational hypertension, and 246 (45.3%) had preeclampsia. Of these, 228 (42.3%) had an HDP diagnosis prior to 37 weeks. The rate of acute fetal and maternal placental inflammation was higher among those with term preeclampsia (46.2%) and gestational hypertension (42.1%) and lower among placentas of preterm preeclampsia (12.6%, p< .001; Table 1). In contrast, the rate of maternal vascular malperfusion was highest in preterm preeclampsia (62.1%) and lowest in gestational hypertension (29.6%, p< .001). The rates of fetal vascular malperfusion did not differ between HDP phenotypes. Table 2 examined placental findings by gestational age at diagnosis of ≥37 weeks, 34-36 weeks, and < 34 weeks. Presence of acute maternal and fetal inflammatory response increased with advancing gestation (19.5% at < 34 weeks, 23.8% at 34-36 weeks, and 49.8% at ≥37 weeks; p< .001) while the prevalence of maternal vascular malperfusion decreased with advancing gestation (48.8% at < 34 weeks, 44.8% at 34-36 weeks, and 31.2% at ≥37 weeks; p< .001).

Conclusion: Maternal vascular malperfusion lesions in the placenta were more common in early-onset HDP while acute inflammatory lesions were more common in late-onset HDP. This distinction helps in understanding that early- and late-onset HDP may have different underlying pathological mechanisms.

866 | Insomnia is an Independent Risk Factor for Severe Morbidity During Pregnancy

Naima E. Ross[1]; Rebecca J. Baer[2]; Scott P. Oltman[2]; Dana R. Gossett[3]; Rashmi N. Aurora[3]; Laura L. Jelliffe-Pawlowski[3]; Justin S. Brandt[3]
[1]NYU Grossman School of Medicine, New York, NY; [2]University of California San Francisco School of Medicine, San Francisco, CA; [3]NYU Langone Health, New York, NY

10:30 AM - 12:30 PM

Objective: Sleep disorders, such as insomnia and obstructive sleep apnea (OSA), are associated with pregnancy complications. In this study, we aimed to determine the impact of insomnia on the risk of severe morbidity (SM) and to compare the magnitude of the associations between insomnia/OSA and SM.

Study Design: We performed a cross-sectional study of liveborn singleton births in California (2011-2020). Birth certificates were linked to hospital discharge records for birthing people and their infants. Insomnia and OSA were identified as exposures using ICD-9 and 10 codes. The primary outcome was SM, as defined by the US Centers for Disease Control and Prevention. Secondary outcomes included components of SM. The relative risks, and corresponding 95% confidence intervals (CI), were calculated for outcomes by sleep disorder using Poisson regression models.

Results: During the study period, there were 4,145,166 singleton live births with linked records. The prevalence of insomnia and OSA were 117.4 and 138 per 1000 live births, respectively. Among people with sleep disorders, only 72 had both diagnoses (0.7%). Compared to people with no sleep disorders (reference), a higher percentage of people with sleep disorders were age >35 years, White, privately-insured, BMI >30 kg/m^2, and had cesarean deliveries. The RR of SM was 3.4 fold higher (95% CI 3.1, 3.8) and 4.3 fold higher (95% CI 3.9, 4.6) for those with insomnia and OSA, respectively (Table). This risk of SM was even greater for non-transfusion SM. The magnitude of risk for disseminated intravascular coagulation, puerperal cerebrovascular disorders, sepsis, shock, and hysterectomy was slightly higher for patients with insomnia versus those with OSA (Table). The magnitude of risk for all other components of SM was greater in OSA versus insomnia.

Conclusion: While both insomnia and OSA confer an increased risk for SM, they are associated with distinct demographic traits. Further study is need to identify baseline patient characteristics associated with each of these sleep disorders during pregnancy and to design targeted preventative interventions.

Table
Risk of severe morbidity by sleep disorder in a cross-sectional study of singleton live births in California (2011-2020)

	No Insomnia or OSA	Insomnia		OSA	
	n (%)	n (%)	RR (95% CI)	n (%)	RR (95% CI)
Sample	4,134,671	4,855		5,714	
No SM[a]	4,040,814 (97.7)	4,481 (92.3)	*Reference*	5,161 (90.3)	*Reference*

Shock	3,264 (0.1)	21 (0.4)	5.8 (3.8, 8.9)	20 (0.4)	4.8 (3.1, 7.4)
Air and thrombotic Embolism	1,969 (0.1)	17 (0.4)	7.8 (4.8, 12.5)	21 (0.4)	8.3 (5.4, 12.8)
Hysterectomy	3,368 (0.1)	16 (0.3)	4.3 (2.6, 7.0)	18 (0.3)	4.2 (2.6, 6.6)
Ventilation	1,403 (0.0)	24 (0.5)	15.3 (10.3, 23.0)	96 (1.7)	52.6 (42.8, 64.7)

[a]Severe morbidity defined to by US Centers for Disease Control and Prevention based on ICD diagnostic and procedure codes.
Data withheld for the following morbidities due to small numbers: acute myocardial infarction, aneurysm, amniotic fluid embolism, cardiac arrest / ventricular fibrillation, conversion of cardiac rhythm, heart failure/arrest during surgery or procedure, severe anesthesia complications, sickle cell disease with crisis, and temporary tracheostomy
CI: confidence interval; OSA: obstructive sleep apnea: RR: relative risk; SM: severe morbidity as defined by the CDC.

867 | Maternal Trauma in Pregnancy - How Bad Are the Consequences?

Nata T. Willner[1]; Nitza Newman[2]; Tamar Wainstock[3]; Eyal Sheiner[3]
[1]Soroka University Medical Center, Soroka University Medical Center, HaDarom; [2]Soroka University Medical Center, Be'er Sheva, HaDarom; [3]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom

10:30 AM - 12:30 PM

Objective: Abdominal trauma during pregnancy may compromise placental perfusion and fetal wellbeing. This study aimed to assess perinatal outcomes following abdominal trauma due to motor vehicle accidents (MVA) and falls.

Study Design: This population-based cohort study included all pregnant women presenting to a tertiary-care center emergency room between the years 1991-2021. Trauma victims were categorized as vehicle occupant MVA, pedestrian MVA, or following a fall. Comorbidities and pregnancy outcomes were compared between patients with and without trauma. Generalized estimation equation (GEE) models were used to control for confounders such as maternal age and gravidity.

Results: A total of 356,356 births were recorded, including 66 (0.02%) following vehicle occupant MVA, 46 (0.01%) following pedestrian MVA, and 142 (0.04%) following a fall. Placental abruption, non-reassuring fetal heart rate (NRFHR), preterm delivery and perinatal mortality were all more common among trauma patients. After controlling for maternal age and gravidity, using GEE models, abdominal trauma was significantly associated with placental abruption (adjusted OR 21.7 for vehicle occupant MVA, adjusted OR 4.7 for pedestrian MVA, OR 2.5 for fall), NRFHR (adjusted OR 3.6 for vehicle occupant MVA, adjusted OR 2.6 for pedestrian MVA, adjusted OR 1.6 for fall), and preterm delivery (adjusted OR 4.1 for vehicle occupant MVA, adjusted OR 1.2 for pedestrian MVA, adjusted OR 2.8 for fall) as compared to non-trauma parturients. Perinatal mortality was higher among vehicle occupant MVA (adjusted OR 9.8) and fall (adjusted OR 4.0) than among non-trauma parturients (Table).

Conclusion: Abdominal trauma during pregnancy is an independent risk factor for adverse perinatal outcomes. The greatest risk seems to be among occupants of a vehicle involved in a collision.

868 | Fetal Pleural Effusions: Natural History and Response to Interventions

Natalie B. Gulrajani[1]; Teresa N. Sparks[2]; Juan Gonzalez[2]
[1]University of California, San Francisco, School of Medicine, San Francisco, CA; [2]Center for Maternal-Fetal Precision Medicine, University of California San Francisco, San Francisco, CA

10:30 AM - 12:30 PM

Objective: Primary fetal pleural effusions (FPEs) require close surveillance, and thoracentesis or thoracoamniotic shunts are often considered for management. However, it can be challenging to predict which FPEs will evolve or respond to interventions. We aimed to analyze the prenatal course of primary FPEs and response to interventions.

Study Design: Retrospective cohort study of pregnancies with primary fetal FPEs referred to our center between 2017-2024. We included isolated unilateral FPEs or asymmetric bilateral FPEs with one side dominant. All ultrasound reports and records were reviewed for the course of the FPEs, other complications, fetal interventions, and relevant test results. Each case was categorized as improved or resolved FPE, stable FPE, or worsened FPE (including progression to non-immune hydrops fetalis).

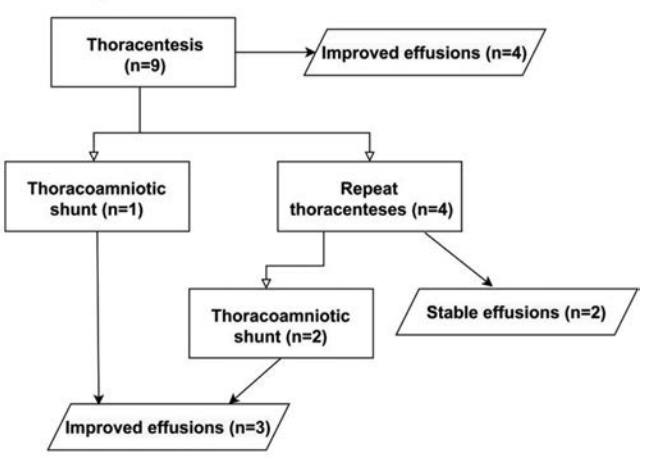
Results: Among 24 cases identified, 9 underwent thoracentesis and/or thoracoamniotic shunt. Median gestational age at diagnosis and first intervention was 19.4 and 20.7 weeks, respectively, for cases with an intervention. A majority (60%) of cases without intervention improved or remained stable (Table). All 9 cases with intervention had additional markers of severity (i.e. mediastinal shift or ascites), compared to only 53% (8/15) without intervention. Each case with an intervention had a thoracentesis, 44% (4/9) had more than one thoracentesis, and 33% (3/9) later had thoracoamniotic shunt placement (Fig). FPEs were chylous in 63% (5/8) of sampled cases; 60% (3/5) of chylous and all (3/3) serous effusions improved after intervention. All cases had a negative viral workup, and among 22 cases that underwent genetic screening and 13 that had diagnostic testing including exome sequencing, only 1 case was identified to have fetal trisomy 21.

Conclusion: Many primary FPEs improved or resolved spontaneously without intervention, and genetic diagnoses were uncommon. Most cases requiring intervention responded to thoracentesis and few ultimately required a thoracoamniotic shunt. These data are useful for anticipating the course of and response to interventions among these complicated pregnancies.

Table. Interventions performed and frequency of improved, stable, and worsened effusions.

	Improved or resolved effusions	Stable effusions	Worsened effusions
No intervention (n=15)	47% (7)	13% (2)	40% (6)
Any intervention (n=9)	77% (7)	22% (2)	0%
Thoracentesis without shunt (n=6)	60% (4)	40% (2)	0%
Thoracoamniotic shunt (n=3)	100% (3)	0%	0%

Fig. Outcomes of fetal interventions



869 | The Correlation of Antenatal Sonographic Parameters and Neurodevelopmental Outcomes in Fetal Growth Restriction

Natalie T. Simon[1]; Roopjit K. Sahi[2]; Emma EH Peek[3]; John Hobbins[2]; Manesha Putra[2]
[1]University of Colorado, Denver, CO; [2]University of Colorado Anschutz Medical Campus, Aurora, CO; [3]University of Colorado, Aurora, CO

10:30 AM - 12:30 PM

Objective: To determine how different antenatal sonographic parameters correlate with early childhood neurodevelopmental outcomes in fetuses categorized as fetal-growth restricted (FGR) or small-for-gestational-age (SGA).

Study Design: This was a prospective cohort of singleton FGR or SGA fetuses diagnosed after 20 weeks of gestation. FGR and SGA were defined using Delphi criteria. Using abdominal circumference (AC), umbilical vein flow (UVF) percentiles by gestational age (GA), corpus callosum length (CCL MoM), corpus vermian height (CVH MoM), transverse cerebellar diameter (TCD MoM), and the ratio of the insula circumference to head circumference (IC) from the last ultrasound before delivery, we tested for correlations to neurodevelopmental outcomes. We evaluated neurodevelopmental outcomes using the Bayley-III Scales of Infant Development (BSID). Mann-Whitney U tests compared the measurements and scales between FGR and SGA. Pearson correlation was used to compare the sonographic parameters to the BSID subscale and sum percentile scores. Using significant ultrasound parameters as predictors, a multivariate linear regression model was created for each BSID scale as a dependent variable.

Results: A total of 90 pregnancies were included in the study. BSID scores were available for 32 infants. SGA fetuses had higher UVF ($p = 0.001$) and higher motor scores ($p = 0.014$) compared to FGR (Table 1). EFW and AC centile correlate with motor scores, UVF correlates with language, adaptive behavior, and sum scores, and IC correlates with adaptive behavior. In the multivariate model, EFW was excluded given collinearity with AC. In the final multivariate analyses, AC was the only significant predictor for motor, UVF was a significant predictor for language, social-emotional, and sum scores, while insula predicted adaptive behavior and sum score (Table 2).

Conclusion: AC, UVF, and IC may be useful predictors of neurodevelopmental outcomes of the growth-restricted fetus. Long-term follow-up studies with larger cohorts are needed to better evaluate the impact of antenatal sonographic parameters on later neurodevelopment.

870 | Impact of Pregnancy Intention on Immediate Pregnancy Outcomes and Postpartum Mental Health

Nehaa Khadka[1]; Vicki Y. Chiu[2]; Michael J. Fassett[3]; Darios Getahun[2]
[1]Kaiser Permanente Southern California, Kaiser Permanente Southern California, CA; [2]Kaiser Permanente Southern California, Department of Research & Evaluation, Kaiser Permanente Southern California/Pasadena, CA; [3]Kaiser Permanente West Los Angeles Medical Center, Department of Obstetrics & Gynecology, Kaiser Permanente West Los Angeles Medical Center/Los Angeles, CA

10:30 AM - 12:30 PM

Objective: To estimate rates of pregnancy intention, describe their characteristics, and examine pregnancy and postpartum mental health outcomes among intended vs. unintended

pregnancies using electronic health records (EHRs) of pregnant patients in a large integrated healthcare system.

Study Design: We conducted a retrospective cohort study using EHRs on singleton pregnancies delivered at ≥20 weeks in Kaiser Permanente Southern California (KPSC) healthcare system (01/01/2014-12/31/2023). Data on pregnancy intentions (wanted, mistimed, unwanted) were extracted from a self-reported questionnaire administered at the first prenatal visit and in combination with an ICD-10 code (Z64.0) for unintended pregnancy. We extracted postpartum mental health outcomes using diagnostic codes. Multivariable logistic regression models were used to estimate adjusted odds ratios (OR) and 95% confidence intervals (CI).

Results: Of 149,739 who had a record of pregnancy intentions, 34% (n = 51,262) were intended and 66% (n = 98,477) were unintended. Young age, lower socioeconomic status, and late/no prenatal care initiation were more common among unintended pregnancies. This group had higher rates of smoking (5.6% vs 2.6%) and illicit drug use (7.9% vs 3.5%) during pregnancy than those with intended. Unintended pregnancy was associated with higher odds of (pre)eclampsia (OR: 1.07, 95% CI: 1.02, 1.12), and lower odds of gestational diabetes (OR: 0.91, 95% CI: 0.87, 0.94), placenta previa (OR: 0.93, 95% CI: 0.88, 0.98) and cesarean delivery (OR: 0.93, 95% CI: 0.91, 0.96). Additionally, those with unintended pregnancies had higher odds of postpartum depression (OR: 1.24, 95% CI: 1.20, 1.28) and anxiety disorders (OR: 1.19, 95% CI: 1.15, 1.23)

Conclusion: Among completed records, unintended pregnancies were over half and independently associated with (pre)eclampsia and postpartum mental health outcomes. Pregnancy intention has a positive influence on selected birth outcomes. Findings suggest that mental health assessments and integrated services supporting high-risk pregnancy management are vital in improving pregnancy outcomes.

871 | Early Vs. Late Placement of Cervical Cerclage Performed due to Cervical Insufficiency in Twins

Neriya Zion Yohay[1]; Tamar Wainstock[2]; Zehava Yohay[3]; Debi Elharar[2]; Talia Birenstock[4]; Guy Elharar[5]; Eyal Sheiner[2]
[1]Department of Military Medicine and "Tzameret", Faculty of Medicine, Hebrew University of Jerusalem and Medical Corps, Israel Defense Forces, Jerusalem, Israel, Beer Sheva, HaDarom; [2]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom; [3]Pain Unit, Soroka University Medical Center, Beer Sheva, Israel, Beer Sheva, HaDarom; [4]Department of Public Health, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom; [5]Sackler Faculty of Medicine, Tel Aviv university., Beer Sheva, HaDarom

10:30 AM - 12:30 PM

Objective: The study was aimed to assess the impact of early vs. late (above 15 weeks gestation) cervical cerclage placement performed due to cervical insufficiency in twins on perinatal outcome.

Study Design: A retrospective cohort study was conducted including all patients with twin pregnancy (n = 92 women) with cervical cerclage. Deliveries occurred between the years 1990 and 2023 in a tertiary medical center. Perinatal outcome was compared between women who underwent cervical cerclage placement ≤15 weeks and women who underwent cervical cerclage placement >15 weeks. Adverse perinatal outcome was defined as either 5 minute Apgar scores < 7 or neonatal intensive care unit (NICU) admission of at least one of the twins. Multiple logistic regression models were used to control for confounders.

Results: A total of 92 women were included in the study, complete data was available for 77 women. Late placement of cervical cerclage (>15 weeks, n = 34), was found as a risk factor for PTD less than 35 weeks (79.4% vs. 58.1%, OR 2.77, 1.01–8.33; P = 0.048). No significant association was noted between late cerclage placement due to cervical insufficiency in twins and adverse perinatal outcome (29.4% vs. 15.6%, OR 2.5, 0.75–7.14; P = 0.138) as compared with early placement (Table). Using multivariable analysis, controlling for maternal age, late cerclage placement was noted as an independent risk factor for PTD < 35weeks gestation (adjusted OR 2.94, 95% CI 1.02 - 8.33; P = 0.047).

Conclusion: Late placement of cervical cerclage (>15 weeks) in twin pregnancies, performed due to cervical insufficiency, is an independent risk factor for preterm delivery of less than 35 weeks gestation. Nevertheless, in our population, late vs. early placement of cerclage is not a risk factor for adverse perinatal outcome.

Table: Early vs. late placement of cervical cerclage performed due to cervical insufficiency in twins

	Cerclage placement > 15 weeks (n=34)	Cerclage placement ≤ 15 weeks (n=43)	OR (95% CI)
PTD < 35w weeks	79.4%	58.1%	2.8 (1.01 – 8.33); P=0.048
Adverse perinatal outcome*	29.4%	15.6%	2.5 (0.75– 7.14); P = 0.138

* 5 minutes Apgar <7 or NICU admission of at least one of the twins.

** Adjusted for maternal age

872 | Decreasing Trend of Gastroschisis Prevalence in the United States between 2014 and 2022

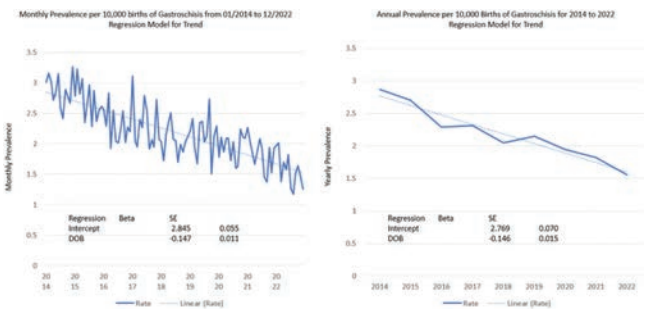
10:30 AM - 12:30 PM

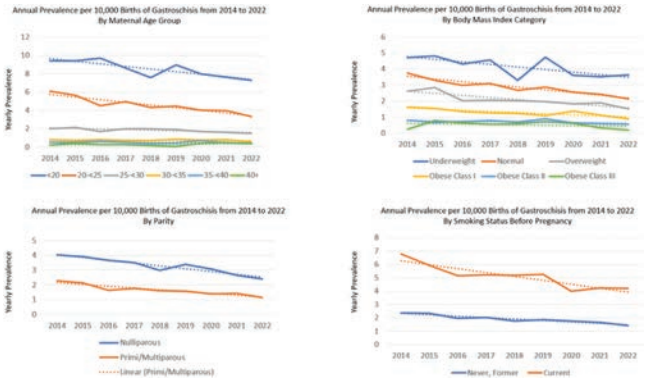
Objective: To investigate the prevalence trend and characteristics of congenital gastroschisis in the United States between 2014 and 2022

Study Design: A cross-sectional retrospective analysis of the Centers for Disease Control and Prevention database for United States live births between 2014 and 2022. Neonatal singleton live births with documented isolated gastroschisis were included, and neonates with other major congenital anomalies and known chromosomal abnormalities were excluded. Prevalence per 10,000 live births along with 95% confidence intervals were estimated, with comparisons to unaffected birth rates in same aged cohorts.

Results: Among 32,088,301 singleton live births (2014–2022), 6,804 cases of isolated gastroschisis were identified (point prevalence: 2 per 10,000 live births). Starting in 2018, a significant decline in gastroschisis prevalence was observed, decreasing from 2.86 in 2014 to 1.55 per 10,000 live births in 2022 ($p<$ 0.001). The risk of gastroschisis was significantly higher in teen and nulliparous gravidae, among non-Hispanic indigenous Americans, with maternal tobacco use, and among vulnerable populations (underweight, < 12th grade education, Medicaid). The declining rate in neonates with gastroschisis, compared to neonates without gastroschisis, is attributable to declines in births among gravidae under 25 (p = 0.02), with significant declines in prevalence of other attributable maternal factors ($p<$ 0.001). Despite early reports suggesting a mediating effect of COVID-19, there was no significant difference of the pandemic on the declining trend rate.

Conclusion: This comprehensive analysis of over 32 million births highlights a notable decline in the prevalence of neonates with gastroschisis, which is attributable to a declining birth rate in the highest at-risk strata of vulnerable gravidae. Given recent increases in birth rates in these same populations, our findings anticipate a reverse of the trend of declining gastroschisis disease prevalence. Further research is necessary to understand the role of access to reproductive care in rates of common congenital anomalies.





873 | Evaluating Surgical Approaches for Prenatal Repair of Open Spina Bifida: A Systematic Review and Meta-Analysis

Nikan Zargarzadeh[1]; Enaja Sambatur[2]; May Abiad[3]; Ehsan Rojhani[4]; Ali Javinani[1]; Weston Northam[1]; Eyal Krispin[5]; Ramen H. Chmait[6]; Kjersti M. Aagaard[7]; Alireza A. Shamshirsaz[8]
[1]Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Fetal Care and Surgery Center, Division of Fetal Medicine and Surgery, Boston Children's Hospital and Harvard School of Medicine, Boston, MA; [3]Maternal Fetal Care Center, Boston Children's Hospital, Boston, MA; [4]Maternal Fetal Care Center (MFCC), Division of Fetal Medicine and Surgery, Boston Children's Hospital, Harvard Medical School, Boston, MA; [5]Harvard Medical School, Boston, MA; [6]Keck School of Medicine, University of Southern California, Los Angeles, CA; [7]Boston Children's Hospital, Division of Fetal Medicine and Surgery, Boston, MA; HCA Healthcare and HCA Healthcare Research Institute, Nashville, TN; HCA Texas Maternal Fetal Medicine, Houston, TX; Baylor College of Medicine and Texas Children's Hospital, Houston, TX, Boston, MA; [8]Fetal Surgeon Chief, Division of Fetal Medicine and Surgery Director of the Maternal Fetal Care Center Director of the Perinatal Surgery Fellowship Professor of Surgery, Boston Children's Hospital Harvard Medical School, Boston, MA

10:30 AM - 12:30 PM

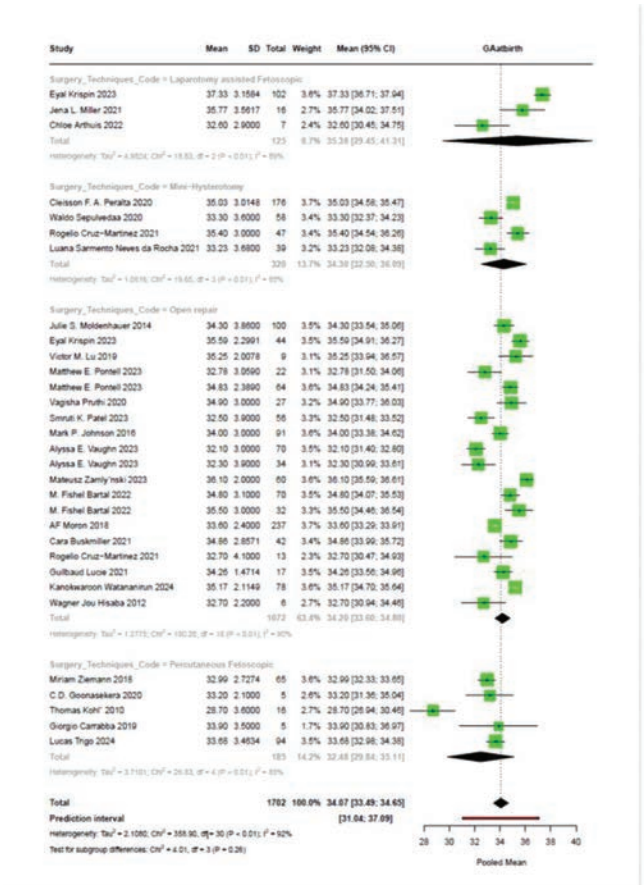
Objective: Over the past decade, prenatal repair of open spina bifida has become well-established. Since the MOMS trial, a widely varying number of surgical approaches have emerged, each focused on optimizing outcomes while minimizing risks. This study aims to compare the outcomes of these different surgical techniques.

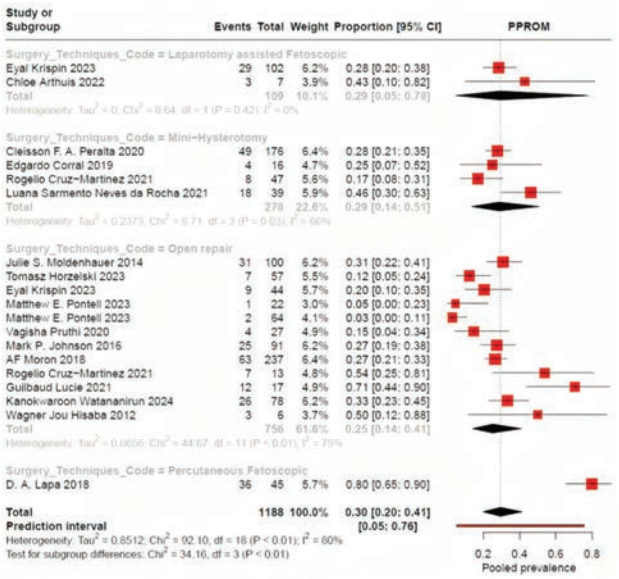
Study Design: This systematic review and meta-analysis synthesizes data from 38 studies between 2010 and 2024. Eligible studies included pregnant patients diagnosed with open spina bifida who underwent the following intrauterine repair techniques: open, mini-hysterotomy, laparotomy-assisted fetoscopic, and percutaneous fetoscopic repair. The primary outcome investigated was gestational age (GA) at delivery, while secondary outcomes were preterm premature rupture of membranes (PPROM), preterm delivery, vaginal birth, and perinatal mortality.

Results: In this study, 2,333 prenatal repair of open spina bifida procedures were analyzed across 14 countries. Of these, open repair accounted for 65.66%, mini-hysterotomy 14.40%, laparotomy-assisted fetoscopic 5.36%, and percutaneous fetoscopic 14.57%. Subgroup analyses revealed a mean GA at birth of

34.20 weeks for open repair, 34.30 weeks for mini-hysterotomy, 35.38 weeks for laparotomy-assisted, and 32.48 weeks for percutaneous fetoscopic method, with no significant difference noted between subgroups. Overall rates of preterm delivery before 37 weeks and PPROM were 0.75 and 0.30, respectively. Both showed significant differences between subgroups (P< 0.01). Vaginal birth rates had significant subgroup differences (P< 0.01), with the laparotomy-assisted fetoscopic group more likely to have vaginal deliveries (0.02, 0.04, 0.49, 0.18 for open, mini, laparotomy, and percutaneous, respectively)

Conclusion: Collectively, the data from this meta-analysis suggests that gestational age does not significantly differ by the surgical technique employed for prenatal repair of open spina bifida.





874 | Planned Versus Emergent Uterine Preserving Cesarean Delivery for Placenta Accreta Spectrum

Nirit Maliyanker[1]; Elias Cstel[2]; Nizan Mor[3]; Lior Fridrich[3]; Shlomi Toussia Cohen[3]; Aviran Ohayon[3]; Alina Weissmann-Brenner[3]; Gabriel Levin[4]; Raanan Meyer[5]

[1]Sheba Medical Center, Givatayim, Tel Aviv; [2]Sheba Medical Center, Ramat gan, HaMerkaz; [3]Sheba Medical Center, Ramat Gan, HaMerkaz; [4]McGill University, Montreal, PQ; [5]Cedars Sinai Medical Center, Los Angeles, CA

10:30 AM - 12:30 PM

Objective: Uterine preserving cesarean delivery is increasingly used to manage placenta accreta spectrum (PAS). Outcomes of emergent compared to elective cesarean hysterectomy were previously studied. The aim of this study is to compare maternal and neonatal outcomes between women who had emergent and elective uterine preserving cesarean delivery for PAS cases.

Study Design: This is a retrospective study conducted at a single tertiary center. PAS cases scheduled for uterine preserving surgery between 3/2011 to 11/2020 were retrieved and analyzed. Delivery was defined as elective when performed at a time and date planned by a dedicated multidisciplinary team, all other cases were defined as emergent. The primary outcome is composite maternal outcome defined by one or more of these variables: unplanned hysterectomy, intensive care unit admission, transfusion of six or more red blood cell units, disseminated intra-vascular coagulation. ureteric injury, bowel injury, unintentional cystotomy and relaparotomy. Secondary outcome included neonatal outcome such as APGAR score, cord pH, admission to the neonatal intensive care and mechanical ventilation.

Results: 274 women with PAS diagnosis were scheduled to uterine preserving surgery. 215 underwent elective surgery and 59 had emergent surgery. Composite maternal outcome occurred in 81 women (29.6%) of all women, no significant difference was found between the elective surgery group and the emergent surgery group (28.8% vs 32.2% p = 0.631). Significant differences were found in neonatal outcomes: longer hospital stay (8.42 ± 7.06 vs 16.28 ± 13.98 p< 0.01), higher rate of mechanical ventilation (7%

vs 18.6% p< 0.01) and neonatal intensive care unit hospitalization in the emergent cesarean group (24.2% vs 55.9% p< 0.01).

Conclusion: Emergent uterine preserving surgery in PAS cases is not associated with increased maternal morbidity. This should be considered against prematurity complication when scheduling uterine preserving surgery. Higher rate of neonatal adverse outcomes was found in the emergency group can be attributed to an earlier gestational week at delivery.

Table 1. A comparison between baseline characteristics in those who had elective cesarean delivery and those who had emergent cesarean delivery.

Characteristics	Elective Cesarean Delivery (215)	Emergent Cesarean Delivery (59)	P
Age	35.62 ± 4.93	34.93 ± 4.45	0.335
Body mass index (BMI)	29.67 ± 5.16	28.79 ± 5.76	0.410
Gravity	5.38 ± 2.91	4.88 ± 2.50	0.229
Parity	3.30 ± 2.27	2.93 ± 2.09	0.261
Previous cesarean delivery	212 (98.6)	57 (96.6)	0.311

10:30 AM - 12:30 PM

Objective: To evaluate whether abnormal sFlt-1/PlGF ratio predicts latency to delivery and development of hypertensive disorders of pregnancy (HDP) among individuals presenting with fetal growth restriction (FGR)

Study Design: A retrospective study including individuals at ≥ 23 weeks presenting to a tertiary care center with suspected FGR (< 10th percentile) (08/2023 to 04/2024). During this period, sFlt-1/PlGF levels were obtained for all individuals with FGR but were not used to guide
clinical management. Patients with HDP on presentation were excluded. Median interval to delivery, rate of HDP, and other adverse outcomes were compared between those with and without abnormal sFLT-1/PLGF ratio (≥ 38).
Odds ratio and 95% confidence interval (95%CI) were calculated.

Results: Of 104 patients with suspected FGR, 36 (34.6%) had an abnormal ratio of sFlt-1/PlGF (≥38). Those with abnormal sFlt-1/PlGF levels were more likely to be nulliparous compared to those with normal testing (Table 1). The rate of HDP was higher among those with abnormal sFlt- 1/PlGF ratio (30.6% Vs 2.94%, p< 0.01, OR14.5 (3-70.2)) with a shorter median latency from test to delivery (20 vs 36 days, p< 0.01) compared to normal testing. Furthermore, those with abnormal sFlt- 1/PlGF ratio delivered earlier (35.4 vs. 37.1, p< 0.01) with a lower birthweight (1876 vs 2182 gram, p< 0.01) compared to those with normal testing.

Conclusion: Abnormal sFlt-1/PlGF ratio in normotensive individuals with suspected FGR may predict short interval to delivery, development of HDP, and adverse perinatal outcomes.

Table 1 – Maternal and obstetrics characteristics

876 | Does an Early Isolated Decrease in Fetal Abdominal Circumference Heighten the Risk of Growth Restriction?

Patrick S. Kim[1]; Tiffany A. Lowtan[1]; David J. Rivera Vazquez[1]; Kelsey M. Pozerski[1]; Krista Howard[2]; Bradley H. Sipe[3]; Rachelle Schwartz[3]

[1]Orlando Health Bayfront Hospital, St. Petersburg, FL; [2]Texas State University, San Marcos, TX; [3]Johns Hopkins All Children's Hospital, St. Petersburg, FL

10:30 AM - 12:30 PM

Objective: To determine if an isolated second trimester fetal abdominal circumference (AC) < 10th %tile is an independent risk factor for fetal growth restriction (FGR) and small for gestational age (SGA) neonates.

Study Design: This multi-center retrospective cohort study analyzed patients who delivered term singletons between 1/1/2019-1/1/2024. The exposed group involved normally grown fetuses with isolated AC's < 10th %tile, measured between 18 and 24 weeks gestation. Control subjects were randomly selected from the same time period. Congenital anomalies were excluded. Statistical analyses included independent t-tests for continuous variables, chi-squared tests for categorical variables, and binary logistic regression models both unadjusted and adjusted for FGR and SGA.

Results: Of the 1,213 patients screened, 589 met the inclusion criteria (AC< 10 n = 213; Control n = 376). The mean AC was 6.3%tile in the exposed group compared to 51.2%tile in the controls. Birthweight in grams (2,782 vs. 3,257, p< 0.001) and %tiles (18.3% vs. 41.8%, p< 0.001) were lower in the AC< 10 group. AC was found to be an independent risk factor for both FGR (AOR 12.5 [6.7, 23.4]) and SGA (AOR 5.08 [3.32, 7.76]). Logistic regressions analysis for primary and secondary outcomes are shown in Table 2. Although there were more pregestational diabetic mothers in the AC< 10 group (10.3% vs. 3.7%, p = 0.001), pregestational diabetes was ultimately protective of FGR (AOR 0.15 [0.04, 0.54]). As maternal BMI increased, the likelihood of FGR (AOR 0.95 [0.90, 0.995]) and SGA (AOR 0.94 [0.91, 0.97]) decreased. Demographically, Black patients were more prevalent in the AC< 10 group compared to controls (36.2% vs. 25.8%, p = 0.027). There were no differences in parity, gestational diabetes, chronic or gestational hypertension, pre-eclampsia, BMI, or mode of delivery between groups.

Conclusion: An isolated second trimester AC< 10th %tile in an otherwise normally grown fetus is an independent risk factor for both FGR and SGA. Increased maternal BMI was protective of both FGR and SGA. A history of pregestational diabetes was protective of FGR but not SGA.

877 | Maternal and Fetal Outcomes of Pregnancies in Women with Cystic Fibrosis

Paul Wasuwanich[1]; Tony Wen[2]
[1]Naples Comprehensive Health, Naples, FL; [2]University of Florida College of Medicine, Gainesville, FL

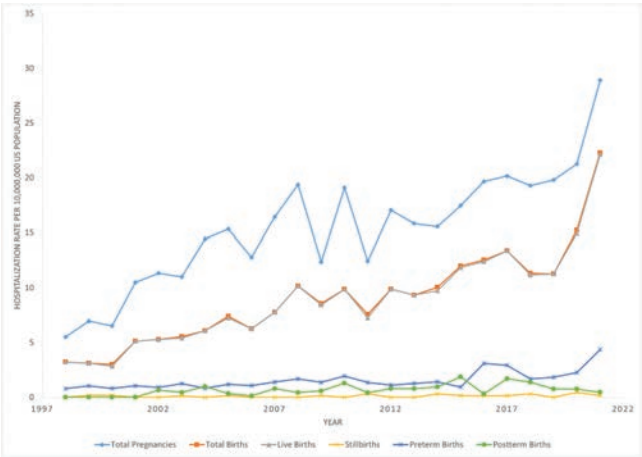
10:30 AM - 12:30 PM

Objective: Cystic fibrosis (CF) is a genetic disease that had previously made pregnancy near impossible. With advancements in therapy, pregnancies in women with CF are increasing. We aim to describe the maternal and fetal outcomes in a large cohort of pregnancies with CF in the U.S.

Study Design: We utilized the National Inpatient Sample and extracted cases of CF-associated pregnancies and deliveries. We described the characteristics and perinatal outcomes of pregnant women with CF and compared them to general non-CF pregnancies in the U.S. from 1998-2021. Trends were analyzed with Poisson regression and rates were analyzed with chi-squared test.

Results: There was a total of 11,496 pregnancies with CF. From 1998 to 2021, hospitalization rates of CF pregnancies and deliveries have increased by 5-fold and 7-fold, respectively (Figure 1). Median age was 26 years in the CF pregnant cohort compared to 28 years in the non-CF cohort (p< 0.0001). Median length of hospital stay was longer in the CF cohort (3 days vs 2 days; p< 0.0001). Maternal deaths occurred at significantly higher rates in the CF cohort (0.496% vs 0.013%; p< 0.0001). Rates of diabetes (6.79% vs 1.11%; p< 0.0001), obesity (4.59% vs 3.81%; p = 0.049), hepatitis C infection (0.51% vs 0.28%; p = 0.033), cirrhosis (0.435% vs 0.006%; p< 0.0001), intravenous drug use (1.16% vs 0.61%; p< 0.001), and coagulopathy (1.24% vs 0.32%; p< 0.0001) were significantly higher in the CF pregnancy group compared to the non-CF pregnancy group. Poor fetal growth was more common in the CF cohort (3.05% vs 2.28%; p = 0.013). Rates of pre-eclampsia, eclampsia, and intrauterine fetal demise were similar between the two groups (p >0.05). Among the 11,496 CF pregnancies, 6,786 (59.0%) had record of delivery. Rates of stillbirths (1.31% vs 0.76%; p = 0.020) and preterm births (17.30% vs 7.83%; p< 0.0001) were higher in the CF cohort. Maternal death during delivery was also higher in the CF cohort (0.147% vs 0.006%; p< 0.0001).

Conclusion: CF pregnancies and deliveries are increasing over time, but morbidity and mortality in this group is higher than in the general pregnant population.



878 | Association Between Hypertensive Disorders and Neonatal Mortality Among Periviable Deliveries

Peeraya S. Sawangkum[1]; Jean Paul P. Tanner[1]; Jason L. Salemi[1]; Jose R. Duncan[2]
[1]Department of Obstetrics and Gynecology, University of South Florida, Tampa, FL; [2]Department of Obstetrics and Gynecology, University of South Florida, Morsani College of Medicine, Tampa, FL

10:30 AM - 12:30 PM

Objective: The objective of this study was to determine the association between hypertensive disorders of pregnancy (including chronic hypertension, gestational hypertension, and pre-eclampsia) and 1-year survival among periviable neonates delivered at 22w0d-25w6d.

Study Design: This is a retrospective cohort study using a maternal-infant linked database of live births in the state of Florida from 2006 to 2019. Singleton deliveries of infants born at 22w0d to 25w6d in which neonatal resuscitation was attempted were included. Adjusted hazard ratios (aHRs) were estimated to compare survival across exposures groups, overall and by week of gestation.

Results: Of the 6,898 periviable deliveries identified during the study period, 1,405 (20.4%) were affected by a hypertensive disorder. Patients affected with hypertension were also more likely to be of advanced maternal age, overweight/obese, non-Hispanic Black, have pre-existing diabetes, have connective tissue / autoimmune conditions, and have a diagnosis of fetal growth restriction. Among all periviable births, hypertensive disorders were associated with increased risk of death during the first year of life (aHR 1.24, 95% CI 1.13-1.38). However, when stratified by gestational age week, hypertensive disorder had no effect on risk of death at 1-year among 22- and 23-week neonates (aHR 0.73, 95% CI 0.50-1.07 and aHR 1.17, 95% CI 0.96-1.43 respectively), but increased risk of death among 24- and 25- week neonates (aHR 1.37, 95% CI 1.16-1.62 and aHR 1.41, 95% CI 1.17-1.69 respectively).

Conclusion: This study demonstrates that hypertensive disorders of pregnancy are associated with increased neonatal mortality among periviable neonates born at 24- and 25-weeks gestation, but not at 22- and 23-weeks gestation. These findings may help guide perinatologists when counseling patients in the periviable period.

879 | Assessment of Cardiac Outcomes in Pregnant Women with Congenital Heart Disease: A Single Center Experience

Poojita Dasika[1]; Shreya Ramineni[2]; Anna E. Bortnick[3]; Manoj Gupta[3]; Daphne Hsu[3]; Diana S. Wolfe[3]
[1]Albert Einstein College of Medicine, The Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY; [3]Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY

10:30 AM - 12:30 PM

Objective: Women with congenital heart disease (CHD) have a significant risk of cardiovascular complications during pregnancy. This study examined the association between current cardiac risk stratification tools and cardiovascular outcomes in adult pregnant women with CHD.

Study Design: A retrospective observational study was performed via chart review of all patients ≥ 18 years of age with underlying mild, moderate, or complex CHD who received care at the Albert Einstein College of Medicine at the Montefiore Medical Center, Bronx, New York from January 2015 until April 2024. Pregnancy risk scores were calculated using the mWHO, ZAHARA, CARPREG I, and CARPREG II risk classification models. The primary outcome was to compare the observed versus predicted occurrence of maternal cardiovascular complications by each model. Secondary outcomes included identifying individual risk factors for maternal cardiovascular complications. A univariate analysis was performed to identify significant predictors of cardiovascular complications.

Results: Of 170 pregnancies, 16 (9.4%) had cardiovascular complications antepartum or up to 6 months postpartum. The ratio of weighted average observed risk within the cohort to weighted average predicted risk was calculated for each model: 0.63 for mWHO, 0.73 for ZAHARA, 0.73 for CARPREG I, and 0.84 for CARPREG II (Figure 1). Significant ($p < 0.05$) univariate risk factors for maternal cardiovascular complications included anticoagulation during pregnancy, prior cardiac event or arrhythmia, cardiac medication during pregnancy, moderate to severe pulmonary hypertension, systemic ventricular dysfunction, cardiac medication before pregnancy, NYHA functional class >II, and late pregnancy assessment (Table 1).

Conclusion: All four risk models overpredicted maternal cardiac risk. CARPREG II was the most accurate representation of cardiac risk in our cohort of pregnant women in the Bronx with CHD. Though not included in any of the risk models, anticoagulation during pregnancy was the most significant individual predictor of maternal cardiovascular complications.

Systemic ventricular dysfunction[d]	**10**	**4 (40.0)**	**8.2 (2.0-33.2)**	**0.0031**
Cardiac medication before pregnancy[b]	**65**	**12 (18.5)**	**5.7 (1.7-18.6)**	**0.0038**
NYHA functional class >II	**2**	**2 (100.0)**	**53.3 (2.4-1163.6)**	**0.0115**
Late pregnancy assessment[e]	**13**	**4 (30.8)**	**5.4 (1.4-20.0)**	**0.0123**
Mechanical valve prosthesis	2	1 (50.0)	10.2 (0.6-171.5)	0.1068
BMI > 30	61	8 (13.1)	1.9 (0.6-5.4)	0.2220
Unrepaired CHD	88	9 (10.2)	1.7 (0.6-4.8)	0.3079
Gestational diabetes	14	2 (14.3)	1.7 (0.3-8.3)	0.5187
Cyanotic heart disease (Corrected or uncorrected)	19	1 (5.3)	0.5 (0.1-4.3)	0.5629
Hypertensive disorders of pregnancy[f]	29	2 (6.9)	0.7 (0.1-3.1)	0.6126
High-risk valve disease/left heart obstruction[g]	16	2 (12.5)	1.4 (0.3-6.9)	0.6582
Coronary artery disease	6	0	0.7 (0.0-12.9)	0.8051
Smoking during pregnancy	3	0	1.3 (0.1-26.5)	0.8596

[a]Including clinically significant arrhythmias, clinically significant heart failure, pulmonary embolism, deep vein thrombosis, need for urgent or invasive cardiovascular intervention
[b]Including beta-blockers, aspirin, diuretics, calcium channel blockers
[c]Right ventricular systolic pressure ≥50 mm Hg in the absence of right ventricular outflow obstruction
[d]Mild ejection fraction (EF) <55%
[e]First antenatal visit after 20 weeks gestation
[f]Presence of pregnancy induced hypertension (PIH) or preeclampsia
[g]Aortic valve area <1.5 cm^2, subaortic gradient >30 mmHg, mitral valve area <2 cm, or moderate to severe mitral regurgitation

880 | Treating Women with Isolated Intrapartum Fever as Chorioamnionitis: A Cost Effectiveness Analysis

Prakrunya Subhasree Badrinarayan; Megha Arora; Aaron B. Caughey
Oregon Health & Science University, Portland, OR

10:30 AM - 12:30 PM

Objective: Intrapartum fever (≥ 38°C) affects many deliveries annually in the U.S., posing risks to mothers and neonates. Standard treatments include expectant management for isolated intrapartum fever and ampicillin-gentamicin for chorioamnionitis. Antibiotic treatment helps reduce infection risk due to expectant management but may increase costs. This study evaluated the cost-effectiveness of treating isolated intrapartum fever as chorioamnionitis.

Study Design: We constructed a decision-analytic model in TreeAge Pro to compare outcomes between isolated intrapartum fever (expectant management) versus chorioamnionitis (ampicillin/gentamicin). Our theoretical cohort was 222,000 patients, representing vaginal singleton pregnancies with intrapartum temperature ≥ 38°C in the U.S. annually. Outcomes were incremental cost per quality-adjusted life years (QALYs), postpartum endometritis, neonatal early-onset sepsis (nEOS), neonatal death, neonatal neurodevelopmental delay (NDD), and acute kidney injury (AKI) from gentamicin toxicity. The willingness-to-pay threshold was $100,000/QALY. We discounted QALYs at a rate of 3%. Model inputs were derived from literature and assessed using univariate sensitivity analyses.

Results: In our theoretical cohort of 222,000 individuals, antibiotic treatment reduced 7,481 cases of postpartum endometritis (8,649 vs 16,131), 6,047 cases of nEOS (961 vs 7,009), 677 neonatal deaths (1,350 vs 2,027), and 331 cases of NDD (15,485 vs 15,815) compared to expectant management. However, gentamicin use for chorioamnionitis resulted in 21,305 more cases of AKI (31,069 vs 9,764). Despite higher costs, treating intrapartum fever as chorioamnionitis was cost-effective with a cost-effectiveness ratio (ICER) of $5,708/QALY. Sensitivity analyses showed treatment remained cost-effective until AKI probability exceeded 70%.

Conclusion: Treating intrapartum fever with antibiotics is a cost-effective strategy to reduce the adverse outcomes of untreated intrapartum fever. Adopting a protocol to treat all intrapartum fevers ≥ 38°C as chorioamnionitis with appropriate antibiotics could benefit health systems.

Table 1. Outcomes in a theoretical cohort of 222,000 pregnant individuals with a temperature ≥ 38°C.

	Antibiotics	No Antibiotics	Difference
Postpartum Endometritis	8,649	16,131	-7,481
Neonatal Early Onset Sepsis (nEOS)	961	7,009	-6,047
Neonatal Death	1,350	2,027	-677
Neurodevelopmental Delay (NDD)	15,485	15,815	-331
Acute Kidney Injury (AKI)	31,069	9,764	21,305
Cost (USD)	16,411,256,352	16,250,183,543	161,072,808
Effectiveness (QALYs)	12,284,432	12,256,214	28,218
Incremental Cost Effectiveness Ratio (ICER)	**$5,708.00 / QALY**

881 | Circumstances and Trends of Pregnancy-Associated Suicides in the United States from 2018 to 2021

Qing Li[1]; Emily S. Miller[2]; Sarah G. Obican[3]; Daniel Romer[4]
[1]Independent Researcher, Denver, CO; [2]Women & Infants Hospital of Rhode Island and Alpert Medical School of Brown University, Providence, RI; [3]Department of Obstetrics and Gynecology, University of South Florida, Tampa, FL; [4]Annenberg Public Policy Center, University of Pennsylvania, Philadelphia, PA

10:30 AM - 12:30 PM

Objective: Pregnancy-associated suicide is a common cause of maternal mortality in the US. Our objective was to investigate the trends and occurrence of circumstances surrounding pregnancy-associated suicide before and during the COVID-19 pandemic, with a specific focus on understanding its relationship with intimate partner adversity (IPA).

Study Design: In a cross-sectional study, we analyzed 315 pregnancy-associated suicide incidents from 34 states, the District

of Columbia, and Puerto Rico with complete case reporting (Figure) in the 2018-2021 National Violent Death Reporting System, which is a national surveillance system for violent death and the largest dataset on suicide decedents. Information was captured by standardized coding in death certificates, records from coroner and medical examiners and law enforcement, and toxicology reports. IPA was defined as a divorce, breakup, argument, jealousy, conflict, or violence among intimate partners, which appeared to have contributed to suicide. The characteristics of the victim, incident, and circumstances were compared, stratified by the presence of documented IPA, using bivariate analyses.

Results: Pregnancy-associated suicide counts decreased 12.5% from 168 (2018-2019) to 147 (2020-2021). Half died between 43 to 365 days postpartum (Table). Firearms were the primary lethal means (41%) followed by hanging, strangulation, or suffocation (40%). Among 315 cases, 63% were White, 60% had a previously identified mental health condition (MHC), and 46% had IPA. Compared to cases without IPA, IPA-involved cases did not vary by the presence of MHC or injury location ($p > 0.05$) but were more likely to involve a suicide following the homicide ($p = 0.04$) and alcohol use ($p = 0.02$).

Conclusion: Pregnancy-associated suicide decreased from two years before to two years during the pandemic in the US. MHC, IPA, and firearm use were common. Policies and programs to screen and respond to MHC, firearm use, IPA and violence among women of reproductive age may be beneficial public health strategies to prevent pregnancy-associated suicide.

Table. Victim and Incident Characteristics of Pregnancy-Associated Suicides by Intimate Partner Problem Status in 34 States, the District of Columbia, and Puerto Rico, the National Violent Death Reporting System, 2018 to 2021

882 | Features of Additional Uterotonic Use Without Postpartum Hemorrhage

Rachel L. Wiley[1]; Ipsita Ghose[2]; Hector M. Mendez-Figueroa[3]; Suneet P. Chauhan[4]

[1]University of California, San Diego, San Diego, CA; [2]Baylor College of Medicine, Houston, TX; [3]McGovern Medical School at UTHealth, Houston, TX; [4]Delaware Center of Maternal-Fetal Medicine at Christiana Care, Delaware, DE

10:30 AM - 12:30 PM

Objective: Use of uterotonics beyond prophylactic ranges from 2-25%, while postpartum hemorrhage (PPH; blood loss $\geq$ 1000 mL) ranges from 3-5%. We examined factors in individuals without PPH who received additional uterotonics versus those who did not.

Study Design: This retrospective cohort included all singleton live births $\geq$ 22 weeks with 24-hour blood loss < 1000 mL at a Level IV center over 24 months. Clinical and demographic elements were abstracted by medical staff, and additional uterotonic use was defined as any agent utilized after prophylactic oxytocin, including additional doses of oxytocin, misoprostol, methylergonovine, tranexamic acid or carboprost. Individuals were stratified by route of delivery and examined by students' t-test and chi-square.

Results: Of 8,623 deliveries, 7,616 (88%) were included with 4,369 (57.4%) vaginal deliveries (VD) and 3,247 (42.6%) cesarean deliveries (CD). VD without PPH was significantly more likely to receive additional uterotonics compared to CD (14% vs. 11%, $p< 0.001$). The average blood loss was higher with vs. without uterotonics (398 ± 211.24 mL vs 241 ± 149.92 mL, $p< 0.001$ for VD; 700 ± 135.43 mL vs 633 ± 129.62 mL, $p< 0.001$ for CD). While some pre-existing characteristics differed, they were inconsistent across routes except for BMI, hypertensive disorders, low platelets, magnesium sulfate and oxytocin use (Table 1 & 2). There were no significant differences in provider characteristics. PPH risk stratification was only different in VD. Deliveries without PPH who received additional uterotonics were more likely to be transfused, receive additional surgical intervention and be admitted to intensive care (Table 2).

Conclusion: About 1 in 10 deliveries without PPH received uterotonics beyond prophylactic. No risk factors or patient characteristic predicted this behavior. Blood loss and interventions

were increased with additional uterotonics, suggesting clinicians may be pre-emptively treating clinical concern rather than risk factors. Additional exploration into risks, benefits, and threshold of early intervention with uterotonics is warranted.

883 | Hypertension in Pregnancy Without a Documented Diagnosis: A Missed Window of Opportunity

Rachel D. Seaman; Caitlin Partridge; Lisbet S. Lundsberg; Jennifer F. Culhane; Anna Denoble
Yale School of Medicine, New Haven, CT

10:30 AM - 12:30 PM

Objective: Obstetric patients with chronic hypertension (HTN) and hypertensive disorders of pregnancy (HDP) may not receive corresponding ICD-10 codes due to missed diagnoses or documentation errors. We aimed to compare (1) healthcare engagement at 6 weeks postpartum (PP) and (2) American College of Cardiology (ACC) HTN staging at 6 months PP between hypertensive patients with and without corresponding ICD-10 codes.

Study Design: This was a retrospective study of patients delivering within a healthcare system from 2013-2023 with ≥1 prenatal visit. Exclusion criteria were < 2 recorded blood pressures (BPs) at < 20 weeks' gestation and no evidence of elevated BPs or cHTN/HDP by ICD-10 code. The electronic medical record was used to identify patients with HTN; these were then classified as "BP only" (≥2 BPs of ≥140/90 mmHg at < 20 weeks and/or 20 weeks to delivery discharge *without* an ICD-10 code for cHTN/HDP) or "ICD-10" (*with* an ICD-10 code for cHTN/HDP). Demographic characteristics and ACC HTN stages at 6 months were compared between groups using chi-square tests. The primary outcomes - attendance at any PP visit or HTN-focused visit within 6 weeks PP - were compared using multivariate logistic regression, adjusted for significant covariates.

Results: Of 21,296 patients, 9,833 (46.2%) were identified as BP only and 11,463 (53.8%) as ICD-10. Compared to the BP only group, the ICD-10 group was significantly more likely to attend any PP visit [80.1% vs. 65.6%; aOR 2.0 (95% CI 1.8-2.1)] or PP HTN-focused visit [36.4% vs. 2.5%; aOR 17.3 (95% CI 15.1-19.8)]. Both BP only and ICD-10 patients demonstrated elevated BP by ACC staging at 6 months PP: elevated (13.1% vs 13.3%), Stage 1 (14.7% vs 22.6%), and Stage 2 (2.3% vs 9.4%).

Conclusion: Elevated BP in pregnancy in the absence of an associated ICD-10 diagnosis code is associated with lower healthcare engagement up to 6 weeks PP. Despite this, patients with elevated BPs without an ICD-10 diagnosis of cHTN or HDP remain at risk for ongoing BP elevation for at least 6 months from delivery, highlighting a need for improved recognition and documentation of antenatal HTN.

10:30 AM - 12:30 PM

Objective: This study aims to evaluate the association between in-vitro fertilization (IVF) and preeclampsia with severe features (sPEC) among very advanced maternal age (vAMA) patients.

Study Design: Retrospective cohort study of vAMA patients who delivered at a large academic health system in New York between January 2019 and December 2022. vAMA was defined as ≥ 45 years old at delivery. Rates of sPEC and other hypertensive disorders of pregnancy were determined for IVF versus non-IVF patients. A multivariate logistic regression was used to estimate the relationship between IVF and sPEC while controlling for obesity, nulliparity, race and ethnicity, public insurance, and primary language using R version 4.3.1. A p-value of < 0.05 was considered statistically significant.

Results: A total of 591 vAMA pregnancies were included, of which 218 (37%) were IVF pregnancies and 373 (63%) were non-IVF pregnancies. Rates of hypertensive disorders were similar between groups (24.7% in the non-IVF cohort and 29.4% in the IVF cohort, $p = 0.212$). The sPEC rate among IVF vAMA patients IVF was 16.1%, compared to 9.7% in the non-IVF group ($p = 0.021$). IVF was associated with an increased likelihood of sPEC among vAMA patients in an unadjusted model, OR 1.79 (95% CI, 1.09 - 2.95); however this was not the case after adjusting for potential confounders, aOR 1.57 (95% CI 0.92 - 2.67).

Conclusion: Although vAMA and IVF have each been independently associated with an increased risk of sPEC, this is the first study to evaluate whether IVF is specifically linked to an increased risk of sPEC and hypertensive disorders of pregnancy in vAMA patients. In this cohort of patients with vAMA, IVF did not independently increase the risk of sPEC or hypertensive disorders of pregnancy.

885 | Increases in Routinely Measured Red Cell Indices During Pregnancy are Associated with Obstetric Complications

Rachel Petherbridge[1]; Veronica Tozzo[2]; Kaitlyn E. James[1]; Sarah Hsu[1]; Chloe Michalopoulos[1]; Brody Foy[3]; Tanayott Thaweethai[1]; Christopher Mow[1]; Jacqueline Maya[1]; Carolina Batlle Camero[4]; Lydia L. Shook[1]; Kathryn J. Gray[3]; Logan Mauney[1]; John R. Higgins[1]; Camille E. Powe[1]

10:30 AM - 12:30 PM

Objective: Pregnancy alters hematological indices, but intra-pregnancy changes in complete blood count (CBC) values have not been rigorously evaluated as markers of pregnancy health.

Study Design: We retrospectively analyzed CBCs routinely measured at 7-14 and 26-29 weeks' gestation to determine the association of rare changes in nine CBC indices (hematocrit, hemoglobin, red cell count, white cell count, platelets, mean red cell volume, mean red cell hemoglobin, red cell volume distribution width, and mean red cell hemoglobin concentration) with a composite outcome (hypertensive disorders of pregnancy, small for gestational age birthweight, preterm birth [both indicated and spontaneous]) and its individual components. Rare changes, defined as statistically uncommon changes in magnitude and direction, were identified in a discovery cohort of 29,162 pregnancies. Direction was chosen as the least frequent variation exceeding established non-pregnant biological variation, and magnitude as the threshold of change with the highest positive predictive value and significant OR ($p < 9\times10^{-6}$ with Bonferroni correction). Identified associations were tested in an out-of-sample validation cohort of 50,603 pregnancies.

Results: In validation, increases in red cell indices between 7-14 and 26-29 weeks' gestation were associated with the composite outcome with an OR [95% CI] of 1.49 [1.30, 1.70] for hematocrit, 1.57 [1.33, 1.86] for hemoglobin and 1.69 [1.48, 1.93] for red cell count. The strongest association with individual outcomes was observed for increases in hemoglobin (>0.67 g/dL, OR 2.03 [1.58, 2.59]) or red cell count (>0.07 106/mm3, OR 2.13 [1.74, 2.6]) and preterm birth (Table 1). These rare increases in hemoglobin and red cell count were observed on average 7 weeks before preterm birth; we did not observe a bias for detection of either spontaneous or indicated preterm birth.

Conclusion: Deviations of routinely measured red blood cell indices from typical longitudinal trajectories during pregnancy may allow for early detection of obstetric complications.

Table 1

		Rare longitudinal behavior	Discovery cohort: Prevalence of rare behavior (%)	Discovery cohort: OR [95% CI]	Validation cohort: OR [95% CI]
Composite outcome	Hematocrit	Increase greater than 1.8%	1.8	1.59 [1.31, 1.94]	1.49 [1.30, 1.70]
	Hemoglobin	Increase greater than 0.67 g/dL	1.1	1.99 [1.57, 2.52]	1.57 [1.33, 1.86]
	Red cell count	Increase greater than 0.07 10^6/mm^3	1.8	1.94 [1.60, 2.35]	1.69 [1.48, 1.93]
	Platelet count	Decrease of less than 0.05 10^9/L or any increase	23.9	1.20 [1.12, 1.29]	1.13 [1.08, 1.20]
	Mean red cell volume	Decrease greater than 0.75fL	11.5	1.32 [1.20, 1.45]	1.34 [1.24, 1.45]
Preterm birth	Hematocrit	Increase greater than 0.26%	7.4	1.47 [1.24, 1.74]	1.45 [1.28, 1.64]
	Hemoglobin	Increase greater than 0.67 g/dL	1.1	2.28 [1.62, 3.20]	2.03 [1.58, 2.59]
	Red cell count	Increase greater than 0.071 10^6/mm^3	1.8	2.33 [1.77, 3.07]	2.13 [1.74, 2.60]
	Mean red cell volume	Decrease greater than 0.75fL	11.5	1.41 [1.22, 1.63]	1.51 [1.33, 1.70]
Preeclampsia	Red cell count	Decrease of less than 0.068 10^6/mm^3 or any increase	6.2	1.40 [1.21, 1.62]	1.36 [1.23, 1.51]
	Mean red cell volume	Increase of less than 0.081fL or any decrease	21.9	1.66 [1.36, 2.02]	1.26 [1.17, 1.36]
SGA	Hematocrit	Increase greater than 1.19%	3.4	1.67 [1.35, 2.05]	1.54 [1.34, 1.78]
	Hemoglobin	Increase greater than 0.22 g/dL	3.4	1.64 [1.34, 2.01]	1.53 [1.32, 1.78]
	Red cell count	Increase greater than 0.071 10^6/mm^3	1.8	1.92 [1.47, 2.51]	1.76 [1.45, 2.13]

Only significant associations ($p<9x10^{-6}$ with Bonferroni correction) are reported. SGA=Small for Gestational Age. Composite outcome includes any pregnancy with preterm birth, hypertensive disorders including preeclampsia or SGA.

886 | The Predictive Value of Angiogenic Factors in Suspected Preeclampsia

Rachel C. Schell; C. Edward Wells; David M. Owen; Donald D. McIntire; David B. Nelson; F. Gary Cunningham
University of Texas Southwestern Medical Center, Dallas, TX

10:30 AM-12:30 PM

Objective: To evaluate the ability of circulating maternal levels of angiogenic factors–soluble FMS-like tyrosine kinase 1 (sFlt-1) and placental growth factor (PlGF)–to predict the development of preeclampsia with severe features (SPE).

Study Design: This was a single-center prospective observational study of pregnant patients admitted for evaluation of hypertensive disorders of pregnancy (HDP) between 24 0/7 weeks and 36 6/7 weeks. At enrollment, a single plasma sample was obtained for the measurement of sFlt-1 and PlGF. All patients underwent standardized evaluation for HDP and were diagnosed with SPE based on standard laboratory and clinical criteria. Patients were examined in two cohorts: those who developed SPE within 1 week (Cohort 1) and those who did not (SPE > 1 week or never, Cohort 2). The predictive value of sFlt-1, PlGF and sFlt-1:PlGF ratio for the development of SPE was analyzed using logistic regression. Demographic, maternal, and neonatal outcomes were compared between cohorts.

Results: From Nov 2022 to May 2023, 152 patients were enrolled, including 60 (39%) diagnosed with SPE, 14 (9%) within 1 week of enrollment (Cohort 1). There were no demographic differences between groups. Patients in Cohort 1 had higher levels of sFlt-1 (43.4 vs 20.3 ng/mL, p-value < 0.001), lower levels of PlGF (150.9 vs 319.0 pg/mL, p-value < 0.001), and higher sFlt-1:PlGF (460 vs 79, p-value < 0.001) versus patients in Cohort 2 (Figure 1). Levels of sFlt-1 and sFlt-1:PlGF were predictive of the development of SPE within 1 week (AUC 0.85 (95%CI 0.74, 0.95) and 0.82 (95%CI 0.71, 0.93), respectively) (Figure 2). At a cutoff of 28 ng/mL, sFlt-1 was associated with a negative predictive value of 0.97, effectively ruling out SPE in these patients.

Conclusion: In pregnant patients with elevated blood pressure between 24 and 36 weeks gestation, elevated sFlt-1 and low PlGF levels are associated with the development of SPE. Levels of sFlt-1 below 28 ng/mL may serve as a triage tool to rule out SPE within 1 week.

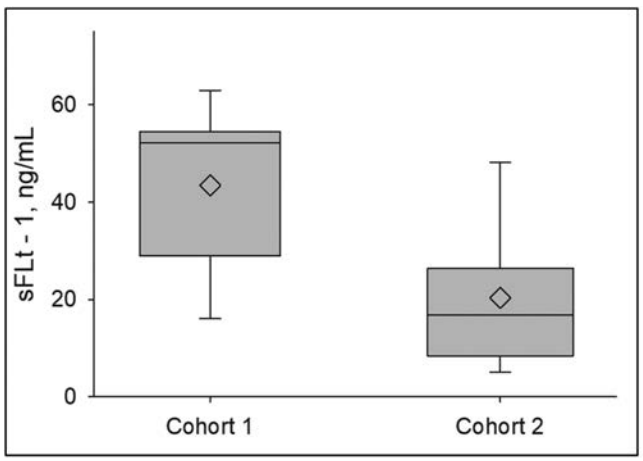

Figure 1: Maternal sFlt-1 level in patients diagnosed with and without preeclampsia within 1 week of evaluation for hypertensive disorders of pregnancy.
Cohort 1: preeclampsia with severe features (SPE) within 1 week; Cohort 2: without SPE within 1 week. Data is represented as: interquartile range (box), mean (◇) and median (horizontal line). Whiskers represent values within 1.5x the interquartile range.

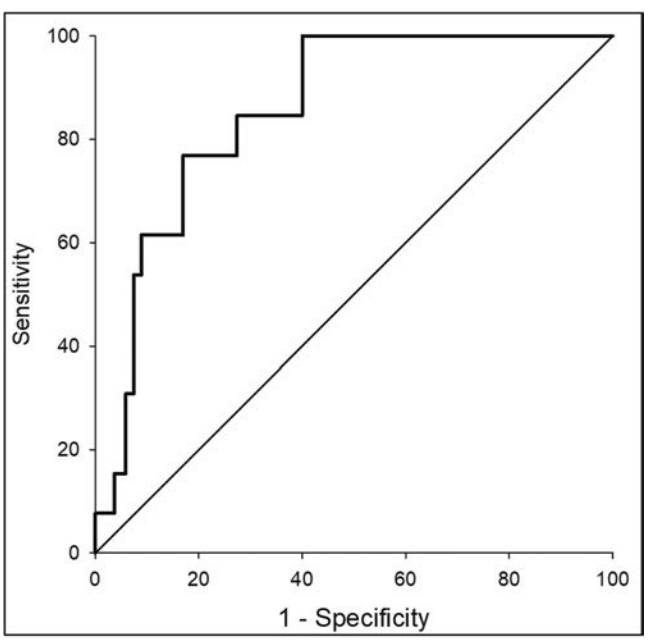

Figure 2: Predictive performance of maternal sFlt-1 level for the diagnosis of preeclampsia within 1 week.
AUC (95% CI): 0.85 (0.74, 0.95)

887 | Association of Features of Fetal Heart Rate Tracings and Adverse Neonatal Outcomes at Term

[7]*Delaware Center of Maternal-Fetal Medicine at Christiana Care, Delaware, DE*

10:30 AM - 12:30 PM

Objective: To ascertain if independent features of term fetal heart rate tracings (FHRT) are associated with adverse neonatal outcomes.

Study Design: FHRTs of consecutive deliveries within 15 months at a Level IV center were reviewed by physicians blinded to outcomes. In 20-min segments, the last 60 minutes available before delivery of all term (≥ 37 weeks), non-anomalous singletons who labored were included. Each feature (variability, decelerations, accelerations) was independently categorized as present < vs. ≥ 50% of the time 60 minutes before delivery. The primary outcome was the rate of composite adverse neonatal outcome (CANO; defined in Table 1). Odds ratio (OR), likelihood ratio (LR) with post-test probability (PTB).

Results: Of 5,160 deliveries, 3,166 (61%) met the inclusion criteria for analysis, of which 49 (1.5%) had CANO. Baseline characteristics differed by age, hypertensive disorders, and neuraxial anesthesia use (Table 1). Individually, absent variability (0.2% vs. 2.0%, unadjusted OR 10.8, 95% CI 1.28-91.5), marked variability (0.4% vs. 6.1%, unadjusted OR 14.5, 95% CI 4.02–52.0) and severe variable decelerations (4.5% vs 16.3%, unadjusted OR 4.18, 95% CI 1.92-9.09) were associated with CANO if present the majority of the time. Moderate variability or the presence of accelerations were not associated with reduced CANO. Moderate variable decelerations were associated with reduced CANO (15.4% vs. 4.1%, OR 0.24, 95% CI 0.06–0.97). LR varied from 0.2 (moderate variables) to 14 (marked variability), with post-test probability being 0 and 18%, respectively (Table 2).

Conclusion: Among term deliveries, during the last 60 min of labor, some FHT elements are individually associated with adverse outcomes. CANO is possible for every 1 in 7 for minimal variability, 1 in 5 for marked variability and 1 in 18 for severe variable decelerations. The presence of majority of time with moderate variability or accelerations were not associated with reduced rates of CANO. Further exploration of the elements of FHRTs that predict adverse outcomes and interventions that mitigate them are warranted.

888 | Changes in Risk-Appropriate Care After Implementation of Maternal Level of Care Designation in Texas

Rajesh Reddy[1]; Justin A. Drake[2]; Corwin Zigler[2]; Jeny Ghartey[2]; Alison G. Cahill[3]; Lorie M. Harper[1]

[1]*Dell Medical School, Austin, TX;* [2]*University of Texas at Austin, Austin, TX;* [3]*Dell Medical School Health Transformation Research Institute, Dell Medical School, The University of Texas at Austin, Austin, TX*

10:30 AM - 12:30 PM

Objective: Perinatal regionalization rests on the assumption that designating hospital levels of care can direct patterns of appropriate site of delivery to improve patient outcomes. We evaluate if a state-mandated maternal level of care program increased risk-appropriate site of care in Texas.

Study Design: Retrospective cross-sectional analysis of all delivery hospitalizations in Texas from 2016-2023 using quarterly

discharge data in the Texas Inpatient Public Use Data File. Of 221 designated hospitals, we included the 215 that reported deliveries in the study period (32 Level IV, 43 Level III, 86 Level II, 54 Level I). As 99% of facilities received their requested designation level, the pre-mandate level was assumed to be the same. Deliveries at sites that were not designated maternal facilities (89 total) were categorized as Undesignated. We organized comorbidities by minimum recommended level of care (highest Level IV, lowest Level I) using criteria in the Texas Administrative Code, ACOG/SMFM Consensus, and literature. We chose a baseline of 2016(Q1) to 2018(Q4) due to (Q4)2015 introduction of ICD-10 and 2018 Texas rule adoption, then a post-intervention of 2021(Q4) to 2023(Q3) based on the September 2021 implementation deadline. We categorized patients into minimum level of care by their highest risk comorbidity and used two-proportion z-tests to compare rates of deliveries at inappropriately low facilities per each risk category. Undesignated site deliveries were considered low level.

Results: The proportion of births at inappropriate level facilities increased for all risk categories (Figure 1). Level III risk and severe maternal cardiac disease patients were more likely to deliver at inappropriately low facilities (Table 1). The exception was a 4.12% decrease for placenta previa with prior uterine surgery. The proportion of undesignated hospital births decreased for all maternal risk groups.

Conclusion: Despite statutory adoption of levels of care, the proportion of deliveries at inappropriately low level facilities increased for all risk groups. Access barriers and transfer behavior may limit efforts.

Figure 1. Deliveries at inappropriately-low level of care facilities per year

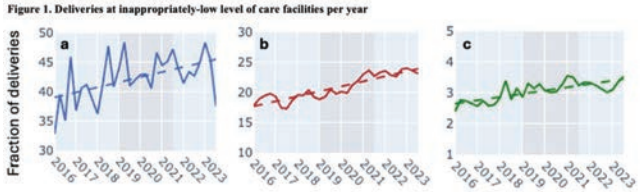

Figure 1. Fraction of deliveries at inappropriately-low level facilities from 2016(Q1)-2023(Q3).
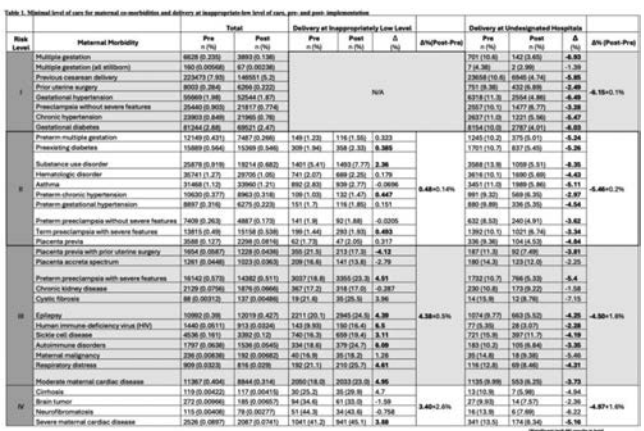
(a) Level IV risk patients delivered at Levels I-III facilities.
(b) Level III risk patients delivered at Levels I-II facilities.
(c) Level II risk patients delivered at Level I facilities.



889 | Changes in Severe Maternal Morbidity Rates in Texas After State-Mandated Perinatal Regionalization

Rajesh Reddy[1]; Justin A. Drake[2]; Corwin Zigler[2]; Jeny Ghartey[2]; Alison G. Cahill[3]; Lorie M. Harper[1]

[1]Dell Medical School, Austin, TX; [2]University of Texas at Austin, Austin, TX; [3]Dell Medical School Health Transformation Research Institute, Dell Medical School, The University of Texas at Austin, Austin, TX

10:30 AM - 12:30 PM

Objective: Seeking to curb severe maternal morbidity (SMM) and mortality, Texas adopted statutory levels of maternal care rules. We evaluated if the state-mandated maternal level of care designation law decreased SMM.

Study Design: Retrospective cross-sectional analysis of all delivery hospitalizations in Texas from 2016-2023 using quarterly discharge data in the Texas Inpatient Public Use Data File. Out of 221 designated hospitals, we included the 215 that reported deliveries in the study period (32 Level IV, 43 Level III, 86 Level II, 54 Level I). As 99% of facilities received their requested designation level, we assumed the same pre-mandate level. Deliveries at sites that were not designated maternal facilities (89 total) were categorized Undesignated. We organized comorbidities by minimum recommended level of care (highest Level IV, lowest 'No risk') using criteria in the Texas Administrative Code, ACOG/SMFM Consensus, and literature. We chose a baseline of 2016(Q1) to 2018(Q4) due to (Q4)2015 introduction of ICD-10 and 2018 Texas rule adoption, then a post-intervention of 2021(Q4) to 2023(Q3) based on the September 2021 implementation deadline. We used the CDC's definition of SMM and ICD-10 codes to calculate SMM rates. We categorized patients into minimum level of care by their highest risk comorbidity and used a z-test for two proportions to compare the SMM rates for each risk group by delivery at appropriate or inappropriate level of care.

Results: SMM rates increased overall during the study period. SMM decreased among patients with maternal risk levels II-IV regardless of appropriate level of care, except for a stable rate in risk level IV patients at inappropriate level facilities (Figure 1). Maternal risk level I patients and those with no risks experienced increases in SMM (Table 1).

Conclusion: SMM decreased for high-risk patients, particularly when delivered at appropriate level facilities, while SMM increased for low-risk patients and overall. As low-risk patients constitute the overwhelming share of births, this cohort may benefit from targeted policies.

Figure 1. SMM rates (per 10,000 deliveries) over time by maternal risk group, with and without blood transfusions

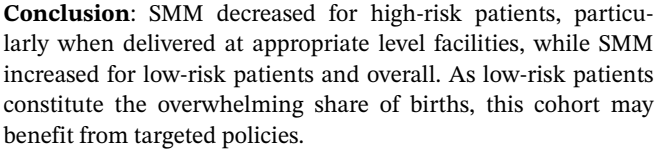


Table 1. Percent of patients by risk category who experienced SMM at each maternal level of care

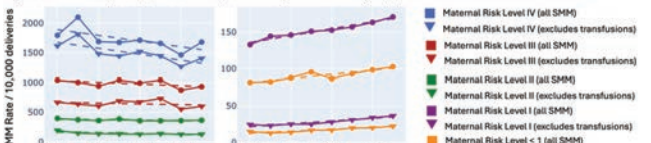

890 | Development of a Novel Machine-Learning-Based Prediction Model to Stratify Risk for Adverse Perinatal Outcomes

Rajet Vatsa[1]; Siguo Li[2]; Jessica L. Cohen[3]; Mark A. Clapp[2]
[1]Harvard University, Boston, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Harvard T.H. Chan School of Public Health, Boston, MA

10:30 AM - 12:30 PM

Objective: An effective risk assessment tool for perinatal deaths is critically needed, given that over one-third of stillbirths after 28 weeks of gestation are potentially preventable. While current guidelines emphasize the role of clinical risk factors (e.g., medical comorbidities), the value of geographic, sociodemographic, and utilization-related factors in risk stratification is less known.
Study Design: We utilized electronic health records data from a large integrated healthcare system between 4/2017 and 6/2023. The analysis was restricted to births ≥ 28 weeks. We developed and internally validated two classes of machine learning models to predict a composite adverse outcome, including stillbirth, early newborn death, and 5-minute Apgar < 7, using features known before 28 weeks. The first class ("clinical") only leveraged clinical risk factors (e.g., chronic hypertension) known to be associated with perinatal death, while the second class ("clinical+") added additional geographic (e.g., distance to hospital), sociodemographic (e.g., household income), and utilization-related (e.g., prenatal care use) features. We tested and compared the top-performing models in each class with respect to their ability to prospectively stratify the risk of adverse perinatal outcomes.
Results: The clinical+ model (AUC: 0.63 [95%-CI: 0.59-0.69]) had modest discrimination overall, similar to the clinical model (AUC: 0.58 [95%-CI: 0.53-0.64]). However, the clinical+ model stratified pregnancies into quartiles of predicted risk with significantly different rates of the composite adverse outcome compared to the clinical model, which did not. For the clinical+ model, the adverse outcome rate was 0.6% (95%-CI: 0.3-0.9%) in the lowest and 4.6% (95%-CI: 3.9-5.3%) in the highest risk quartile.
Conclusion: A machine-learning-based model developed using clinical, geographic, sociodemographic, and utilization-related factors known at the start of the third trimester may more accurately stratify risk than using clinical factors alone. Prospective and external validation studies are needed to demonstrate its utility in practice.

Figure 1: Risk Stratification Performance of Top-Performing Clinical Model

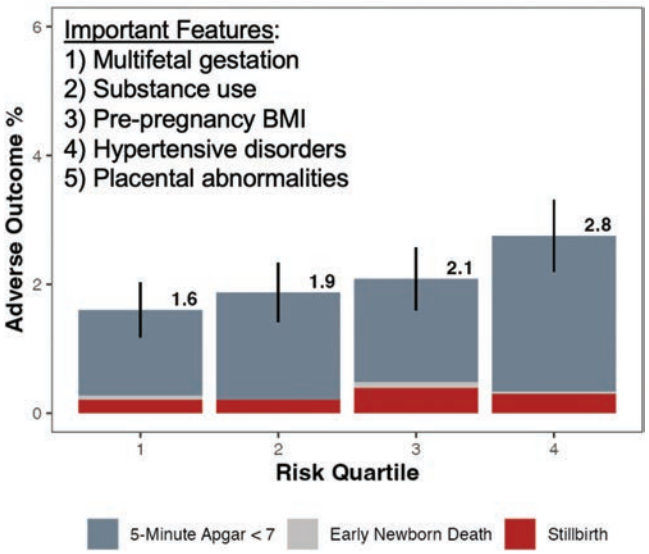

Figure 2: Risk Stratification Performance of Top-Performing Clinical+ Model

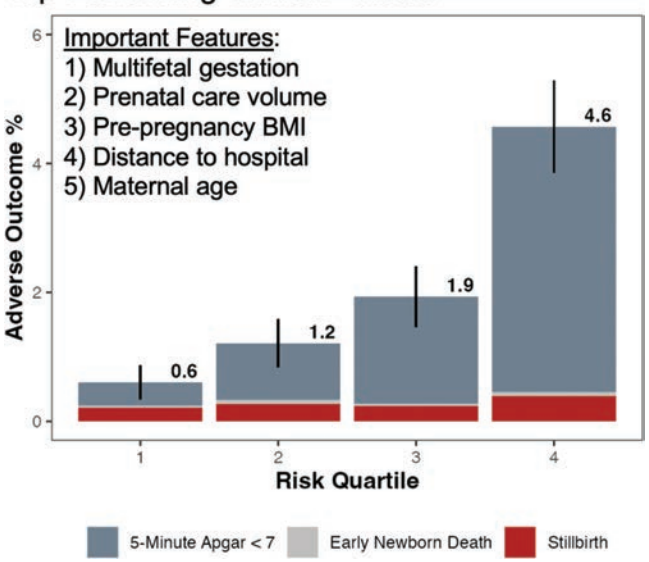


891 | Antepartum Fetal Surveillance Use and Rates of Stillbirth by Predicted Risk of Adverse Perinatal Outcomes

Rajet Vatsa[1]; Siguo Li[2]; Jessica L. Cohen[3]; Mark A. Clapp[2]
[1]Harvard University, Boston, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Harvard T.H. Chan School of Public Health, Boston, MA

10:30 AM - 12:30 PM

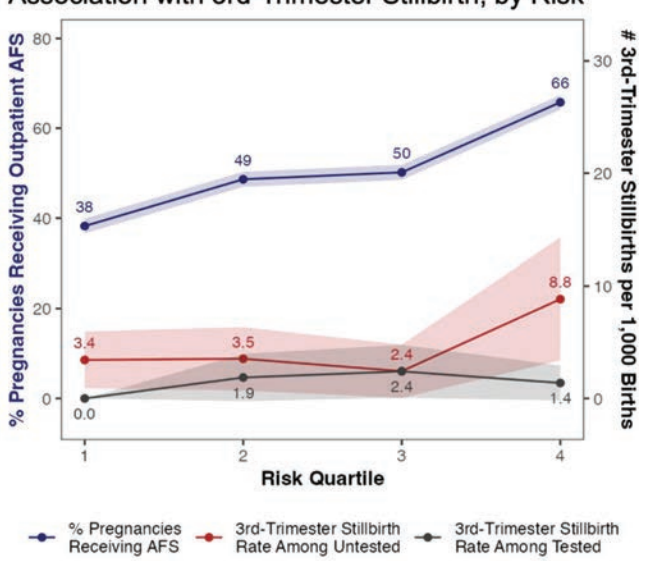
Objective: Over a third of stillbirths after 28 weeks of gestation are thought to be potentially preventable, with antepartum fetal surveillance (AFS) constituting the primary clinical tool for prevention. We sought to compare the rates of stillbirths among those who did and did not receive AFS, stratified by their baseline risk.
Study Design: We utilized electronic health records data from a large integrated healthcare system between 4/2017 and 6/2023

to evaluate the association between AFS, specifically biophysical profiles and nonstress tests conducted in the outpatient setting prior to one's admission for childbirth, and stillbirths occurring after 28 weeks of gestation. Patients were stratified into quartiles of risk for an adverse perinatal outcome using a machine-learning-based model that incorporated information known by the start of the third trimester. Characteristics of patients at highest risk were compared between those who did and did not receive AFS.

Results: Overall, 51% of pregnancies received at least one AFS test. After prospectively stratifying pregnancies into risk quartiles, rates of AFS utilization ranged from 38% in the lowest-risk to 66% in the highest-risk quartile. Among pregnancies at highest risk, there was a significant negative association between receipt of AFS and rates of stillbirth: 8.8 per 1,000 births (95% CI: 3.4-14.3) among un-surveilled pregnancies vs. 1.4 per 1,000 births (95% CI: 0.0-2.9) among surveilled pregnancies (p = 0.01). High-predicted-risk individuals who did not receive AFS lived further from the hospital and obtained less prenatal care but had lower rates of nearly all traditional clinical risk factors.

Conclusion: Using a machine-learning-based model to stratify risk of adverse perinatal outcomes, we demonstrated that AFS was associated with an over 80% lower rate of third-trimester stillbirth among those at highest risk. Further studies are required to causally identify the effect of AFS by risk; however, these findings suggest a potential role for policies to address barriers that may prevent high-risk individuals from accessing AFS to prevent stillbirth.

Figure 1: Antepartum Fetal Surveillance Use and Association with 3rd-Trimester Stillbirth, by Risk



892 | Maternal Mental Health After Stillbirth Delivery

10:30 AM - 12:30 PM

Objective: Stillbirth has a significant impact on maternal mental health. The decision to pursue autopsy following stillbirth can yield knowledge about cause of death (COD), both of which may impact subsequent mental health outcomes for parents. Our objective was primarily to examine associations between autopsy decision and known cause of death with subsequent poor mental health after stillbirth, and secondarily to determine characteristics and factors associated with poor mental health after stillbirth.

Study Design: This was a secondary analysis of singleton stillbirth cases in the Stillbirth Collaborative Research Network case-control study. Primary exposures were decision to perform autopsy (none, partial, full) and autopsy results (known COD, otherwise.) The primary outcome was a mental health composite assessed 1-3 years after the index pregnancy (Edinburgh depressive scale, elevated grief, elevated distress, low post-traumatic growth, or self-reported increase in drinking or smoking).

Results: Of 620 parents, 272 participated in the follow up interview (44%), with autopsy decision full (66%), partial (19%), and none (14%), and known COD 57% (82% of full autopsy, 52% of partial, 0% of no autopsy). 54% had poor mental health at follow up including depression (26%), elevated distress (25%), grief (18%), increased smoking or drinking (15%), and low resilience (11%).) Neither autopsy decision nor knowledge from autopsy were associated with mental health at follow up (Table 1). Factors associated with poor mental health after stillbirth were childhood physical/emotional abuse/trauma, angry feeling internalization, chronic autoimmune conditions, prior mental health conditions, low income, and feeling blamed for stillbirth (Table 2). When modeled jointly, only childhood trauma (OR: 4.1 (1.6-10.7)) and low income (2.3 (1.3-4.0)) remained significantly associated with poor mental health.

Conclusion: Adverse mental health outcomes were remarkably high after stillbirth and were associated with low income, and prior trauma. Additional follow-up and screening tools could optimize mental health after stillbirth.

Abstract Table 1. Study outcomes by autopsy decision and known/unknown cause of death from autopsy

Outcome	Autopsy Decision				Cause of death findings

893 | Obstetric Emergencies, When to Provide Abortions, and State Restrictions: a Survey of Us Emergency Physicians

Rauvynne N. Sangara[1]; Priscilla Garza[2]; Emma Lantos[2]; Sophie Terp[2]; Sarah Axeen[2]; Brian Nguyen[2]
[1]Division of Maternal Fetal Medicine, Department of Obstetrics and Gynecology, University of Southern California, Los Angeles, CA; [2]University of Southern California, Los Angeles, CA

10:30 AM - 12:30 PM

Objective: To explore emergency medicine (EM) provider attitudes about obstetric emergencies, the appropriateness of their management via abortion, and the influence of abortion restrictions on clinical decision making.

Study Design: We distributed an anonymous, cross-sectional, electronic survey to EM providers nationwide using social media platforms and specialty listservs. Using Likert-type scales, the survey listed several obstetric presentations; participants then reported (1) which might qualify as obstetric emergencies, (2) the appropriateness of abortion as management for these conditions, (3) the availability of abortion at their site, and (4) their beliefs on obligation to provide abortion if against state law. We examined variations based on the abortion permissiveness or restrictiveness of the participant's state of practice via bivariate analysis.

Results: Most respondents (N = 203) identified as non-Hispanic white (69%), female (57%), attending physicians (74%), in abortion-permissive states (61%). A majority thought that ruptured ectopic pregnancy (96%), hemorrhage (82%), septic abortion (59%), pulmonary embolism (51%), and hypertensive disease (51%) were obstetric emergencies requiring immediate, life-saving intervention. Abortion was viewed as often/always appropriate for ectopic pregnancy (97%), septic abortion (89%), incomplete abortion (83%), hemorrhage (65%), hypertensive disease (52%), pregnancy loss (50%), infection (45%), preterm premature rupture of membranes (38%), and pulmonary embolism (11%). Many (21%) believed legal restrictions would prevent EM providers from considering abortion for obstetric emergencies; 9% reported that abortion restrictions personally affected their clinical decision-making. Most (84%) agreed that EM clinicians must provide and/or facilitate abortion for obstetric emergencies, even if prohibited by state law. Responses did not vary by abortion permissive versus restrictive states (p = 0.48).

Conclusion: EM providers consider many diagnoses to be obstetric emergencies with abortion being an appropriate treatment in many cases, even if prohibited by state law.

894 | Does First Trimester Blood Pressure Affect Uterine Artery Doppler Changes During Pregnancy?

Rebecca Horgan[1]; Erkan Kalafat[2]; Elena Sinkovskaya[1]; Alfred Z. Abuhamad[1]; George R. Saade[1]
[1]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [2]Koc University Hospital, Istanbul, Istanbul

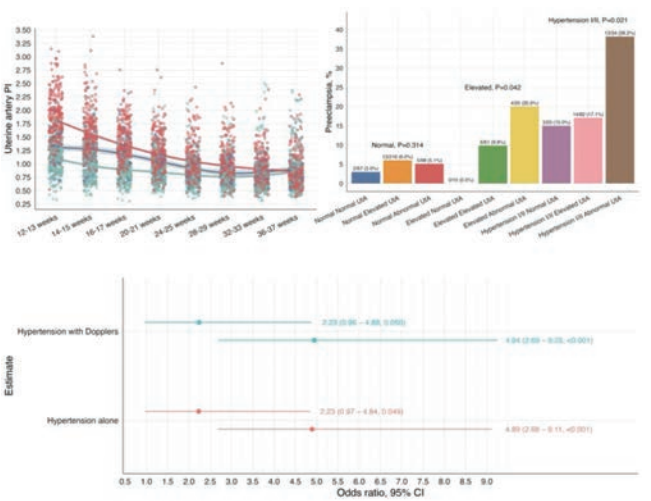
10:30 AM - 12:30 PM

Objective: First trimester blood (BP) has been shown to have an association with preeclampsia (PE) development later in pregnancy. Our objective was to determine whether this association is dependent on change in uterine perfusion which is also known to be associated with PE.

Study Design: This was a prospective longitudinal cohort study within the Human Placenta Project which enrolled patients at ≤ 13+6 weeks' gestation. Data was obtained by trained research coordinators. At the 1st trimester study visit, BP was measured and categorized according to the American Heart Association (AHA) classification as normal, elevated, or hypertension which included stage 1 and stage 2. Uterine artery Doppler pulsatility index (UtA-PI) was obtained at eight timepoints during pregnancy beginning in the first trimester (Figure). Doppler values were modeled with mixed-effects regression and longitudinal trajectories were formed with k-means clustering. Additive effect of Doppler values to blood pressure was assessed with Cochrane-Armitage test for trend. A mediation analysis was undertaken to elucidate how much of the effect of blood pressure (BP) is exerted over Doppler values.

Results: 608 pregnancies were included in the analysis, with 60 developing PE. Longitudinal assessment of UtA-PI revealed 3 trajectory groups (normal, elevated, abnormal, Figure). Addition of UtA-PI to first trimester blood pressure categorization improved the risk classification for AHA elevated BP (PE developed in 0.0%, 9.8%, 20.0% of UtA normal, elevated, and abnormal, P = 0.042) and AHA hypertension categories (PE developed in 15.0%, 17.1%, 38.2% of UtA normal, elevated, and abnormal, P = 0.021) (Figure). On the mediation analysis, the odds ratio of elevated BP (OR: 2.23, 95% CI: 0.96-4.88 vs. 2.23, 95% CI: 0.97-4.84) and hypertension categories (OR: 4.94, 95% CI: 2.69-9.25 vs. 4.89, 95% CI: 2.68-9.11) changed very little with the addition of Doppler values.

Conclusion: First trimester BP categorization according to AHA is an independent risk factor for preeclampsia and related risk is not exerted over uterine artery function.



895 | First and Third Trimester Ultrasound Markers for Prediction of Placenta Accreta Spectrum & Clinical Outcomes

Rebecca Horgan[1]; Elizabeth Miller[2]; Yara Hage Diab[1]; Juliana Martins[3]; George R. Saade[1]; Camille Kanaan[1]; Jerri A. Waller[1]
[1]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [2]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medial

School at Old Dominion University, Norfolk, VA; [3]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medial School at Old Dominion University, Virginia Beach, VA

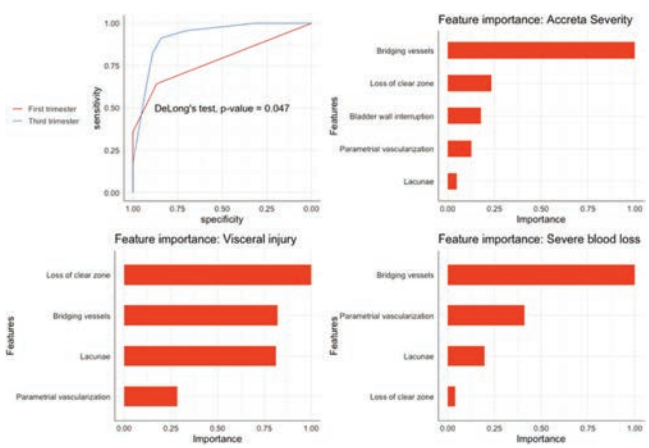
10:30 AM - 12:30 PM

Objective: To evaluate the predictive accuracy of ultrasound markers for placenta accreta spectrum (PAS) and associated clinical outcomes in patients with prior cesarean delivery and placenta previa.

Study Design: This retrospective cohort study included patients with prior cesarean delivery and placenta previa who received prenatal care at our tertiary center from Jan 2015 to June 2022. Ultrasound markers evaluated in the first and third trimester included lacunae presence/count, bladder wall interruption, loss of retroplacental clear zone, bridging vessels, and parametrial vascularization. Ultrasounds were reviewed blindly by an MFM physician. Primary outcome was PAS and secondary outcomes included PAS severity (accreta, increta, percreta), visceral injury during surgery (bladder, ureter, bowel), and severe blood loss (EBL >1000 mL or blood transfusion). Shallow gradient booster models assessed prediction model performance with area under the curve (AUC) values and feature importance plots.

Results: Of 111 pregnancies, the final diagnosis was PAS in 33 and placenta previa without PAS in 78. Third-trimester ultrasound markers were highly predictive of PAS (AUC: 0.92, 95% CI: 0.86-0.98) vs. first-trimester markers (AUC: 0.79, 95% CI: 0.63-0.93) (P = 0.047). The most predictive feature of PAS severity was bridging vessels, followed by loss of clear zone. Increta or percreta diagnosis rates were 34.4% (both features present), 18.2% (one feature), and 4.4% (absent). Visceral injury prediction was highest with loss of clear zone, followed by bridging vessels: 21.9% (both present), 18.2% (one), 2.9% (absent). Severe blood loss predictors were bridging vessels and parametrial vascularization: 89.7% (both present), 82.1% (one), 44.4% (absent).

Conclusion: Third-trimester ultrasound is an excellent predictor of PAS diagnosis. PAS ultrasound features vary in predictive potential for clinical outcomes. Top predictors of PAS severity, visceral injury, and severe blood loss are bridging vessels, loss of clear zone, and parametrial vascularization.



896 | Machine Learning Prediction of Gestational Hypertensive Complications at Point-of-Care

Reetam Ganguli[1]; Julia Sroda Agudogo[2]; Stephen Wagner[2]

[1]Elythea, San Jose, CA; [2]Beth Israel Deaconess Medical Center, Boston, MA

10:30 AM - 12:30 PM

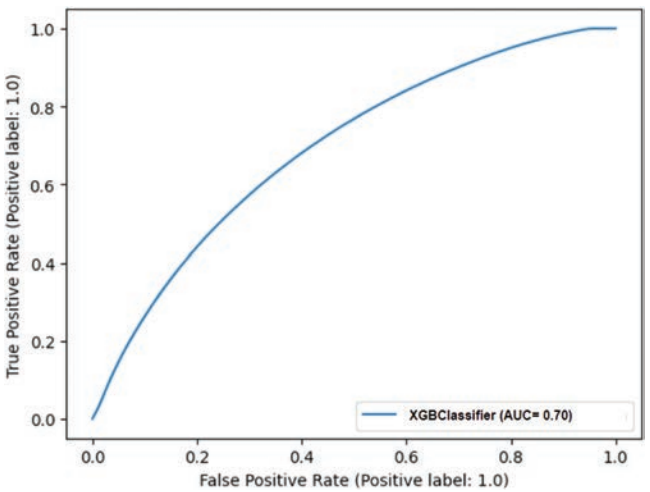
Objective: Hypertensive disorders of pregnancy (HDP) pose significant risks to both maternal and fetal health, potentially leading to early induction and NICU admission. Early identification and intervention have been shown to prevent up to 80% of preeclampsia cases. This study aims to develop and evaluate a machine learning model to predict preeclampsia using routinely collected prenatal variables.

Study Design: An extreme gradient boosting model was developed to predict the risk of HDP, inclusive of preeclampsia and gestational hypertension. The model was trained on data from the American College of Surgeons National Surgical Quality Improvement Program database comprising prenatal and demographic variables from a large cohort of pregnant women from 2018 to 2021 and tested on data from 2022.

Inclusion criteria were term deliveries without missing data for hypertensive complications. Patients missing hypertensive complication data were excluded. The model incorporated clinical history, demographic information, and early-stage comorbidities. To address class imbalance, weight scaling algorithms were utilized and patients from 2014-2017 with hypertensive complications to enhance the representation of the positive class, with the exception of 2015 patients due to corrupted data.

Results: 35 factors across 11,298,212 patients were used to develop the model. Of these patients, 1,551,321 (13.7%) had prenatal hypertensive complications, The model was tested on 3,258,442 total patients, of which 907,974 (27.9%) had hypertensive complications. The XGBClassifier model achieved an AUC-ROC of 0.70, with a 74.9% accuracy, 48.2% sensitivity and 0.75 F1 score.

Conclusion: Early-stage predictive models used at the point of care can detect nearly half of all hypertensive complications at the point of care with discriminative ability. Early identification through such models may allow for targeted clinical interventions, harboring potential for the prevention of hypertensive cases and cost savings for payors.



897 | Transfer Status and Severe Hemorrhage Risk in Cesarean Section Patients

Reetam Ganguli[1]; Joshua Woo[2]; Alice Lin[2]; Maguire Anuszewski[2]; Julia Sroda Agudogo[3]; Stephen Wagner[3]
[1]Elythea, San Jose, CA; [2]Warren Alpert Medical School, Brown University, Providence, RI; [3]Beth Israel Deaconess Medical Center, Boston, MA

10:30 AM - 12:30 PM

Objective: Transfer status influences severe hemorrhage risk in cesarean section patients, highlighting the importance of tailored preoperative management strategies to mitigate complications. This study evaluated the association between transfer indications and severe hemorrhage necessitating transfusion in patients undergoing cesarean sections.

Study Design: A retrospective cohort study was conducted using data from the American College of Surgeons National Surgical Quality Improvement Program (ACS NSQIP) database from January 2009 to December 2021. Included were patients undergoing cesarean sections identified by Current Procedural Terminology (CPT) codes 59510, 59514, 59515, 59618, 59620, and 59622. Exclusion criteria included missing data for the outcome variable indicating severe hemorrhage necessitating transfusion. Chi-square tests determined statistical significance, and odds ratios (OR) with 95% confidence intervals (CI) quantified the risk of severe hemorrhage for patients with different transfer statuses compared to patients who were not transferred.

Results: In our cohort of 43,713 patients, 61.27% were not transferred (admitted from home). Transfers from home/permanent residence had a significantly lower risk of severe hemorrhage (OR = 0.755, 95% CI: 0.677-0.842, $p < 0.001$). Conversely, transfers from outside emergency departments (OR = 4.307, 95% CI: 2.057-9.020, $p < 0.001$) and other facilities (OR = 5.653, 95% CI: 1.263-25.302, $p = 0.079$) exhibited markedly higher risk. Acute care hospital transfers were also associated with a significantly lower risk of severe hemorrhage (OR = 0.336, 95% CI: 0.218-0.517, $p < 0.001$). Transfers from acute care hospital inpatient and unknown transfer reasons did not show statistically significant differences.

Conclusion: Cesarean deliveries transferred from outside emergency departments and other facilities are at higher hemorrhage risk, making enhanced preoperative management vital. These findings emphasize considering transfer status in risk stratification and preoperative planning to mitigate hemorrhage risks in cesarean section patients.

Transfer Reason	Count	Percentage (%)	p-value	OR	95% CI Lower	95% CI Upper

898 | Weighing the Options: A Six-Year Single-Center Analysis of Second No-Call Non-Invasive Prenatal Testing Results

Ronan Daly[1]; Fianat Bligh[2]; Sirisha Bellamkonda[2]; Claire O'Rourke[2]; Elizabeth Tunney[1]; Patrick Dicker[1]; Sieglinde Mullers[3]; Fergal D. Malone[4]; Karen Flood[5]
[1]Royal College of Surgeons in Ireland, Dublin, Dublin; [2]RCSI Rotunda Hospital, Dublin, Dublin; [3]Rotunda Hospital Dublin, Dublin, Dublin; [4]Royal College of Surgeons in Ireland, Dubiln, Dublin; [5]Royal College of Surgeons in Ireland, Dublin, DE

10:30 AM - 12:30 PM

Objective: While a low-risk Non-invasive Prenatal Screening (NIPS) can offer reassurance for expectant parents, a no-call result (NCR) can cause significant anxiety. A definitive result is not guaranteed with repeat NIPS and a second NCR may compound patient uncertainty. This study aims to inform clinical practice and counselling for patients who receive NCRs by analyzing the demographics and outcomes of NCRs over the past six years.

Study Design: This retrospective cohort study was conducted at a large obstetric hospital in Ireland, utilizing a SNP-based cell-free fetal DNA test. We identified NCRs through an integrated electronic healthcare record. Data were collected on all patients who received NCRs from November 2017 to January 2024.

Results: 10,025 NIPS were conducted with 376 of patients receiving an initial NCR (3.8%). The median gestational age at first NIPS draw was 10.4 weeks [IQR: 9.7,11.7] with no significant difference across weight groups ($p = 0.566$). 354 (94%) underwent a second NIPS with a result yielded in 76% (n = 269) and 85 patients (24%) receiving a second NCR. A significant difference was found in the distribution of second NCRs by weight ($p = 0.001$), with 40% of patients in the > 90 kg group receiving a further NCR. Fetal fraction (FF) at second NIPS decreased significantly according to maternal weight, with a median FF of 6.5% [IQR: 4.3,10.0] in patients < 65kgs and a median FF of 3.1% [IQR: 2.5,4.3] in those > 90kgs ($p = 0.001$). 24% of second NCRs (n = 20) underwent invasive testing, with half of these pregnancies affected by fetal aneuploidy. Table 1 summarizes the trends in NCRs and FF according to maternal weight.

Conclusion: Despite repeat NIPS often providing a definitive result following an initial NCR, our study shows a significant correlation between maternal weight above 90kgs and the likelihood of a second NCR. Given this 40% risk of a further NCR and the underlying risk of fetal aneuploidy, we recommend offering invasive diagnostic options following an initial NCR to provide certainty for this patient group.

Table 1.

Outcome		All (N=376)	Weight Group (Quartiles) < 65 kg	65–75 kg	75-90 kg	> 90 kg	P-value†

899 | Assessing Antenatal and Postnatal Growth in Severe and Non-Severe Fetal Growth Restriction

Roopjit K. Sahi; Manesha Putra; John Hobbins
University of Colorado Anschutz Medical Campus, Aurora, CO

10:30 AM - 12:30 PM

Objective: Our aim was to determine if severity of fetal growth restriction (FGR) is related to growth trajectory after birth, and whether an in-utero marker of body composition, including thigh volume, correlates with growth after birth.

Study Design: In this retrospective observational study, FGR pregnancies were included, and subdivided as severe or non-severe (severe FGR indicating estimated fetal weight, EFW or abdominal circumference, AC less than 3rd percentile, with or without Doppler abnormalities). Measures of EFW, AC, total thigh volume (TTV), lean mass volume (LMV) were extracted from antenatal scans. Fat mass volume (FMV) was calculated by subtracting TTV from LMV. Postnatally, weight (and z-scores) was measured at birth, 1-3 months, 6 months, 1-year, 3 years, and 5 years of age. Median values (and interquartile range) of indices were compared between both groups. Using Pearson correlation analysis, correlation coefficients (r) were calculated between antenatal and postnatal parameters.

Results: The cohort includes 42 severe and 14 non-severe FGR pregnancies. In the severe FGR group, median values of TTV, LMV, FMV, EFW, EFW percentile, and AC percentile were lower compared to those in non-severe group (p< 0.05); ultrasounds done at the median gestational age of 35.93 weeks in both groups. Incidence of 'accelerated growth' (increase in weight z-score greater than 0.8) was higher in severe FGR group (80.9% versus 35.7%, p 0.01), typically observed between 6 months-3 years of age (Figure 1(a), 1(b)). By 5 years of age, weight (and z-score) of infants from severe group was lower than non-severe group (p 0.04). Birthweight (BW) correlated well with TTV (r 0.62, p < 0.01), and EFW percentile (r 0.69, p < 0.01). However, no significant correlations were observed during subsequent follow-ups.

Conclusion: In severe FGR group, despite accelerated growth of infants between 6 months-3 years, the median weight is lesser compared to non-severe group at 5 years of age, which could result in false reassurance in earlier years. In-utero markers, TTV and EFW, correlate significantly and similarly with BW.

Figure 1 (b). Scatter plot depicting the infant growth as weight (kgs) between birth and 5-years of age in severe and non-severe FGR groups, with associated trendlines.

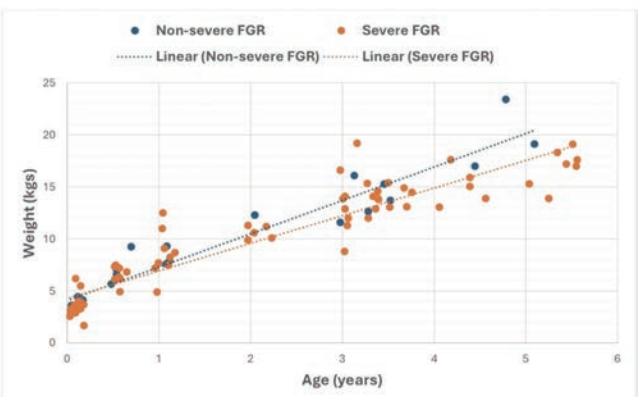

Figure 1 (b). Scatter plot depicting the infant growth as z-scores between birth and 5-years of age in severe and non-severe FGR groups, with associated trendlines.

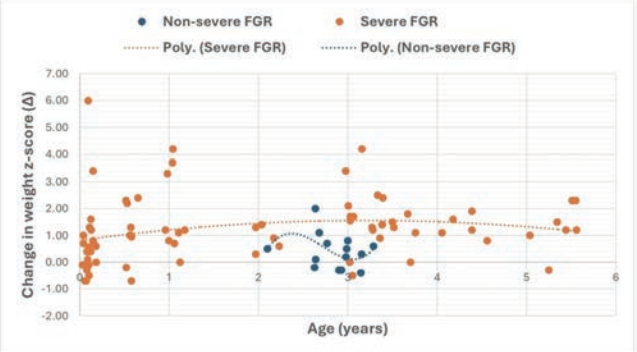

900 | Prediction Model for Spontaneous Onset of Active Labor After Pre-Labor Rupture of Membranes at Term

Roza Berkovitz-Shperling[1]; Omri Dominsky[2]; Yariv Yogev[3]; Shai Ram[4]
[1]Tel Aviv Sourasky Medical Center, Tel Aviv Sourasky Medical Center, Tel Aviv; [2]Tel Aviv Sourasky Medical Center, Tel Aviv Sourasky Medical Center, HaMerkaz; [3]Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv University, Tel Aviv Sourasky Medical Center, Tel Aviv; [4]ICHILOV, Tel Aviv, HaMerkaz

10:30 AM - 12:30 PM

Objective: Term pre-labor rupture of membranes (PROM) is a significant event that may pose risks for maternal and fetal complications. We aimed to develop a predictive model for the spontaneous onset of active labor within 24 hours following membrane rupture at term.

Study Design: 1. 1. A retrospective cohort study in a single, university-affiliated tertiary medical center which included women who presented at term (37-41 weeks) with PROM and were managed conservatively upon patient request, without induction of labor, (January 2011–December 2023).

2. The primary outcome was spontaneous onset of active labor, defined as cervical dilation to 6 centimeters (cm), within 24 hours after membrane rupture.

3. Exclusion criteria included: women who received oxytocin during the 24 hours after PROM and before reaching active labor (6 cm dilatation), women with non-clear amniotic fluid, the necessity for cesarean delivery, suspected infection and non-reassuring fetal monitoring.

4.Potential risk factors including demographic, medical and obstetric characteristics were examined.

5. Repeat amniotomy was defined as the need for additional amniotomy, after admission with PROM.

6. Prediction model was built using a backward variable selection based upon significant risk factors which were found in the multivariable logistic regression ($P < .05$).

Results: 1. Overall, during the study period 10,633 women met the inclusion criteria and were enrolled.

< 2.Within 24 hours after PROM, 6,961 (65.4%) had spontaneous onset of active labor.

< 3. Spontaneous onset of labor after PROM was associated with parity, cervical dilatation and cervical length at admission, repeat amniotomy, and GBS status.

< !4. The prediction model for onset of labor within 24 hours after PROM had an area under the curve (AUC) of 0.813 with accuracy of 75.94%

Conclusion: The predictive model effectively identifies women at higher chance of spontaneous active labor within 24 hours following PROM. This model may improve clinical decision-making and labor management strategies after term PROM.

Table 1 – Prediction model for spontaneous labor within 24 hours following PROM

Variable	OR	95% OR	P -value

10:30 AM - 12:30 PM

Objective: To evaluate the association between birth location (birth center vs. hospital) and the risk of infant death in twin pregnancies.

Study Design: This retrospective cohort study analyzed data from the NCHS linked multiple birth and infant death database from 2016 to 2020. Inclusion criteria were matched twin pregnancies without congenital anomalies. Infant mortality was the primary outcome. Chi-square tests and logistic regression models were used to assess the association between birth location and infant mortality, adjusting for gestational age at delivery (GA ≤ 34 weeks and GA > 34 weeks) and order of birth (Twin A and Twin B).

Results: Among 607,355 twin births, the overall rate of neonatal death was 0.97%. Neonatal death was higher in birth centers (3.04%) compared to hospitals (0.96%) (p < 0.001). For GA > 34 weeks, neonatal death was 0.82% in birth centers vs. 0.18% in hospitals (p < 0.001, OR 4.59 [95% CI 2.75-7.67]). For GA ≤ 34 weeks, neonatal death was 13.68% in birth centers vs. 4.24% in hospitals (p < 0.001, OR 3.58 [95% CI 2.67-4.81]). In Twin A, neonatal death was 3.65% in birth centers vs. 0.93% in hospitals (p < 0.001, OR 4.06 [95% CI 3.00-5.50]), while in Twin B, neonatal death was 2.30% in birth centers vs. 1.00% in hospitals (p < 0.001, OR 2.32 [95% CI 1.53-3.52]).

Conclusion: Birth center delivery is associated with a significantly higher risk of infant mortality in twin pregnancies compared to hospital delivery. This increased risk persists across different gestational ages and the order of birth. These findings suggest that hospital deliveries might offer safer outcomes for twins, particularly those at higher risk of neonatal complications.

Table: Birth location and risk of infant death in twins

	Birth Center	Hospital	P Value	OR (95% CI)
All twins	67/2,203 (3.04%)	5,836/605,152 (0.96%)	<0.001	3.584 (2.671 - 4.809)
GA > 34 weeks	15/1,823 (0.82%)	880/488,155 (0.18%)	<0.001	4.594 (2.752 - 7.669)
GA ≤ 34 weeks	52/380 (13.68%)	4,956/116,997 (4.24%)	<0.001	3.584 (2.671 - 4.809)
Twin A	44/1,204 (3.65%)	2,802/302,863 (0.93%)	<0.001	4.062 (2.999 - 5.501)
Twin B	23/999 (2.30%)	3,034/302,289 (1.00%)	<0.001	2.324 (1.535 - 3.520)

902 | is Expectant Management of Late Pprom an Option in Patients with Gbs Colonization?

Sabina Razdolsky; Elior Eliasi; Elana Minic; Hadel Jamal; Ariel Mani; Miriam Lopian

Mayanei Hayeshua Medical Center, Mayanei Hayeshua Medical Center, Tel Aviv

10:30 AM - 12:30 PM

Objective: To determine if carriers of group B streptococcus (GBS) have adverse obstetric and neonatal outcomes when preterm premature rupture of membranes (PPROM) occurs between 34 to 37 weeks of pregnancy.

Study Design: A retrospective cohort study was conducted at a single university-affiliated medical center between 2012 and 2022. Patients who had preterm premature rupture of membranes (PPROM) between 34 to 37 weeks of pregnancy carrying a singleton gestation, with no contraindications to expectant management were included in the study group. According to the department protocol, all patients with PPROM receive 1G of IV Azithromycin once and 4g of IV penicillin every 4 hours. Antibiotics are discontinued in patients negative for GBS and continued for one week in GBS positive patients. Outcomes were compared to those with a negative GBS culture. Baseline demographic characteristics were compared between the groups. The primary outcome was latency from PPROM till delivery. Secondary outcomes included cesarean delivery, composite adverse maternal outcome (PPH, chorioamnionitis, abruption of

placenta) and composite neonatal outcome (NICU admission, respiratory distress syndrome, early onset GBS disease).

Results: Two hundred and seventeen patients were included in the study. 98(45.2%) were GBS carriers and 119 (54.8%) were noncarriers. There were no significant between group differences in mean maternal age (27.3±6,29.7±6.1;p = 0.37) or gestational age at delivery (252 days±5,252 days±6;p = 0.4), rate of diabetes (10.1%,10.2%;p = 0.97) neonatal mean birthweight (2602g,2698g;p = 0.32).

There were no significant differences between the groups for the primary outcome of duration from membrane rupture until delivery (2.83 ± 2.9 days,3.03 ± 2.9 days;*P* = 0.98) nor the rate of cesarean delivery (9.8%,10.9%;p = 0.45) or in composite maternal (2.7%,1.9%;p = 0.26) or neonatal outcomes(23%,22%;p = 0.34).

Conclusion: Expectant management of late PPROM in GBS carriers is not associated with an increased risk of adverse maternal or neonatal outcomes.

baseline demographic characteristics			
	GBS carriers	noncarriers	P value
Mean maternal age	27.3±6	29.7±6.1	0.37
Gestational age at delivery	252 days±5	252 days±6	0.4
Rate of diabetes	10.1%	10.2%	0.97
Hypertension disease	2%	1.7%	0.84
Neonatal mean birthweight	2602g±36	2698g±55	0.32
Maternal and neonatal outcomes			
Rate of cesarean delivery	9.8%	10.9%	0.45
PPH	4.2%	1.7%	0.27

Composite neonatal outcomes	23%	22%	0.34
Duration from membrane rupture until delivery	2.83 ± 2.9 days	3.03 ± 2.9 days	0.98

903 | Perinatal Mortality and Other Severe Outcomes Following Planned Birth at 39 Weeks Versus Expectant Management

Kylie Crawford[1]; Waldemar A. Carlo[2]; Anthony O. Odibo[3]; Aris T. Papageorghiou[4]; William Tarnow-Mordi[5]; Sailesh Kumar[6]; On behalf of the Mater Research Institute and The University of Queensland

[1]Mater Research Institute-The University of Queensland, Brisbane, Queensland; [2]University of Alabama at Birmingham, Birmingham, AL; [3]University of Missouri - Kansas City, Leawood, KS; [4]University of Oxford, Oxford, England; [5]The University of Sydney, Sydney, New South Wales; [6]The University of Queensland, Brisbane, Queensland

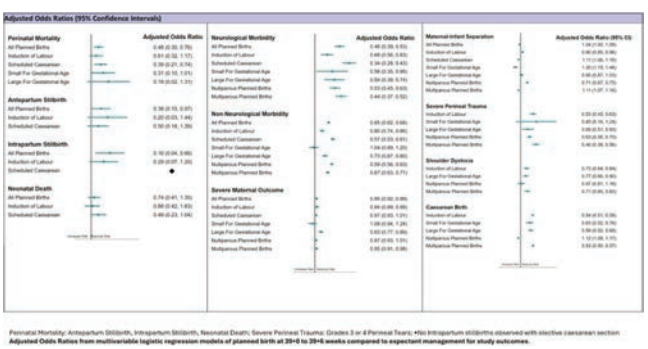
10:30 AM - 12:30 PM

Objective: To investigate differences in perinatal and maternal outcomes in low-risk women following **any type of planned birth** (induction of labour or scheduled caesarean section) at 39^{+0}–39^{+6} weeks versus expectant management.

Study Design: Retrospective cohort study. Study outcomes were perinatal mortality, severe neonatal neurological morbidity, severe neonatal non-neurological morbidity, severe maternal outcome, maternal-infant separation, severe perineal trauma, shoulder dystocia, and caesarean birth. Subgroup analyses according to parity and birthweight were also performed.

Results: Of 472,520 low-risk pregnancies $\geq 39^{+0}$ weeks planned birth at 39^{+0}–39^{+6} weeks occurred in 97,438 (20.6%) women of whom 39,697 (40.7%) underwent induction of labour and 57,741 (59.3%) had scheduled caesarean delivery. Compared with expectant management, planned birth at 39^{+0}–39^{+6} weeks was associated with lower odds of perinatal mortality (aOR 0.48; 95%CI 0.30, 0.76, p = 0.002), antepartum stillbirth (aOR 0.38; 95%CI 0.15, 0.97, p = 0.04), and intrapartum stillbirth (aOR 0.16; 95%CI 0.04, 0.66, p = 0.01). Planned birth was also associated with reduction in the odds of severe neonatal neurological morbidity (aOR 0.46; 95%CI 0.39, 0.53, p = 0.00004), severe neonatal non-neurological morbidity (aOR 0.65; 95%CI 0.62, 0.68, p = 0.00004), severe maternal outcome (aOR 0.95; 95%CI 0.92,0.99, p = 0.008) and increased odds of maternal-infant separation (aOR 1.04; 95%CI 1.00, 1.08, p = 0.075). Planned birth by induction of labour was associated with reduced odds of caesarean delivery (aOR 0.54; 95%CI 0.51, 0.58, p = 0.00004), severe perineal trauma (aOR 0.53; 95%CI 0.45, 0.63, p = 0.00004), and shoulder dystocia (aOR 0.73; 95%CI 0.64, 0.84, p = 0.00004).

Conclusion: Planned birth between 39^{+0}–39^{+6} weeks in low-risk women compared to expectant management was associated with lower odds of perinatal mortality, severe neonatal neurological and non-neurological morbidity and severe maternal outcome. For women who were induced, it was associated with lower odds of severe perineal trauma, shoulder dystocia, and caesarean birth.



904 | Twin Twin Transfusion Syndrome (TTTS) Stage 1: Do We Manage Expectantly vs. Treat Immediately?

Sami Backley[1]; Eric P. Bergh[2]; Jimmy Espinoza[1]; Felicia V. LeMoine[1]; Neha Agarwal[3]; Gustavo Vilchez[4]; Percy N. Pacora-Portella[5]; Anthony Johnson[6]; Edgar A. Hernandez-Andrade[7]; Ashley Salazar[8]; Sen Zhu[9]; Ramesha Papanna[7]

School at UTHealth Houston, Houston, TX; [6]McGovern Medical School University of Texas Health Science Center at Houston (UThealth), Houston, TX; [7]McGovern Medical School at UTHealth Houston, Houston, TX; [8]Division of Fetal Intervention, Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern Medical School at UT Health Houston, Houston, TX; [9]McGovern Medical School at the University of Texas, Houston, TX

10:30 AM - 12:30 PM

Objective: Randomized controlled trial (RCT) for twin-twin transfusion syndrome (TTTS) Stage 1 showed no difference in survival between expectant management and immediate fetoscopic laser surgery (FLS). However, higher perinatal survival with immediate FLS for TTTS Stage 1 has been reported and may justify immediate treatment. We aimed 1) to compare perinatal survival between expectant management and immediate treatment in TTTS Stage 1 and 2) to compare perinatal survival across TTTS Stages 1-4 who underwent FLS for treatment of TTTS.

Study Design: Perinatal survival of TTTS Stage 1 undergoing expectant management reported by Stirnemann et al, were compared to perinatal survival rates at our center utilizing prospective data from 90 monochorionic, diamniotic twin pregnancies complicated by TTTS Stage 1. All pregnancies underwent immediate FLS between 2011-2024. Pregnancies with cervical length < 1.5cm, non-isolated TTTS, missing delivery or neonatal outcomes were excluded. The primary outcome was dual perinatal survival. Survival outcomes for TTTS Stage 1 were also compared to TTTS stages 2-4.

Results: Our center's dual survival to birth was higher than the previously reported rates with expectant management of TTTS Stage 1 (Table 1). There was no difference in dual perinatal survival between our center and the previously reported rates in expectantly managed TTTS Stage 1 (Table 1); however, the sample size was not sufficient to detect the 10% difference in dual perinatal survival. Perinatal survival was higher in TTTS Stage 1 with immediate FLS when compared to other TTTS stages with FLS (Table 2).

Conclusion: Perinatal outcomes following immediate FLS for TTTS Stage 1 are more favorable when compared to other TTTS Stages and similar, or better, than expectant management. Immediate FLS should be considered a viable treatment option for TTTS stage 1, though a larger randomized trial to test the efficacy of immediate FLS should be considered.

Table 1: RCT* Expectant Management compared to UT-Houston Immediate FLS

	RCT-Expectant*	UTH-Immediate Treatment	p-value
Survival to Birth			
2	48 (83%)	82 (91%)	0.04

905 | Risk Factors for PPROM Following Laser Surgery in Twin-to-Twin Transfusion Syndrome

Sami Backley[1]; Eric P. Bergh[2]; Felicia V. LeMoine[1]; Neha Agarwal[3]; Gustavo Vilchez[4]; Ashley Salazar[5]; Edgar A. Hernandez-Andrade[6]; Anthony Johnson[7]; Ramesha Papanna[6]; Jimmy Espinoza[1]

[1]Division of Fetal Intervention, Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern Medical School at UTHealth Houston, Houston, TX; [2]UT Health, Houston, TX; [3]Division of Fetal Intervention, Department of Obstetrics, Gynecology and Reproductive Sciences, UTHealth McGovern Medical School, Houston, TX, USA, Houston, TX; [4]UTHealth Houston, Houston, TX; [5]Division of Fetal Intervention, Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern Medical School at UT Health Houston, Houston, TX; [6]McGovern Medical School at UTHealth Houston, Houston, TX; [7]McGovern Medical School University of Texas Health Science Center at Houston (UThealth), Houston, TX

10:30 AM - 12:30 PM

Objective: Preterm prelabor rupture of membranes (PPROM) is the most frequent complication of in-utero surgery. The intraoperative use of distention media, such as lactated Ringer's, is thought to be caustic to the amniotic membrane. We sought to identify risk factors of PPROM following fetoscopic laser surgery (FLS) for twin-twin transfusion syndrome (TTTS).

Study Design: This single-center prospective cohort study included monochorionic-diamniotic twin pregnancies who underwent FLS between 2011 and 2024 for management of TTTS. PPROM was defined as PROM < 34 weeks' gestation. Pregnancies with missing delivery or neonatal outcomes were excluded. Maternal characteristics and perioperative factors were compared using comparative statistics. Multiple logistic regression was performed to evaluate the relationship between PPROM and the following factors: gestational age (GA) at FLS, amnioinfusion, and other confounders. Cox proportional hazard modeling was performed to evaluate factors influencing the procedure-to-delivery interval (days).

Results: PPROM occurred in 292 (39%) of 748 eligible pregnancies. Clinical characteristics are displayed in Table 1. GA at delivery was earlier and smaller amnioreduction volumes were seen in pregnancies with PPROM compared pregnancies without PPROM (Table 1). GA at FLS (adjusted odds ratio [aOR] 0.85, 95% confidence interval [CI] 0.77-0.94), pre-operative cervical length (aOR 0.98, 95% CI 0.96-0.99), placental abruption (aOR 1.94, 95% CI 1.01-3.72), collagen plug placement (aOR 2.17, 95% CI 1.18, 3.98) and chorioamnion membrane separation (CAS) (aOR 5.42, 95% CI 2.54-11.56) were associated with the diagnosis of PPROM. PPROM, CAS, cervical length prior to FLS, placental abruption, and GA at FLS independently influenced procedure-to-delivery interval (Figure 1).

Conclusion: PPROM remains a major complication of FLS resulting in an earlier GA at delivery. CAS is the most important risk factor for PPROM after FLS surgery while amnioinfusion of ≥1 L is not a risk factor for PPROM following FLS for the management of TTTS.

906 | Rurality is Associated with Increased Risk for Severe Maternal Morbidity Among Socially Vulnerable Communities

Sara EK Phillips; Bharti Garg; Sophie Neuner Weinstein; Aaron B. Caughey
Oregon Health & Science University, Portland, OR

10:30 AM - 12:30 PM

Objective: To evaluate the association between severe maternal morbidity (SMM) and rural residence among communities of high social vulnerability.

Study Design: We performed a retrospective cohort study using California's linked vital statistics-hospital discharge data (2018-2020). The study population composed of individuals with singleton, non-anomalous pregnancies delivered between 20-44 weeks' gestation with maternal residence (at time of birth) in communities deemed high on the Center for Disease Control's (CDC) Social Vulnerability Index (SVI) in 2020. Our primary outcome was a composite of SMM, defined using the CDC's published list of 21 indicators. Multivariable Poisson regression was used to calculate an adjusted risk ratio to assess whether rural residence in socially vulnerable communities was associated with SMM.

Results: Of the 605,301 births meeting inclusion criteria, 38,350 (6.3%) were from rural California. Rural Californians were more likely to be Non-Hispanic White (34.2% vs 21.8%), less than 20 years of age (6.4% vs 4.3%), publicly insured (71.2% vs. 55.9%) and have an education level of high school or below (54.1% vs 41.9%). Compared to urban centers, the prevalence of SMM was greater in rural communities of high SVI (1.75% vs. 1.46%, p< 0.001). The indicator with the highest proportion was maternal blood transfusion (1.5% for rural, 1.1% for urban, p< 0.001). There was an increased risk of SMM in rural communities after adjusting for maternal race/ethnicity, age, education, insurance, parity, and preexisting diabetes and hypertension (aRR 1.21; 1.12-1.31).

Conclusion: SVI reflects a community-level resilience for combating external stressors. Our findings suggest that individuals from rural communities with high social vulnerability may face additional disadvantages compared to their urban counterparts. More research is needed to explore the root causes of rural maternal disparities, so we may design meaningful interventions to optimize the health of our rural patients.

Table 1. Severe maternal morbidity and its indicators among rural and urban socially vulnerable communities in California, 2018-2020

907 | Rurality is Associated with Decreased Risk for Adverse Neonatal Outcomes Among Socially Vulnerable Communities

Sara EK Phillips; Bharti Garg; Sophie Neuner Weinstein; Aaron B. Caughey
Oregon Health & Science University, Portland, OR

10:30 AM - 12:30 PM

Objective: To assess the relationship between rural residence and adverse neonatal outcomes among socially vulnerable communities.

Study Design: This is a retrospective cohort study using California's linked vital statistics-hospital discharge data (2018-2020). Our study population included all singleton, non-anomalous pregnancies delivered between 20-44 weeks' gestation with maternal residence in communities deemed high on the Center for Disease Control's (CDC) Social Vulnerability Index (SVI). The outcome of interest was an adverse neonatal composite including preterm delivery, neonatal intensive care unit (NICU) admission, small for gestational age, low birth weight, seizures, birth injury, and neonatal sepsis. Adjusted risk ratios were calculated using multivariable Poisson regression to assess whether rural residence in socially vulnerable communities was associated with the neonatal composite.

Results: Of the 605,301 births within high SVI communities, 38,350 (6.3%) were from rural California. The rural cohort were more likely to be Non-Hispanic White (34.2% vs 21.8%), younger than 20 years of age (6.4% vs 4.3%), publicly insured (71.2% vs. 55.9%) and have an education level of high school or below (54.1% vs 41.9%). The adverse neonatal composite was significantly higher among urban communities compared to their rural counterparts (23.8% vs 21.8%, P< 0.001). After adjusting for maternal race/ethnicity, age, education level, insurance status, parity, and preexisting diabetes and hypertension, the risk of the adverse neonatal composite was lower among the rural cohort (aRR = 0.94; 95% CI: 0.92-0.95).

Conclusion: Social Vulnerability measures a community's ability to face external stressors and public health emergencies. Our analysis suggests that rural communities with high SVI may have protective factors that positively impact reproductive outcomes compared to their urban counterparts. However, more research is needed to better understand disparities in health outcomes between rural and urban birthing individuals.

Table 1. Adverse neonatal outcomes among rural and urban socially vulnerable communities in California, 2018-2020

	Urban	Rural	P*
	N=566,807	N=38,350

908 | Blood Pressure Patterns in Pregnancy using In-Clinic and Remote Monitoring and Hypertensive Disorders of Pregnancy

Sara M. Sauer[1]; Timothy Wen[2]; Noam Finkelstein[1]; Mia Charifson[1]; Chloe Li[1]; Adesh Kadambi[1]; Shreyas Kadambi[1]; Kartik K. Venkatesh[3]; Isabel Fulcher[1]
[1]Delfina Care Inc, Delfina Care Inc, CA; [2]University of California, San Diego, Irvine, CA; [3]The Ohio State University, Columbus, OH

10:30 AM - 12:30 PM

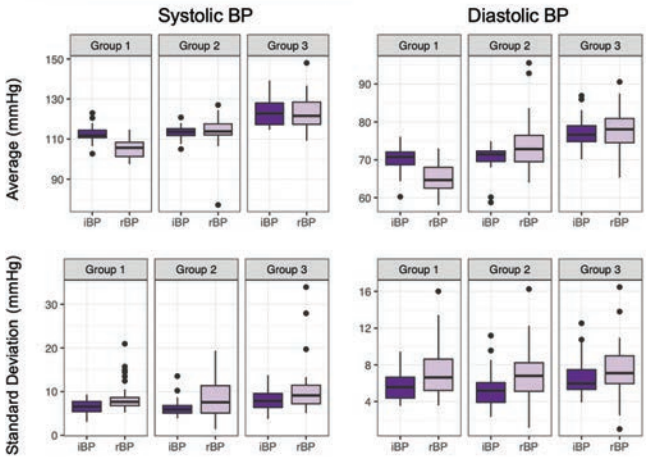
Objective: Despite the established association of in-clinic blood pressure (iBP) with hypertensive disorders of pregnancy (HDP) and the increasing use of remote blood pressure monitoring (rBP), integrating both modalities of BP monitoring to inform HDP risk remains understudied. We identified BP pattern groups in early pregnancy using both iBP and rBP measures and examined their collective ability to predict HDP.

Study Design: Prospective cohort study of pregnant individuals without chronic hypertension who delivered at one of three clinics enrolled in a digital health platform from 2022-2024. BP data < 20 weeks gestation was transformed into a total of 30 summary statistics characterizing centrality, spread, trends, and concordance of iBP and rBP measures. These BP summary statistics were computed separately for iBP versus rBP data and systolic versus diastolic data. The outcome was HDP. K-means clustering identified BP pattern groups, and the association between these groups and HDP was estimated using logistic regression. Area under the curve (AUC) was used to assess predictive performance.

Results: Using both iBP and rBP measures from 106 assessed individuals, we identified three BP pattern groups. Individuals in group 1 (n = 35, 2.9% with HDP) were more likely to have within range BP values and different values between rBP and iBP (Figure 1). Individuals in group 2 (n = 38, 7.9% with HDP) generally had within range BP values and similar values between rBP and iBP. Individuals in group 3 (n = 33, 33.3% with HDP) were more likely to have high average BP, high BP variability, and concordance between rBP and iBP. BP pattern groups arising from both iBP and rBP data were able to accurately predict subsequent HDP diagnosis (AUC = 0.77, 95% CI: 0.66, 0.89).

Conclusion: K-means clustering of BP measures based on iBP and rRP identified three distinct BP pattern groups that were predictive of HDP. Further research is needed to determine the optimal integration of rBP with iBP to inform HDP risk and care delivery.

Figure 1. Average and standard deviation of BP measures from three identified BP pattern groups: 1) BP within range and different values between rBP and iBP (n=35, 2.9% with HDP), 2) BP within range and similar values between rBP and iBP (n=38, 7.9% with HDP), 3) high BP with high variability and concordance between rRB and iBP (n=33, 33.3% with HDP). Note: for ease of exposition, only 8 of the 30 features included in the K-means clustering algorithm are shown.



iBP: in-clinic blood pressure; rBP: remote blood pressure monitoring

909 | Prevalence of Undiagnosed Placenta Accreta Spectrum After Unplanned Postpartum Hysterectomy

Sarah T. Mehl[1]; Abigail S. Zamorano[2]; Beatrice Valentini[3]; Zakaria Doughan[4]; Elias Kassir[5]; Edgar A. Hernandez-Andrade[1]; Sean C. Blackwell[1]; Baha M. Sibai[1]; Farah H. Amro[1]

[1]McGovern Medical School at UTHealth Houston, Houston, TX; [2]Division of Gynecology Oncology, Department of Obstetrics, Gynecology, and Reproductive Sciences, University of Texas Health Science Center in Houston, McGovern Medical School, Houston, TX; [3]University of Parma, University of Parma, Emilia-Romagna; [4]Division of Maternal-Fetal Medicine, Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern Medical School at UTHealth Houston, Houston, TX; [5]University of Texas Health Science Center at Houston, McGovern Medical School, Houston, TX

10:30 AM - 12:30 PM

Objective: Antenatal diagnosis of placenta accreta spectrum (PAS) is crucial for maternal counseling and surgical planning. There is minimal data describing frequency of missed diagnosis of PAS by ultrasound, particularly in those without risk factors. Our objective was to identify rate and reason of undiagnosed PAS in unplanned postpartum hysterectomy.

Study Design: A retrospective cohort study of pregnancies resulting in unplanned postpartum hysterectomy from 2019–2024 and delivered within our institution's hospital system. Pregnancy outcomes were evaluated in two groups: PAS and no PAS. Maternal characteristics, pre-existing risk factors for PAS, antenatal ultrasound findings, and outcomes including PAS severity by pathology were analyzed.

Results: A total of 45 unplanned postpartum hysterectomies were reviewed. All but 1 patient had prenatal care. PAS by pathology was identified in 14 (31%) patients. Table 1 describes characteristics including prior uterine surgery and placenta previa. Similar risk factors were seen between those with PAS and without. Among the 14 cases of PAS, 11 (79%) did not have placenta previa, 8 (57%) did not have prior CD, and 5 (42%) did not have anterior placenta. All 8 cases without prior CD also did not have placenta previa yet had PAS. Table 2 further describes additional risk factors among those with PAS. Accreta was the most common pathology finding, seen in 10 (71%) cases.

Conclusion: In this cohort, approximately 30% of unplanned postpartum hysterectomies were due to PAS. Routine risk factors such as previa and prior CD were not present in 57% of cases. Our findings suggest a need for detailed placental evaluation for all pregnant women regardless of prior uterine surgery or previa.

910 | Severe Neonatal Morbidity Among Preterm Infants After Standard Versus Accelerated Betamethasone Dosing

Frank I. Jackson; Sarah H. Abelman; Nathan A. Keller; Luis A. Bracero; Annemarie Stroustrup; Matthew J. Blitz
Northwell, New Hyde Park, NY

10:30 AM - 12:30 PM

Objective: For patients expected to deliver before 34 weeks, betamethasone is usually given in two doses, 24 hours apart, to promote fetal lung maturity. If delivery is anticipated in less than 24 hours, some providers use an accelerated dosing regimen, but evidence for this practice is limited. Our objective was to determine the rate of severe neonatal morbidity (SNM) among early preterm deliveries (< 34 weeks) that occurred < 24 hours after the first dose of betamethasone was administered, and to compare the group that received one dose (standard) versus two doses (accelerated).

Study Design: This is a retrospective cohort study of singleton preterm deliveries from 2019-2023 at two tertiary hospitals in New York. Patients were included if they delivered at less than 34-0/7 weeks of gestation, received at least one dose of betamethasone prior to delivery, and delivered less than 24 hours after the first dose of betamethasone was administered. The primary outcome was SNM, a composite neonatal adverse outcome indicator which includes diagnoses and procedures indicative of severe morbidity. A logistic regression model was used to compare the rates of SNM among individuals who received one (standard) or two doses (accelerated) of betamethasone within the 24 hours prior to delivery, controlling for gestational age at birth, as well as race and ethnicity group.

Results: A total of 79 patients were included for analysis: 45 (56%) received standard betamethasone dosing and 34 (43%) received an accelerated dosing regimen. On adjusted analysis, there was no difference in composite SNM between the two groups (OR 1.16, 0.39-3.42, P = 0.79). There was also no difference in rates of neonatal respiratory distress syndrome (OR 2.78, 0.81-10.35, P = 0.11).

Conclusion: For infants born before 34 weeks who delivered within 24 hours of a first betamethasone dose, there was no difference in SNM between those who received an accelerated second dose and those who did not.

911 | Maternal and Neonatal Morbidity after Prolonged Latent Labor

Sarah Heerboth; Emma Trawick Roberts; Joy McNeal; Tracy A. Manuck
University of North Carolina, Chapel Hill, NC

10:30 AM - 12:30 PM

Objective: Cesarean delivery (CD) is often recommended after 12-18h of latent labor (LL) due to concern for futility/risk of morbidity. We sought to quantify the odds of morbidity and CD among individuals with prolonged LL.

Study Design: Secondary analysis of two MFMU labor studies: (1) APEX and (2) ARRIVE. We included those with singleton pregnancies ≥37w admitted for IOL who had LL ≥9h. We defined LL as <5cm dilated with rupture of membranes and exposure to oxytocin. Participants with LL 9-12h were compared to those with LL >12h (prolonged LL). The primary outcome was maternal morbidity (ICU admission, sepsis, postpartum hemorrhage [PPH], unplanned procedure during hospitalization other than CD, thromboembolism); secondary outcomes were neonatal morbidity, PPH, intraamniotic infection (IAI), and CD. We used Liu cutpt methodology to evaluate the duration of LL that optimized sensitivity and specificity for morbidity.

Results: We included 2193 participants, 1000 of which had LL >12h. Of those with LL ≥12h, 12% had maternal and 16% had neonatal morbidity. Clinical characteristics are in Table 1. In the prolonged LL group, 61% delivered by CD. Outcomes are shown in Fig 1a. Those with LL >12h had increased odds of maternal morbidity (aOR 2.4, 95% CI 1.7-3.2), neonatal morbidity (aOR 1.4, 95% CI 1.1-1.8), IAI (aOR 1.4, 95% CI 1.1-1.7), PPH (aOR 2.1, 95% CI 1.5-2.9), and CD (aOR 1.9, 95% CI 1.6-2.2). However, the duration of LL alone was a poor predictor of maternal morbidity (AUC 0.61 at 12h). Because the alternative to prolonged LL is CD, outcomes after >12h of LL were compared to a referent group of those having CD after 9-12h LL: there were increased odds of maternal morbidity and PPH among those who had a CS after >12h LL; there were not significantly increased odds of maternal morbidity, neonatal morbidity, PPH, or IAI among those who ultimately delivered vaginally. (Fig1b)

Conclusion: Prolonged LL was associated with increased overall morbidity, and CD may increase the risks associated with prolonged LL. The time point when morbidity associated with prolonged LL can be best mitigated with CD remains unknown.

Referent group is those who underwent cesarean section after 9-12hrs of latent labor (n=534). Adjusted odds of neonatal morbidity and intraamniotic infection were not significantly different between those having cesarean after 9-12hrs of latent labor and those delivering by vaginal delivery or cesarean after ≥12hrs latent labor. * denotes p-value <0.05

912 | Interval to Ultrasound-Indicated Cerclage Placement and Delivery Timing in Patients with Prior Preterm Birth

Sarah H. Abelman; Frank I. Jackson; Nathan A. Keller; Julie Chen; Luis A. Bracero; Cara S. Wetcher; Matthew J. Blitz
Northwell, New Hyde Park, NY

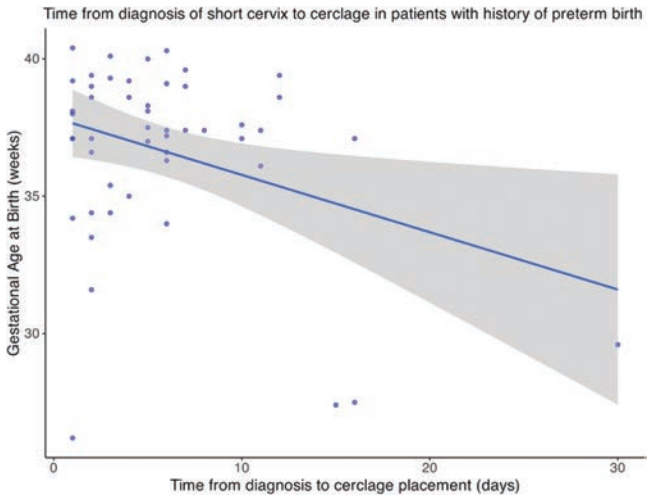
10:30 AM - 12:30 PM

Objective: Patients with a history of preterm birth and a cervical length less than 25mm benefit from cerclage to prevent recurrence. The urgency of cerclage placement after diagnosing a short cervix varies. This study aimed to determine if the time from diagnosis to cerclage placement affects delivery timing.

Study Design: This was a retrospective cohort study of all patients with a history of preterm birth who received an ultrasound-indicated cerclage in a subsequent pregnancy from 2018-2023 within a large health system in New York. The primary exposure was time interval from diagnosis of short cervix (< 25mm) to cerclage placement. The primary outcome was gestational age at delivery. Outcomes were compared using a linear mixed model regression analysis and were then adjusted for obesity, gestational age at diagnosis of a short cervix and cervical length at diagnosis.

Results: A total of 49 patients were included for analysis. The mean time interval for cerclage placement after diagnosis was 5.9 days and mean gestational age at cerclage placement was 19.0 ± 2.6 weeks. The mean cervical length on ultrasound at time of diagnosis of a short cervix was 1.8 ± 0.6 cm. The mean gestational age at delivery was 36.6 ± 3.3 weeks. Overall, for each additional day that elapsed between diagnosis of a short cervix and cerclage placement, pregnancy on average was shortened by 1.6 days (P = 0.01) (figure 1).

Conclusion: For patients with a history of preterm birth receiving an ultrasound-indicated cerclage, earlier placement after diagnosis of short cervix significantly benefited pregnancy length, resulting in a later gestational age at delivery.



913 | Impact of Nurse Support on Readmission Rates Among Patients in a Postpartum Blood-Pressure Monitoring Program

Sarah Shim[1]; Jeanne Larson Moore[1]; Sarah Fladhammer[1]; Karen Wutolia[1]; Tiffany Corlin[1]; Martina S. Burn[2]; Sarah A. Wernimont[1]; Bethany Sabol[1]
[1]University of Minnesota, Minneapolis, MN; [2]University of Minnesota, Minneapolis,, MN

10:30 AM - 12:30 PM

Objective: To assess the impact of nursing support on postpartum readmission rates for patients participating in our home observation of postpartum elevated blood pressure (HOPE-BP) monitoring program.

Study Design: HOPE-BP is a 6-week postpartum remote monitoring program for patients with hypertensive disorders of pregnancy (HDP) discharging after birth from our institution. It was implemented in 2023 and uses Epic Care Companion and a registered nurse (RN) driven protocol, with physician oversight, for antihypertensive medication initiation/titration. Blood pressures (BPs) are monitored by the RN team Monday-Friday from 8AM-5PM. Outside of these hours, patients are directed to call the on-call provider for severe hypertension or escalating symptoms; however, active surveillance or response to increasing BPs does not occur during this unsupported time. We hypothesized that readmission rates would be higher during times when RN support was unavailable.

Results: We evaluated postpartum readmissions for all patients participating in HOPE-BP from the start of the program in November 2023 through June 2024. Among those enrolled in HOPE-BP (N = 280; 75% of eligible patients), 2.8% were readmitted (N = 8). 7 of the 8 were admitted for a new diagnosis of preeclampsia with severe features based on blood pressure criteria (chronic hypertension N = 3, gestational hypertension N = 3, and preeclampsia without severe features N = 1). We observed, that as hypothesized, 75% (N = 6) of these readmissions occurred at times without RN coverage. Figure 1 demonstrates the

impact of HOPE-BP on the reduction of postpartum readmissions during RN-supported hours.

Conclusion: Our data uniquely demonstrates the impact RN support has on reducing postpartum readmissions. Supported BP surveillance and management is critical to the program's success in the prompt recognition and treatment of worsening hypertension and reducing preventable readmissions.

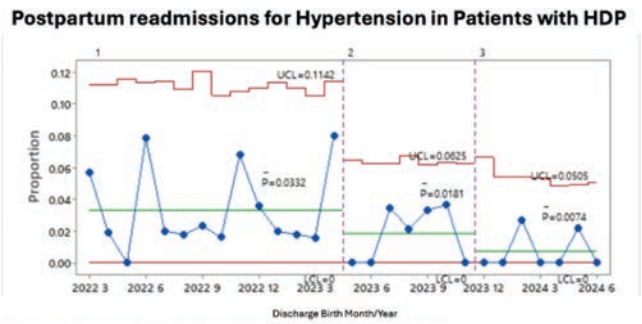


Figure 1: Postpartum Readmissions for Hypertension in patients with HDP
Box 1 represents baseline postpartum readmissions for hypertension in patients discharging with HDP
Box 2 indicates implementation of a system-wide HDP improvement project
Box 3 represents readmissions for hypertension in HOPE-BP patients during RN-support hours

914 | Impact of Maternal Anxiety and Depression on Perinatal Outcomes

Sarah K. Dzubay; Bharti Garg; Aaron B. Caughey
Oregon Health & Science University, Portland, OR

10:30 AM - 12:30 PM

Objective: To investigate whether anxiety, depression, or both anxiety and depression have differential impacts on perinatal outcomes relative to those without anxiety or depression.

Study Design: We performed a retrospective cohort study among singleton, non-anomalous births delivered at 23-42 weeks in California between 2008 and 2020. We compared perinatal outcomes between pregnant individuals without depression or anxiety to those with anxiety, depression, or both anxiety and depression. Births were excluded if the mother had bipolar disorder. We performed a multivariable Poisson regression, controlling for race/ethnicity, age, pre-pregnancy BMI, parity, insurance type, education level, and smoking during pregnancy.

Results: Of the 5,048,487 births meeting inclusion criteria, 97.12% of mothers had no anxiety or depression, 1.17% had depression, 1.25% had anxiety, and 0.47% had anxiety and depression (Table 1). Individuals with anxiety had higher risk of gestational hypertension (aIRR = 1.62; 95% CI: 1.57-1.67), preeclampsia (aIRR = 1.48 (1.43-1.53)), and SMM (aIRR = 2.00 (1.90-2.11)); however, individuals with depression had higher risk of gestational diabetes (aIRR = 1.20 (1.17-1.23) and postpartum hemorrhage (aIRR = 1.77 (1.71-1.83)) (Table 2). With regards to neonatal outcomes, individuals with both depression and anxiety had higher risk of preterm birth < 37 weeks (aIRR = 1.27 (1.23-1.33)), NICU admission (aIRR = 1.11 (1.07-1.15)), lower Apgar scores (aIRR = 2.34 (2.15-2.54)), respiratory distress syndrome (aIRR = 1.65 (1.49-1.81)), hypoglycemia (aIRR = 1.96 (1.83-2.09) and low birth weight (aIRR = 1.15 (1.06-1.24)).

Conclusion: Individuals with anxiety, depression, or both had higher risk of maternal and neonatal outcomes relative to those without a mood disorder. Interestingly, individuals with depression or anxiety had higher risk of maternal outcomes while individuals with both depression and anxiety had higher risk for neonatal outcomes. Prenatal screening and treatment for anxiety and depression may be beneficial in protecting against adverse outcomes.

915 | Fetal Doppler Progression and Outcomes in Pregnancies with Late Onset Fetal Growth Restriction and Preeclampsia

Scott Infusino; Jeanette Larson; Natalia Gontarczyk Uczkowski; Amy Godecker; Jacquelyn H. Adams; Jesus Iruretagoyena
University of Wisconsin Hospitals and Clinics, Madison, WI

10:30 AM - 12:30 PM

Objective: To determine if fetal Doppler abnormalities, as well as pregnancy outcomes, in late onset fetal growth restriction (FGR) are impacted by preeclampsia.

Study Design: This was a retrospective cohort study from 2016 to 2021 at a single academic center evaluating singleton, nonanomalous pregnancies with a diagnosis of late onset FGR (≥32 weeks) who underwent serial fetal Doppler evaluation. Doppler evaluation included umbilical artery (UA) pulsatility index (PI) and characterization of UA end diastolic flow (forward, absent, or reversed). Pregnancy outcomes were also collected.

Results: Five hundred forty-five pregnancies were diagnosed with late onset FGR and met inclusion criteria. Ten percent of pregnancies (n = 56) developed preeclampsia. When compared to patients with only a diagnosis of FGR, those with both FGR and preeclampsia were more likely to have an earlier diagnosis of FGR (34.3 vs 35.2 weeks, p = 0.003), deliver at an earlier gestational age (36.2 vs 38.2 weeks p< 0.001), and have a shorter interval from diagnosis of FGR to delivery (13.5 vs 21 days, p< 0.001). Pregnancies with both FGR and preeclampsia were more likely to have an elevated UA PI at the time of delivery (p< 0.001). When an elevated UA PI was diagnosed, the interval from diagnosis to delivery was significantly shorter in the preeclamptic group (6.8 vs 22.3 days, p< 0.001).

Conclusion: Pregnancies complicated by both late onset fetal growth restriction and preeclampsia were more likely to have an elevated UA PI at the time of delivery, an earlier gestational age at delivery, and a shorter interval to delivery. This information can

help providers appropriately manage these complex pregnancies and adequately counsel patients.

Table 1: Fetal Doppler Characteristics and Pregnancy Outcomes

	FGR (n=489)	FGR and Preeclampsia (n=56)	p value
Gestational age at diagnosis of FGR (wks)	35.2 (2.1)	34.3 (1.8)	0.003**

916 | Middle Cerebral Artery Pulsatility Index and Cerebroplacental Ratio in Late Onset Growth Restriction and Preeclampsia

Scott Infusino; Jeanette Larson; Natalia Gontarczyk Uczkowski; Amy Godecker; Jacquelyn H. Adams; Jesus Iruretagoyena
University of Wisconsin Hospitals and Clinics, Madison, WI

10:30 AM - 12:30 PM

Objective: To determine if the presence of preeclampsia impacts the rate of abnormal middle cerebral artery (MCA) pulsatility index (PI) and cerebroplacental ratio (CPR) in pregnancies complicated by late onset fetal growth restriction (FGR).

Study Design: A retrospective cohort study was performed from 2016 to 2021 at a single academic medical center of singleton, nonanomalous pregnancies with a diagnosis of late onset FGR (>32 weeks) who underwent weekly fetal Doppler evaluation. MCA PI and CPR were considered abnormal if they were noted to be less than the 5th percentile for gestational age. Gestational age at delivery was recorded for all patients.

Results: Five hundred forty-five pregnancies were diagnosed with late onset FGR and met inclusion criteria. Fifty-six (10%) patients were also diagnosed with preeclampsia (Table 1). When compared to pregnancies with only a diagnosis of FGR, those with both FGR and preeclampsia were more likely to have an abnormal MCA PI (31.7% vs 11.5%, p = 0.001) or CPR (39.0% vs 16.0%, p< 0.001). Patients with both preeclampsia and FGR had an earlier diagnosis of abnormal CPR (34.4 vs 35.5 weeks, p = 0.028) and delivered at an earlier gestational age (35.7 vs 37.6 weeks p< 0.001). Gestational age at diagnosis of abnormal MCA PI did not significantly differ between groups.

Conclusion: Pregnancies complicated by both late onset FGR and preeclampsia were more likely to have abnormal MCA PI and CPR, than pregnancies only complicated by FGR. An abnormal cerebroplacental ratio was associated with the greatest difference in findings between groups. Future work should evaluate neonatal outcomes related to these Doppler characteristics in the presence of fetal growth restriction and preeclampsia.

Table 1: Doppler Characteristics

	Late Onset Fetal Growth Restriction (n=489)	Late Onset Fetal Growth Restriction and Preeclampsia (n=56)	p value
Abnormal CPR, n (%)	51 (16.0)	16 (39.0)	<0.001
Abnormal MCA PI, n (%)	36 (11.5)	13 (31.7)	0.001
Abnormal MCA PI & CPR, n (%)	20 (4.0)	12 (19.7)	<0.001*

* Fisher's Exact Test

Table 2: Gestational Age at Diagnosis and Delivery Timing with Doppler Abnormality

	Gestational Age at Diagnosis			Gestational Age at Delivery		
	Late Onset FGR	Late Onset FGR and Preeclampsia	p value	Late Onset FGR	Late Onset FGR and Preeclampsia	p value
Normal Doppler, mean(sd)	N/A	N/A	-	38.2 (1.3)	36.4 (2.0)	<0.001
CPR < 5%, mean (sd)	35.5 (1.8)	34.4 (1.4)	0.028	37.6 (1.2)	35.7 (1.6)	<0.001
MCA PI < 5%, mean (sd)	35.7 (1.6)	34.9 (1.1)	0.084	37.9 (1.5)	36.3 (1.5)	0.003
CPR & MCA PI < 5%, mean (sd)	35.8 (1.7)	34.9 (1.2)	0.098	37.9 (1.4)	36.1 (1.4)	0.001

917 | Non-Invasive Prenatal Detection of Copy-Number Variations Based on Maternal Cfdna Fragmentomics

Shahar Shohat Koren[1]; Sapir Saar[1]; Dolev Rahat[2]; Ravit Mesika[2]; Reut Tomashov Matar[3]; Lina Basel-Salmon[3]; Noa Liscovitch-Brauer[4]; Noam Shomron[2]
[1]Identifai Genetics, Identifai Genetics, Tel Aviv; [2]Identifai Genetics, Tel Aviv, Israel; [3]Raphael Recanati Genetic Institute, Rabin Medical Center, Beilinson Hospital, Tel Aviv; [4]Identifai Genetics, Tel Aviv

10:30 AM - 12:30 PM

Objective: Cell-free DNA (cfDNA) based prenatal screening determines the risk of genetic abnormalities using cfDNA of fetal origin circulating in maternal plasma. Current methods detect chromosomal scale aberrations or very large (>1 Mb) copy number variants (CNVs), missing smaller ones which account for up to 15% of developmental disorders in children. To identify shorter CNVs, we developed a whole genome sequencing (WGS) approach that utilizes both read coverage and fragmentomics features.

Study Design: Our cohort includes 10 women with singleton pregnancies for whom WGS was performed on cfDNA and maternal gDNA. Seven out of the ten pregnancies were sampled in the 1st trimester, with a median fetal fraction (FF) of 7.7%. CNVs causing genetic disorders are typically de novo and dominant, or,

in the case of a recessive condition, inherited alongside another pathogenic variant from the other parent, resulting in compound heterozygosity. Therefore we focused on the detection of *de novo* CNVs >0.1 Mb and smaller CNVs that could cause compound heterozygosity. Paternal CNVs are detected in a similar manner to de novo variants and so were also included in the analysis.

Results: We implemented an algorithm which calculates a Z-score for the difference in cfDNA read lengths across the genome. Two deletions, of size 690 KB and 209 KB were detected in two families. Validation with fetal WGS confirmed the deletions as true positives, with no other relevant deletions found. In a third family, the mother is a known carrier of a pathogenic ~5 KB deletion in the CERS3 gene, and the father carries a pathogenic SNV in the same gene. Our algorithm successfully determined that the fetus did not inherit the maternal CNV (Figure 1).

Conclusion: We present a method to identify CNVs in a cfDNA-based prenatal screening and show that combining read length with coverage data allows reliable CNV detection. Importantly, we demonstrate our method on mostly 1st trimester pregnancies with a low FF, representing a clinically relevant scenario, thus enhancing the potential scope and resolution of noninvasive prenatal screening.

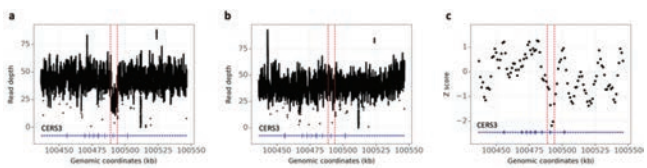

Figure 1: Sequencing read depth for the gene CERS3 in (a) the maternal gDNA sample and (b) the fetal amnio gDNA sample. Red lines represent the deletion borders. (c) CNV detection algorithm Z-scores for the gene CERS3 in the cfDNA sample. Red lines represent the deletion borders.

918 | Can Blood Pressure Monitoring Reduce Racial Disparities in Healthcare Utilization and Morbidity Among Postpartum Patients?

Shana D. Talbot[1]; Ntami P. Echeng[1]; Scott Machado[2]; Tracy L. Jackson[2]; Nicole Konecke[2]; William Hunt[2]; Maria Mejia Castillo[2]; Danielle Simmons[2]; Heather A Smith[1]; Nina K. Ayala[1]; William A. Grobman[3]; Adam K. Lewkowitz[2]; Methodius G. Tuuli[1]

[1]Women & Infants Hospital of Rhode Island / Alpert Medical School of Brown University, Providence, RI; [2]Women & Infants Hospital of Rhode Island / Alpert Medical School of Brown University., Providence, RI; [3]The Ohio State University, Columbus, OH

10:30 AM - 12:30 PM

Objective: Remote self-measured blood pressure (SMBP) monitoring programs have been shown to reduce racial inequity in postpartum blood pressure ascertainment. However, their effect on disparities in healthcare utilization and severe maternal morbidity (SMM) is less clear. We aimed to compare outcomes between participants in our remote SMBP program who self-identified as Black versus non-Hispanic White.

Study Design: Postpartum individuals with hypertension (HTN) at our tertiary hospital are offered enrollment in our remote SMBP program. For this analysis, participants who did not self-identify as Black or non-Hispanic White were excluded. The primary outcome was a composite of HTN-related postpartum readmission or ED visit within 30 days of delivery. Secondary outcomes were individual components of the primary composite, HTN-related SMM, and anti-hypertension medication initiation or titration. A log-link binomial generalized linear model was used to estimate relative risks (aRR) adjusting for potential confounders.

Results: Among 2003 participants in the SMBP program from 2022 - 2024, 1363 met inclusion criteria. Of these, 988 (49.3%) self-identified as non-Hispanic White and 375 (18.7%) as Black. Compared to non-Hispanic White participants, Black participants were younger, and more likely to have public insurance and gestational HTN (**Table 1**). After adjusting for these factors, there was no significant difference in the composite of HTN-related postpartum readmission or ED visit between Black and non-Hispanic White participants (19.2% vs 16.7%; aRR 1.29, 95% CI 0.98, 1.69). Risk of HTN-related readmission alone was significantly higher among Black participants (12.2% vs 9.9%; aRR 1.48, 95% CI 1.03, 2.11). There was no significant difference in HTN-related SMM (12.5% vs 11.7%; aRR 1.00, 95% CI 0.72, 1.42). There was also no difference in anti-hypertensive medication initiation or titration (**Table 2**).

Conclusion: Our remote SMBP program for postpartum patients with HTN eliminated racial disparities in overall HTN-related healthcare utilization and HTN-related SMM.

Table 1: Demographics of participants

Variable	Black (n=375)	Non-Hispanic White (N= 988)	P value

919 | The Effect of Pre-Pregnancy and Delivery Bmi on Tolac Success in a High-Risk Cohort

Shannon R.O Moran; James A. Shelton; Dawei David Wang

University at Buffalo, Buffalo, NY

10:30 AM - 12:30 PM

Objective: Rates of trial of labor after cesarean section (TOLAC) and obesity have increased in today's population. Vaginal birth after cesarean section (VBAC) has been shown to reduce maternal morbidity. Published predictive models for VBAC success take into account both body mass index (BMI) and chronic hypertension. However, no previous studies have specifically analyzed the effect of BMI on TOLAC success in those with any form of hypertension. Therefore, we sought to investigate whether pre-pregnancy BMI or delivery BMI has a greater effect on TOLAC success rate in this high-risk cohort.

Study Design: This was a retrospective cohort study of national birth certificate data from 2022. We included all singleton, vertex livebirths with no fetal anomalies who had 1 prior cesarean delivery and a diagnosis of either chronic hypertension or a hypertensive disorder of pregnancy who attempted TOLAC. Those with prior vaginal deliveries were excluded. Patients were divided into 6 groups by pre-pregnancy and delivery BMI. Two logistic regression models, one for pre-pregnancy and one for delivery BMI, were created. These were compared using Akaike Information Criterion (AIC) and receiver operating characteristic (ROC) curves. Confounding variables included were maternal age and race, maternal weight gain, chronic and gestational diabetes, gestational age, birthweight, and induction of labor.

Results: 5,144 patients were included. 2,382 had a repeat cesarean section. 2,762 had a VBAC. For both pre-pregnancy and delivery BMI, the rate of VBAC decreased as obesity class increased. In the AIC analysis, pre-pregnancy BMI and delivery BMI produced almost identical results (6685 versus 6670, respectively). Furthermore, in the ROC curve, again pre-pregnancy BMI and delivery BMI produced almost identical results (0.631 versus 0.634, respectively).

Conclusion: Pre-pregnancy BMI and delivery BMI have similar effects on TOLAC success in those with hypertension of any form, with decreased rates of VBAC seen with increasing BMI. Both should be used to counsel patients on TOLAC in this high-risk cohort throughout the antepartum period.

Table 1: VBAC and failed TOLAC rates by pre-pregnancy and delivery BMI

Characteristic	Failed TOLAC, N = 2,382[1]	VBAC, N = 2,762[1]	p-value[2]

920 | The Impact of Pre-Pregnancy Anxiety Or Depression and Adverse Neonatal Outcomes

Shannon E. Beermann[1]; Nandini Raghuraman[2]; Bridget C. Huysman[1]; Jeannie C. Kelly[2]; Antonina I. Frolova[3]; Candice Woolfolk[4]

[1]Washington University in St. Louis, St. Louis, MO; [2]Washington University School of Medicine in St. Louis, St. Louis, MO; [3]Washington University School of Medicine, St. Louis, MO; [4]Washington University School of Medicine in Saint Louis, St. Louis, MO

10:30 AM - 12:30 PM

Objective: Nearly 30% of females are affected by mental illness, particularly anxiety and depression. Prior studies investigating the relationship between prenatal anxiety and depression and adverse neonatal outcomes have inconsistent findings. We sought to examine the relationship between pre-pregnancy anxiety or depression or a dual diagnosis and adverse neonatal outcomes.

Study Design: This is a secondary analysis of a prospective cohort study of singleton pregnancies at single tertiary medical center from 2017 to 2020. The primary outcomes were preterm birth and composite neonatal morbidity (Table 1). The secondary outcomes were spontaneous preterm birth, small for gestational age (SGA), and 5-minute APGAR< 7. Secondary analyses compared dual diagnosis of anxiety and depression to patients with no diagnosis. Multivariable logistic regression was used to estimate adjusted odds ratios (aOR) and 95% confidence intervals (CI) after adjusting for potential confounders.

Results: Of 1220 patients with live births, 253 (20.7%) had pre-pregnancy anxiety or depression and 967 (79.3%) did not. After adjusting for maternal race and advanced maternal age, patients with pre-pregnancy anxiety or depression were significantly more likely to have preterm birth [19.8% vs 10.9%, aOR 2.07 95% CI 1.42, 3.02] and composite neonatal morbidity [35.2% vs 23.2%, aOR 1.80 95% CI 1.31, 2.41]. Spontaneous preterm birth, SGA, and 5-minute APGAR< 7 were significantly more likely among patients with anxiety or depression. Secondary analyses comparing dual diagnosis to no diagnosis showed an even greater likelihood of preterm birth, 5-minute APGAR< 7, and composite neonatal morbidity compared to patients without anxiety or depression (Table 2).

Conclusion: Patients with pre-pregnancy anxiety or depression are at higher risk of adverse neonatal outcomes. This risk is further increased with concurrent diagnoses. Further research is

needed to determine if optimization of pre-pregnancy anxiety and depression can improve neonatal outcomes.

Table 1: Pre-pregnancy anxiety or depression and neonatal outcomes

	Pre-pregnancy Depression or Anxiety Diagnosis (n=253)	No Pre-pregnancy Depression or Anxiety Diagnosis (n=967)	p-value	OR (95% CI)	aOR (95%CI)

921 | Impact of Maternal Age on Likelihood of Cesarean Delivery

Shaun R. Wesley; Sarah Crimmins
University of Rochester, Rochester, NY

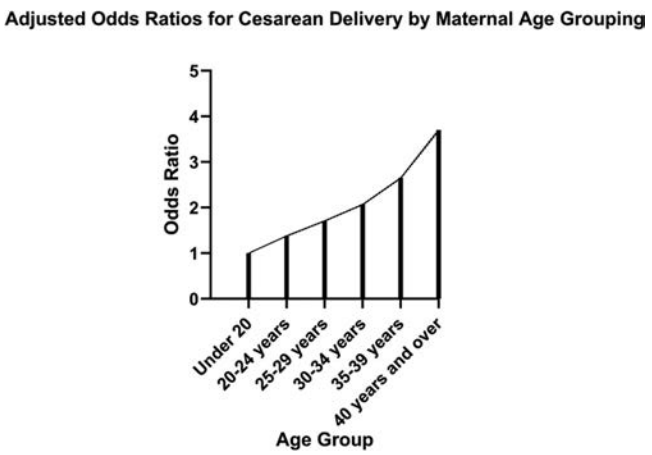
10:30 AM - 12:30 PM

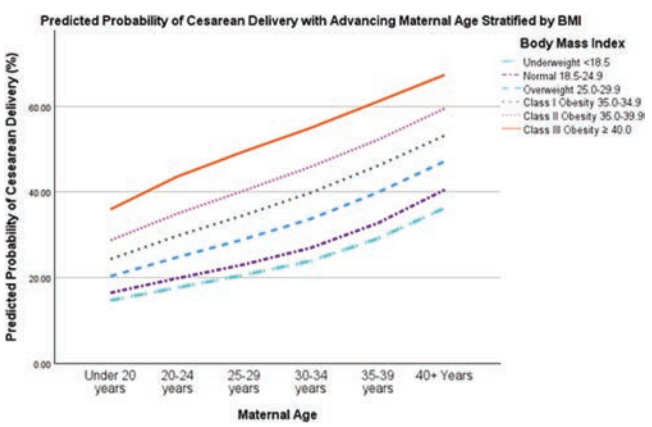
Objective: To evaluate the impact of maternal age on the likelihood of undergoing cesarean delivery (CD) while adjusting for clinical and demographic confounders, focusing on clinically meaningful odds ratios.

Study Design: This retrospective cohort study utilized the United States Vital Statistics Natality Birth Data from 2018 to 2022, comprising 18,524,899 births. Multivariable logistic regression was performed to analyze the association between maternal age and CD, adjusting for body mass index (BMI), pre-pregnancy hypertension, pre-pregnancy diabetes, previous cesarean section, parity, and chorioamnionitis. The analysis highlights odds ratios greater than 2.0 or less than 0.5, indicating clinical significance in delivery outcomes.

Results: The final analysis included 18,062,643 cases after excluding missing data. Compared to individuals under 20, cesarean delivery rates increased with age. Individuals aged 35-39 had significantly increased odds of CD (aOR: 2.65, 95% CI: 2.63, 2.66), and those aged 40 and older had even higher odds (aOR: 3.70, 95% CI: 3.67, 3.73). Previous cesarean delivery strongly predicted future CD (aOR: 35.74, 95% CI: 35.60, 35.88). Conversely, being multiparous significantly decreased odds of CD (aOR: 0.32, 95% CI: 0.32, 0.33). Notably, individuals with Class III obesity (BMI ≥ 40.0) had more than double the odds of CD with all other covariates held constant (aOR: 3.36, 95% CI: 3.33, 3.39).

Conclusion: Maternal age is a significant predictor of CD, especially for those over 35, showing a clinically significant increase in CD likelihood. Our data emphasizes factors representing meaningful clinical thresholds, aiding healthcare providers in decision-making and patient counseling. These findings enhance risk assessment strategies and inform future research on targeted interventions for higher risk populations.





922 | Association of Ultrasound Determined Hysterotomy Thickness and Intraoperative Scar Thinning/Dehiscence After Fetal Spina Bifida Closure

Shelly Soni[1]; Federica Bellussi[2]; Suzanne Debari[2]; Nahla Khalek[1]; Juliana S. Gebb[3]; Christina Paidas Teefey[1]; N. Scott Adzick[4]; Julie S. Moldenhauer[1]
[1]Richard D. Wood Jr. Center for Fetal Diagnosis and Treatment at CHOP, Philadelphia, PA; [2]The Children's Hospital of Phildelphia, Philadelphia, PA; [3]Richard D. Wood, Jr Center for Fetal Diagnosis

and Treatment, Children's Hospital of Philadelphia, Philadelphia, PA; [4]The Children's Hosiptal of Philadelphia, Philadelphia, PA

10:30 AM - 12:30 PM

Objective: To study the association between ultrasound determined myometrial thickness and intraoperative findings of scar thinning or dehiscence at the time of cesarean delivery in patients undergoing open maternal fetal surgery (OMFS) for fetal spina bifida (fSB) closure.

Study Design: A retrospective review of all cases of OMFS for fSB closure from 2016-2022. Hysterotomy scar thickness was measured on archived images at 30 weeks, 32 weeks, 34 weeks and 36 weeks. Three measurements of myometrial thickness were taken for every timepoint in sagittal plane. The group with intact hysterotomy was compared to those with scar thinning/ dehiscence.

Results: 111 patients met the inclusion criteria. The average hysterotomy scar thickness was 0.83 ± 0.18 cm, 0.78 ±0.19 cm, 0.72 ± 0.18 cm and 0.71 ± 0.22 cm at 30, 32, 34 and 36 weeks, respectively. 54.1% patients had at least some degree of scar thinning and 6.3% patients had some degree of dehiscence including focal. Scar thickness was significantly lower at 34 weeks (p = 0.02) and 36 weeks (p< 0.0001) in patients that had thinning/dehiscence. δ scar thickness between 30 and 36 weeks was significantly more in patients with scar thinning/dehiscence (p = 0.0009). AUC was 0.63 with a p-value of 0.02 for hysterotomy thickness at 34 weeks predicting absence of thinning. AUC was 0.82 with a p-value of < 0.0001 for hysterotomy thickness at 36 weeks predicting absence of thinning. A thickness of ≥ 0.71 cm was 68.6% sensitive and 84.9% specific in predicting absence of thinning. AUC was 0.76 with a p-value of 0.0003 for ð hysterotomy thickness between 30-36 weeks predicting presence of thinning/dehiscence. A change of ≥ 0.13 cm was 69.7% sensitive and 73.5% specific in predicting presence of thinning/dehiscence.

Conclusion: In patients undergoing OMFS for fSB repair, gradual thinning of hysterotomy scar was observed with significantly less scar thickness at 34 and 36 weeks in patients diagnosed with scar thinning/ dehiscence. δ scar thickness between 30 and 36 weeks can be used to predict presence of thinning/dehiscence.

924 | The Accuracy of the sFlt-1/PlGF Ratio Assay in Predicting Time-to-Delivery in Patients with Preeclampsia

Siobhan Wilson[1]; Elaine Carson[2]; Lei Fu[3]; Nir Melamed[4]
[1]University of Toronto, Toronto, ON; [2]Department of Maternal Fetal Medicine, Leeds Hospital Trust, Leeds, England; [3]Sunnybrook Health Sciences Centre, Toronto, ON; [4]Division of Maternal Fetal Medicine, Department of Obstetrics and Gynecology, Sunnybrook Health Sciences Centre, Toronto, ON

10:30 AM - 12:30 PM

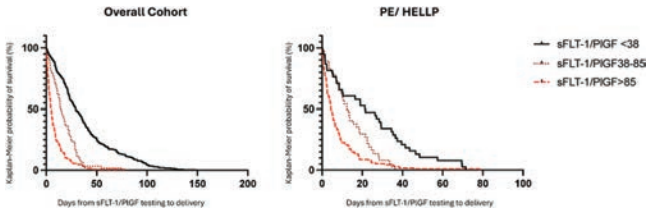
Objective: Preeclampsia (PET) is a leading cause of maternal and fetal morbidity and mortality, but the clinical course of PET is often difficult to predict. This can make management decisions such as the administration of antenatal corticosteroids (ACS) challenging, given that the optimal ACS timing is 1-7 days before birth. Abnormal levels of the angiogenic proteins soluble fms-like tyrosine kinase (sFLT-1) and placental growth factor (PlGF) have been shown to improve the diagnostic accuracy for PET. However, data on their accuracy in predicting time to delivery are limited. The objective of the current study was to evaluate the accuracy of these proteins in predicting the time-to-delivery in patients with PET.

Study Design: A retrospective cohort study of patients with a singleton pregnancy evaluated in a single center for suspected preeclampsia using the Roche Elecsys sFlt1/pPlGF Ratio Assay between 2020-2023. Modified Poisson regression was used to estimate the associations of the sFlt1/PlGF ratio with the risk of delivery within 3 and 7 days. Time-to-event analysis was used to describe the cumulative risk of delivery by the sFlt1/PlGF ratio result.

Results: Of the 509 patients who met the study criteria, 40.6% had a final diagnosis of PET. Compared with a low-risk result (≤ 38), a high-risk ratio (> 85) was associated with an increased risk of preterm birth < 32 weeks (RR 16.4 [95%-CI 6.2-42.6]) and delivery within 3 or 7 days (RR 3.5 [2.3-5.2] and 3.6 [2.6-4.9], respectively). A moderate-risk (38-85) and high-risk (> 85) ratios were associated with a shorter time-to-delivery compared to a low-risk ratio (p< .001) (Figure 1). The positive predictive value of a high-risk ratio and the negative predictive value of a low-risk ratio for delivery within 7 days were 63% and 99%, respectively.

Conclusion: The sFLT-1/PlGF ratio is a useful prognostic tool to predict the time to delivery in patients with PET, and can

therefore guide management decisions such as the administration of antenatal corticosteroids.



925 | A New Reference for Umbilical Artery Doppler in the Second and Third Trimesters

Sophia Rahimi[1]; John C. Kingdom[2]; Arietta Vayenas[3]; Vasilica Stratulat[4]; Nir Melamed[5]
[1]Temerty Faculty of Medicine, University of Toronto, Toronto, OR; [2]Dept OBGYN Mount Sinai Hospital University of Toronto, Toronto, ON; [3]Sunnybrook Health Sciences Centre, Toronto, OR; [4]Mount Sinai Hospital, Toronto, ON; [5]Division of Maternal Fetal Medicine, Department of Obstetrics and Gynecology, Sunnybrook Health Sciences Centre, Toronto, ON

10:30 AM - 12:30 PM

Objective: Umbilical artery (UA) Doppler is a key component in the diagnosis of early-onset fetal growth restriction (FGR). However, the interpretation of UA Doppler is complicated by the considerable variability of available UA Doppler references, which can have a profound impact on the proportion of small fetuses diagnosed with FGR. Our aim was to explore the methodological factors contributing to the heterogeneity of existing references and develop a UA Doppler pulsatility index (UA-PI) reference using an approach that addresses some of the limitations of prior studies.

Study Design: This was a retrospective longitudinal study of individuals with an uncomplicated singleton pregnancy who underwent assessment of UA Doppler at a single academic center (2012-2022) where UA Doppler is measured routinely in all ultrasound exams. We explored the effect of estimated fetal weight (EFW) percentile threshold (>10th, >25th, or >50th centile), parity, and statistical modeling approach (LMS, quantile regression, and quantile sheets) on the reference values. Based on these findings, a final UA-PI chart was developed and compared to existing charts.

Results: A total of 25,069 UA-PI measurements from 12,394 patients were analyzed. The study population's EFW percentile threshold had a considerable impact on the UA-PI reference (**Figure 1**), whereas the effect of parity was minimal. LMS and quantile regression methods yielded similar UA-PI reference charts, unlike the quantile sheets method. Therefore, our final UA-PI reference was based on observations from fetuses with EFW >50th percentile using the LMS method. The differences between the new chart and previously published charts in the UA-PI 95th percentile are illustrated in **Figure 2**.

Conclusion: To our knowledge, this study is the first to explore the impact of methodological factors on a UA-PI reference chart. The newly developed chart addresses several limitations of previous studies. As such, it may reflect more accurately the distribution of UA-PI in uncomplicated singleton pregnancies and improve the accuracy of FGR diagnosis.

926 | a Fetal Blood-Brain-Barrier Microphysiological System to Study the Effect of In-Utero Toxicant Exposure

Sourabh Sharma[1]; Lauren Richardson[2]; Ramkumar Menon[2]
[1]University of Texas Medical Branch Galveston, Galveston, TX; [2]University of Texas Medical Branch, Galveston, TX

10:30 AM - 12:30 PM

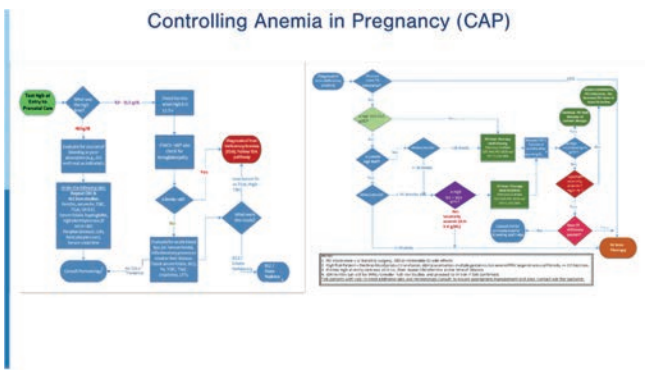
Objective: Glutamate dysregulation resuling in neuronal damage is associated with the development of many neurological disorders. The lack of physiologically relevant in-vitro models has limited our mechanistic understanding. This study evaluated the effect of environmental pollutant Polybrominated Diphenyl Ethers (PBDE), using a microphysiologic (MPS) model of human fetal blood-brain-barrier (FB).

Study Design: The FB-OOC is composed of 3-cell culture chambers, connected by microchannels, containing 1)brain microvessel endothelial cells, 2)human vascular pericytes, and 3)a triculture of neurons, astrocytes, and microglia in a 5:2:1 ratio, respectively. To assess the effect of toxicants on glutamate dysregulation and neuroinflammation, endothelial cells were exposed to PBDE(150ng/ml). To mimic the passage of PBDE through the placenta, endothelial cells were exposed to conditioned PDBE media from a placenta-OOC (1:1). In parallel, triculture cells were directly treated in a 96-well plate. Dextran propagation over 72 hours and zonula occludens-1 expression confirmed FB barrier function. Cell morphology (microscopy), cell cytotoxicity, and cytokines were measured. Statistical significance was determined by unpaired t-tests (N = 5; p< 0.05).
Results: Control FB-OOC were characterized by 1)viable cell cultures expressing standard cell morphologies and cell-specific markers, 2)barrier formation confirmed by lack of dextran propagation over 72 hours, and 3) baseline pro-inflammatory cytokines. On-chip PBDE and placenta-derived metabolites of PBDE treatment in the endothelial chamber induced cell cytotoxicity and upregulation of glutamate in the triculture but did not induce neuroinflammation. Conversely, 2D triculture experiments showed direct PBDE treatment-induced neuroinflammation compared to PBDE placenta-derived metabolites or controls.
Conclusion: This study established a model of FB that assessed the role of glutamate dysregulation independent of neuroinflammation. Advanced MPS models are needed to evaluate the impact of various exposures at the FB, as 2D neuronal cultures cannot model intercellular interactions.

927 | Prenatal Anemia: Examining Trends and Racial Disparities Before and After Standardized Clinical Interventions

Supraja Rachuri[1]; Edward Lievanos[1]; Aida Shirazi[1]; Deanna Fink[2]; Zahra Samiezade-Yazd[3]; Lauren Gong Barres[1]
[1]Kaiser Permanente San Francisco, Kaiser Permanente San Francisco, CA; [2]Kaiser Permanente, Oakland, CA; [3]Kaiser Permanente Division of Research, Kaiser Permanente San Francisco, CA

10:30 AM - 12:30 PM
Objective: Anemia is a common complication of pregnancy that disproportionately affects Black women and is linked to adverse maternal outcomes including cesarean delivery, postpartum hemorrhage, intraamniotic infections and need for blood transfusions. The Controlling Anemia in Pregnancy (CAP) project introduced a clinical algorithm that standardized diagnosis and treatment of anemia across a large healthcare institution. We sought to assess the impact of this algorithm on the incidence of prenatal anemia and identify racial disparities.
Study Design: We conducted a retrospective cohort study of adult pregnant patients with term, singleton live-born deliveries. Data was collected from two cohorts: Cohort 1 (January-December 2016) pre-CAP and Cohort 2 (January-December 2019) post-CAP implementation. Primary outcomes included incidence of both prenatal anemia overall and on admission to labor and delivery. Secondary outcomes included prenatal ferritin and IV iron orders. Outcomes were stratified by ethnicity.
Results: 68,839 patients were included in the study. The incidence of anemia was 38.7%. After the CAP project, diagnosis of anemia increased across all ethnicities 1,344 (3.8%) in 2016 vs. 4,901 (14.4%) in 2019 (P< 0.0001). The percentage of patients with anemia on admission to labor and delivery decreased 4,723 (36%) in 2016 vs. 4,398 (32.6%) in 2019 (P< 0.0001). Ferritin orders increased 2,802 (21.3%) in 2016 vs. 7,377 (54.6%) in 2019 (P< 0.0001) and IV iron infusions increased 407 (3.1%) in 2016 vs. 1,392 (10.3%) in 2019 (P< 0.0001). Black women had a 1.8 times higher incidence (IRR [95%CI]:1.8 [1.7-1.9], p< 0.001) of anemia compared to white women. Identification of anemia increased in both black and white women after implementation of the CAP project 218 (8.9%) in 2016 vs 642 (25.2%) in 2019 in black women and 295 (2.2%) in 2016 vs 1290 (10.6%) in 2019.
Conclusion: The CAP protocol effectively improved the identification and treatment of prenatal anemia, with increased ferritin orders and IV iron treatments. Despite this, Black women remain disproportionately affected by anemia.



Outcomes of Patients with Prenatal Anemia, 2016 vs 2019

	Overall N = 26,630	2016 N = 13,130	2019 N = 13,500	P-value
Hgb < 11.0 g/dL on admission to Labor and Delivery	9,121 (34.3)	4,723 (36.0)	4,398 (32.6)	<.0001
Ferritin orders during pregnancy IV	10,179 (38.2)	2,802 (21.3)	7,377 (54.6)	<.0001
Iron use during pregnancy	1,799 (6.8)	407 (3.1)	1,392 (10.3)	<.0001

928 | Association Between Gestational Weight Gain and Short-term Pregnancy Outcomes

Susan Dalton[1]; Amanda A. Allshouse[1]; Torri D. Metz[1]; Ann M. Bruno[2]
[1]University of Utah, Salt Lake City, UT; [2]University of Utah Health, Salt Lake City, UT

10:30 AM - 12:30 PM
Objective: Despite established Institute of Medicine (IOM) gestational weight gain (GWG) guidelines, there is ongoing debate as to whether these cutoffs are too liberal or strict, especially for pregnant people with obesity. We aimed to evaluate

short-term adverse pregnancy outcomes by GWG above or below IOM guidelines.

Study Design: Secondary analysis of a prospective cohort study of nulliparous, singleton pregnancies (2010-2013). Pregnancies > 20 weeks' were included while those with genetic or structural anomalies or missing outcome data were excluded. The exposure was GWG classified as below, within, or above IOM guidelines. Primary outcomes were composites of maternal and neonatal morbidity and mortality (Table), and secondary outcomes were their individual components. Those above or below recommended GWG were compared with those within IOM guidelines. Rates of outcomes by GWG category are reported. Multivariable modeling estimated the association between GWG and the selected outcomes.

Results: Of 8,997 pregnancies analyzed, 449 (32.2%) were below, 741 (30.5%) were within, and 2,205 (43.2%) were above IOM guidelines. Individuals within guidelines were more likely to have a normal pre-pregnancy body mass index. The overall prevalence of composite maternal morbidity was 38.1% and composite neonatal morbidity was 24.0%. GWG above IOM guidelines was associated with higher maternal morbidity (43.2% vs 30.5%, aOR 1.48 95% CI 1.33-1.65; Table). GWG above IOM guidelines was associated with a lower odds of neonatal morbidity (26.3% vs 27.2%, aOR 0.85, 95% CI 0.76-0.95), with preterm delivery and SGA driving this relationship. GWG below IOM guidelines was associated with higher neonatal morbidity (aOR 1.55, 95% CI 1.34-1.78; Figure).

Conclusion: While there is an association between GWG above IOM guidelines and maternal morbidity, there was an inverse relationship with neonatal morbidity. A better understanding of both short and long-term adverse pregnancy outcomes based on GWG is needed.

929 | Association Between the Intensity and Type of Exercise and the Risk of Gestational Diabetes

Takaki Tanamoto[1]; George R. Saade[2]; Tetsuya Kawakita[2]
[1]United States Naval Hospital Yokosuka, Yokosuka City, Kanagawa; [2]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA

10:30 AM - 12:30 PM

Objective: While some studies have shown that exercise reduces the incidence of gestational diabetes mellitus (GDM), the recommended intensity of exercise has been anecdotal. Our objective was to examine the rate of (GDM) according to exercise intensity during pregnancy.

Study Design: We analyzed data from the Nulliparous Pregnancy Outcomes Study: Monitoring Mothers-to-Be (nuMoM2b), in which patients were enrolled prospectively starting in the first trimester, and data was obtained by trained research coordinators. Individuals with pregestational diabetes or delivery < 20 weeks were excluded. The primary exposure was the intensity of exercise performed in the first trimester categorized according to metabolic equivalent hours per week (MET-hr/week) into: none, low-intensity (< 7.5 MET-hr/week), moderate-intensity (7.5-14.9 MET-hr/week), or high intensity (≧15 MET-hr/week). Our primary outcome was GDM. We also examined a composite of adverse pregnancy outcomes, including preeclampsia, gestational hypertension, preterm birth, small-for-gestational-age birth, and stillbirth. Adjusted relative risks (aRR) with 95% confidence intervals (95% CI) were calculated using modified Poisson regression, adjusting for potential confounders.

Results: Of 9,551 individuals, 3,132 (29.7%) had no exercise, 2,531 (26.5%) had low-intensity exercise, 1,959 (20.5%) had moderate-intensity exercise, and 2,223 (23.3%) had high-intensity exercise. Demographics and socioeconomic status were different across the groups (Table 1). Compared to individuals with no exercise, those who performed high-intensity exercise had a lower risk of GDM (5.1% vs. 2.8%; aRR 0.61; 95% CI 0.45-0.82). However, other secondary outcomes remained similar (Table 2). Moderate and low-intensity exercise compared to no exercise were not associated with significant differences in GDM or other outcomes.

Conclusion: High-intensity exercise was associated with a lower risk of GDM compared to no exercise. Future intervention studies focusing on exercise to prevent GDM are warranted.

Table 1. Demographics

	No exercise	Low intensity	Moderate intensity	High intensity	P-value

Smoking before pregnancy	618 (21.4)	387 (17.3)	269 (15.1)	368 (14.8)	<0.001

Abbreviations: BMI (body mass index); EPDS (Edinburgh Postnatal Depression Scale)
Data presented as mean (SD) or n (%) as appropriate.

Table 2. Outcomes

	No exercise	Low intensity		Moderate intensity		High intensity	
	n (%)	n (%)	adjusted RR (95%CI)	n (%)	adjusted RR (95%CI)	n (%)	adjusted RR (95%CI)
Gestational diabetes	140 (4.9)	110 (4.9)	0.97 (0.75-1.25)	75 (4.2)	0.87 (0.66-1.16)	69 (2.8)	0.61 (0.45-0.82)
Adverse pregnancy outcomes	701 (24.5)	541 (24.4)	1.01 (0.91-1.12)	356 (20.2)	0.91 (0.80-1.02)	537 (21.9)	1.01 (0.91-1.12)
Preeclampsia	283 (9.9)	198 (8.9)	0.94 (0.78-1.12)	126 (7.1)	0.81 (0.65-1.00)	189 (7.7)	0.94 (0.78-1.13)
Gestational hypertension	139 (4.9)	131 (5.9)	1.08 (0.85-1.38)	89 (5.0)	1.05 (0.80-1.37)	129 (5.2)	1.08 (0.84-1.39)
Preterm birth	276 (9.5)	202 (9.0)	0.97 (0.81-1.17)	128 (7.2)	0.88 (0.71-1.09)	180 (7.2)	0.85 (0.70-1.04)
Spontaneous preterm birth	153 (5.3)	117 (5.2)	1.04 (0.81-1.34)	86 (4.8)	1.05 (0.80-1.39)	113 (4.5)	0.96 (0.74-1.26)
Small for gestational age	138 (4.8)	98 (4.4)	1.03 (0.78-1.35)	74 (4.2)	1.02 (0.76-1.37)	108 (4.3)	1.10 (0.84-1.44)
Stillbirth	19 (0.7)	15 (0.7)	1.14 (0.52-2.50)	10 (0.6)	1.00 (0.41-2.43)	8 (0.3)	0.66 (0.25-1.71)

Adjusted RRs were controlled for maternal age, body mass index, chronic hypertension, pregestational diabetes, marital status, education, insurance, high stress, EPDS ≥10, and smoking before pregnancy.
APO was defined as preterm birth, preeclampsia, gestational hypertension, small for gestational age <5th %ile, or stillbirth.

930 | Glycemic Status and Fetal Growth in Twin Gestations

Tasneem Sannah[1]; Stefanie Hinkel[2]; Lorraine Dugoff[2]
[1]*Corewell Health Grand Rapids, Grand Rapids, MI, MI;*
[2]*University of Pennsylvania, Philadelphia, PA*

10:30 AM - 12:30 PM

Objective: In this study, we compared fetal growth curves in twin pregnancies affected by gestational diabetes with normoglycemic twin pregnancies. We hypothesized that fetal growth curves in twin gestations affected by gestational diabetes mellitus (GDM) would be significantly different from fetal growth curves for normoglycemic twin gestations, given the well-established fetal growth acceleration which occurs in singleton pregnancies affected by GDM.

Study Design: This study is a secondary analysis of a retrospective cohort study of twin pregnancies conducted at 17 centers in the US. Our primary exposure group was GDM, and our primary outcome was estimated fetal weight (EFW) as a function of gestational age. Dichorionic twin pregnancies with data from at least one ultrasound were included in the study. Demographic data were collected and compared between the two groups. The means of EFW at each gestational week were calculated for both groups, plotted onto curves, and subsequently compared.

Results: Our results demonstrated no statistically significant difference between groups in terms of demographic characteristics. However, the comparison between fetal growth curves also revealed no significant difference between the two groups, so we were unable to reject our null hypothesis after this initial analysis of the primary outcome.

Conclusion: We aimed to evaluate the association of GDM with longitudinal fetal growth in twin pregnancies. Contrary to our hypothesis, we did not find a statistically significant difference in longitudinal fetal growth between normoglycemic twin pregnancies and twin pregnancies affected by GDM. These results are not entirely inconsistent with what has been demonstrated in prior literature; namely, that GDM likely does not affect fetal growth in twin pregnancies nearly as dramatically as it has been shown to affect fetal growth in singleton pregnancies. This may be because any accelerated growth caused by GDM in twins would be masked by the expected growth deceleration that has been demonstrated in twins in the third trimester.

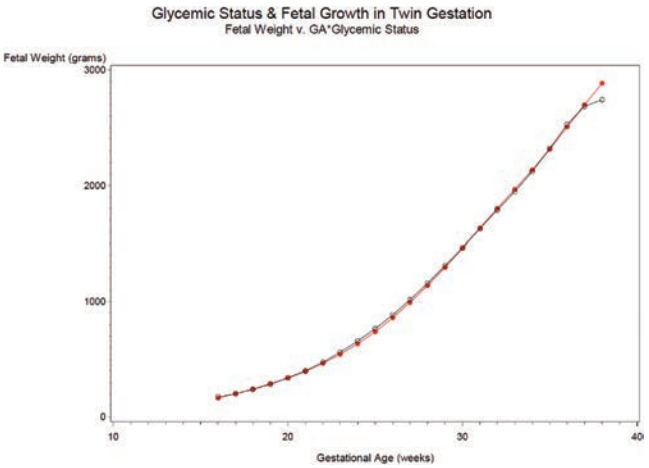

Table 1. Characteristics of the study population

Variable		Normoglycemic (n=825)	Gestational Diab Mellitus (n=119)	P-value

931 | Food Desert Proximity and Gestational Weight Gain During Pregnancy

Taylor Martin[1]; Babatamilore Alade[2]; Mary Taylor Winsten[3]; Kylie Mulvaney[4]; Felicia Hamilton[3]; Alexandra Piselli[2]; Fatimah Z. Fahimuddin[4]
[1]Georgetown School of Medicine, Washington, DC; [2]Georgetown University, Washington, DC; [3]Medstar Washington Hospital Center, Washington, DC; [4]MedStar Washington Hospital Center, Washington, DC

10:30 AM - 12:30 PM

Objective: A lack of access to healthy and nutritious food has been identified as an independent risk factor for pregnancy morbidity, but there is a lack of evidence outlining the relationship between gestational weight gain (GWG) and food desert (FD) proximity. In this study, we sought to evaluate the impact of living in FDs on GWG during pregnancy.

Study Design: This single-center, retrospective study examined patients undergoing cesarean delivery (CD) at MedStar Washington Hospital Center from July 2021 to December 2022. Exclusion criteria included multifetal gestation, prenatal care outside of our hospital system, and entry into prenatal care after 14 weeks of gestation. Patients were classified as having low food access (LFA) if they lived more than 1 mile (urban) or 10 miles (rural) from the nearest supermarket. GWG was defined as inadequate, adequate, or excessive weight gain based on pre-pregnancy BMI as delineated by ACOG recommendations. Multivariate multinomial logistic regression models compared patients with LFA and GWG as the primary outcome, adjusting for insurance type, marital status, and low income area.

Results: A total of 370 patients were included in the study, of whom 73 (19.7%) lived in an LFA neighborhood. Women in the LFA category had an average weight gain of 13.4 kg as compared to 11.84 kg for those that lived in food secure neighborhoods, although this difference was not statistically significant (p = 0.105). When assessed by pre-pregnancy BMI category, we found a directional trend suggesting that living in LFA neighborhood was associated with excessive weight gain, but this result was also not statistically significant (aOR: 0.60 [0.324-1.101]).

Conclusion: Living in a LFA community showed no statistically significant correlation for excessive weight gain when compared to patient's living in communities with adequate food access. This study emphasizes the need for further exploration of alternative factors that may be impacting the discrepancy in pregnancy morbidity in these populations.

Table 5: Average Gestational Weight Gain (kgs) by Pregnancy BMI Category and Food Desert Status

932 | Association between Social Vulnerability Index and Adverse Pregnancy Outcomes

Tetsuya Kawakita[1]; Lindsay S. Robbins[1]; George Mcleod[2]; George R. Saade[1]
[1]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [2]Old Dominion University, Norfolk, VA

10:30 AM - 12:30 PM

Objective: To examine the association between the social vulnerability index (SVI) and adverse pregnancy outcomes, including maternal mortality.

Study Design: This was a cross-sectional study of county-level data analysis of individuals who delivered in the United States from 2016 to 2021. The study population includes individuals aged 10-44 at the time of delivery who gave live births, stillbirths, or suffered maternal death. The SVI ranges 0-1, with 1 being the highest vulnerability. Counties were categorized based on the SVI quartile (Q1 < 25th percentile, Q2 25-49th percentile, Q3 50-74th percentile, Q4 75th or greater). Our primary outcome was maternal mortality, defined as "the death of a woman while pregnant or within 42 days of termination of pregnancy." Secondary outcomes included maternal mortality up to one year postpartum, stillbirth, and preterm birth < 37 weeks. We conducted Bayesian spatial models with Conditional Autoregressive Priors to calculate log relative risk (RR) with 95% confidence intervals (95%CI), which considered spatial autocorrelation.

Results: Of 22,667,460 births, there were 6,731 maternal mortalities, 9,702 mortalities up to one year postpartum, 275,884 stillbirths, 2,285,797 preterm births, and 7,225,076 cesarean deliveries from 3,012 counties. Maternal mortality rate (MMR) per 100,000 births and SVI categories are shown in Figure 1. As the SVI increases, incidences of maternal mortality increase (Q1 22.8; Q2 25.7; Q3 31.1; and Q4 34.5 per 100,000 births) (Table 1). Higher SVI groups had increased risks of maternal mortality (Q2 RR 1.10, 95%CI 0.99-1.22; Q3 RR 1.27, 95%CI RR 1.15-1.41; Q4 RR 1.54, 95%CI 1.39-1.72). Higher SVI groups also had increased risks of other adverse pregnancy outcomes (Table 1).

Conclusion: High SVI is associated with an increased risk of adverse pregnancy outcomes. The SVI could be used to identify counties that need policies to address health disparities.

933 | Association Between the Dietary Inflammatory Index and Adverse Pregnancy Outcomes

Ummayhany F. Bharmal[1]; George R. Saade[2]; Tetsuya Kawakita[2]
[1]Medical College Baroda, Medical College Baroda, Gujarat; [2]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA

10:30 AM - 12:30 PM

Objective: The impact of pre-conception inflammatory load has not been adequately evaluated. We sought to determine whether a pre-conception diet that promotes inflammation, as measured by the dietary inflammatory index (DII), is associated with adverse pregnancy outcomes.

Study Design: This is a secondary analysis of data from the Nulliparous Pregnancy Outcomes Study: Monitoring Mothers-to-Be (nuMoM2b) study, in which dietary habits were assessed for three months before conception via a food frequency questionnaire. Data was obtained through patient interviews and chart abstraction. Individuals with spontaneous abortion or missing dietary data were excluded. DII was calculated from 28 pro-and anti-inflammatory food items. Participants were classified into DII quartiles, with the highest quartile indicating the most pro-inflammatory diet. The primary outcome was a composite of adverse pregnancy outcomes including preeclampsia, preterm birth less than 37 weeks, small for gestational age less than 5th percentile, and stillbirth. Adjusted relative risks (aRR) along with the 95% confidence intervals (CI) were calculated for all outcomes, using modified Poisson regression while controlling for confounders.

Results: Of the 7,911 participants included in this analysis, 1,443 (18.2%) had an adverse pregnancy outcome. Demographics and socioeconomic factors including age, race, marital status, insurance, education, and depression varied across the groups (Table 1). Outcomes according to DII quartiles are presented in Table 2. Individuals in the highest DII quartile compared with those in the lowest quartile had an increased risk of the primary outcome (20.8% vs 17.4%, aRR: 1.17, 95% CI: 1.02-1.34) as well as stillbirth (0.9% vs. 0.3%; aRR 2.94, 95% CI: 1.04-8.32). Other secondary outcomes were not statistically significant.

Conclusion: A pro-inflammatory diet in the immediate pre-conception period is associated with a composite of adverse pregnancy outcomes. Investigation of pre-pregnancy nutritional interventions is warranted.

Adverse pregnancy outcomes included preeclampsia, preterm birth less than 37 weeks, small for gestational age less than 5th percentile, and stillbirth.
Adjusted RRs were controlled for maternal age, race, BMI, chronic hypertension, pregestational diabetes, marital status, education, insurance, high stress, depression, and smoking before pregnancy

934 | Association between Stillbirth and the Social Vulnerability Index

Tetsuya Kawakita[1]; Ann Harper[2]; John Brush[2]; Misa Hayasaka[3]; George R. Saade[1]
[1]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [2]Sentara Health Research Center, Norfolk, VA; [3]Department of Obstetrics and Gynecology, Macon and Joan Brock Virginia Health Sciences at ODU, Norfolk, VA

10:30 AM - 12:30 PM

Objective: To examine the association between stillbirth and the social vulnerability index using electronic data from a large health system.

Study Design: This was a retrospective cohort study of pregnant individuals aged 18-50 who delivered singleton fetuses at any of 6 hospitals within our healthcare system from 2015 to 2022 and were 20 weeks or greater. We excluded pregnancies with known major fetal anomalies or chromosomal abnormalities and intrapartum stillbirth. Individuals with their unavailable addresses were also excluded. Stillbirth was defined as the birth of a fetus without signs of life at 20 weeks' gestation or greater. The social vulnerability index (SVI) was obtained based on the census tract that pregnant individuals lived in. The overall SVI and the four domains of SVI (Socioeconomic status, household characteristics, racial and ethnic minority status, and housing type and transportation) were compared between stillbirths and live births. Multivariable logistic regression was used to calculate adjusted odds ratios (aOR) with 95% confidence intervals (95%CI), adjusting for confounders (1st quartile as referent).

Results: Of 61,323 pregnancies, 603 (1.0%) had stillbirths and 60720 (99.0%) had live births. The distribution of the SVI in our region is presented in Figure 1. Compared to live births, stillbirths were associated with increased odds of higher overall SVI quartiles (3rd quartile aOR 1.54, 95%CI 1.22-1.96; 4th quartile

aOR 1.45, 95%CI 1.13-1.87; Table 1). In the socioeconomic status domain, stillbirths were associated with increased odds of 3rd quartile SVI (but not 4th quartile). Household characteristics status domain SVI was not associated with increased odds of stillbirth. In the racial and ethnic minority status domain and housing type and transportation domain, stillbirth was associated with 4th quartile SVI.

Conclusion: The overall SVI and the socioeconomic status, racial and ethnic minority status, and housing type and transportation SVI domains are significantly associated with increased odds of stillbirth.

935 | Ethnic/Racial Differences in Pregnancy Outcomes for Patients Requiring Antepartum Antihypertensive Maintenance for Non-severe Hypertension

Tiffany Yang[1]; Hannah K. Agoglia[2]; David Garry[1]; Samantha Gobioff[3]; Cassandra Heiselman[1]
[1]Stony Brook University Hospital, Stony Brook, NY; [2]Renaissance School of Medicine at Stony Brook University, Stonybrook, NY; [3]Stony Brook University, Stonybrook, NY

10:30 AM - 12:30 PM

Objective: This study aimed to determine differences in pregnancy outcomes and hypertension control for pregnant patients requiring antepartum antihypertensive maintenance across race/ethnicity groups.

Study Design: Patients who received prenatal care at an academic institution with a non-severe hypertensive disorder (chronic, gestational, preeclampsia) requiring oral antihypertensive maintenance medications were included. Medications had to be initiated prior to 34 weeks for a minimum of 2 weeks. Pregnancies with fetal anomalies and multiples were excluded. Patients were stratified by self-identified race/ethnicity. Hypertension outcomes included dosage changes and adherence, escalation in hypertension diagnosis (i.e. chronic to preeclampsia), and acute management of severe hypertension intrapartum. Pregnancy outcomes included mode of delivery, composite peripartum complications, GA at delivery, and BW. Statistics done with significance level of $p < 0.05$.

Results: 121 patients met inclusion criteria: 86 (71.1%) White, 16 (13.1%) Black, 6 (5.0%) Asian, and 10 (8.3%) Hispanic. Non-White patients experienced higher rates of antenatal dosage changes (80% v 55%, p = 0.046), escalation in hypertensive diagnosis (64% v 38%, p = 0.02), and need for acute antihypertensives intrapartum (42% v 21%, p = 0.02) compared to White patients (Table 1). Black patients had higher rates of medically-indicated preterm delivery (69% v 36%, p = 0.01), peripartum complications (31% vs 11%, p = 0.04), and medication non-adherence (33% v 8%, p = 0.01) compared to non-Black patients (Table 2). Asian patients had higher initial diastolic pressures upon delivery (99.5±26.1 v 85.8±13.9, p = 0.03) compared to non-Asian patients. Hispanic patients were less likely to have cesarean delivery (30% v 64.9%, p = 0.04) compared to all others.

Conclusion: Non-White patients have a higher risk for inadequate blood pressure control, requiring more antihypertensive medication, along with greater difficulty with medication adherence. To optimize maternal outcomes equally across all racial/ethnic groups, understanding specific risks and needs remain paramount.

936 | The Impact of Inter-Pregnancy-Interval After Delivery of SGA Fetus on Recurrence Rate - Multicenter Study

Tzory Jan Misgav[1]; Hen Y. Y. Sela[1]; Tzuria Peled[2]; Sorina Grisaru Granovsky[3]; Misgav Rottenstreich[4]
[1]Shaare Zedek, Jerusalem, Yerushalayim; [2]Shaare Zedek Medical Center, Shaare Zedek Medical Center, Yerushalayim; [3]Hebrew University, Jerusalem, Yerushalayim; [4]McMaster University, Hamilton, ON

10:30 AM - 12:30 PM

Objective: To evaluate the association between IPI after delivering an SGA infant and the recurrence of this condition in the subsequent pregnancy. This study aims to identify high-risk populations for recurrence and provide counseling on the recommended waiting period before the next pregnancy.

Study Design: **Methods**: A multi-center retrospective cohort study. The study population included all women who delivered a live SGA infant between 24-42 weeks of gestation and subsequently conceived and delivered in all university-affiliated obstetrical centers in a single geographic area between 2003 and 2021. The study population was divided into several IPI groups, with an IPI of 18 to 23 months serving as the reference group. The primary outcome measured was the recurrence rate of SGA in the subsequent pregnancy.

Results: During the study period, 12,689 women who delivered an SGA infant and subsequently delivered again were identified. The control group (IPI between 18-23 months) included 1,765 women. The overall recurrence rate of SGA in the study population was 19.3%. Univariate analysis showed that an IPI of less than 3 months and an IPI between 6 to 11 months were associated with higher rates of SGA recurrence (24.6% vs. 17.5%, p< 0.01 and 20% vs. 17.5%, p = 0.03, respectively). However, multivariate analysis controlling for confounders such as maternal age, gravidity, parity, birthweight percentile at first delivery, and smoking showed no significant association between different IPI groups and SGA recurrence compared to the control group.

Conclusion: Approximately one-fifth of women with a previous SGA child will experience a recurrence. No significant association was found between IPI and SGA recurrence. Further studies are needed to identify factors that can prevent SGA recurrence.

10:30 AM - 12:30 PM

Objective: To compare placental histologic findings to perinatal outcomes from pregnant patients with COVID-19 based on predominant SARS-CoV-2 variant at time of infection.

Study Design: Retrospective cohort study of pregnant patients between March 1, 2020 to February 28, 2023 with confirmed PCR-positive COVID-19 in singleton pregnancy > 6 weeks and available placental pathology. Exclusion criteria: patients with preexisting risk factors for abnormal placentation. Exposures: COVID-19 wild-type, Delta and Omicron strains. Primary outcomes: placental findings [maternal vascular malperfusion (MVM), fetal vascular malperfusion (FVM), and infectious/inflammatory findings], development of hypertensive disorders of pregnancy (HDP), and spontaneous or indicated preterm birth. Placental findings were categorized by strain, infection severity, trimester. Delivery timing was categorized by placental findings. Univariate techniques were utilized.

Results: 708 out of 1536 patients met inclusion criteria. COVID symptoms and placental findings were similar across strains (Table 1). The three cases of severe placental findings were

seen in patients with Omicron that were asymptomatic or had mild symptoms. Four patients with severe/critical symptoms had non severe placental findings. HDP after COVID infection was similar across all strains (Table 1). The proportion of patients with placental findings was similar across all trimesters (Table 2). MVM was more common in full-term deliveries, likely explained by the common finding of villous infarction < 5%. Placental inflammatory/infectious findings were significantly associated with spontaneous preterm birth (45.9% vs. 24.5% full-term, 20.0% indicated preterm; p = 0.01).

Conclusion: Our data does not suggest a difference in placental findings based on COVID strain, infection severity, or trimester. Placental inflammatory/ infectious findings were most common in patients who experienced spontaneous preterm birth.

938 | Perinatal Outcomes Following Implementation of a Remote Patient Monitoring Program for Hypertensive Disorders in Pregnancy

Vincent Tang; Matthew P. Romagano; Joanne N. Quiñones; Danielle Durie; Shae Duka; Nichola Bomani Gonzalez; Ebtisam Zeynu; Meredith Rochon
Lehigh Valley Health Network, Allentown, PA

10:30 AM - 12:30 PM

Objective: Telehealth and remote patient monitoring programs (RPM) are used increasingly in obstetrics to improve care and decrease hospital admissions. Our goal was to evaluate the impact on perinatal outcomes of an RPM for management of antepartum hypertensive disorders of pregnancy (HDP).

Study Design: Retrospective cohort study of singleton gestations with HDP < 37 weeks expectantly managed before and after implementation of an RPM for HDP (controls 6/2020-5/2022, RPM 6/2022-4/2024). Patients were excluded if they had severe features or an indication for immediate delivery. RPM management was outpatient and included remote vital signs, nurse phone visits, and fetal surveillance. Control group management was both inpatient and outpatient at the discretion of the obstetrician. Primary outcome was gestational age (GA) at delivery. Secondary outcomes were readmission rates and select perinatal outcomes.

Results: 162 patients were identified: 66 RPM and 96 controls (Table 1). Median GA at enrollment and duration in RPM was 32.9 wks (IQR 29.9-34.6) and 20.0 days (IQR 9-31), respectively. RPM patients were more likely to have underlying chronic hypertension (cHTN); demographics were otherwise similar. Controls were more likely to deliver during the index hospitalization and develop severe features; RPM were more likely to be readmitted. RPM participants had a longer latency period between HDP diagnosis and delivery (27.5 vs 14.0 days, p = 0.0036), delivered at a later GA (35.9 vs 35.4 wks, p = 0.0051), and were more likely to have a planned delivery at 37 wks (31.8% vs 0%, p< 0.0001). NICU admission rate was higher in the control group (78.1% vs 57.6%, p = 0.0051), primarily due to prematurity. After adjusting for cHTN, preeclampsia history and BMI, RPM was associated with pregnancy prolongation of 0.949 wks (95% CI 0.188, 1.710), an 83% reduction in development of severe features [AOR 0.169 (95% CI 0.073, 0.391), p< 0.0001] and a 60% reduction in NICU admission [AOR 0.398 (95% CI 0.191, 0.833), p = 0.0144).

Conclusion: Use of RPM for outpatient management of preterm HDP is safe and may improve select perinatal outcomes.

939 | Randomized Trial of Postpartum Aspirin and Impact on Nt-Probnp as a Marker of Maternal Health

Virginia Y. Watkins; Anthony E. Melendez Torres; Maria C. Prado; Eden Singh; Jerome J. Federspiel; Sarah C. Snow; Sarahn M. Wheeler; Shakthi Unnithan; Alaattin Erkanli; Brenna L. Hughes
Duke University School of Medicine, Durham, NC

10:30 AM - 12:30 PM

Objective: To compare levels of NT-proBNP, a marker of cardiac dysfunction, and clinical outcomes in patients at risk of preeclampsia randomized to continuation of low-dose aspirin (LDA) or placebo for 6 weeks postpartum.

Study Design: This double-blinded randomized-controlled trial included patients at risk of preeclampsia randomized in a 1:1 fashion to LDA (81 mg) versus an identical-appearing placebo continued for 6 weeks postpartum (Table 1). The primary outcome was NT-proBNP levels at the postpartum visit. A sample size of 90 was required to detect a clinically significant difference in NT-proBNP between LDA and placebo with 80% power. A sample size of 110 subjects was planned due to anticipated loss to follow-up in the postpartum period. Pre-specified secondary outcomes were postpartum preeclampsia, eclampsia, hospital readmission, initiation or titration of blood pressure medications, and blood transfusion. The primary outcome was compared using the Wilcoxon rank sum test. Secondary outcomes are reported as counts (%) and were compared using Fisher's exact test after adjusting for multiple testing using Bonferroni correction.

Results: From July 2023 to March 2024, 110 participants were randomly assigned to LDA (n = 55) or placebo (n = 55). Baseline demographics were similar between groups (Table 1). There was no difference in the primary outcome of NT-proBNP levels between groups (median (IQR), 36.5 ng/mL (36.0, 61.0) vs. 39.5 ng/mL (36.0, 74.0), p = 0.49). Rates of postpartum preeclampsia in patients randomized to LDA vs. placebo (5.6% vs. 12.7%) were numerically but not statistically significantly lower, with similar rates of hospital readmission and bleeding complications (Table 2). There were no cases of postpartum eclampsia or blood transfusion. Adherence was higher in the LDA (75% vs. 69%) than the placebo group.

Conclusion: Continuation of LDA after delivery was not associated with decreased NT-proBNP levels compared to placebo. Additional studies powered to detect differences in maternal outcomes are needed to evaluate the role of LDA in the postpartum period.

940 | Concordance of Clinical GBS Status with Bacterial Culture Obtained at Delivery Admission

William L. Riley[1]; Callie Reeder[1]; Jill M. Maples[2]; Kimberly B. Fortner[1]; Jessica Da Conceicao Mendonca[3]; Zachary Burcham[3]; Lindsey Burcham[3]
[1]University of Tennessee Graduate School of Medicine, Knoxville, TN; [2]University of Tennessee Health Science Center, College of Medicine, Knoxville, TN; [3]University of Tennessee Knoxville, Knoxville, TN

10:30 AM - 12:30 PM

Objective: To evaluate the vaginal microbiome at term and compare routine prenatal GBS screening with culture data obtained through specimen collection at delivery hospital admission.

Study Design: This prospective cohort study, funded by an institutional Human Health and Wellness grant, enrolled 50 term-pregnant patients to assess the vaginal microbiome through culture and 16S full-length sequencing approaches at delivery admission. Following consent, a sterile speculum examination was performed for vaginal swab and lavage. Records were reviewed for demographics, clinical GBS status, and obstetric outcomes.

Results: Clinical GBS status was ascertained from routine antenatal care records, and bacterial culture data were obtained from vaginal swab at the time of delivery admission for 39 participants. Of these, 9/38 (24%) were GBS-positive and 19/38 (50%) were GBS-negative by both sampling methods, giving concordant results in 28/38 patients (74%). Four (11%) participants had negative routine GBS screening but were GBS-positive by culture at admission, three (8%) had positive GBS clinical screens without GBS detected by culture at admission, and three (8%) were missing either data point (Figure 1). One participant with GBS bacteriuria followed by negative routine GBS screen was GBS-positive by culture on admission. Twenty-eight (74%) patients were colonized with opportunistic pathogens including *S. agalactiae, E. faecalis, E. faecium, S. aureus, S. epidermidis* and *E. coli*.

Conclusion: While ~75% of clinical GBS status and admission cultures agreed, 14% likely received unnecessary antibiotics during labor. More importantly, 11% of participants did not receive antibiotic prophylaxis due to negative routine screening; however, were found to be colonized with GBS by culture. Future work includes complete microbiome analyses to evaluate unrecognized GBS colonization due to opportunistic pathogen overgrowth and determination of GBS capsular serotype distribution for downstream molecular analyses. Clinical questions still exist regarding the optimal method, timing, and cost efficiency for determining GBS status.

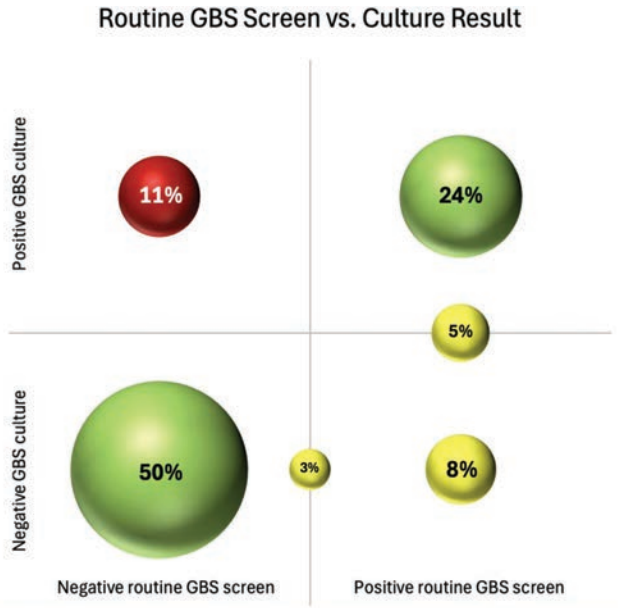

Figure 1. Plot of routine prenatal care GBS screening results compared to GBS culture obtained on admission for delivery.

941 | Race, Ethnicity, and Outcomes in Pregnancies with Gestational Diabetes: a Secondary Analysis of Numom2B Dataset

Xiang Yu Feng[1]; Jenny Chang[2]; Argyrios Ziogas[2]; Rebecca J. Post[2]; Judith H. Chung[3]; On behalf of the nuMoM2b Network

10:30 AM - 12:30 PM

Objective: Studies have demonstrated higher rates of gestational diabetes in racial and ethnic minorities. Management of gestational diabetes requires various dietary and lifestyle changes in pregnancy. This study evaluates the association between race, ethnicity, specific risk factors and outcomes in nulliparous pregnancies affected by gestational diabetes.

Study Design: This study is a secondary analysis of the Nulliparous Pregnancy Outcomes Study: Monitoring Mothers-to-be (nuMoM2b), a prospective cohort study following nulliparas throughout pregnancy. Patients diagnosed with gestational diabetes were analyzed by racial/ethnic groups. Primary outcome was neonatal hypoglycemia. Secondary outcomes were selected neonatal and maternal morbidities. ANOVA test and Fisher's exact were used for analysis of difference in race/ethnicity group. Multivariate logistic regression was used to adjust for confounders.

Results: Of the cohort of 10,037 patients, 396 were diagnosed with gestational diabetes, with 54.5% patients identifying as non-Hispanic White, 10.4% non-Hispanic Black, 18.7% Hispanic, and 16.4% all other. Variance by race/ethnicity was found for multiple characteristics such as age, body mass index, dietary caloric and carbohydrate intake, chronic hypertension, socioeconomic status, health literacy, and experience of racism (all p values < 0.047). After adjusting for these potential confounders, rates of neonatal hypoglycemic were not statistically significant. However, rate for cesarean was higher for non-Hispanic Black patients (aOR 2.18,

95% CI 1.02-4.70) and macrosomia higher for Hispanic patients (aOR 2.98, 95% CI 1.10-8.09).

Conclusion: Variance was observed in racial/ethnic groups for multiple characteristics including dietary caloric intake and carbohydrate intake in patients with gestational diabetes. Although odds of neonatal hypoglycemia were not significant between groups, differences in cesarean delivery and macrosomia rates were seen. These findings may impact developing culturally individualized care in counseling and management of gestational diabetes.

943 | Betamethasone for Preterm Premature Rupture of Membranes at Late Prematurity

Yossi Bart[1]; Michal Fishel Bartal[2]; Farah H. Amro[1]; Sean C. Blackwell[1]; Baha M. Sibai[1]

[1]*McGovern Medical School at UTHealth Houston, Houston, TX;*
[2]*UTH Houston & Sheba Medical Center Israel, Houston, TX*

10:30 AM - 12:30 PM

Objective: As of 2020, the American College of Obstetricians and Gynecologists extended the upper limit of expectant management of preterm premature rupture of membranes (PPROM) to 36 weeks. Treatment with betamethasone (BMZ) in the subset of patients with PPROM in the late preterm period has not been well studied. Therefore, we sought to investigate this.

Study Design: A secondary analysis of the Antenatal Late Preterm Steroids (ALPS) trial. All individuals enrolled in the parent trial were included. The primary outcome was a composite of respiratory support at 72 h, including continuous positive airway pressure or high flow nasal cannula ≥ 2 h, oxygen with an inspired fraction of ≥ 30% for ≥ 4 h, or mechanical ventilation, together with extracorporeal membrane oxygenation, or stillbirth or neonatal death within 72 h after delivery. Poisson regression was implemented to adjust for confounders.

Results: Overall, 22% (620/2,831) had PPROM upon enrollment. Among individuals with PPROM, compared to those without, the median latency period was 15.6 hours (IQR 8.3-24.1) versus 45.0 hours (IQR 20.0-158.0; P< 0.001) (Figure). Among the patients who received BMZ, two doses were given to 26% (83/316) of those with PPROM vs. 70% (775/1,110; P< 0.001) of those without. Latency ≥ 48 hours, compared to < 48 hours, was associated with a lower primary outcome rate: 9% (94/1,078) vs. 16% (273/1,749); P< 0.001.

Among patients with PPROM, 49% (304) received BMZ and 51% (316) received placebo. The BMZ and placebo groups had similar baseline characteristics. In this subgroup, there was no difference in the primary respiratory outcome rate (adjusted RR 0.91, 95% CI 0.60-1.38) between BMZ and placebo (Table). Secondary neonatal and maternal outcomes did not differ as well.

Conclusion: Compared to those without, individuals with PPROM in the late preterm period had shorter latency; three out of four delivered within 24 hours from randomization. Among individuals with PPROM, there were no differences in neonatal morbidity following treatment with BMZ compared to placebo. However, our study was underpowered to detect such differences.

Table – Neonatal outcomes among individuals with preterm premature rupture of membranes at risk for late preterm birth, following treatment with betamethasone vs. placebo

Outcome	Placebo (N=304)	BMZ (N=316)	Unadjusted RR [a] (95% CI)	Adjusted RR (95% CI)
Primary respiratory outcome [b]	13.2	11.7	0.89 (0.59-1.35)	0.91 (0.60-1.38)
CPAP / HFNC ≥ 2h	12.2	10.1	0.83 (0.53-1.29)	0.84 (0.54-1.31)
Inspired oxygen fraction ≥ 30% for ≥ 4 h	3.3	2.8	0.86 (0.35-2.09)	0.97 (0.40-2.38)
Mechanical ventilation	3.3	1.9	0.57 (0.21-1.56)	0.62 (0.23-1.68)

944 | Novel Roles of Et-1 in Superimposed Preeclampsia

Yuye Wang[1]; Rebecca Ssengonzi[2]; Feng Li[2]; Nobuyo Maeda-Smithies[2]
[1]*University of North Carolina at Chapel Hill, Durham, NC;* [2]*University of North Carolina at Chapel Hill, Chapel Hill, NC*

10:30 AM - 12:30 PM

Objective: This study aims to determine if low maternal endothelin-1 (ET-1) expression causes preeclampsia-like phenotypes during pregnancy using mice with modified *Edn1* alleles (L) that have ~30% of the wild type (WT) circulating ET-1 levels.

Study Design: At 8-10 weeks of age, $Edn1^{L/L}$ females were mated with $Edn1^{L/L}$ males, and WT females were mated with WT males. One batch of dams from each group was sacrificed at 18.5 days post coitus (dpc) and maternal urine, plasma, and kidneys were collected. Urine albumin, and serum markers of preeclampsia—soluble fms-like tyrosine kinase 1 (sFlt-1), vascular endothelial growth factor (VEGF), and soluble endoglin (sENG)—were measured using ELISA kits. Electron microscopy of the glomeruli was examined at 18.5 dpc. A separate batch of dams from each group was reared through term delivery (19.5 to 21.5 dpc). Tail-cuff blood pressure measurement was performed on WT and $Edn1^{L/L}$ female mice before pregnancy, at 13.5 dpc, at 17.5 dpc, and at 7 days postpartum.

Results: Virgin $Edn1^{L/L}$ females were hypertensive but did not demonstrate any other obvious abnormalities. $Edn1^{L/L}$ females developed the full spectrum of preeclampsia-like phenotypes during pregnancy, including elevated systolic blood pressure and urinary albumin secretion, and glomerular endothelial damage. On the day of delivery, $Edn1^{L/L}$ dams had fewer live neonates. At 18.5 dpc, $Edn1^{L/L}$ dams also had fewer live fetuses and reduced fetal weight. The placental weights were not different between $Edn1^{L/L}$ and WT dams. Interestingly, all serum markers of PE were lower in $Edn1^{L/L}$ dams compared to WT dams.

Conclusion: Our results show low maternal ET-1 expression causes preeclampsia-like phenotypes during pregnancy and leads to adverse pregnancy outcomes in mice.

945 | Evaluating Associations Between a Continuous Measure of Midtrimester Cervical Length and Gestational Age at Delivery

Zahava P. Michaelson[1]; Daniel L. Kuhr[1]; Nicola F. Tavella[2]; Raina Kishan[2]; Nicole Parkas[1]; Helen Feltovich[1]; Kimberly B. Glazer[3]
[1]*Division of Maternal-Fetal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY;* [2]*Icahn School of Medicine at Mount Sinai, New York, NY;* [3]*Department of Population Health Science and Policy; Department of Obstetrics, Gynecology and Reproductive Science, Blavatnik Family Women's Health Research Institute, Icahn School of Medicine at Mount Sinai, New York, NY*

10:30 AM - 12:30 PM

Objective: A dichotomous measure of short cervical length (CL) (< 25 mm) is correlated with spontaneous preterm birth (sPTB) but cannot predict gestational age (GA) at delivery. Our aim was to examine the relationship between continuous CL and delivery GA.

Study Design: This was a retrospective cohort study of 1,000 patients who delivered at a single tertiary, urban academic hospital from January 2013-August 2023 after transvaginal CL was measured at 16w0d-24w6d GA. We abstracted delivery GA and CL taken closest to 20w0d from the electronic medical record. We used linear regression to model associations between a 1 mm increase in CL and mean change in GA at delivery for the full cohort as well as a sub-cohort with CL < 25 mm. We used model r^2 to measure the proportion of variance in GA explained by CL in each group.

Results: 1,038 pregnancies in 1,000 patients met inclusion criteria. 21.4% of pregnancies were in patients with prior sPTB (Table 1), consistent with a high-risk population. 13.3% of index pregnancies ended in sPTB. CLs were normally distributed with a mean (standard deviation) of 38 (7) mm (Table 2). The median (min, max) delivery GA was 39.0 (21.0, 42.0) weeks. CL and GA were weakly positively correlated (Spearman r = 0.07, p = 0.02). In the overall cohort, 1 mm CL increase was associated with a mean increase of 0.5 (95% confidence interval (CI) 0.4-0.7) days GA at delivery (r^2 = 0.06). In the short cervix cohort, 1 mm increased CL was associated with increased GA of 2.7 (95% CI 0.9-4.4) days (r^2 = 0.25).

Conclusion: Continuous CL was positively associated with delivery GA in all patients, but small changes in CL explained more variation in GA at delivery in patients with CL < 25 mm. Because every additional day of gestation improves neonatal outcomes in sPTB, further research should investigate the use of continuous CL along with other predictors for risk stratification in high-risk patients.

946 | Cesarean Section Rates and Maternity Populations at Risk: a Single Center 16 Year Follow Up

Maxim Shapiro[1]; Zvi Ehrlich[2]; Rivka Farkash[1]; Yael Lerner[1]; Ronit Calderon Margalioth[1]; Sorina Grisaru Granovsky[3]
[1]SZMC, SZMC, Yerushalayim; [2]Shaare Zedek Medical Center, Jerusalem, Yerushalayim; [3]Hebrew University, Jerusalem, Yerushalayim

10:30 AM - 12:30 PM

Objective: To estimate the association between CS rates and the different maternity populations as classified Robson 10-group Classification (RGC) at a single large maternity center with uniform clinical protocols, between 2005-2021.

Study Design: 235,280 recorded births were categorized using RGC. CS risk was assessed by logistic regressions using both univariate and adjusted multivariate models. All models were re analyzed for parity groups in the RGC, nulliparous and multiparous. Within the nulliparous groups, RG1 was a reference for RG 2a, 2b, 6 and 8-10, and for multiparous, RG 3 was a reference for RG 4, 5, 7 and 8-10).

Results: CS rate increased from 11.0% to 13.8% during the study period (Figure). The largest groups were nulliparous and multiparous women with single cephalic, spontaneous labor at term (RG1 and RG3, respectively); 71.1%. The group that contributed the most to overall CS rate was RG 5 (multiparous, single cephalic pregnancy at term with prior CS), 33.6% of CS. RG5 also had the highest risk among the multiparous analysis (aOR = 45.2, 95% CI: 42.5-48.0). Apart from malpresentations, the groups with the highest risk for CS were RG8 (all multifetal pregnancies at any gestational age) overall and among nulliparous women (aOR = 6.1 95% CI: 5.4-6.8, and aOR = 24.7 95% CI: 20.4-29.8, respectively). Notably, labor induction increased the risk for CS in both nulliparous and multiparous (aOR = 3.5 95% CI: 3.5-4.0, and aOR = 3.7 95% CI: 3.2-3.9, respectively). (Table)

Conclusion: CS rates are still rising, even in populations with a basic low rate. Interventions to reduce CS rates should be focused on decreasing multifetal pregnancies rate in the setting of assisted reproduction and a careful revision of the limited trial of labor after cesarean. Labor induction was shown to increase the risk for CS in both nulliparous and multiparous groups, warranting inspection of this rising practice.

[1]SZMC, SZMC, Yerushalayim; [2]Shaare Zedek Medical Center, Jerusalem, Yerushalayim; [3]Hebrew University, Jerusalem, Yerushalayim

10:30 AM - 12:30 PM

Objective: To analyze the association between the different maternity women groups classified by Robson 10 Group Classification (RGC) and the risk for adverse maternal and neonatal outcomes, at a single large maternity center.

Study Design: An observational study including 235,280 births. Outcomes included post-partum hemorrhage (PPH), puerperal fever, extended length of hospitalization (LOH ≥4 days), maternal readmission within 42 days, in-hospital neonatal mortality, 5-minutes APGAR score< 7 and NICU ≥3 days. The associations and risks were assessed by adjusted logistic regression models for the entire populations as well as by maternal age, background medical condition prior to delivery, GDM, hypertensive disorder during pregnancy, prior miscarriage, gestational age. Analysis was conducted separately by parity. For nulliparous groups, RG1 was a reference for RG 2a, 2b, 6 and 8-10, and for multiparous, RG 3 was a reference for RG 4, 5, 7 and 8-10). In these comparisons, groups 8-10 were selected by their appropriate parity for each analysis.

Results: All multifetal pregnancies (RG8) had the higher risk for PPH (aOR = 1.7, 95% CI: 1.4-2.0) and extended LOH (aOR = 4.7, 95% CI: 4.0-5.5). RG 2b and 4b; Nulliparous and multiparous pre-labor CS at term, respectively, as well as RG 6; nulliparous breech (unrelated to the mode of delivery), had the highest risk for neonatal mortality (aOR = 9.1, 8.0 and 8.0, 95% CI, respectively). Both RG2a and RG4a groups; nulliparous and multiparous single cephalic labor induction at term, markedly showed that labor induction was significantly associated with low 5' APGAR and neonatal mortality, both for nulliparous and multiparous (RG2a low APGAR aOR = 1.7 95% CI: 1.4-2.0, mortality aOR = 4.2 95% CI: 2.6-6.7. RG4a- low APGAR aOR = 3.3 95% CI: 2.7-3.9, mortality aOR = 7.7 95% CI: 6.0-9.9) Tables 1 & 2.

Conclusion: The maternal and neonatal risk for adverse perinatal outcome is strongly associated with breech presentation, multifetal pregnancies at any gestational age and labor induction. Focused interventions to these groups may reduce the perinatal adverse outcomes in specific populations.

4:00 PM - 6:00 PM

Objective: Area Deprivation Index (ADI) is strongly associated with obstetric outcomes but understudied during the COVID-19 pandemic. We sought to evaluate the relationship between ADI and preterm birth during the early pandemic.

Study Design: We performed a secondary analysis of a prospective longitudinal cohort study investigating the impact of COVID-19 exposure in pregnancy on perinatal outcomes. Pregnant patients were recruited 12/23/20-7/18/22 and serially tested with serum antibody testing for COVID-19 exposure during pregnancy. Delivery residence address was used to categorize patients into low ADI ($\leq 50^{th}$ percentile) and high ADI ($\geq 75^{th}$ percentile, indicating high level of deprivation) groups. The primary outcome was preterm birth, using multivariable regression and stratified by gestational age at birth; secondary outcomes included other perinatal complications.

Results: 306 patients were included. Overall, preterm birth rates did not differ between high and low ADI groups; however, low ADI was significantly associated with lower rates of extreme preterm birth < 28 weeks and < 34 weeks (Table 1). After adjusting for obesity and tobacco use, the association persisted at < 28 weeks (aOR 0.26, 95% CI 0.07-0.73) and < 34 weeks (aOR 0.35 95% CI 95% 0.14-0.87; Table 2). There were no other differences found in perinatal outcomes except for a higher rate of neonatal intracranial hemorrhage in the low ADI group (3.2% vs 0%, p = 0.03).

Conclusion: High ADI was associated with increased risk of extremely preterm birth during the early COVID-19 pandemic even when controlling for obesity and tobacco use. The interplay of social determinants of health and preterm birth must be better studied to target interventions to modifiable risk factors.

HaMerkaz; [6]The Sheba Medical Center, Ramat Gan, HaMerkaz; [7]Sheba Medical Center, Ramat Gan, HaMerkaz

4:00 PM - 6:00 PM

Objective: To determine real-world accuracy of circulating angiogenic factors in predicting preeclampsia with severe features (sPE) in singleton and twin gestations.

Study Design: This retrospective cohort study consisted of individuals admitted to the antepartum unit of a tertiary academic center from 2023 to 2024. We included individuals with hypertensive disorders of pregnancy (HDP) at 23+0 to 34+6 weeks of gestation with available sFlt-1/PlGF measurements obtained as part of the clinical flow. Exclusion criteria included developing sPE on the day of measurement. The area under the curve (AUC) was used to assess accuracy of the prediction of sPE within two weeks. The discriminatory ratio of ≥40 was evaluated for clinical performance. Similar to the PRAECIS study, measurements were re-included if delivery did not occur within two weeks. In addition, we developed a logistic regression model integrating sFlt-1/PlGF with blood pressure (BP). Prediction of sPE by the integrated model was compared to prediction based on sFlt-1/PlGF alone using AUC and likelihood ratio test (LRT).

Results: The study group included 59 individuals (71 sflt-1/PlGF measurements). In 35% of measurements, the individuals developed sPE within two weeks. Table 1 reports the discriminatory clinical performance of the ≥40 ratio stratified by singleton and twin pregnancies. The ≥40 ratio showed better sensitivity and NPV in twins than in singletons. Moreover, although specificity in twins was lower than in singletons, the PPV was higher in twins due to the increased prevalence of sPE. Integrating sFlt-1/PlGF with BP measurement increased the model accuracy (AUC 0.83 VS 0.88, figure 1) and enhanced the model fit (LRT $p = 0.005$).

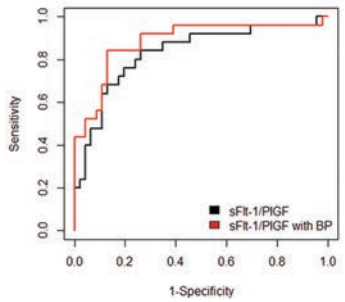
Conclusion: Real-world evidence supports extending the clinical use of the sFlt-1/PlGF ratio to assess the risk of developing sPE in twin pregnancies as well. Integrating sFlt-1/PlGF with clinical risk factors like BP can enhance predictive performance and clinical decision-making.

Table 1 – Clinical performance of the sFlt-1/PlGF≥40 ratio in prediction of preeclampsia with severe features within two weeks

	True positive	False positive	False Negative	True Negative	Sensitivity	Specificity	PPV	NPV
Singleton	11	9	4	29	0.73	0.76	0.55	0.88
Twins	10	3	0	4	1.00	0.57	0.77	1.00
All	21	12	4	34	0.84	0.74	0.64	0.89

PPV, positive predictive value; NPV, negative predictive value

Figure 1 – Receiver-operating characteristic (ROC) curve for prediction of preeclampsia with severe features within two weeks. Area under ROC curve =0.83 for sFlt-1/PlGF versus 0.88 for Sflt-1/PlGF integrated with blood pressure (BP) measurement at the same day.



950 | What to Expect of Expectant Management in Preterm Preeclampsia with Severe Features

Ahmed Zaki Moustafa[1]; Beatrice Valentini[2]; Joe Haydamous[3]; Cabrina Becker[4]; Jasmin Abdeldayem[5]; Khalil M. Chahine[6]; Sean C. Blackwell[7]; Baha M. Sibai[7]

[1]Division of Maternal-Fetal Medicine, Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern Medical School at UTHealth Houston, University of Texas - Houston, TX; [2]University of Parma, University of Parma, Emilia-Romagna; [3]Division of Maternal-Fetal Medicine, Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern Medical School at UTHealth Houston, Houston, TX; [4]UT Health Science Center at Houston, McGovern Medical School, Houston, TX; [5]Texas Tech Health Sciences Center of El Paso, El Paso, TX; [6]McGovern Medical School at UTHealth, Houston, TX; [7]McGovern Medical School at UTHealth Houston, Houston, TX

4:00 PM - 6:00 PM

Objective: Despite common practice in the US, Level I data from RCT's of expectant management of preterm preeclampsia with severe features (PSF) is limited. Of the three RCT's conducted, only one was performed in the US 30 years ago. There is also limited evidence guiding management in the setting of fetal growth restriction (FGR). Our objective was to describe maternal and perinatal outcomes with expectant management of early onset PSF by gestational age (GA) at diagnosis and by presence of FGR.

Study Design: This is a retrospective cohort study of pregnant individuals with a diagnosis of PSF between 24-34 weeks at a single Level 4 center between January 2022 to April 2024. Exclusion criteria was delivery < 24 hours of admission. We compared the latency period (time interval from diagnosis to delivery) by GA at diagnosis and presence or absence of FGR. Indications for delivery, maternal and perinatal outcomes were evaluated.

Results: Over the study period, 241 patients were admitted with PSF < 34 weeks and 73% (n = 175) met criteria for analysis. Patients were divided by GA: 24w0d–27w6d (n = 43), 28w0d–31w6d (n = 90), and 32w0d–33w-6d (n = 42). There were no significant differences in maternal characteristics.

Latency was longer with earlier GA at PSF diagnosis. The median (IQR) latency in days was 6.4 (2.7–14.2) in group 1, 4.2 (2.5-11.0) in group 2, and 3.0 (1.7-6.4) in group 3 (p = 0.024).

Rate of FGR was significantly higher with earlier onset at 51%, 46%, and 21% in groups 1, 2, and 3 (p = 0.01) and was associated with decreased latency though it did not reach statistical

significance (Figure 1). Latency when PSF is diagnosed beyond 32 weeks in the presence of FGR was only 1.7 days (1.5–7.6). Fetal indications for delivery were higher in group 1 (65 vs 47, and 24%, p = 0.002) (Table 1).

Conclusion: In pregnancies complicated by preterm PSF, latency decreased with advancing gestational age at diagnosis especially in the setting of FGR. Further studies are needed to evaluate if there is a benefit in attempting expectant management beyond administration of corticosteroids when PSF is diagnosed beyond 32 weeks with FGR.

There were no cases of eclampsia, stroke, or maternal mortality in our cohort.

951 | Early Anatomic Ultrasound to Detect Fetal Anomalies in High Risk Patients at 12-14 Weeks Gestation

Akos Herzeg[1]; Yili Zhao[1]; Mary E. Norton[2]
[1]UCSF, San Francisco, CA; [2]Center for Maternal-Fetal Precision Medicine, University of California San Francisco, San Francisco, CA

4:00 PM - 6:00 PM

Objective: Detailed evaluation of the fetus in the late first trimester is now possible. We report on the outcomes of a cohort of high-risk patients who underwent detailed fetal evaluation at 12-14 weeks' gestation (WG).

Study Design: Patients referred for early anatomy scans underwent detailed evaluation using a protocol based on AIUM practice parameters. Outcomes of all referred patients from 01/2021 through 07/2024 were collected. Variables included referral indications, maternal age, gestational age, need for endovaginal scan, detection of minor and major anomalies, genetic testing results, and outcomes based on second-trimester anatomy scan, fetal echo, or at birth.

Results: In all, 217 patients were included. Indications included prior pregnancy with genetic or structural anomalies (34%), maternal age or patient request (14%), abnormal screening (10%), suspected abnormalities on a routine scan (8%), teratogen exposure (7%), perinatal risk factors (5%), and complicated twins (1%). Median gestational age was 13+2 weeks' (IQR 1+1), 1.4% were twins and 2.8% required an endovaginal scan. In all, 55 (25.3%) had abnormal results: 36 of these were confirmed, 1 minor finding was not confirmed, 3 had fetal demise, 14 terminated, and 1 pregnancy is ongoing. Terminations without confirmation were for severe limb anomalies (2), acrania (1), abnormal CVS (8), sirenomelia (1), and bladder outlet obstruction (2). In the 162 (74.6%) cases with normal findings, 139 were confirmed normal at 20 WG or birth, 2 had mild pelviectasis at 20 WG, 4 terminated for CVS abnormalities*, 12 had follow-up elsewhere, and 5 have ongoing pregnancies. No major abnormalities were detected, and the only false positive result was a suspected persistent left superior vena cava that was not confirmed on fetal echo.

Conclusion: Dedicated anatomic evaluation at 12-14 weeks' gestation in high-risk patients has a high yield of abnormal findings and a high accuracy. For patients at high-risk, this option can provide earlier detection of significant anomalies as well as earlier reassurance/counseling.

Total Pregnancies	**N=217**
Maternal age (mean, SD)	37.6 years (SD 5.02)
Gestational age (median, IQR)	13+2 weeks' (IQR 1,1)
Endovaginal ultrasound (n, %)	6 (2.8)

952 | Establishing Blood Loss Thresholds Predictive of Transfusion at the Time of Delivery

Alesha M. White[1]; Kristina Fin[1]; Jessica E. Pruszynski[2]; R. Nicholas Burns[2]; Anne M. Ambia[2]; Brenda Anyaehie[1]; Elaine L. Duryea[1]
[1]*University of Texas Southwestern Medical Center, Dallas, TX;*
[2]*University of Texas Southwestern, Dallas, TX*

4:00 PM - 6:00 PM

Objective: In 2014, the American College of Obstetricians and Gynecologists established a standardized definition of postpartum hemorrhage (PPH) to be blood loss greater than 1000mL from any form of delivery. Prior to this in 1965, Pritchard established the definition of normal blood loss for spontaneous vaginal deliveries (SVD) to be 500mL and for cesarean deliveries (CD) to be 1000mL. Our objective was to establish blood loss thresholds at the time of delivery as they relate to transfusion using quantitative blood loss (QBL).

Study Design: This is a prospective observational study conducted from November 2023 until March 2024 at a single institution that included all SVDs and CDs at which QBL was collected. QBL was calculated and recorded in the electronic medical record by the nursing team, but not reported to providers, who used estimated blood loss (EBL) and clinical indices to guide clinical care, per existing practices. Receiver operating characteristic (ROC) curves were generated based on the probability of transfusion.

Results: QBL data was available for 4,543 deliveries. 3,236 (71%) of total deliveries were via SVD and 1,234 (27%) of deliveries were via CD. Based on an ROC curve for SVDs, the optimal cut point for transfusion was determined to be 449.5mL. This represented a sensitivity of 71% and a specificity of 79% with an AUC of 0.81. Based on an ROC curve for CDs, the optimal cut point for transfusion was determined to be 1012.5mL. This represented a sensitivity of 61% with a specificity of 72% and an AUC of 0.7. The prevalence of transfusion at each respective cut point for type of delivery represented a 10.90% prevalence of transfusion for CDs and a 4.60% prevalence of transfusion for SVDs.

Conclusion: The QBL cut points associated with transfusion in this study are very similar to prior cut points determined to represent normal blood loss at delivery, which is known to differ by mode of delivery. Such that, not all deliveries should be classified as normal based on a 1000mL cut point alone and a heightened awareness should be present when QBL exceeds 500cc for SVD.

Figure. Probability of transfusion based on quantitative blood loss with corresponding ROC curve for spontaneous vaginal deliveries

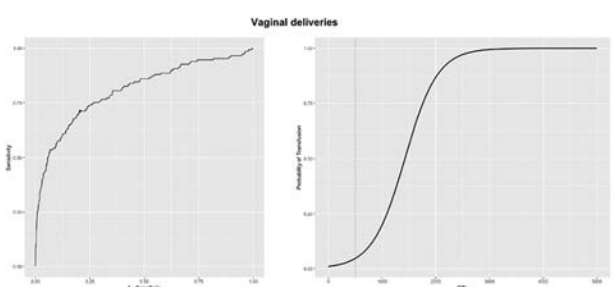

Figure. Probability of transfusion based on quantitative blood loss with corresponding ROC curve for cesarean deliveries

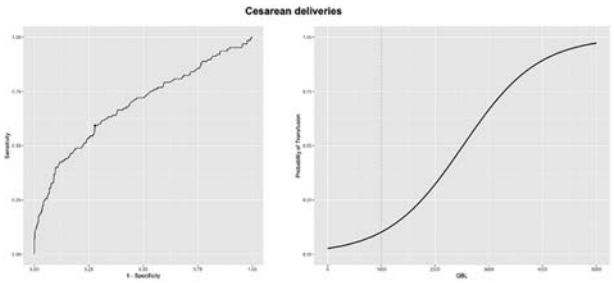

953 | Defining Postpartum Hemorrhage in Vaginal Deliveries Based on Quantitative Blood Loss

Alesha M. White[1]; Kristina Fin[1]; Jessica E. Pruszynski[2]; R. Nicholas Burns[2]; Anne M. Ambia[2]; Brenda Anyaehie[1]; Elaine L. Duryea[1]
[1]*University of Texas Southwestern Medical Center, Dallas, TX;*
[2]*University of Texas Southwestern, Dallas, TX*

4:00 PM - 6:00 PM

Objective: Postpartum hemorrhage (PPH) is a leading cause of maternal mortality across the world. In 2014, the American College of Obstetricians and Gynecologists (ACOG) defined PPH as blood loss ≥ 1000cc regardless of delivery mode. The objective of this study was to compare the sensitivity of various quantitative blood loss (QBL) thresholds for detection of need for transfusion for spontaneous vaginal deliveries (SVD), including maternal anemia status.

Study Design: This is a prospective observational study conducted at a single institution including all SVDs at which QBL was collected. QBL was calculated and recorded in the electronic medical record by the nursing team, but not reported to providers, who used estimated blood loss (EBL) and clinical indices to guide clinical care, per existing practices. Performance characteristics of QBL cut points of 500cc, 750cc, and 1000cc were examined, including examination according to maternal anemia at presentation for delivery antepartum, defined as a hematocrit < 33 based on current recommendations from ACOG.

Results: QBL was available for 3,250 SVDs between November 1st 2023 until March 31st 2024. The prevalence of transfusion for a QBL ≥1,000cc was 4.5%. A universal cut-point of 1,000cc demonstrated a 0.34 sensitivity for transfusion with a positive likelihood ratio (PLR) of 16.35. Maternal anemia was present at admission in 444 (14%) patients. The prevalence of transfusion for patients with and without anemia was 14.20% and 2.9% respectively. PLR reached 10 (a common threshold) at the 750cc cut point for patients with and without anemia, however the sensitivity of this cut point was lower for patients with anemia (0.41) compared to those without (0.6) (Table). A cut point of 500cc in patients with anemia achieved a sensitivity of 0.52.

Conclusion: Use of 1000cc as a definition of PPH for SVD results in a remarkably high PLR for transfusion while failing to detect the majority of patients requiring transfusion. Use of a cut point of 750cc for patients without anemia, and 500cc for patients with anemia is recommended.

Table. Performance characteristics of different cut points for quantitative blood loss as predictive for transfusion.

954 | Oxytocin Requirements Among Patients with a BMI Greater Than 30

Alexander M. Saucedo[1]; Miriam Alvarez[2]; Alison G. Cahill[3]; Lorie M. Harper[2]

[1]Baylor College of Medicine, Houston, TX; [2]Dell Medical School, Austin, TX; [3]Dell Medical School Health Transformation Research Institute, Dell Medical School, The University of Texas at Austin, Austin, TX

4:00 PM - 6:00 PM

Objective: Patients with obesity undergoing induction of labor (IOL) may require increased oxytocin (OT) administration when compared to normal weight patients. The OT product (mU/min x hours), defined by multiplying the maximum OT rate (mU/min) by the total OT duration (hours), is a labor variable that highly correlates with total OT dose received in labor. We aimed to determine the effect of increasing obesity on the OT product in obese patients undergoing IOL.

Study Design: Secondary analysis of a single center, double-blinded RCT between 6/2022 and 7/2023, which randomized near-term, singleton gestations with a BMI ≥ 30 kg/m^2 undergoing IOL, with a cervical dilation ≤ 3cm, to either 25mcg or 50mcg of vaginal misoprostol. For this analysis, patients were excluded if they did not receive OT during labor. We compared patients with a BMI of 30-39 kg/m^2 to those with a BMI ≥ 40 kg/m^2. The primary outcome was the overall OT product. Multivariable linear regression was used to adjust for randomization group, nulliparity, cervical ripening balloon use, and cervical dilation on admission.

Results: A total of 154 patients received OT with 109 (70.8%) in the BMI 30-39 group versus 45 (29.2%) in the BMI 40+ group. Baseline characteristics were similar. Following adjustment, an increased but non-significant OT product was seen in the BMI 40+ group (143.09 vs. 191.78 mU/min-hours; p = 0.19). Among only those who underwent vaginal delivery, a similar OT product was seen between groups (128.87 vs. 130.17 mU/min-hours; p = 0.96). Patients in the BMI 40+ group did have an increased overall time to delivery (20.38 hrs vs. 24.89 hrs; p = 0.03), increased risk for failed IOL (3.7% vs. 24.4%; p = 0.01), and an increased quantitative blood loss at delivery (345 mL vs. 450 mL; p = 0.04).

Conclusion: Patients in the BMI 40+ group had an increased but non-significant OT requirement when compared to the BMI 30-39 group. This OT difference was reduced when excluding patients who underwent cesarean. Increasing obesity was associated with an increased duration of labor, cesarean due to failed IOL, and increased blood loss at delivery.

955 | Misoprostol Dose Requirements Among Patients with a BMI Greater Than 30

Alexander M. Saucedo[1]; Miriam Alvarez[2]; Alison G. Cahill[3]; Lorie M. Harper[2]
[1]Baylor College of Medicine, Houston, TX; [2]Dell Medical School, Austin, TX; [3]Dell Medical School Health Transformation Research Institute, Dell Medical School, The University of Texas at Austin, Austin, TX

4:00 PM - 6:00 PM

Objective: Compared to normal weight persons, patients with obesity experience fewer uterine contractions after administration of vaginal misoprostol (VM). Therefore, patients with obesity may require higher doses of VM for induction of labor (IOL). We aimed to determine the effect of increasing obesity on the total VM dose requirement in obese patients undergoing IOL.

Study Design: Secondary analysis of a single center, double-blinded RCT between 6/2022 and 7/2023, which randomized near-term, singleton gestations with a BMI ≥ 30 kg/m^2 undergoing IOL, with a cervical dilation ≤ 3cm, to either 25mcg or 50mcg of VM. For this analysis, we included all patients from the primary study. We compared patients with a BMI of 30-34.9 kg/m^2 to those with a BMI ≥ 35 kg/m^2. The primary outcome was the overall misoprostol dose required during IOL. Multivariable linear regression was used to adjust for randomization group, nulliparity, cervical ripening balloon use, and cervical dilation on admission.

Results: A total of 179 patients were enrolled with 74 (41.3%) in the BMI 30-34.9 group versus 105 (58.7%) in the BMI 35+ group. Baseline characteristics were similar between groups with the majority of patients having an unfavorable cervical exam upon initiation of IOL. Following adjustment, patients in the BMI 35+ group required an increased overall misoprostol dose requirement during IOL (55.0 mcg vs. 66.2 mcg; P = 0.02). While cesarean delivery did not differ between BMI groups, the indication for cesarean was significantly different between groups, with more patients in the BMI 35+ group being diagnosed with failed IOL (4.1% vs. 12.4%; P = 0.04). No other differences in maternal/neonatal outcomes were seen.

Conclusion: In patients undergoing IOL, increasing obesity (BMI ≥ 35 kg/m^2) was associated with an increased overall misoprostol dose requirement as well as an increased risk for cesarean due to failed IOL. These findings highlight the potential pharmacokinetic differences with increasing obesity and vaginal misoprostol which may impact overall IOL efficacy.

956 | Does Increased Antenatal Depression Screening Impact Postpartum Depression Scale Scores?

Alexandra L. Berra[1]; Kelly S. Gibson[2]; Anna Rybinska-Campbell[3]; Katlyn Sullivan[2]
[1]Case Western Reserve University Metrohealth Medical Center, Cleveland, OH; [2]MetroHealth Medical Center / Case Western Reserve University, Cleveland, OH; [3]Metrohealth, Cleveland, OH

4:00 PM - 6:00 PM

Objective: With mental health disorders a leading cause of maternal mortality, perinatal mental health screening and care is a strategy for prevention. The use of a validated screening tool, including the Edinburgh Postnatal Depression Scale (EPDS) has been recommended, but the optimal timing for screening and the impact of repeated screening has yet to be established. This study aimed to assess whether prenatal screening and identification of depression impacted postpartum EPDS scores.

Study Design: In this retrospective single site study, pregnant persons who enrolled in prenatal care prior to 20w gestation and

delivered at the same institution from 2018-2024 were included (N = 6,735). EPDS screening was performed at postpartum visits only until 2023 when EPDS was given at entry to care, during the third trimester, while inpatient postpartum and at postpartum visits. A score of >12 was considered positive for depression. Prenatal screening, socio-demographic profiles, and PPD prevalence were analyzed pre/post implementation using t-tests, chi-square tests, and multiple variable logistic regression.

Results: Overall, 57.8% of patients delivered prior to the expanded EPDS implementation. The mean age at delivery was 28.5±6.0 years, 46.6% identified as White, 39.6% as Black, and 18.2% were Hispanic. Prior to implementation, 12.7% of all patients had a high postpartum EPDS score compared to 7.4% after (p< 0.001). Adjusting for demographic factors, patients who delivered after the implementation were less likely to have a high postpartum EPDS score (OR: 0.21, 95%CI: 0.19-0.24, p-value< 0.001). This association remained after accounting for additional screening (OR: 0.29, 95%CI: 0.26-0.33, p-value< 0.001).

Conclusion: Serial antenatal depression screening was associated with lower postpartum EPDS scores. Future investigation will examine the relationship between pre-existing mental health disease, prenatal identification, and referral on postpartum depression screening patterns.

957 | The Impact of the SCOTUS Dobbs Decision on Adolescent Postpartum Contraceptive Method Selection

Zuha Khan[1]; Alicia Mastronardi[2]; Megan L. Young[3]; Zachary J. Shelton[2]; William S. Havron, IV[4]; Jill M. Maples[5]; Nikki B. Zite[4]
[1]University of Tennessee, Knoxville, TN; [2]University of Tennessee Graduate School of Medicine, Department of OB/Gyn, Knoxville, TN; [3]University of Tennessee Medical Center, Center for Women and Infants, Knoxville, TN; [4]University of Tennessee Graduate School of Medicine, Knoxville, TN; [5]University of Tennessee Health Science Center, College of Medicine, Knoxville, TN

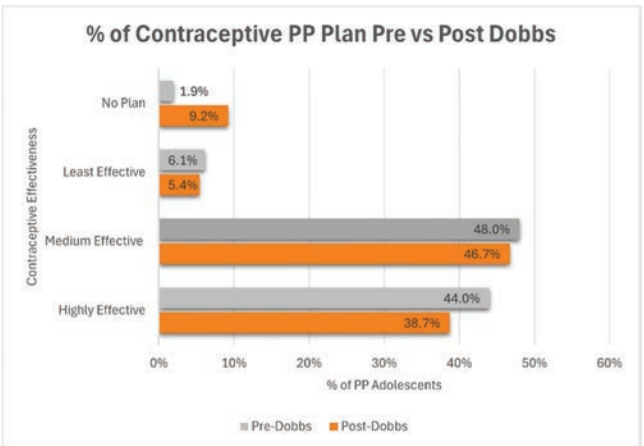
4:00 PM - 6:00 PM

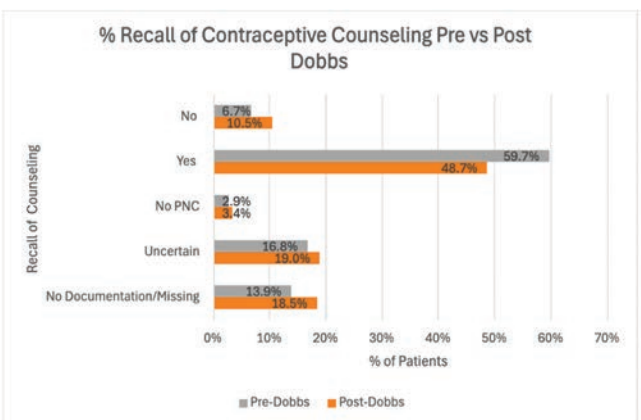
Objective: To investigate the potential impact of the SCOTUS Dobbs Decision on postpartum adolescent contraceptive method selection immediately postpartum in a state with high teen birth rates.

Study Design: This retrospective cohort study used electronic health delivery records two years before (May 2020-April 2022) and after (May 2022-April 2024) the Dobbs Decision leak. Patients < 20 years old were analyzed and those with no documented contraceptive preference were excluded. Contraceptive methods were categorized based on the American College of Obstetricians and Gynecologists efficacy categories: highly effective (implant, IUD, sterilization), medium effective (injection, pill, patch, ring), least effective (condom, fertility awareness-based methods), and no plan/abstinence. Pearson Chi-square tests were performed in SPSS to compare contraceptive methods, recall of prenatal contraceptive counseling, and other demographic characteristics including residence categorized by March of Dimes maternity care access level, race and ethnicity, and insurance status.

Results: Analysis included 786 adolescent births (47.7% pre-Dobbs; 52.3% post-Dobbs). After the Dobbs decision, a higher percentage of postpartum adolescents opted for no contraceptive method (1.9%, 9.2%), while fewer adolescents opted for the highly effective contraception (44.0%, 38.7%), (p< 0.001). Additionally, recall of contraceptive counseling decreased post-Dobbs (59.7% to 48.7%, p = .027). Demographics considered, including maternity care access level, were not significantly different between contraceptive method efficacy categories.

Conclusion: Postpartum adolescents showed a greater tendency to select no contraception post-Dobbs. The decreased recollection of prenatal contraceptive counseling may contribute to that finding. Greater effort is needed to ensure prenatal contraceptive counseling and access to all methods immediately postpartum as this may decrease repeat teen pregnancy.





958 | Maternal Anxiety Moderates the Effect of Exogenous Oxytocin on the HPA axis

Alison M. Stuebe[1]; Katharine Bruce[1]; Anna E. Bauer[1]; Samantha Meltzer-Brody[1]; Nisha O'Shea[2]
[1]UNC School of Medicine, Chapel Hill, NC; [2]RTI International, Research Triangle Park, NC

4:00 PM - 6:00 PM

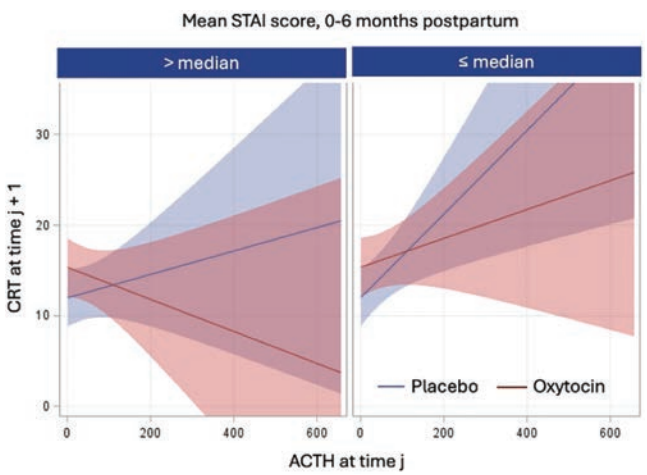
Objective: Oxytocin (OT) has multiple behavioral effects. We sought to quantify the effect of inhaled OT on the HPA axis response to stress among mothers of school-age children.

Study Design: We conducted a double-blind randomized controlled trial of nasal OT embedded within the Mood, Mother, and Infant Study, a longitudinal observational cohort recruited in the 3rd trimester of pregnancy. In the first postpartum year, participants completed periodic assessments, including the Edinburgh Postnatal Depression Scale (EPDS), Spielberger State-Trait Anxiety Inventory (STAI), and Beck Depression Inventory

(BDI-II). At about 6 years postpartum, participants were randomized to 24 IU of nasal OT or placebo, followed by the Trier Social Stress Test (TSST), which is comprised of a speech task and a math task. The TSST reliably induces large and consistent HPA responses. We quantified the extent to which postpartum depression and anxiety symptoms above vs. below the median modified the effect of OT on the lagged association between ACTH and CRT. Mixed effects models were used for repeated measures analysis with $\alpha = .05$.

Results: Of 222 individuals in the parent study, 105 completed the RCT, and measures of ACTH and lagged CRT were available for 85. COVID interrupted data collection, and there were no significant differences between completers and non-completers. In unstratified analysis, we found that OT vs. placebo did not modify the association between ACTH and lagged CRT ($p = 0.21$). We found an interaction between mean STAI (baseline- 6 months postpartum) and ACTH ($p = 0.03$, Figure 1), and between trait anxiety at 12 months and ACTH ($p = 0.04$). The EPDS-ACTH interaction was not significant ($p = 0.06$). We found no effect modification by BDI-II ($p = 0.79$).

Conclusion: Symptoms of postpartum anxiety, but not depression, were associated with modification of the effect of oxytocin on the HPA axis during a standardized social stressor. These findings suggest that dysregulation of oxytocin effects on the HPA axis may contribute to perinatal anxiety symptoms.



959 | Optimizing Postpartum Care in Pregestational Diabetes: Impact of a Comorbidity Index on Follow-Up and Outcomes

ALISSA PRIOR[1]; Lea Almahameed[2]; Megan Weatherborn[3]; Christopher Nau[4]

[1]The Metrohealth System/Case Western Reserve University Program, Cleveland, OH; [2]The Metrohealth System, OH; [3]UMass Chan Medical School - Baystate, Springfield, MA; [4]University Hospitals Cleveland Medical Center, Cleveland, OH

4:00 PM - 6:00 PM

Objective: Coordination of postpartum care for patients with pregestational diabetes mellitus (PDM), including timely diabetes follow-up, is imperative for their long-term health. At our institution, only 21% of patients have a postpartum diabetic care visit in the first 6 months postpartum. A maternal comorbidity index (CMI), a published score to summarize the severity of maternal illness, is a tool to identify high risk pregnant parturients (Table 1). In a cohort of patients with PDM, our objective was to compare a patient's CMI and postpartum outcomes. We predict a higher CMI would be associated with suboptimal glycemic control and follow up.

Study Design: This is a retrospective cohort study at a single urban hospital of patients with PDM who attended the center's diabetes in pregnancy clinic from 2009-2018. Patients who delivered at an outside institution were excluded. Our independent variable was the CMI, dichotomized into low (score 1-4) vs high (score ≥5) groups. The primary outcome was attendance of a diabetes care visit, with Primary Care or Endocrinology, in the 1st year postpartum. Secondary outcomes included postpartum HbA1c, contraception, breastfeeding, and a short-interval pregnancy. Outcome data was analyzed with Fisher's exact, Wilcoxon rank sum, and Pearson's Chi-squared tests.

Results: There were 469 patients included; CMI scores ranged from 1-12 with 346 and 123 patients in the low and high groups, respectively. Baseline demographics, diabetes severity and type, and pregnancy outcomes were similar between groups. Attendance rates of a diabetes care visit were similar, with 51% in the low and 52% in the high CMI group (p >0.9). HbA1c median values were 7.30 in the low vs 7.85 in the high CMI group (p = 0.2). All other study outcomes were similar between groups (Table 2).

Conclusion: Maternal CMI was not associated with differing rates of HbA1c or follow up in patients with PDM up to 12 months postpartum. Only 50% of patients had a diabetes visit in the 1st year postpartum. Further research is needed to identify patients at highest risk of poor follow up.

Table 1. Maternal Comorbidity Index, score (0-46) to summarize the severity of maternal illness in pregnant and postpartum patients.

[1]The George Washington University, The George Washington University, DC; [2]George Washington University, Washington, DC; [3]The George Washington University, Washington, DC; [4]University of North Carolina at Chapel Hill; UNC -Global Projects Zambia, Lusaka, Lusaka; [5]Christian Medical College, Vellore, Christian Medical College, Tamil Nadu; [6]KEMRI, Kisumu, Nyanza; [7]Kintampo Health Research Center, Kitampo, Brong-Ahafo; [8]Aga Khan University, Karachi, Sindh; [9]UNC Lusaka, UNC Lusaka, Lusaka; [10]Kintampo Health Research Center, Kintampo, Brong-Ahafo; [11]Society for Applied Studies, Delhi, Delhi; [12]Christian Medical College, Vellore, Tamil Nadu; [13]UNC Lusaka, UNC Zambia, Lusaka

4:00 PM - 6:00 PM

Objective: To examine how pregnancy-related physical, emotional, social, and financial challenges are conceptualized, discussed, and experienced by pregnant women in six demographic and health surveillance study areas in Africa and Asia and how these challenges impact health and wellbeing during pregnancy.

Study Design: Thirteen focus groups discussions (FGDs) were conducted, with a total of 120 pregnant women in Ghana (2 FGDs, n = 22), Kenya (2 FGDs, n = 20), Zambia (3 FGDs, n = 23), India (4 FGDs, n = 34), and Pakistan (2 FGDs, n = 21) using a semi-structured guide. FGDs were transcribed verbatim in the local language and translated into English. A subset of translated transcripts from each site was coded independently by two coders (one from the country of collection) to develop six preliminary site-specific codebooks, which informed the development of two regional codebooks. All translated transcripts were coded independently by two coordinating site coders using Dedoose; themes and subthemes were identified using thematic analysis and discussed with local site teams, after which refinements were made and representative quotations were selected.

Results: Three overarching themes were identified: 1) Pregnancy symptoms pose a barrier to daily life; 2) Lack of social support exacerbates physical and emotional challenges during pregnancy; and 3) Social support alleviates physical, emotional, and financial challenges of pregnancy. One additional minor theme was that support from the healthcare system impacts health and wellbeing.

Conclusion: These findings demonstrate that pregnant women experience a variety of health and wellbeing challenges during pregnancy, which are exacerbated when social support is not available and alleviated in the context of help from family and community. Additional physical, emotional, and family and community support during pregnancy is needed to alleviate the plethora of complex and multifaceted challenges women face during pregnancy and improve their physical and mental health and overall quality of life.

961 | Risk of Severe Maternal Morbidity and Mortality in Relation to ARRIVE Trial

Amanda M. Baucom[1]; Heather N. Czarny[2]; Robert M. Rossi[2]; Isabella Toledo[3]
[1]University of Cincinnati, Cincinnati, OH; [2]University of Cincinnati College of Medicine, Cincinnati, OH; [3]Indiana University School of Medicine, Indianapolis, IN

4:00 PM - 6:00 PM

Objective: Since the 2018 ARRIVE (A Randomized Trial of Induction versus Expectant Management) trial, the rate of elective 39-week induction has increased. However, the population impact of this trial on obstetric and maternal outcomes is unknown. This study aims to evaluate trends in severe maternal morbidity (SMM) and obstetrical outcomes among low-risk term patients following the ARRIVE trial.

Study Design: This study is a population-based, retrospective cohort analysis of U.S. delivery hospitalizations, utilizing data from the National Inpatient Sample database. Deliveries were identified using ICD-10 codes and categorized into two epochs: Epoch 1, Pre-ARRIVE (2015 Q4 to 2018 Q2), and Epoch 2, Post-ARRIVE (2019 Q2 to 2021 Q4), with the dissemination phase 2018 Q3 to 2019 Q1. Patients with medical indications for induction, outlined by the ARRIVE trial, were excluded. SMM was defined according to the CDC with related subgroups. The primary outcome was the difference in risks (aRR, 95% CI) of SMM and obstetrical outcomes as estimated by multivariate logistic regression analyses.

Results: Among 8,404,920 deliveries, the rate of 39-week delivery increased from 52.4% to 57.7% (P< 0.001) among low-risk patients. The rate of SMM increased (0.31 vs 0.38%, p< 0.001), while cesarean delivery decreased (14.0 vs 13.8%, p = 0.0422) between Epoch 1 and 2. Risk of SMM increased (aRR 1.20, CI 1.12-1.28), as did SMM subgroups including acute renal failure, respiratory SMM, sepsis, shock, and hemorrhagic SMM (Fig. 1). Eclampsia rates decreased (aRR 0.59, CI 0.49-0.72), despite an increase in pregnancy-associated hypertension. There were also reductions in cesarean delivery (aRR 0.97, CI 0.95-0.98), obstetric anal sphincter injury (aRR 0.96, CI 0.94-0.98), and hospital length of stay exceeding the 95th% (aRR 0.91, CI 0.87-0.95) (Fig 2).

Conclusion: Following the ARRIVE trial, there has been an increase in SMM and pregnancy-related hypertension. However, there has been a decrease in the rates of eclampsia, OASIS, and cesarean sections, suggesting a complex potential impact of the ARRIVE trial on outcomes in low-risk patients.

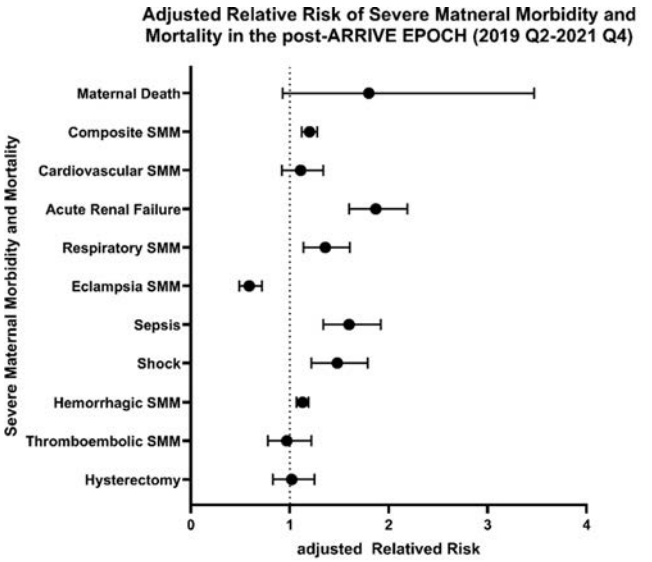

Figure 1: Adjusted relative risk of severe maternal morbidity (SMM) and mortality in the post-ARRIVE trial epoch (2019 Q2 to 2021 Q4) compared to pre-ARRIVE epoch (2015 Q4 to 2018 Q2; dotted line). Composite SMM indicates any event falling within the following categories (excluding blood transfusion): Cardiac SMM: (acute myocardial infarction, aneurysm, cardiac arrest or ventricular fibrillation, conversion of cardiac rhythm, heart failure or arrest during surgery, puerperal cardiovascular disorders, pulmonary edema or acute heart failure), acute renal failure, respiratory SMM (adult respiratory distress syndrome, temporary tracheostomy, ventilation, severe anesthesia complications), eclampsia, sepsis, shock, hemorrhagic SMM (blood transfusion, disseminated intravascular coagulation), thromboembolic SMM (air and thrombotic embolism, sickle cell disease with crisis, amniotic fluid embolism), and hysterectomy. Error bars represent 95% confidence intervals.

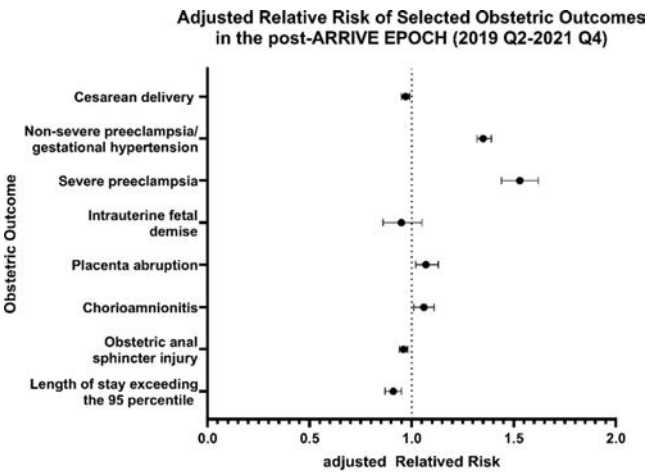

Figure 2: Adjusted relative risk of selected obstetrical outcomes in the post-ARRIVE trial epoch (2019 Q2 to 2021 Q4) compared to pre-ARRIVE epoch (2015 Q4 to 2018 Q2; dotted line). Erros bars represent 95% confidence intervals.

962 | Impact of Emergency Room Abortion Bans on Pregnancies with Previable PPROM: A Cost-Effectiveness Analysis

Amelia H. Gagliuso[1]; Meghana Narahari[2]; Megha Arora[3]; David M. Monroe[3]; Aaron B. Caughey[3]
[1]Oregon Health & Sciences University, Portland, OR; [2]Oregon Health and Science University, Portland, OR; [3]Oregon Health & Science University, Portland, OR

4:00 PM - 6:00 PM

Objective: Preterm premature rupture of membranes (PPROM) is a serious condition that affects 0.4-0.7% of all pregnancies. Pregnancies with PPROM are associated with increased neonatal morbidity and mortality. Additionally, children surviving PPROM have higher rates of physical disability and neurode-

velopmental delay. Under the Emergency Medical Treatment and Labor Act (EMTALA), any patient who presents with an emergency medical condition must be appropriately screened and stabilized, including instances in which treatment entails stabilization through emergency abortion. This analysis evaluated the cost-effectiveness of emergency abortions for previable PPROM between 18-22 weeks.

Study Design: In this analysis, a TreeAge model was created to compare outcomes in previable PPROM patients with emergency abortion available to those who do not have access to emergency abortion under EMTALA. The cohort consisted of 1,183 individuals, the estimated number of pregnant people with previable PPROM seeking abortion. Clinical outcomes measured in the model included chorioamnionitis, maternal sepsis, maternal death, stillbirth, neonatal death, and neurodevelopmental delay. Probabilities, utilities and costs were derived from literature. QALYs were discounted at a rate of 3%.

Results: In this theoretical cohort, abortion access under EMTALA was associated with a decrease of 12 cases of maternal sepsis, 1 case of maternal death, 621 cases of stillbirth, 125 cases of neonatal death, and 95 cases of neurodevelopmental delay. Emergency abortion availability was the dominant strategy as it saved $97,131,562 and led to 1,952 additional QALYs.

Conclusion: Restrictive abortion bans that bar emergency abortion as care to treat previable PPROM results in increased maternal morbidity and mortality, as well as increased costs and decreased quality of life.

Table 1. Outcomes in a theoretical cohort of 1,183 pregnancies with PPROM at 18-22 weeks desiring abortion

	Abortion available	Abortion unavailable	Difference (Treatment-No Treatment)
Maternal Chorioamnionitis	0	87	-87
Maternal Sepsis	0	12	-12
Maternal Death	0	1	-1
Stillbirth	0	621	-621
Neonatal Death	0	125	-125
Neurodevelopmental Delay	0	95	-95
Cost ($)	1,661,752	98,793,314	-97,131,562
Effectiveness (QALYs)	31,846	29,894	1,952
Strategy	Dominant	Dominated	

963 | Risk Factors Associated with Antiseizure Medication Discontinuation During Pregnancy

Amelie Pham[1]; Andrew D. Wiese[1]; Andrew J. Spieker[1]; Chad You[2]; Ashley A. Leech[1]; Margaret A. Adgent[1]; Carlos G. Grijalva[1]; Sarah S. Osmundson[1]
[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University Medical Center, Nasvhille, TN

4:00 PM - 6:00 PM

Objective: Evaluate factors associated with discontinuation of antiseizure medication (ASM) by the first trimester of pregnancy.

Study Design: We constructed a retrospective cohort of births (2007-2019) among Tennessee Medicaid pregnant patients with enrollment from 90 days before conception through delivery. Data included healthcare claims, prescription fills, hospital discharge and birth certificates. We included births ≥ 20 weeks' gestation among patients aged 15-44 years on ASM monotherapy. Among patients with filled prescriptions for ASMs before conception or in the first trimester, we defined discontinuers as those with no ASM prescription filled after the first trimester, and continuous users as those who filled prescriptions after the first trimester. We used logistic regression to model the association between clinical factors and ASM discontinuation overall and among patients with an epilepsy diagnosis, adjusting for relevant confounders.

Results: Of 5279 pregnant patients with ASM exposure before conception or in the first trimester, 54% discontinued by the first trimester (Table 1). Factors associated with ASM discontinuation included the absence of an epilepsy diagnosis, the presence of a psychiatric or other diagnosis, younger age, nulliparity, earlier study delivery year, living in a rural area, and use of older ASM class (Table 2). While 26% of pregnant patients with ASM use had an epilepsy diagnosis, 35% had no diagnosis traditionally associated with ASM use. Among patients with epilepsy, 29% discontinued ASMs by the first trimester. In this group, older ASM class and earlier study delivery year were associated with higher odds of discontinuation. Non-Hispanic Black individuals had lower odds of discontinuation than non-Hispanic White individuals (Table 2).

Conclusion: For patients with indications for ASM use, national guidelines recommend continuing most ASMs during pregnancy or discontinuing with clinician guidance. The majority of pregnant patients in our cohort, including those with epilepsy, discontinued use around pregnancy diagnosis.

Table 1. Demographic and clinical factors of continuous users versus discontinuers of antiseizure medications on monotherapy during pregnancy (N= 5,279)

Clinical Factors	Continuous users (N=2,403)	Discontinuers (N=2,876)	p-value

4:00 PM - 6:00 PM

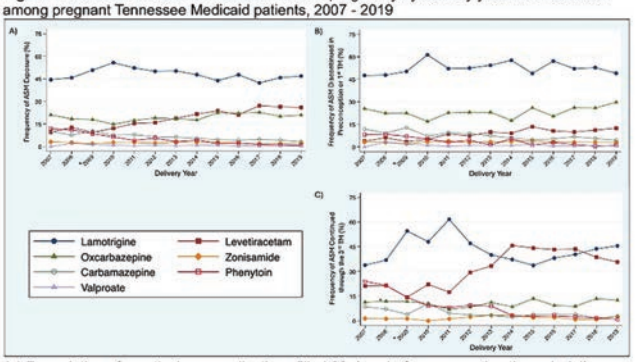
Objective: To evaluate trends in antiseizure medication (ASM) use and discontinuation in pregnancy, by delivery year and medication.

Study Design: We constructed a retrospective cohort of births from 2007 to 2019 among pregnant patients enrolled in Tennessee Medicaid with continuous enrollment from 90 days before pregnancy through delivery. Enrollment files were linked to healthcare encounters, prescription fills, hospital discharges, and birth certificate data. We included births ≥ 20 weeks gestation among patients aged 15 to 44 years with any ASM exposure, defined as ≥ 1 prescription fill for a single ASM (monotherapy) between the 90 days before conception through delivery. We evaluate trends in ASM use, including newer (levetiracetam, lamotrigine, oxcarbazepine, zonisamide) and older (carbamazepine, phenytoin, and valproate) ASM class. We further classified our cohort into two subgroups: 1) ASM exposure only from 90 days before conception through the first trimester (discontinued use) and 2) ASM exposure initiated by the first trimester with continued use through the third trimester or delivery (continued use during pregnancy).

Results: Among 5,278 pregnant patients exposed to ASM monotherapy, lamotrigine was consistently the most used ASM overall, while levetiracetam use increased over the study period (all users, Figure 1A). Lamotrigine was also the most commonly used medication among subgroup 1 (Figure 1B). By 2013, levetiracetam use increased and remained similar to lamotrigine use among subgroup 2 (Figure 1C). Use of all older ASMs decreased over the study period. Valproate exposure was rare (< 1%) and no valproate use was found in subgroup 2.

Conclusion: Starting in 2009, national guidelines recommended continuing most ASMs during pregnancy or discontinuing with clinician guidance based on ASM class, specifically use of valproate, phenytoin, and polytherapy with valproate in pregnancy. This study highlights how practice patterns are slowly changing to reflect the predominance of newer ASM use, but that early pregnancy discontinuation remains common.

Figure 1. Trends in antiseizure medication use in pregnancy by delivery year and medication among pregnant Tennessee Medicaid patients, 2007 - 2019



A) Prescriptions for antiseizure medications filled 90 days before conception through delivery, from 2007-2019 (all users, N=5,278)
B) Filled prescriptions for antiseizure medications with discontinued use before conception or in the first trimester, from 2007-2019 (subgroup 1: N=2,876)
C) Filled prescriptions for antiseizure medications with continued use through the third trimester of pregnancy, from 2007-2019 (subgroup 2: N= 1,220)
Abbreviations: ASM: antiseizure medications; TM: Trimester
*American Academy of Neurology (AAN) and American Epilepsy Society (AES) guidelines published in 2009 recommending against the use of valproate, phenytoin, and phenobarbital monotherapy, or any polytherapy with valproate during pregnancy.

965 | The Effect of Antibiotic Treatment in Late Preterm Premature Rupture of Membranes on pregnancy Outcomes

Anat Pardo[1]; Raud Qassim[2]; Michal Axelrod[3]; Shiri Barabash Hazan[4]; Noam Pardo[5]; Ohad Houri[6]; Anat Shmueli[4]; Eran Hadar[6]

[1]The Helen Schneider Hospital for Women at Rabin Medical Center, Petach Tikwa, HaMerkaz; [2]Helen Schneider Hospital for Women, Rabin Medical Center, Petach-Tikva, Petach-Tikva, HaMerkaz; [3]Department of Obstetrics and Gynecology, Sheba Medical Center, Tel HaShomer, Ramat Gan, HaMerkaz; [4]Helen Schneider Hospital for Women, Rabin Medical Center, petach tikwa, HaMerkaz; [5]Maternal Fetal Medicine Division, Sheba Medical Center, Tel Hashomer, Sheba Medical Center/Ramat Gan, HaMerkaz; [6]Rabin Medical Center, Petach Tikva, HaMerkaz

4:00 PM - 6:00 PM

Objective: To Compare pregnancy outcomes in women with late preterm premature rupture of membranes (PPROM) between 34+0 and 36+6 weeks, treated with antibiotics versus those not receiving antibiotics, to assess its efficacy in the late preterm period

Study Design: Retrospective cohort study at a single tertiary center between 2020 and 2023, included 228 women who presented with late PPROM. The outcomes of 95 treated with antibiotics were compared to 133 untreated with antibiotics. Primary outcomes were duration of latency period, chorioamnionitis and neonatal sepsis. Secondary outcomes included maternal complications (Post partum hemorrhage, Fever, Endometritis, Operative deliveries) and neonatal complications (5-min Apgar< 7, umbilical cord pH< 7.1, and neonatal intensive care unit admission). The groups were compared using demographic and clinical independent variables in a univariate and multivariate analysis

Results: Baseline characteristics did not significantly differ between the groups. In a univariate analysis the group treated with antibiotics demonstrated longer latency period in comparison to the non-treated group (2 vs.1 day, p< 0.001). Despite an earlier gestational age (GA) at PPROM (p = 0.01) in the treated group, no difference was observed at gestational age at delivery. No difference in chorioamnionitis or neonatal sepsis rate was seen between the groups, however the group treated with antibiotic demonstrated less positive placental cultures compared to untreated women (p = 0.04). No other significant adverse maternal or neonatal outcome was significantly different. Same pattern of longer latency but without significant difference in delivery GA was observed in a sub analysis of women who progressed to active labor spontaneously (p = 0.005). A multivariate analysis of the latter which included parity, GBS status, GA and cervical dilatation at diagnosis failed to show that antibiotic treatment prolonged latency (aOR = 0.70, 95% CI 0.27-1.79, p = 0.46)

Conclusion: Antibiotic treatment in the management of late PPROM did not prolong latency period nor influenced maternal and neonatal outcomes

Table 1: Baseline Characteristics and Pregnancy Outcomes for Antibiotic Treatment vs. No Treatment in the Management of Late PPROM

Variables	No Antibiotic Treatment n=95	Antibiotic Treatment N=133	p-value
Baseline characteristics

966 | Equitable Implementation of Obstetric Life Support in Maternity Care Deserts and Low Access Areas

Andrea D. Shields[1]; Rogie Royce Carandang[2]; Andy Lowe[3]; Ann Marie Day[4]; Thomas Trimarco[5]; Les R. Becker[6]; Vincent N. Mosesso, Jr.[7]; Shayna Cunningham[8]

[1]University of Connecticut Health, Avon, CT; [2]University of Connecticut Health, University of Connecticut Health, CT; [3]New England Rural Health Association, New England Rural Health Association, VT; [4]New England Rural Health Association, Barre, VT; [5]Dartmouth Health, Dartmouth CREST, NH; [6]MedStar Health, Rockville, MD; [7]University of Pittsburgh, Pittsburgh, PA; [8]University of Connecticut School of Medicine, Farmington, CT

4:00 PM - 6:00 PM

Objective: Obstetric Life Support (OBLS) is an evidence-based, interdisciplinary simulation-based curriculum to train prehospital and hospital-based healthcare workers (HCWs) on prevention, recognition, and management of maternal medical emergencies. We aimed to identify barriers and facilitators to implementing OBLS in rural and low-resource settings to inform adaptations for optimizing medical emergency education in these contexts.

Study Design: We conducted a nationwide survey (n = 122) of administrators and HCWs in rural settings, exploring Consolidated Framework for Implementation Research (CFIR) elements that may influence implementation outcomes across multiple levels. Focus groups were conducted with a subset of 15 participants to discuss strategies for promoting OBLS adoption, implementation, and sustainability.

Results: Both prehospital and hospital-based participants found the OBLS learning objectives and content highly appropriate and acceptable but expressed concerns regarding the feasibility of implementation in their work contexts. Salient CFIR domains identified included: 1) Intervention Characteristics: Evidence strength and quality, relative advantage, design quality and packaging, and cost; 2) Inner Setting: Implementation climate and readiness for implementation; 3) Outer Setting: Patient needs and resources, and external policy and incentives.
Resource constraints were perceived to be a significant barrier, especially time, staffing, space, and equipment. Suggested adaptations included the development of eLearning course modules, a shortened in-person component, a web-based megacode evaluation tool, and an implementation toolkit to facilitate planning, progress monitoring, and change management. Participants also highlighted the importance of local champions to drive the implementation process and endorsed a train-the-trainer approach to build local capacity and ensure sustainability.
Conclusion: Equitable scale-up of OBLS requires an implementation plan that considers the training program's context, delivery mechanisms, and resource requirements.

967 | Race and Insurance Disparities in Partner Screening for Autosomal Recessive Conditions During Pregnancy

Ajitha Chivukula[1]; Makayla Murphy[2]; Brittany Gancarz[2]; Andrea D. Shields[3]
[1]University of Connecticut School of Medicine, University of Connecticut School of Medicine, CT; [2]University of Connecticut Health, University of Connecticut Health, CT; [3]University of Connecticut Health, Avon, CT

4:00 PM - 6:00 PM
Objective: We aim to identify if race and insurance statuses of pregnant people and their partners impact decisions to undergo genetic carrier screening.
Study Design: Retrospective chart review was conducted on pregnant people receiving care at tertiary academic medical center from 6/1/2021-5/31/2024. Inclusion criteria were pregnant people (18+) with singleton pregnancies who tested positive for autosomal recessive conditions in 1st or 2nd trimesters and had genetic counseling. The primary outcome was comparison of uptake rates for genetic screening in partners of pregnant people with abnormal carrier screens by race and insurance status. Continuous variables were summarized with mean and standard deviations. Categorical variables were analyzed by Pearson's Chi square test, summarized with % and frequencies.
Results: Out of 62 pregnant people with abnormal genetic screens, 48% of partners opted for a genetic screen. Table 1 shows race and insurance statuses for pregnant people and partners. There was significant difference in racial makeup of patients ($p < 0.0001$) and partners ($p < 0.0001$) comparing tested and declined groups. There was no significant difference between insurance types of partners who tested vs. did not ($p = 0.422$). More pregnant people identified as Hispanic/Latino (31%) and had Medicaid (63%), while more partners identified as White (31%) and had private insurance (42%). Couples with matching insurance were more likely to have both partners test vs. those with nonmatching insurance ($p = 0.0001$). Couples with Medicaid had highest proportion of tested partners (77%). While there was no association between the insurance type of pregnant patients and whether their partners tested ($p = 0.306$), there was an association between whether their partners tested and whether they were insured ($p < 0.0001$).
Conclusion: Our results suggest a correlation between partner demographics and insurance and uptake rates of partner carrier testing. This shows disparities in uptake rates of genetic carrier screening, suggesting that SES factors may impact the decision for partner to test even with genetic testing access.

Race						
	Tested Partners		Declined Partners		Total	
	Patient	Partner	Patient	Partner	Patient	Partner
White	30%	40%	19%	22%	24%	31%
Black	20%	20%	28%	25%	24%	23%
Hispanic/Latino	23%	13%	38%	25%	31%	19%
Asian	17%	13%	3%	3%	10%	8%
Mixed	10%	13%	13%	13%	11%	13%
Other	0%	0%	0%	13%	0%	6%
Insurance						
Medicaid	60%	33%	69%	9%	65%	21%
Private	40%	53%	31%	28%	39%	40%
None, N/A	0%	13%	0%	63%	0%	39%

968 | Simulation Training to Improve Dilation and Evacuation Counseling in a Restrictive State

Anjali Nambiar[1]; Courtney C. Baker[1]; R. Nicholas Burns[2]
[1]UT Southwestern Medical Center, Dallas, TX; [2]University of Texas Southwestern, Dallas, TX

4:00 PM - 6:00 PM
Objective: Following restrictive abortion legislation in Texas, OB/GYN residents have reduced exposure to Dilation and Evacuation (D&E). To address this training gap, a simulation and quality improvement initiative was implemented to increase resident familiarity with D&E and improve options counseling for patients with intrauterine fetal demise (IUFD).
Study Design: Residents at a single teaching institution participated in a monthly simulation activity, that included a pre-assessment of perceived barriers to D&E, a didactic video reviewing perioperative considerations and D&E steps, and a case-guided D&E simulation on a low-fidelity uterine model. The rate of complete options counseling (D&E vs medical induction) documented by residents in the electronic medical record and rate of D&E performed for patients with 2nd trimester IUFD (< 22 weeks gestation) was assessed before (9/2023-12/2023) and after (3/2024-6/2024) simulation implementation. Statistical significance was assessed via chi-squared test.
Results: 42 residents participated in the activity. On pre-assessment, most residents (76%) reported "rarely" or "never" discussing D&E with patients. "I do not know how to perform a D&E," "I do not have available staff to supervise me during D&E," and "I do not know how to counsel patients regarding D&E" were the most perceived barriers to D&E, identified by 71%, 67%, and 50% of residents respectively. In the pre-simulation period, 9/19 (47%) patients with IUFD had complete options counseling, and 3/9 (33%) elected for D&E. In the post-implementation period, 24/26 (92%, $p = 0.001$) had complete options counseling and 8/24 (33%) chose D&E.
Conclusion: Documentation of complete options counseling was significantly improved after initiative implementation. Despite

perceived barriers to D&E, residents counseled patients more consistently and performed more D&Es after simulation training. Rate of patient desire for D&E was unchanged. Low-fidelity D&E simulation may be an effective quality improvement initiative to address resident education gaps and improve options counseling for patients that are candidates for D&E.

D&E Simulation Pre-Assessment (N=42)							
PGY1			10 (24%)				
PGY2			8 (19%)				
PGY3			14 (33%)				
PGY4			10 (24%)				
1. How often do you discuss D&E with patients with indication for 2nd trimester uterine evacuation?			Never (0% of patients)	Rarely (25% of patients)	Sometimes (50% of patients)	Often (75% of patients)	Always (100% of patients)
			19 (45%)	13 (31%)	8 (19%)	1 (2%)	1 (2%)
2. Which of the following are barriers to D&E at this institution?	"I do not know how to perform D&E"	"I do not have available staff to supervise me during D&E"	"I do not know how to counsel patients regarding D&E"	"I do not know which patients are appropriate for D&E"	"My patients do not desire D&E"	"I did not know D&E was an option at this institution"	"I have not identified any barriers to performing D&E"
	30 (71%)	28 (67%)	21 (50%)	16 (38%)	11 (26%)	9 (21%)	1 (2%)
Clinical Outcomes Pre and Post Implementation of D&E Simulation

969 | Black Birthing persons' Perspectives on Factors Leading to Medical Mistrust in Obstetric Settings

Anna Palatnik[1]; Erica Marion[1]; Jessica Olson[1]; Dalvery Blackwell[2]; Joni Williams[1]; Katherine Quinn[1]
[1]Medical College of Wisconsin, Milwaukee, WI; [2]African American Breastfeeding Network Inc., Milwaukee, WI

4:00 PM - 6:00 PM

Objective: To examine factors leading to medical mistrust among Black birthing persons.

Study Design: In this prospective qualitative study, 30 Black birthing people participated in semi-structured interviews to elicit their perspectives on factors leading to medical mistrust during their obstetric care. Purposive sampling was used to ensure a cohort diverse in terms of obstetric experiences such as parity, current mode of delivery, and with or without doula support in current pregnancy. Interviews were recorded, transcribed, and coded twice by two different team members in MAXQDA2022. Data were analyzed using thematic analysis to identify patterns and develop and refine themes.

Results: The average age of participants was 28 (range 19-41 years of age); 13% were married, 27% had a high school diploma, 40% were unemployed, 40% had an income of $20-000-$40,000, 77% had public insurance, and 27% had used doula services for the most recent pregnancy. Majority of participants were multiparous (70%), delivered vaginally (53%) and interviewed within 6 weeks postpartum. Five themes contributing to medical mistrust were identified: 1) lack of sufficient education provided to birthing people around possible obstetric complications 2) not feeling heard by the medical team due to lack of time and feeling rushed at prenatal appointments, 3) overuse of the medical terminology and jargon by the medical team, 4) discrepancies in expectations regarding birthing experiences in the hospital, and 5) inadequate support and reassurance after traumatic pregnancy or birth experience.

Conclusion: Perspectives gathered in this analysis identify inadequate communication, and insufficient time and knowledge for shared decision making as key factors leading to medical mistrust among Black birthing persons.

970 | Detection of Individual Bile Acids by Sebum Sampling in Cholestasis of Pregnancy

Anne M. Ambia[1]; Jeffrey McDonald[2]; Yevgenia Y. Fomina[1]; Andrea Rizkallah[2]; C. Edward Wells[3]; Catherine Y. Spong[3]; Donald D. McIntire[3]; David B. Nelson[3]
[1]University of Texas Southwestern, Dallas, TX; [2]UT Southwestern, Dallas, TX; [3]University of Texas Southwestern Medical Center, Dallas, TX

4:00 PM - 6:00 PM

Objective: Intrahepatic cholestasis of pregnancy (ICP) is characterized by elevated bile acids and pruritis of palms as a disease unique to pregnancy. There is a paucity of information on the individual bile acids that contribute to palmar pruritis in ICP. We aimed to perform a feasibility study to utilize a novel methodology of extraction of steroids through sebum sampling in those undergoing evaluation for ICP.

Study Design: This was a prospective, observational cohort study of pregnant individuals evaluated for ICP from December 2023 to July 2024 a single academic center. Patients were characterized into pruritis of pregnancy (total BA < 10 mmol/L, referent), ICP (BA ≥10 mmol/L), using a quantitative enzymatic assay. At the time of initial evaluation for ICP, sebum sampling was performed after preparation of the skin to be sampled with an alcohol wipe cleanse. Three-five strips of sebutape were placed for 15 minutes and removed. Extraction of bile acids were performed through liquid chromatography mass spectrometry methods.

Results: There were 5 patients with cholestasis of pregnancy and 2 patients with pruritis of pregnancy whose samples were analyzed. There were no significant demographic differences between those with and without cholestasis of pregnancy. Gestational age at sebum sampling did not differ between the groups 35.9±0.9 vs 36.0±2.4, P = 0.97. The mean total bile acids of those with cholestasis were 52.6±19.1. Corresponding analysis of serum samples from these cholestasis patients detected taurocholic acid as the main analyte. Levels of taurocholic acid, glycolcholic acid, taurochenodeoxycholic acid, cholic acid, glycol-chenodeoxycholic acid, and glycol-deoxycholic acid were detected in both upper back and palmar samples.

Conclusion: Beyond serum sampling of total bile acids, we have demonstrated a novel methodology of detection of bile acid levels in sebum samples in patients with cholestasis of pregnancy. This may offer further insight into disease characteristics and symptomatology.

Table 1: Demographics of patients undergoing sebum sampling

	No evidence of cholestasis N=2	Cholestasis N=5	P-value

971 | Rates of Cesarean-Delivery and Perinatal Outcomes in OA Verses OP Position by Birth-Weight in Nulliparous

Annika Willy[1]; Bharti Garg[2]; Aaron B. Caughey[2]
[1]Oregon Health & Science University, Bend, OR; [2]Oregon Health & Science University, Portland, OR

4:00 PM - 6:00 PM

Objective: We aimed to evaluate how birth weight affects cesarean delivery rates and delivery outcomes for fetuses in occiput-anterior (OA) versus occiput-posterior (OP) positions. Specifically, we investigated whether the impact of fetal position on cesarean delivery varies with different birth weight categories and how it influences neonatal outcomes in nulliparous patients.

Study Design: This was a retrospective cohort study of singleton, non-anomalous, term deliveries with vertex presentation in nulliparous individuals of California (2008-2020). Birth weight into eight categories: < 3500g, 3500-3749g, 3750g-3999g, 4000-4249g, 4250-4499g, 4500-4749g, 4750-4999g, ≥5000g. Multivariable Poisson regression model was used to examine the association of OP position and cesarean delivery along with outcomes (shoulder dystocia and scalp injury) for each weight category. Adjusted risk ratios (aRR) with 95% CI were estimated.

Results: In this study, we included 1,781,036 births of which 1.5% (n = 26,943) were in OP position. Cesarean delivery rates were higher in OP presented neonates in all birthweight categories, such as in < 3500 grams (77.6% vs 21.1%; aRR = 3.50; 95% CI: 3.46-3.54), and ≥5000g (100% vs. 76.2%; aRR = 1.29 (1.22-1.38)). Risk of shoulder dystocia was found to be increased in all most all birth weight categories in OP neonates, such as< 3500 g (0.92% vs 0.59%; aRR = 1.51 (1.05-2.19)) and 3750-3999 g (6.25% vs 3.69%;aRR = 1.72(1.23-2.39)). Risk of scalp injuries were found to be higher in OP neonates in birth weight categories such as < 3500 g (12.06 vs 4.69 aRR = 2.53 (2.30-2.78)).

Conclusion: We found that OP fetuses had a higher rate of cesarean delivery in all weight categories compared to OA. The difference between OA and OP cesarean delivery rates decreased as birth weight increased. In regards to perinatal outcomes we found OP neonates in most weight categories had higher rates of shoulder dystocia. Additionally scalp injury was increased in OP neonates compared to OA neonates.

Figure 1: Proportions and adjusted risk ratios of cesarean deliveries in persistent OP vs OA positioned neonates by birthweight

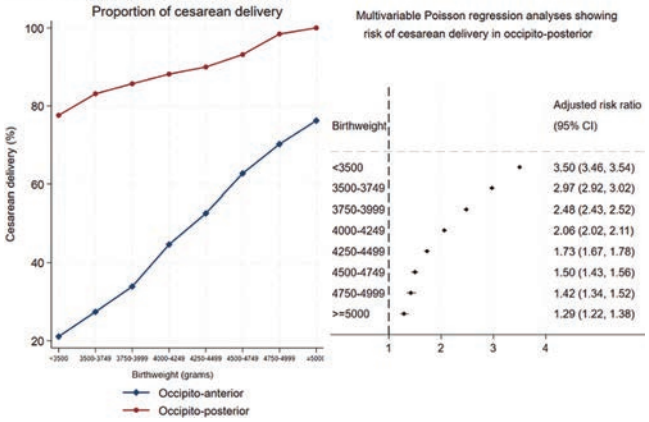

Table 1: Proportions and adjusted risk ratios for adverse neonatal outcomes by birth weight

	Shoulder Dystocia			Scalp Injury		
Birth Weight (g)	OA (%)	OP (%)	aRR (95% CI)	OA (%)	OP (%)	aRR (95% CI)
3000-3500	0.59%	0.92%	1.51 (1.05-2.19)	4.69%	12.06%	2.53 (2.30-2.78)
3500-3749	2.06%	3.30%	1.64 (1.16-2.32)	5.68%	12.77%	2.23 (1.88-2.64)
3750-3999	3.69%	6.25%	1.72 (1.23-2.39)	6.19%	13.05%	2.11 (1.69-2.63)
4000-4249	6.82%	7.91%	1.06 (0.66-1.71)	6.58%	16.28%	2.53 (1.87-3.41)
4250-4499	10.96%	8.11%	0.74 (0.35-1.57)	7.31%	17.57%	2.11 (1.23-3.64)

All models were adjusted for maternal race and ethnicity, age, education, pre-pregnancy BMI, chronic hypertension and pre-existing diabetes.

972 | Preterm Birth in Patients with Fontan Circulation: Looking to the Placenta for Answers

Ashley M. Hesson; Caroline Simon; Angela Quain; Michael R. Joynt; Elizabeth S. Langen
University of Michigan, Ann Arbor, MI

4:00 PM - 6:00 PM

Objective: Pregnant patients with Fontan circulation have relative hypoxemia with limited ability to augment cardiac output. Preterm birth (PTB) and fetal growth restriction (FGR) are common complications. We integrate clinical, histopathologic, and spatial transcriptomic data to characterize PTB with and without FGR in this population.

Study Design: 17 live births in 15 patients with Fontan circulation were identified and Cardio-obstetric variables were abstracted from the medical record. Placentas were analyzed by a pathologist. RNA was extracted from 6 preterm (3 normally grown, 3 FGR), formalin fixed, paraffin embedded samples with representative findings for spatial transcriptomics. Samples were sequenced with Visium CytAssist and analyzed in Loupe Browser/R.

Results: Mean pre-pregnancy SpO2 was 93.3±3.5%, where SpO2 at delivery decreased with increasing gestational age (GA, R = -0.48, P = 0.046). Over 1/3 (41.2%, N = 7/17) had FGR and most (82.4%, N = 14/17) had PTBs (mean GA 233.1±24.9 days [33 weeks]). Of PTBs, 64.2% (N = 9/14) labored spontaneously. 64.7% of the placentas (N = 11/17) showed accelerated maturation for GA (Fig 1). Spatial capture spots clustered based on clinical and histopathologic features, contrasting samples from FGR vs normally grown placentas and regions of frank vs minimal pathology (Fig 2). Spots with frank pathology showed upregulation of hypoxia pathways with peri-lesion upregulation of pro-fibrotic transcripts; structural integrity transcripts (PLEC,

SPTAN1, SRGN) were downregulated. Regions without frank pathology in FGR placentas also overexpressed pro-fibrotic markers and markers of placental dysfunction (PSG11, ALPP). Adverse pregnancy outcome markers (PAEP, PAPPA2) were upregulated in early PTB (< 34 weeks) compared to late PTB; PLEC, SPTAN1, SRGN were downregulated.

Conclusion: We identify a transcriptomic profile of consistently downregulated structural genes that unify placentas from early PTB with histopathologic placental findings in patients with Fontan circulation. These markers should be explored as potential mediators of PTB in cases of significant maternal cardiac disease.

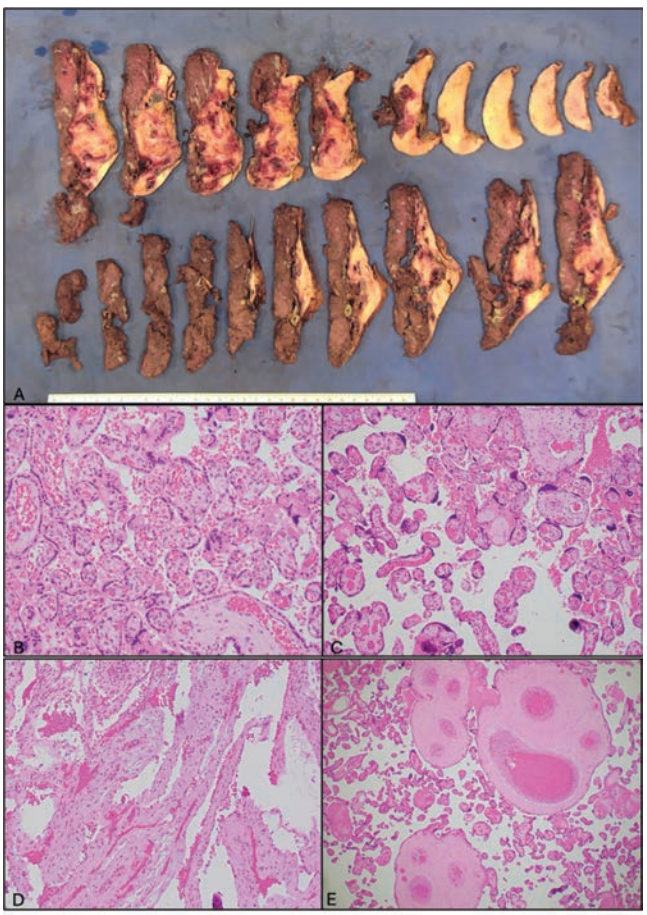

Figure 1. Gross and Microscopic Features of Placentas From Fontan Patients. 17 placentas from 15 patients were examined. Grossly, the weight of the placentas varied widely (from <3rd to 95-97th percentile). Most of the placentas (11/17) showed subchorionic hematomas (A). Microscopically, 6/17 placentas showed appropriate villous maturation for gestational age (B [H&E 200x]). While the remaining 11/17 showed increased syncytial knotting and distal villous hypoplasia, consistent with accelerated maturation for gestational age (C [H&E 200x]). 3/17 placentas showed features of decidual arteriopathy (D [H&E 100x]). 3/17 cases showed features of fetal vascular malperfusion, including 1 case of high grade (E [H&E 40x)].

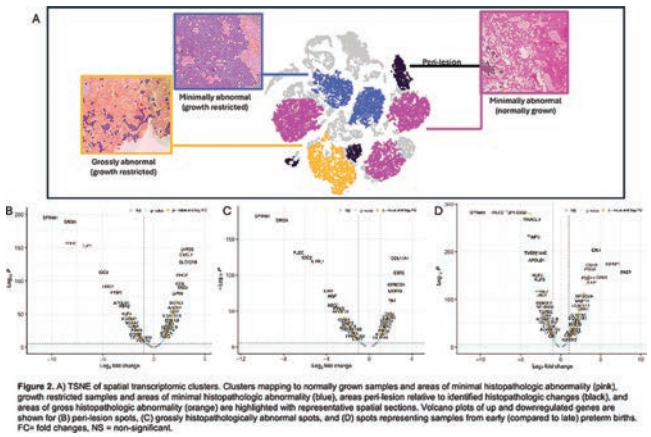

Figure 2. A) TSNE of spatial transcriptomic clusters. Clusters mapping to normally grown samples and areas of minimal histopathologic abnormality (pink), growth restricted samples and areas of minimal histopathologic abnormality (blue), areas peri-lesion relative to identified histopathologic changes (black), and areas of gross histopathologic abnormality (orange) are highlighted with representative spatial sections. Volcano plots of up and downregulated genes are shown for (B) peri-lesion spots, (C) grossly histopathologically abnormal spots, and (D) spots representing samples from early (compared to late) preterm births. FC= fold changes, NS = non-significant.

973 | Uterine Inflammatory Characteristics Following Cesarean Delivery

Aya Mohr-Sasson[1]; Tal Dadon[2]; David Stockheim[3]; Jigal Haas[3]; Adva Aizer[3]; Roy Mashiach[3]; Raoul Orvieto[3]

[1]Division of Minimally Invasive Gynecological Surgery, Department of Obstetrics, Gynecology and Reproductive Sciences, UTHealth McGovern Medical School, Houston, TX; [2]Sheba Medical Center, Ramat Gan, Tel Aviv; [3]Sheba Medical Center, Ramat-Gan, Tel Aviv

4:00 PM - 6:00 PM

Objective: An incomplete healed scar (niche) is a long-term complication of cesarean delivery (CD), and is associated with symptoms including subfertility. One theory refers to inflammatory process at the area of the niche that harms the endometrial environment, however, data is limited. The aim of this study is to compare the inflammatory characteristics of women with cesarean uterine scar to those without.

Study Design: This is a prospective study including all women visiting hysteroscopy ambulatory clinics for diagnostic hysteroscopy. Study population included women with cesarean uterine scar (study group that were compared to those without (controls). A syringe was attached to the outlet of the diagnostic hysteroscope and the first 5 cc of 0.9% normal saline fluid used for hydro dissection were collected. The samples were analyzed for inflammatory factors levels, including: GM-CSF, IFN-gamma, IL-1, IL-2, IL-5, IL-6, IL-7. IL-13, IL-15, IL-17, IL-17F, IL-22, IL-23, IL-31, IL-36 and TNF-alpha. Primary outcome was defined as the difference in inflammatory factors level.

Results: 80 women met inclusion criteria, of them 29(36%) had history of CD and 51(64%) had no uterine scar. No difference was found in the level of any of the 17 factors collected. Analysis by indication to perform the procedure, comparing infertility to all other indications, revealed significantly higher IL33 levels in the infertility group [25.60(2.80-185.83) vs. 5.98((0-43.84pg/ml; p = 0.02]. While comparing the 9 women with infertility to the 20 women without infertility in the CD group, no difference was found in uterine scar characteristics, however, IL 33 was found to be 25 times higher in the infertility group [61.23(19.84-169.44) vs. 4.61(0-33.72) pg/ml;p = 0.004]. This difference was not demonstrated in women without CD (p = 0.29).

Conclusion: Women undergoing evaluation due to infertility with history of uterine scar have significantly higher level of

inflammatory marker IL33. This novel finding might be grounds for future treatment for this population.

974 | Robotic-Assisted Abdominal Cerclage: A Single-Center Journey

Asha Bhalwal; Elio Tahan; Aya Mohr-Sasson
Division of Minimally Invasive Gynecological Surgery, Department of Obstetrics, Gynecology and Reproductive Sciences, UTHealth McGovern Medical School, Houston, TX

4:00 PM - 6:00 PM

Objective: Transabdominal cerclage (TAC) is currently considered following unsuccessful transvaginal cerclage. The placement of the cerclage can serve for all future pregnancies as it is not removed once it was placed, and following its placement, women are obligated to deliver by Cesarean delivery. Increasing evidence suggests improved neonatal survival rates following abdominal cerclage compared with repeat vaginal cerclage. The aim of this study is to present patient's characteristics and clinical outcomes of women following robotic assisted abdominal cerclage placed for history indicated cervical insufficiency

Study Design: This is a retrospective study conducted at a single tertiary medical center. All women following robotic assisted abdominal cerclage placement between November 2020 to February 2024 were included in the study. Data were collected from women's' medical files. Primary outcome was defined as the rate of delivery ≥32 weeks of gestation.

Results: 16 women underwent robotic assisted abdominal cerclage during the study period, of them 6 (37.5%) were pregnant during the procedure. Women's mean age and body mass index were 34.4(±4.4SD) years-old and 35.7(±6.9SD) kg/m^2, respectively. The mean gravida was 4(±1.8SD) with parity of 1(±1.0SD). 60% of the women had history of previous vaginal cerclage (n = 9). The mean gestational age of previous miscarriages was 21.5 (±4.6SD). Mean surgical duration was 136 (±40) minutes with minimal blood loss [mean: 50(±40SD) cc]. Two of the procedures performed during pregnancy were converted, one to open approach as the patient did not tolerate Trendelenburg and one to vaginal approach due substantial pelvic adhesions. Four of the seven women (70% of the non-pregnant) attempted to conceive, got pregnant with an average time of 3.1(±3.3SD) months. Six of the women included in the study (36%) had already given birth with an average gestational age of 34.7(±3.4SD).

Conclusion: Robotic assisted abdominal cerclage is a feasible option for the treatment of cervical insufficiency with low complication rate.

975 | Epigenetic Age Acceleration and Blood Pressure in Pregnancy: Findings from the CHAP Study

Bertha A. Hidalgo; Amit Patki; Hemant K Tiwari; Marguerite Ryan Irvin; On behalf of the CHAP Consortium
University of Alabama at Birmingham, Birmingham, AL

4:00 PM - 6:00 PM

Objective: Elevated blood pressure (BP) during pregnancy can have cardiovascular health consequences for the mother in the short and long term. Measures of biological age including DNA methylation age (DNAmAge) and derived epigenetic age acceleration (EAA) have been associated with cardiovascular traits. However, few studies have examined if epigenetic age measures are associated with BP during pregnancy and PreE.

Study Design: We performed a secondary analysis of the Chronic Hypertension and Pregnancy (CHAP) study of n = 2408 individuals with mild hypertension randomized to standard care versus treatment. We measured DNAmAge from blood samples drawn between 6-23 weeks gestation in n = 1310 from the trial. DNAmAge was measured using 4 calculators: 1) Horvath, 2) Hannum, 3) skin and blood, and 4) PhenoAge. We analyzed correlations between the DNAmAge clocks and chronological age, as well as associations between EAA and five BP variables as outcomes 1) PreE; 2) systolic and diastolic BP (SBP/DBP) at baseline (6-23 weeks), 3) visit 2 SBP/DBP (23-34 weeks), 4) delivery SBP/DBP, and 5) 6-weeks post-partum (PP) SBP/DBP). Regression models (linear for BP and logistic for PreE) were adjusted for ancestry and smoking during pregnancy.

Results: The study population was 50% Black, 38% White and 12% other, and the average age was 32.3 ± 5.7 years. DNAmAge was highly correlated with chronological age for each of the 4 calculators. EAA from the skin and blood clock was associated with baseline SBP (p = 0.006), baseline DBP (p = 0.029), and DBP PP (p = 0.029). No EAA estimate was statistically significantly associated with PreE or BP at delivery. See Table 1 for the association of EAA with baseline SBP, DBP and PreE.

Conclusion: There was a cross-sectional association between two EAA measures with early pregnancy BP, but not BP later in pregnancy or PreE. Other epigenetic variables and/or estimates from assays measured at additional time points may give additional insight into the relationship between biological aging and BP during pregnancy in women with chronic hypertension.

Table 1: Epigenetic Age Acceleration Associations with baseline blood pressure and PreE in CHAP

	Epigenetic Age Acceleration	Parameter Estimate* or OR^	SE& or 95% CI#	p-value

976 | National Prevalence of Healthcare Provider-Recommended Bedrest and Activity Restriction by Pregnancy Condition

Maria A. Fernandez[1]; Ellie C. Mayers[2]; Gladys E. Smith[2]; Ellen C. Caniglia[2]; Stefanie N. Hinkle[3]; Sunni Mumford[3]; Enrique Schisterman[2]; Lisa D. Levine[3]; Beth L. Pineles[2]
[1]Perelman School of Medicine, University of Pennsylvania, Boston, MA; [2]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA

4:00 PM - 6:00 PM

Objective: Bedrest and activity restriction (BAR) are often recommended in pregnancy despite an association with worse pregnancy outcomes. With guidelines recommending against BAR, some consider it an issue of the past, yet the contemporary national prevalence remains unknown. We aimed to determine the contemporary national prevalence of healthcare provider-recommended BAR among pregnant individuals, the pregnancy conditions associated with these recommendations, and adherence to BAR.

Study Design: An internet-based survey was distributed to females aged 18-54 who were pregnant or had been pregnant in the past year. The survey was tested and validated. Participants were asked, "Has anyone recommended bedrest or advised you to do less physical activity?," in addition to details about these recommendations, whether their pregnancy was considered, "high-risk," and their pregnancy conditions. The primary outcome was a recommendation for BAR by an obstetrician-gynecologist or midwife. To account for differential response rates, weighting for age and race/ethnicity was performed based on the target population of all births in the 2022 U.S. Natality Database, and all results presented are weighted. Two-sided p< 0.05 was considered statistically significant.

Results: 1500 survey responses were obtained. After weighting, 539 (38%) participants reported high-risk pregnancies. The frequency of BAR was 40% (95% confidence interval [CI] 37-43%); greater in high-risk pregnancies [61% (95% CI 57-65%)] than low-risk pregnancies [27% (95% CI 24-30%)], p-value< 0.01. Frequency of recommendations and recommendation type varied by pregnancy condition (chi-squared p < 0.01, Table). Adherence to BAR varied by both pregnancy condition and restriction type, with most participants across groups adherent (p values < 0.01, Figure).

Conclusion: Despite clear national guidelines recommending against BAR, recommendations for BAR practices remain prevalent, especially among high-risk pregnancies but common even among low-risk pregnancies. Future studies should focus on the deimplementation of this prevalent and harmful practice.

Table. Frequency and type of bedrest and activity restriction by pregnancy condition

	Low-risk pregnancy (n=872)	High-risk pregnancy (n=539)				
		Short cervix or cerclage (n=63)	History of preterm birth (n=42)	Multiple gestation (n=26)	Vaginal bleeding or placental condition (n=77)	Other condition (n=356)
No restriction	638 (73%)	15 (37%)	7 (16%)	12 (47%)	19 (24%)	134 (38%)
Activity Restriction[a]	191 (22%)	22 (56%)	32 (75%)	11 (40%)	50 (65%)	195 (55%)
Lifestyle restriction[b]	129 (15%)	18 (46%)	27 (65%)	9 (35%)	39 (50%)	134 (38%)
Pelvic rest	71 (8%)	7 (18%)	22 (52%)	7 (28%)	31 (41%)	73 (21%)
Bedrest	42 (5%)	10 (26%)	12 (28%)	7 (26%)	20 (26%)	60 (17%)

Numbers are weighted for age and race/ethnicity, and do not add to totals due to each participant being included in all applicable categories.

977 | Risk Factors for Failing Aspirin Prophylaxis for Preeclampsia Prevention: A Prospective Cohort Secondary Analysis

Bhaskari Burra[1]; Danetta Green[1]; Traci Carson[2]; Lisa M. Foglia[2]
[1]*Mountain Area Health Education Center, Asheville, NC;*
[2]*Mountain Area Health Education Center (MAHEC), Asheville, NC*

4:00 PM - 6:00 PM

Objective: We aimed to identify demographic characteristics and risk factors associated with failure of aspirin (ASA) prophylaxis in a nulliparous population with singleton pregnancies.

Study Design: We conducted a secondary analysis of the prospective NuMom2B cohort of 9289 nulliparous women. We included participants with a gestational age of 20 weeks' gestation or greater. Our sample included 8741 women. The exposure of interest was ASA. The primary outcome was the development of any hypertensive disorder of pregnancy. We compared demographic factors among women who did and did not use aspirin during their pregnancy and outcomes by group.

Results: Patients who used aspirin during pregnancy (n = 117) were older (31 vs. 27, p< 0.001), more likely to be White (87% vs. 65%, p< 0.001), non-Hispanic (87% vs. 73%, p< 0.001) and more likely to have chronic hypertension (HTN) (9% vs 3%, p< 0.001), compared to non-aspirin users (n = 8624). ASA users were more likely to develop preeclampsia (11% vs 6%, p< 0.05), versus the non-aspirin group. There were no notable differences in risk factors between ASA users and non-ASA users for development of hypertensive disorders. There was no significant difference in the gestational age at delivery between the two groups.

Within the ASA group, women who developed hypertensive disorders had a lower mean BMI (24.4 vs 27.4, p< 0.05) and were slightly older (33 vs 31, p = 0.15) compared to those who did not develop hypertensive disorders.

Conclusion: In this study, we found that there is no difference in risk factors for the development of hypertensive disorders between ASA and non-ASA users. We did find a higher incidence of hypertensive disorders in the ASA group. This is possibly due to our relatively small sample size of patients taking ASA, but also could represent a higher apriori risk in this group. The similar gestational ages at delivery amongst ASA and non-ASA also supports the theory that ASA use prevents the onset of hypertensive disorders of pregnancy by delaying the "metabolic clock" of placental maturation during pregnancy.

Table 1. Demographics

979 | Differential Protein Expression Associated with Persistent Hypertension Following a Hypertensive Disorder of Pregnancy

Brian Kleiboeker[1]; Janet Catov[2]; Koen Raedschelders[3]; Aleksandra Binek[3]; Simion Kreimer[3]; C. Noel Bairey Merz[4]; Jennifer Van Eyk[3]; Arun Jeyabalan[1]; Adam C. Straub[5]; Agnes Koczo[1]; Alisse Hauspurg[6]

[1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Magee-Womens Hospital, Pittsburgh, PA; [3]Cedars Sinai Medical Center, Cedars-Sinai, CA; [4]Cedars-Sinai Medical Center, Los Angeles, CA; [5]University of Pittsburgh, Pittsburgh, PA; [6]Alpert Medical School of Brown University, Providence, RI

4:00 PM - 6:00 PM

Objective: Hypertensive disorders of pregnancy (HDP) are associated with future cardiovascular risk, however, the underlying mechanisms are unclear. We sought to identify differentially expressed proteins in individuals who developed chronic hypertension (HTN) in the first year postpartum following a HDP compared to those who remained normotensive.

Study Design: We used data from a randomized clinical trial evaluating lifestyle intervention and home blood pressure (BP) monitoring of individuals with pre-pregnancy body mass index (BMI) ≥25 kg/m^2 and a new-onset HDP. The primary outcome was feasibility and no differences were seen in BP between arms, thus randomization groups were combined. BP was measured at remote research visits at 6 weeks and 1 year postpartum and blood microsamples were collected at the second visit. Mass-spectrometry was used to quantify 381 proteins, from which differential expression and pathway enrichment analyses were performed to detect alterations with persistent HTN (BP ≥140/90 mmHg). All analyses controlled for BMI, tobacco use, and the social construct of race.

Results: Of the 100 randomized individuals, 88 (88%) completed sample collection with 85 yielding usable proteomics data. 4 proteins were differentially expressed in individuals with persistent HTN. Stage 2 HTN was associated with increased levels of Complement C4-B (C4B) and inter-alpha-trypsin inhibitor heavy chain 4 (ITIH4) and decreased levels of Afamin (AFM) and the smooth muscle protein myosin light chain 6 (MYL6) compared with Stage 1 HTN or normalization of BP. Pathway enrichment analysis suggests a shared function of endopeptidase inhibitor activity (such as Neprilysin, which degrades natriuretic peptides) in upregulated proteins and ubiquitin-proteasome mediated proteolysis activity in downregulated proteins.

Conclusion: Home microsampling is a promising methodology for postpartum sample collection. Serum proteomics using this approach suggest that protein homeostasis may be dysregulated in persistent HTN following HDP and provides novel candidates for future interventions to reduce progression to HTN following HDP.

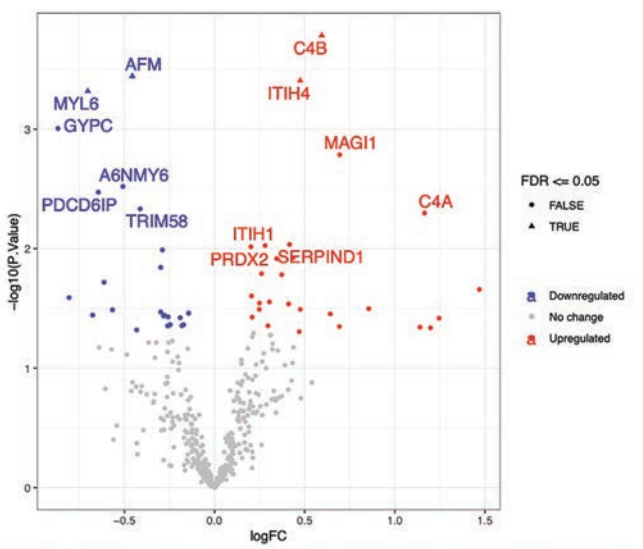

Figure 1. Volcano plot of differential expression analysis results of individuals with Stage 2 hypertension versus individuals with Stage 1 hypertension and normotension. Proteins in red correspond to those upregulated in individuals with Stage 2 hypertension while those in blue are downregulated. FDR = False discovery rate, FC = fold change.

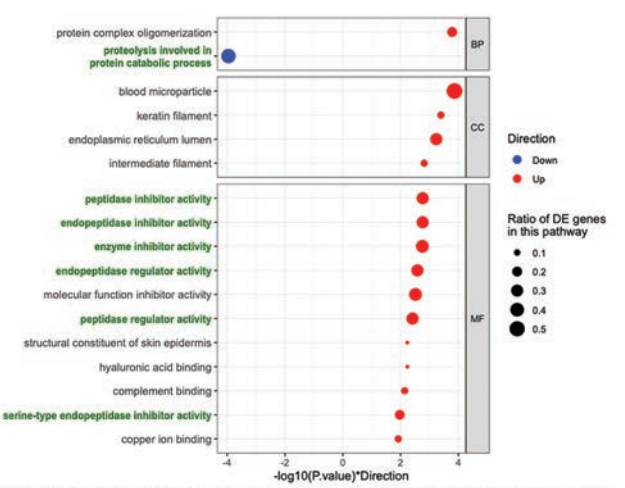

Figure 2: Gene ontology (GO) terms which had p value < 0.01 for being enriched in proteins which were upregulated (red) or downregulated (blue) in serum of individuals with Stage 2 hypertension. GO terms in green relate to protein homeostasis. DE = differentially expressed.

980 | Comparison of Various Community Level Social Indices and their Associations with Adverse Pregnancy Outcomes

Bridget C. Huysman[1]; Loren Adler[2]; Sarah Cohen[1]; Candice Woolfolk[3]; Sarah K. England[4]; Antonina I. Frolova[5]; Jeannie C. Kelly[6]; Nandini Raghuraman[6]; Peinan Zhao[4]
[1]Washington University in St. Louis, St. Louis, MO; [2]Washington University in St. Louis/Barnes-Jewish Hospital, St. Louis, MO; [3]Washington University School of Medicine in Saint Louis, St. Louis, MO; [4]Washington University, St. Louis, MO; [5]Washington University School of Medicine, St. Louis, MO; [6]Washington University School of Medicine in St. Louis, St. Louis, MO

4:00 PM - 6:00 PM

Objective: The social vulnerability (SVI), maternal vulnerability (MVI), and area deprivation (ADI) indices measure community-level resilience to stressors, vulnerability to adverse maternal health outcomes, and socioeconomic disadvantage, respectively. Prior work has shown that ADI, SVI, and MVI can identify those at risk for preterm birth. The objective of this study was to compare the three indices and their associations with adverse pregnancy outcomes.

Study Design: This is a nested case control study within a prospective cohort study of singleton pregnancies from 2017 to 2020. The parent study excluded non-English speaking patients and IVF pregnancies. The primary outcome for this analysis was composite adverse obstetric outcomes (Table 1). These outcomes were compared between patients with low SVI, MVI, and ADI (< 75th percentile, representing higher resilience/less vulnerable/prosperity) versus high SVI, MVI, and ADI (≥75th percentile, representing lower resilience/more vulnerable/deprivation) and stratified by race.

Results: Among 1260 birthing people, patients with high SVI and ADI were more likely to have composite obstetric adverse outcomes compared to those with lower SVI and ADI, respectively (aOR 1.86, 95% CI [1.43, 2.42] and aOR 1.36, 95%CI [1.04, 1.78]). High MVI was not associated with adverse outcomes. In the stratified analysis, race did not modify the association between SVI, MVI, ADI and adverse outcomes (P for interaction > 0.05 for all three).

Conclusion: Among the three indices, SVI and ADI might be the most reliable indices to capture community-level determinants of obstetric outcomes. Social vulnerability and community-level deprivation, independent of race, are associated with adverse pregnancy outcomes.

Table 1: Comparison of risk of composite OB adverse outcomes by indices

	No composite OB adverse outcome	Composite OB adverse outcome	OR (95% CI)	aOR* (95% CI)
SVI[1] (n=1055)

University School of Medicine, Indianapolis, IN; [4]Indiana University and Riley Children's Hospital, Indianapolis, IN

4:00 PM - 6:00 PM

Objective: To evaluate the impact of prior blood transfusion on diagnosis and severity of maternal alloimmunization.

Study Design: A single-center retrospective cohort study of alloimmunized singleton gestations with antibodies known to be associated with hemolytic disease of the fetus and newborn (HDFN) from 2018 to 2023. We excluded pregnancies if the fetus was determined to be not at risk for HDFN either by negative paternal genotyping or negative invasive diagnostic testing. Multiple gestations were excluded as well. Univariate and multivariate analyses were performed. P-value < 0.05 was considered statistically significant.

Results: 76 patients with alloimmunization were identified who had a documented history of blood transfusion. 40 patients had no prior history of blood transfusion while 36 did report a prior transfusion. The type of antibody present differed significantly between the two groups. Patients with a history of blood transfusion presented with a wider variety of antibodies than those who did not. Patients with a history of blood transfusion predominantly presented with anti-K, whereas those without prior blood transfusion history presented with primarily anti-D. Both groups were equally likely to have more than one antibody present. Patients with a history of blood transfusion had their first titer drawn at a later gestational age (11.02 ± 2.2 vs. 9.6 ± 2.3). However, there was no significant difference between the maximum antibody titer reached during pregnancy (101.5 ± 251.3 vs. 220.2 ± 475.5). Moreover, both groups were equally likely to have MCA Dopplers initiated, reach maximum MCA PSV MoM $\geq$1.5, and require IUT.

Conclusion: Patients who develop alloimmunization due to blood transfusion are more likely to present with a wider variety of antibodies but this does not impact the need for MCA Doppler monitoring or IUT in a clinically significant way.

Table: Characteristics of alloimmunized pregnancies with and without a history of maternal blood transfusion

Variable		History of prior blood transfusion (n=36)	No history of prior blood transfusion (n=40)	P-Value

[1]Women & Infants Hospital of Rhode Island / Alpert Medical School of Brown University., Providence, RI; [2]Women & Infants Hospital of Rhode Island / Alpert Medical School of Brown University, Providence, RI; [3]Warren Alpert Medical School of Brown University / Women and Infants Hospital of Rhode Island, Providence, RI; [4]University of Massachusetts Chan School of Medicine, Worcester, MA; [5]Medical College of Wisconsin, Milwaukee, WI

4:00 PM - 6:00 PM

Objective: Breastfeeding has established benefits for maternal and childhood health. However, mixed evidence exists on the impact of breastfeeding and childhood dental caries. Preventative pediatric dental care can mitigate the risk of dental caries in this population. Thus, we examined the association of breastfeeding and preventative dental care visits among children age 0-5 years in the United States.

Study Design: We analyzed data from the 2021 National Survey of Children's Health, an annual cross-sectional survey across multiple domains of a family unit's social determinants of health. The primary outcome was preventative dental care visit, defined by presence or absence of a dentist or oral health provider visit in past 12 months (check-ups, education, cleanings, sealants, fluoride, or x-ray). The main exposures were breastfeeding and breastfeeding exclusivity. Established parental and household unit characteristics were explored. A weighted and multivariable logistic regression analysis calculated adjusted odds ratios of preventative dental care visits.

Results: The majority 24,668 (81%) of children age 0-5 years had received breastmilk via direct or expressed breast milk. More than half 14,929 (56%) of these children had a preventative dental care visit. Dental check-up, cleaning, education, x-ray, fluoride, and sealant visits occurred more frequently in those children who were breastfed compared to those who were not (Table 1). After adjusting for differences between groups, breastfeeding or exclusive breastfeeding was not associated with odds of preventative dental visits, while having unmarried parents and less severe household poverty was associated with reduced odds (Table 2).

Conclusion: Social determinants such as family and economic instability–not breastfeeding status–were key drivers of preventative dental care. Dental health care education should be integrated into prenatal care conversations around breastfeeding to dispel myths and promote optimal parental and early childhood health.

Table 1. Preventative dental care visits and specific treatment by children breastfed or fed breast milk from age 0-5 years.

Preventative dental care visit and specific treatment	Received at least some breast milk via direct feeding or expressed breast milk n = 24,668	Did NOT receive at least some breast milk via direct feeding or expressed breast milk n = 4,478	p

983 | Longitudinal Change in Short-Term Variation with Intraamniotic Infection After PPROM: A Historical Cohort Study

Brynhildur T. Birgisdottir[1]; Tomas Andersson[2]; Ingela Hulthén Varli[3]; Sissel Saltvedt[3]; Ke Lu[4]; Farhad Abtahi[5]; Ulrika Åden[6]; Malin Holzmann[6]

[1]Karolinska University Hospital, Stockholm, Stockholms Lan; [2]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Stockholms Lan; [3]Department of Women's and Children's Health, Karolinska Institute, Stockholm, Stockholms Lan; [4]Department of Electrical Engineering, Chalmers University of Technology, Gothenburg, Vastra Gotaland; [5]Department of Clinical Science, Intervention and Technology, Karolinska Institutet, Stockholm, Stockholms Lan; [6]Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Stockholms Lan

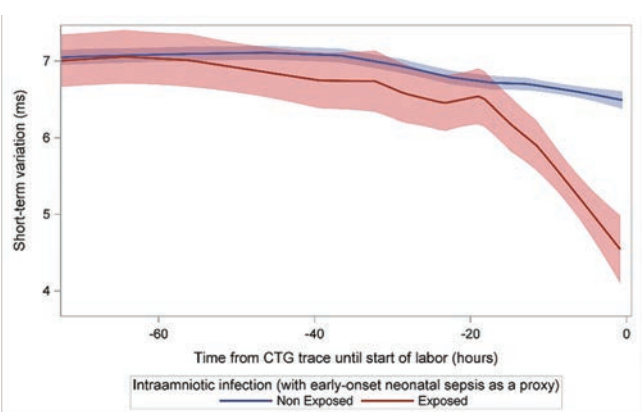
4:00 PM - 6:00 PM

Objective: Currently used diagnostic tools have been shown to have poor diagnostic performance for intraamniotic infection (IAI). In search of better diagnostic tools we have studied short-term variation (STV) in fetal heart rate in pregnancies with preterm prelabor rupture of membranes (PPROM). We have previously shown that in IAI exposed pregnancies, STV was > 20% lower in the last cardiotocography trace before start of labor, as compared to those not exposed. The current study was aimed at further examining this association by examining the longitudinal change in STV in association with IAI after PPROM.

Study Design: We performed a historical cohort study on 628 singleton pregnancies with PPROM, delivering between 24 + 0 to 33 + 6 gestational weeks. The studied exposure was IAI, using early onset neonatal sepsis as a proxy as no easily available method exists for confirming IAI antepartum, and IAI and early onset neonatal sepsis are strongly associated. The main outcome was STV in fetal heart rate. At least two available cardiotocography traces per fetus were required. A total of 9 690 cardiotocography traces were analyzed.

Results: Fetuses exposed to IAI had a 26.5% steeper decline in their STV during the last 24 hours before the start of labor when compared to fetuses not exposed (95% CI -32.9% to -19.4%; $P < 0.001$). After adjustment for antenatal corticosteroids, the decline remained significant. The decline became less prominent but remained significant when also adjusting for the baseline frequency (-12.7% [95% CI -19.3% to -5.5%], $P < 0.001$). In the IAI-exposed group, the baseline frequency increased by 11.1 bpm during the last 12 hours before the start of labor, beyond those who were not exposed (95% CI 8.3 bpm to 13.8 bpm; $P < 0.001$).

Conclusion: In pregnancies affected by IAI the STV has a steeper decline in the last 24 hours before start of labor as compared to pregnancies not affected by IAI, even after adjustment for increasing baseline frequency. The association of STV in relation to IAI needs to be further studied in order to evaluate and establish STVs usefulness in monitoring patients for IAI.



984 | Racial and Ethnic Differences in Delivery Characteristics in Patients with a Cesarean Wound Infection

Carmen Rauh Garrido[1]; Rachel L. Wood[2]; Sarah K. Dotters-Katz[3]; Janice Wong[3]

[1]Duke School of Medicine, Durham, NC; [2]Duke University, Durham, NC; [3]Duke University School of Medicine, Durham, NC

4:00 PM - 6:00 PM

Objective: Black race and Hispanic ethnicity have been identified as risk factors for cesarean wound infection. This likely represents systemic bias, as there is no biological explanation for these differences. This study sought to identify differences among self-reported racial and ethnic groups in delivery or postpartum factors that could be targeted to lessen disparities.

Study Design: This was an IRB-approved, retrospective cohort study of patients with post-cesarean wound infections requiring an emergency department or triage wound-related visit from a single healthcare system between 6/1/2013-7/31/2022, excluding patients with placenta accreta or severe preeclampsia. Primary exposure was self-reported race and ethnicity. Outcomes of interest were delivery characteristics predisposing to wound infection (GBS status, cesarean operative time, antibiotics received, estimated blood loss, skin closure with staples, peripartum infection). Bivariate statistics were used to analyze data. Regression models developed to control for confounders.

Results: Of 533 patients with post-cesarean wound infections, 180(33.7%) identified as non-Hispanic Black(NHB), 233(43.7%) non-Hispanic White(NHW), and 80(15.0%) as Hispanic. NHB and Hispanic patients had a significantly higher BMI and were more likely to have public insurance than NHW patients. NHB patients were more likely to use tobacco than NHW patients(Table 1). Hispanic patients had a higher rate of PP endometritis treatment(n = 16,8.7%), compared to NHW(n = 7,3.0%), and NHB(n = 3,3.8%). In regression models, NHB patients were significantly more likely to be GBS positive(OR 1.70 (1.01,2.85)) and were more likely to be diagnosed in triage(OR 1.51 (0.98, 2.33)), though this finding was not statistically significant(Table 2).

Conclusion: Among patients with wound infections after cesarean, PP endometritis, GBS, and diagnosis location differed, yet no modifiable delivery characteristics were noted among racial and ethnic groups. Future research may investigate disparities in peripartum infection as a risk factor for wound infection and differences in postpartum healthcare access.

985 | Tight Versus Standard Postpartum Control Following Hypertensive Disorders of Pregnancy: A Randomized Controlled Feasibility Trial

Carrie Bennett[1]; Rosemary Shay[1]; Sanjana Ghosh[1]; Sila Yavan[1]; Jennifer Hernandez[1]; Hyagriv Simhan[1]; Malamo Countouris[1]; Janet Catov[2]; Alisse Hauspurg[3]
[1]University of Pittsburgh Medical Center, Pittsburgh, PA; [2]Magee-Womens Hospital, Pittsburgh, PA; [3]Alpert Medical School of Brown University, Providence, RI

4:00 PM - 6:00 PM

Objective: To assess the feasibility of performing a randomized controlled trial (RCT) investigating tight versus standard postpartum blood pressure (BP) control following hypertensive disorder of pregnancy (HDP) through a postpartum remote monitoring program.

Study Design: We performed a single-blinded feasibility RCT from 11/2023-4/2024. Tight BP control was defined as medication initiation consistent with American Heart Association guidelines: inpatient BP (mmHg) ≥140/90 and/or outpatient ≥135/85 for two values at least 4 hours apart. Standard BP control was defined as medication initiation for BP ≥150/100 at least 4 hours apart. Eligible individuals were ≥18 years of age, diagnosed with HDP, and enrolled in our institution's remote BP management program. Individuals were excluded if they were diagnosed with chronic hypertension, pre-gestational diabetes, renal or cardiac disease, a fetal anomaly, or currently used anti-hypertensives. We compared demographics, inpatient medication initiation, and outpatient medication initiation among groups.

Results: We enrolled 60 individuals over a 5-month time course out of 143 who were approached (43%); 29 were randomized to tight control and 31 to standard control. Average age, body mass index, race/ethnicity, health insurance status, and household incomes were similar among groups (Table). Those in the standard control arm were more likely to be diagnosed with preeclampsia, including with severe features (p = 0.04). Antihypertensive medications were initiated at similar rates among groups both inpatient (31% tight vs 25.8% standard, p = 0.65) and outpatient (20.7% tight vs 22.6% standard, p = 0.86).

Conclusion: While a single center trial of tight versus standard postpartum BP control is feasible, there were similar rates of oral anti-hypertensive initiation among groups. This may be due to a differential representation of HDP severity among groups with a trend toward higher enrollment BP in patients randomized to standard control.

Patient Characteristics by Intervention

986 | Prenatal Characteristics Predictive of Xylazine Positivity: Who is being Exposed?

Cassandra Trammel[1]; Vahid Azimi[2]; Bridgit Crews[2]; Stephen Roper[2]; Nandini Raghuraman[3]; Antonina I. Frolova[4]; Megan L. Lawlor[2]; Hayley Friedman[2]; Jeannie C. Kelly[3]
[1]Washington University in St Louis, St. Louis, MO; [2]Washington University in St. Louis, St. Louis, MO; [3]Washington University School of Medicine in St. Louis, St. Louis, MO; [4]Washington University School of Medicine, St. Louis, MO

4:00 PM - 6:00 PM

Objective: Xylazine, a non-opioid veterinary sedative, is increasingly present as a contaminant in nonprescribed fentanyl. We sought to assess demographic and prenatal characteristics' association with odds of xylazine positivity in pregnant patients who use fentanyl.

Study Design: We performed a case control study of all patients positive for nonprescribed fentanyl on urine drug screening (UDS) at any point during pregnancy on an urban Midwestern tertiary care center labor unit in 2023. Patients with xylazine on any pregnancy or neonatal UDS were classified as xylazine cases, while fentanyl only patients were controls. Data was collected via chart review and odds ratios calculated. For cells with no occurrences, a Haldane correction was used to approximate an odds ratio.

Results: A total of 65 patients with nonprescribed fentanyl use were identified, with 40 xylazine exposure cases based on testing of the pregnant person or neonate. There were no factors identified that were associated with an increased or decreased odds of xylazine positivity. The majority of patients in both groups reported public insurance (xylazine positive 97.3, negative 100%) concurrent use of a non-opioid substance (100%, 91.3%), and tobacco (100%, 93.3%), and having an antepartum admission (50%, 60%). A large proportion reported intravenous use (41.5%, 16.7%), had evidence of stimulant use (100%, 75%), a comorbid psychiatric condition (61%, 79%) and infection with hepatitis C (53.7%, 29.2%). The majority presented to care after the first trimester (80.5%, 62.5%), and approximately half in both groups were on medication treatment for opioid dependence.

Conclusion: Fentanyl exposure continues to be associated with a high degree of social vulnerability, concomitant use of other substances, comorbid conditions, and limited prenatal care, however none of the background variables evaluated were associated with an increased or decreased odds of xylazine exposure. As xylazine may increase perinatal morbidity, all patients with fentanyl use should be counseled regarding potential risks of xylazine exposure.

987 | Fentanyl Exposure in the Era of Xylazine: an Update on Perinatal Outcomes

Cassandra Trammel[1]; Vahid Azimi[2]; Bridgit Crews[2]; Stephen Roper[2]; Nandini Raghuraman[3]; Antonina I. Frolova[4]; Hayley Friedman[2]; Megan L. Lawlor[2]; Jeannie C. Kelly[3]
[1]Washington University in St Louis, St. Louis, MO; [2]Washington University in St. Louis, St. Louis, MO; [3]Washington University School of Medicine in St. Louis, St. Louis, MO; [4]Washington University School of Medicine, St. Louis, MO

4:00 PM - 6:00 PM

Objective: Xylazine, a non-opioid veterinary sedative, is increasingly contaminating nonprescribed fentanyl. We sought to explore outcomes in fentanyl-exposed obstetric patients in an urban labor unit with high prevalence of xylazine in the local fentanyl supply.

Study Design: We performed a retrospective cohort study of all pregnant patients with nonprescribed fentanyl on urine drug screening (UDS) at a Midwestern tertiary care center in 2023. UDS via mass spectrometry is performed after a positive result on universal verbal screening. The primary outcome was preterm birth (PTB). Secondary outcomes included out of hospital birth (OOHB), adult intensive care unit (ICU) admission, neonatal ICU (NICU) admission, and other perinatal metrics. A secondary analysis comparing xylazine positive and negative dyads was performed with X^2 or Mann Whitney U tests as appropriate.

Results: 65 patients were identified. 57 had peripartum care in our facility, and 56 had neonatal data available with 59 neonates after accounting for twins. 62% of pregnant patients had xylazine exposure. Groups were similar aside from higher rates of intravenous drug use in the xylazine group (41.5 vs 16.7%, p = 0.04). 41.7% of xylazine exposed patients experienced PTB, compared to 28.6% of unexposed patients (RR 1.46, 95% CI 0.67-3.18) with a median gestational age of 37 weeks. Unplanned OOHB occurred in 19.4% of xylazine positive dyads and 9.5% of negative dyads, maternal ICU admission in 5.9% and 16.7%, and NICU admission in 76.5% and 70%, though differences were not significant. Xylazine dyads had lower rates of antepartum bleeding (2.4 vs 25%, RR = 0.09, [0.01-0.76]) and higher fentanyl positivity at delivery (100 vs 81%, RR = 1.23, [1.003-1.52]). Xylazine exposed neonates were less likely to be discharged in parental custody (5.6 vs 26.1%, RR 0.21, [0.58-2.3]).

Conclusion: Perinatal fentanyl use is associated with significant obstetric and neonatal morbidity regardless of xylazine exposure. Preliminary data suggests that xylazine may be a marker of severe disease and should be targeted for future study.

4:00 PM - 6:00 PM

Objective: Cervical cerclage before 24 weeks gestation prolongs pregnancy in patients at risk for preterm birth. Its benefits after 24 weeks are unclear due to limited safety data. We sought to describe maternal and perinatal outcomes with cerclage placement at 24-27 weeks.

Study Design: This is a secondary analysis from the International Collaborative for Cerclage Longitudinal Evaluation and

Research (IC-CLEAR), a cohort study of women with singleton pregnancies and cerclage placement. Participants were enrolled at 6 institutions in the U.S. and 2 in Colombia from June 2016 to June 2020. For this study, the primary exposure was cerclage placement between 24 0/7 and 27 5/7 weeks; the comparator group was cerclage between 20 0/7 and 23 6/7 weeks. Maternal and neonatal outcomes were evaluated using a test of medians and chi-squared test.

Results: 35 out of 839 pregnancies underwent cerclage placement between 24 0/7 and 27 5/7 weeks; 88% (n = 31) were from the centers in Colombia and 12% (4) in the U.S. Cerclage was performed at a median gestational age of 25.4 weeks (IQR 24.8-26.3) and the median latency from placement to delivery was 10.7 weeks (IQR 7.4-11.35). Premature rupture of membranes occurred in 18% (n = 6), and clinical chorioamnionitis in 3% (n = 1). Three patients required ICU admission, two due to preeclampsia with severe features. NICU admission was required for 10 neonates (32%), with two cases of sepsis and two neonatal deaths. When comparing maternal and perinatal safety outcomes in those with cerclage at 24-27 weeks to those with cerclage at 20-24 weeks (n = 328), there was a higher rate of maternal ICU admission, not associated with cerclage use; no significant differences were observed in maternal or neonatal infectious morbidity, or in other neonatal morbidity or mortality (Table 1).

Conclusion: Cervical cerclage performed between 24 and 27 weeks is not associated with a significant increase in maternal morbidity or adverse neonatal outcomes. Randomized controlled studies to evaluate the effectiveness and safety of cerclage in patients at 24 or more weeks of gestation are needed.

989 | Sonographic Indicators of Intralesional Haemorrhage in Fetal Lymphatic Malformation: a Retrospective Cohort Study

Charles Litwin[1]; Yada Kunpalin[1]; Lennart Van der Veeken[1]; Paolo Campisi[2]; Manuel Carcao[3]; Johannes Keunen[1]; Nimrah Abbasi[1]; Greg Ryan[4]; Tim Van Mieghem[5]; Shiri Shinar[1]
[1]Fetal Medicine Unit, Department of Obstetrics and Gynaecology, Mount Sinai Hospital and University of Toronto, Toronto, ON; [2]Department of Otolaryngology–Head & Neck Surgery, Hospital for Sick Children and University of Toronto, Toronto, ON; [3]Department of Haematology/Oncology, Hospital for Sick Children and University of Toronto, Toronto, ON; [4]University of Toronto, Toronto, ON; [5]Mount Sinai Hospital and University of Toronto, Toronto, ON

4:00 PM - 6:00 PM

Objective: To review the rate of intralesional hemorrhage (IH), sonographic indicators of IH and outcomes in a cohort of fetuses with lymphatic malformations (LMs).

Study Design: We performed a single-center retrospective cohort study of fetal LMs over a 13-year period. IH was defined as ultrasound findings demonstrating reticular echogenicity, fluid-fluid levels or clot without flow on Doppler. Fetal transfusion was considered if the middle cerebral artery peak systolic velocity (MCA-PSV) was elevated >1.5 MoM. Lymphangioma volume ratio (LVR) was calculated using the formula: 0.532 x (tumour width x length x height in cm)/head circumference (cm). Predictive strength of LVR on IH was determined by ROC analysis.

Results: Twenty-six isolated LMs were identified antenatally. Three pregnancies were terminated and 5 were lost to follow-up. Of the remaining, 10 involved the head and neck (H&N) and 8 involved the axilla. H&N LMs were diagnosed at 26.1 weeks gestation (IQR 21.6-28.8 weeks) with an LVR at presentation of 2.24 (IQR 0.68-17.29). Axillary LMs were diagnosed at 28.1 weeks gestation (IQR 23.6-32.3 weeks) with an LVR at presentation of 4.17 (IQR 1.26-7.02). Lesion growth was observed over the course of pregnancy (Fig 1). Five cases of IH were detected at 28.7 weeks gestation (IQR 24.4-35.2) and were found to have significantly larger tumour volume compared to those without bleeding (LVR: 11.09±5.25 vs 5.33±4.11, p = 0.04, table 1). LVR greater than 6.86 had a detection rate of 80% (95%CI 37.6-99.0%) for IH with a specificity of 66.7% (95% CI 39.1-86.2%). Polyhydramnios was present in all cases of IH but only in 2 out of 13 without IH. Of the 5 cases of IH, 2 died in utero, 2 required fetal transfusions and all 3 survivors were treated with sclerotherapy and rapamycin postnatally.

Conclusion: Intralesional hemorrhage is a recognized complication of fetal LMs with polyhydramnios. LVR may serve as a good predictor for IH prompting serial follow-up with MCA-PSV. Surviving fetuses typically require further treatment postnatally.

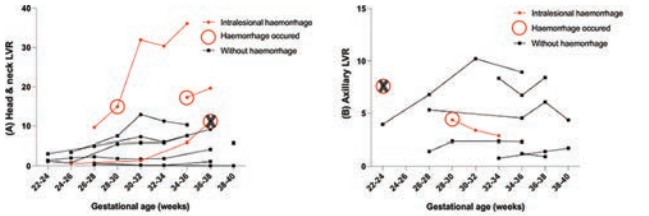

Figure 1. Natural history of tumour growth represented by lymphangioma volume ratio (LVR) in (A) head & neck lymphatic malformations anc (B) axillary lymphatic malformations. X demonstrates intrauterine death.

990 | Diuretics for Preventing Postpartum Readmission: A Systematic Review and Meta-Analysis

Chase Calvert[1]; Rajesh Reddy[1]; Molly Singer[2]; Jeny Ghartey[3]; Lorie M. Harper[1]
[1]Dell Medical School, Austin, TX; [2]Dell Medical School, University of Texas at Austin, Austin, TX; [3]University of Texas at Austin, Austin, TX

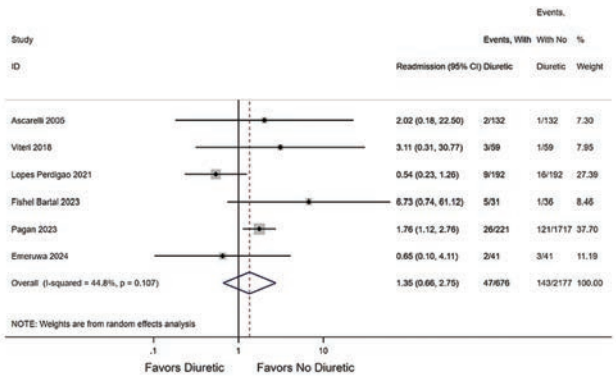
4:00 PM - 6:00 PM

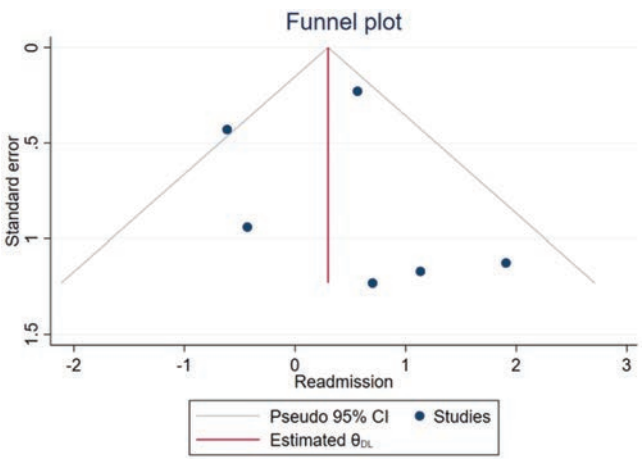
Objective: Hypertensive disease of pregnancy (HDP) is a leading cause of maternal postpartum readmission. While diuretics have been shown to reduce postpartum hypertension in women with HDP, their effectiveness in preventing postpartum readmission remains unclear. We performed a meta-analysis and systematic review to evaluate the impact of diuretic use on postpartum readmission rates in patients with HDP.

Study Design: We conducted a comprehensive search on PubMed, MEDLINE, Web of Science, PROSPERO, Cochrane Library, and ClinicalTrials.gov using a combination of key terms. Studies were included if they were published after 1995 and comprised clinical trials or observational cohorts. Eligible studies compared diuretic treatment to non-diuretic-based or no treatment in the postpartum period for patients with HDP. The primary outcome measured was readmission rates.

Results: Six studies, encompassing a total of 2,893 patients, were included. Five studies utilized loop diuretics (furosemide [4] and torsemide [1]), and one utilized a thiazide. The pooled odds ratio (OR) for readmission with any diuretic use was 1.35 (95% CI: 0.66 to 2.75). Visual inspection of the funnel plot revealed some asymmetry, suggesting that smaller studies showing positive results (i.e., those indicating a beneficial effect of diuretics on reducing readmission rates) might be missing. This asymmetry indicates potential publication bias. The variability among the studies was moderate (I^2 = 44.8%, P = 0.107). Metaregression analysis highlighted that the type of diuretic used had a significant impact on the results. Specifically, secondary analyses focusing only on studies that used loop diuretics (furosemide and torsemide) consistently showed a trend towards increased readmission rates.

Conclusion: Diuretic use in postpartum patients with HDP is not associated with decreases in readmission. Potential publication bias and the significant impact of diuretic type, particularly loop diuretics, on readmission rates highlight the need for targeted, large-scale prospective studies to accurately assess their role in managing postpartum hypertension.





991 | Poor Periconceptional Diet and Sleep Quality are Associated with Hypertensive Disorders of Pregnancy

Chelsea A. DeBolt[1]; Zhan Zhao[1]; Katharine McCarthey[1]; Kimberly B. Glazer[2]
[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Department of Population Health Science and Policy; Department of Obstetrics, Gynecology and Reproductive Science, Blavatnik Family Women's Health Research Institute, Icahn School of Medicine at Mount Sinai, New York, NY

4:00 PM - 6:00 PM

Objective: Hypertensive disorders of pregnancy (HDP) remain a leading problem in the US and risk factor for future adverse cardiovascular health. While recommendations to support long-term cardiovascular health exist for adults, specific lifestyle and wellness guidelines intended to improve pregnancy health are limited. We sought to examine the relationship between periconceptional lifestyle-related factors, including nutrition, sleep, and physical activity and development of HDP.

Study Design: We conducted a secondary analysis of singleton pregnancies to nulliparous individuals in the Nulliparous Pregnancy Outcomes Study: Monitoring Mothers-to-be (nuMoM2b) prospective cohort. We studied 7,942 participants without chronic

hypertension or pregestational diabetes. We assessed periconceptional dietary quality using the Alternative Healthy Eating Index-2010 (AHEI-2010) score, sleep quality based on duration and snoring, and physical activity based on duration and adequacy as reported at study visit 1 (6 to 13 weeks' gestation). Multivariable logistic regression estimated odds ratios for HDP adjusted for markers of socioeconomic status, depression, perceived social support, maternal age, tobacco use, and medical comorbidities.

Results: Individuals who developed HDP were more likely to be older, non-Hispanic Black, unmarried, and use tobacco, with higher BMI compared to those who did not (Table 1). In adjusted models, AHEI-2010 score in the lowest quartile was associated with 1.3 times (95% confidence interval 1.04-1.58) higher odds of HDP compared to the highest quartile (Table 2). Early pregnancy snoring was associated with 1.4 times (95% confidence interval 1.18-1.63) higher odds of HDP (Table 2).

Conclusion: Poor diet quality and early pregnancy snoring were associated with HDP in nulliparas without preexisting hypertension or diabetes. Findings support developing low-cost lifestyle interventions targeting diet and snoring to reduce HDP risk, emphasizing the importance of preconception and early pregnancy care to improve maternal and infant health.

Table 1. Maternal and Pregnancy Characteristics

992 | Is the Timing of Gestational Diabetes Screening Associated with Adverse Perinatal Outcomes?

Chloe Getrajdman[1]; Isabelle C. Band[2]; Sara Wetzler[2]; Alexandra N. Mills[3]; Guillaume Stoffels[2]; Chelsea A. DeBolt[2]; Calvin E. Lambert, Jr.[2]

[1]Icahn School of Medicine at Mount Sinai, Icahn School of Medicine at Mount Sinai, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Division of Maternal-Fetal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY

4:00 PM - 6:00 PM

Objective: Though there is a universal recommendation to screen for gestational diabetes (GDM) from 24-28 weeks, the impact of the timing of screening within this 5-week interval has yet to be studied. The study objective was to determine whether the gestational age of 2-step GDM screening among those diagnosed with GDM is associated with adverse outcomes

Study Design: A retrospective cohort study of singleton, non-anomalous pregnancies at one institution from 2019-2022 and diagnosed with GDM via the 2-step test. The early cohort included patients screened from 24-26.6 and the late cohort included those screened from 27-28.6. The primary outcome was a composite of perinatal morbidity: macrosomia, shoulder dystocia, hypertensive disorders of pregnancy, cesarean delivery for presumed macrosomia, neonatal intensive care unit (NICU) admission, among other adverse neonatal outcomes. Additional secondary maternal and neonatal outcomes were collected. Bivariate analyses, univariate and multivariate regressions were performed

Results: Of 433 patients included, 213 (49.2%) screened early and 220 (50.8%) screened late. More patients self-identified as Asian in the early group ($p = 0.0002$) and a larger proportion of patients had 1st trimester GDM screening ($p = 0.001$) in the late group (Table 1). In univariate and multivariate analyses, there were no significant differences in the composite outcome between the groups (late vs early screening: aOR 0.82, 95% CI 0.54-1.26, $p = 0.36$). A significantly higher incidence of macrosomia (7 vs 2.7%, $p = 0.04$) and trend toward increased NICU admission (8.9 vs 4.5%, $p = 0.07$) was seen in the early group (Table 2)

Conclusion: Among patients diagnosed with GDM using the 2-step test, there was no difference in odds of composite perinatal

morbidity among patients screened at the earlier or later end of the 24-28 week screening interval, though there were differences in race and prevalence of early glucose screening between the groups. Additional research is needed to further elucidate these findings and understand the implications of the timing of GDM screening on maternal and neonatal outcomes

993 | Is Time Between Screening and Diagnosis of Gestational Diabetes Associated with Adverse Outcomes?

Chloe Getrajdman[1]; Sara Wetzler[2]; Isabelle C. Band[2]; Alexandra N. Mills[3]; Guillaume Stoffels[2]; Calvin E. Lambert, Jr.[2]; Chelsea A. DeBolt[2]
[1]Icahn School of Medicine at Mount Sinai, Icahn School of Medicine at Mount Sinai, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Division of Maternal-Fetal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY

4:00 PM - 6:00 PM

Objective: To determine whether the interval between gestational diabetes (GDM) screening glucose challenge test (GCT) and diagnostic glucose tolerance test (GTT) is associated with adverse perinatal outcomes

Study Design: A retrospective cohort study of singleton, non-anomalous pregnancies at one institution from 2019-2022 and diagnosed with GDM via the 2-step test. The primary outcome was a composite of perinatal morbidity: macrosomia, shoulder dystocia, hypertensive disorders of pregnancy, cesarean delivery for presumed macrosomia, neonatal intensive care unit (NICU) admission, among other adverse neonatal outcomes. The comparison groups included patients with an interval between GCT and GTT of less than 10 days or greater than or equal to 10 days. Bivariate analyses, univariable and multivariable regressions were performed

Results: Of 389 patients included, 258 (66.3%) had an interval of less than 10 days between GCT and GTT and 131 (33.7%) had an interval of greater than or equal to 10 days. Patients in the ^{3}10 days group were more likely to be obese at time of GCT (30 vs 43.7%, p = 0.009) and more likely to be of Black race (9.4 vs 19.2%, p = 0.001) and have public insurance (16.3 vs 35.1%, p< 0.0001) (Table 1). There was a trend toward increased need for medication initiation in the ^{3}10 day group (32.9 vs 42%, p = 0.08) and a significantly later gestational age at initiation of medication (31.0 vs 32.9 weeks, p = 0.003) (Table 2). In the univariate and multivariate analyses there was no significant differences in the composite outcome between the groups (< 10 vs ^{3}10 days: aOR 1.03, 95% CI 0.64-1.67, p = 0.9)

Conclusion: While patients who had GTT ^{3}10 days after GCT were more likely to be Black, obese at time of GCT, have public insurance and initiated antihyperglycemic medication on average 2 weeks later than patients who had GTT within 10 days of GCT, no difference was seen in odds of adverse perinatal outcomes.

994 | Prevalence and Screening Methods for Asymptomatic Bacteriuria in Pregnancy in Low Resource Settings

Md Shahjahan Siraj[1]; Masum Billah[1]; Rashidul Haque[1]; Elizabeth M. McClure[2]; William A. Petri, Jr.[3]; Christian A. Chisholm[3]
[1]*International Centre for Diarrheal Disease Research, Bangladesh, Dhaka, Dhaka;* [2]*RTI International, Research Triangle Park, NC;* [3]*University of Virginia, Charlottesville, VA*

4:00 PM - 6:00 PM

Objective: Screening for asymptomatic bacteriuria (AB) has been recommended to reduce the risk of pregnancy complications. The evidence for this practice is outdated and of low quality, and global implementation is inconsistent. We conducted a prospective study in a rural Bangladeshi population to ascertain the prevalence of AB, assess the utility of point of care screening methods, determine antimicrobial sensitivity patterns, and report the prevalence of low birth weight (LBW) in pregnancies with AB.

Study Design: We obtained urine samples from 600 asymptomatic pregnant women (1150 samples) being enrolled in a prospective registry of women in antenatal care. Samples were cultured on blood and MacConkey agar plates. AB was defined as presence of a single organism ≥105 CFU/mL. Antimicrobial sensitivity testing was performed. Samples were inoculated on urine dipslides and analyzed for nitrite and leukocyte esterase (LE) using urine dipsticks (positive dipstick = presence of both nitrite and LE). The performance of dipslide and dipstick were calculated using culture as the reference.

Results: A positive culture was found in 37/1150 samples (3.2%); the overall prevalence of AB during pregnancy was 5.2% (31/600 subjects positive on at least one sample). E. coli was most common (65% of total) followed by Enterococcus and Enterobacter. 90% of all isolates were sensitive to nitrofurantoin, including 100% of E. coli (Table). When compared to culture, the sensitivity of dipslide and dipstick for AB were 65% and 14%. 26% of pregnancies with AB resulted in a LBW newborn vs 21% of pregnancies with negative culture (p = 0.56).

Conclusion: AB was present in 1 in 20 pregnant subjects in this cohort. The sensitivity of dipstick and dipslide were poor, indicating lack of suitability to serve as a primary method of screening for AB in this population. Future trials assessing the impact of screening and treating AB in pregnancy on the incidence of adverse outcomes in low resource settings must address logistics and cost of widespread implementation of urine culture capacity given the low sensitivity of point of care screening tests.

Table – Oral Antibiotic Sensitivity Pattern

Agent	Susceptible (%)	Intermediate (%)	Resistance (%)
Ampicillin / Amoxicillin	27.03	2.70	70.27
Cefixime	45.16	9.68	45.16
Nitrofurantoin	91.67		8.33
Cotrimoxazole	84.38		15.63
Azythromycin		28.13	71.88
Erythromycin	14.29	14.29	71.43

995 | Impact of an Addiction in Pregnancy Program on Breastfeeding in Patients with Substance Use Disorder

Christianna L. Tu[1]; Yumo Xue[2]; Charlotte B. McCarley[1]; Victoria C. Jauk[1]; Ayodeji Sanusi[2]; Rachel G. Sinkey[1]

4:00 PM - 6:00 PM

Objective: Breastfeeding (BF) plays a crucial role in promoting maternal and neonatal health. However, BF disparities exist among patients with substance use disorder (SUD). We evaluated the association between participation in a comprehensive addiction in pregnancy program (CAPP) and BF in patients with SUD.

Study Design: Retrospective cohort of pregnant patients with SUD who delivered between 4/2028—8/2022 at a tertiary care center in the southeast US. Exclusion criteria were: HIV, fetal demise, or infant adoption. CAPP provided multi-disciplinary group-based prenatal care to pregnant patients with SUD; patients were CAPP eligible if < 32 weeks, used ≥1 illegal substance, and scored ≥4 on the National Institute on Drug Abuse—Modified Assist Tool. The primary outcome was BF rate at discharge from the delivery-associated hospitalization in those who participated in CAPP compared to patients with SUD who were CAPP eligible but did not enroll (non-CAPP). Secondary outcomes included rate of BF at 6 weeks postpartum, BF intention, rate of neonatal opioid withdrawal syndrome (NOWS), highest modified Finnegan score, and neonatal length of stay (LOS). Outcomes were compared between groups.

Results: A total of 421 patients were included: 147 CAPP, 274 non-CAPP. Of the patients who participated in CAPP, 69.4% BF their infant at discharge compared to 42.9% of non-CAPP patients (p< 0.001, OR 2.89 (95% CI 1.85, 4.52)). Of CAPP patients who BF, 44.8% exclusively BF compared to 14.5% non-CAPP (OR 4.63, 95% CI 2.84, 7.55); and 24.6% of CAPP patients provided both breastmilk and formula compared to 28.4% non-CAPP (OR 0.80, 95% CI 0.50–1.30). At the postpartum visit, 32.1% of CAPP patients and 39.5% of non-CAPP patients were still BF, with no significant difference between cohorts. There was no difference in NOWS, highest Finnegan score, or NICU LOS between groups (Table).

Conclusion: Participation in a comprehensive addiction in pregnancy program is positively associated with BF at discharge from the delivery-associated hospitalization. Additional postpartum interventions are warranted to support BF after hospital discharge.

996 | Association of Fetal Heart Rate Tracing with Neonatal Adverse Outcomes at 32.0 to 36.6 weeks

Christina Cortes[1]; Kristen A. Cagino[2]; Aaron W. Roberts[3]; Rachel L. Wiley[4]; Claudia J. Ibarra[1]; Shareen Patel[1]; Khalil M. Chahine[1]; Natalie L. Neff[5]; Kimen S. Balhotra[1]; Tala Ghorayeb[1]; Holly Flores[6]; Fabrizio Zullo[7]; Hector M. Mendez-Figueroa[1]; Suneet P. Chauhan[8]

[1]McGovern Medical School at UTHealth, Houston, TX; [2]UT Houston, Houston, TX; [3]McGovern Medical School at UTHealth Houston, Houston, TX; [4]University of California, San Diego, San Diego, CA; [5]McGovern Medical School at UT Health, Houston, TX; [6]University of Texas Health Science Center, Houston, TX; [7]University of Rome La Sapienza, Rome, Lazio; [8]Delaware Center of Maternal-Fetal Medicine at Christiana Care, Delaware, DE

4:00 PM - 6:00 PM

Objective: The objective was to determine if features of fetal heart rate tracings (FHRT) were associated with an increased rate of neonatal adverse outcomes among preterm deliveries at 32.0–36.6 weeks.

Study Design: A retrospective review of all available FHRT among non-anomalous singletons attempting labor at 32.0 to 36.6 weeks. The study was conducted at a Level IV maternal center during a consecutive 15-month period. Obstetricians reviewing FHRT were blinded to the maternal characteristics, gestational age, and peripartum outcomes. Features of FHRT were dichotomized by time spent during the last hour before delivery (<50% vs. ≥50%). The primary outcome was the rate of composite neonatal adverse outcomes (CNAO). Chi-square test was used to compare groups, and likelihood ratios (LR) were calculated for FHRT features that differed significantly for those with and without CNAO. A priori, LR greater than 10 was considered a useful diagnostic test (Jeschker R et al. JAMA 1994).

Results: Of 5,160 patients, 672 (13%) met the inclusion criteria. CNAO occurred in 57 (8.5%) newborns. Maternal characteristics (age, nulliparity, race/ethnicity, tobacco use, and hypertensive disorders) were similar between groups (Table 1). Compared to those without, minimal variability was significantly more likely to occur with CNAO (11.2% vs. 24.6% p< 0.01). Two features of FHRT occurred significantly less often with CNAO: moderate variability (85.4% vs. 66.7%, p < 0.01) and presence of accelerations (66.8% vs. 50.9% p < 0.02). The LR of the three features which differed significantly among those with and without CANO ranged from 1 to 2. Notably, there was no significant difference between CNAO with any of the following: prolonged decelerations, combination of decelerations, and recurrent decelerations (Table 2).

Conclusion: Though certain features of fetal heart rate tracings differed significantly in those with and without composite neonatal adverse outcomes at 32.0 to 36.6 weeks, the likelihood ratios of 1 to 2 suggest these characteristics are poor predictors of adverse neonatal outcomes in this cohort.

4:00 PM - 6:00 PM

Objective: Given the profound impacts of substance use disorders (SUDs) in pregnancy on the health and wellbeing of parents and newborns, improving access to perinatal services for this population is a priority. The objective of this study was to use human-centered design methodologies to map the steps through which families affected by parental substance use progress through prenatal and postpartum care, with the goal of identifying opportunities to improve systems of care for substance-exposed families.
Study Design: We used process mapping–a human-centered design methodology–to characterize the steps associated with engaging in perinatal care systems as a parent with a SUD. Clinical and community-based staff working within a safety-net healthcare system participated in mapping workshops in which they responded 39 questions corresponding to the steps taken throughout a patient's journey from prenatal to postpartum care. Using a human-centered design approach to inductive thematic analysis, we identified themes, constructed insight statements, and generated corresponding design opportunities.
Results: Forty-seven stakeholders participated in process mapping. Eight insights emerged which clustered into 3 overarching themes: (1) provider variability in understanding policies and procedures, (2) care coordination challenges between team members, and (3) lack of standardization in engaging with child welfare. These findings generated 13 actionable design opportunities to strengthen perinatal care delivery.
Conclusion: Process mapping is a unique methodology to understand complex service delivery challenges and to improve systems of care for pregnant people with SUDs. In our ecosystem, process mapping revealed that unstandardized policies and care coordination challenges complicated perinatal care for substance-exposed families. Strengthening healthcare systems to better serve the needs of this population is central to improving family outcomes.

998 | Improving Care Coordination for Socially Complex Perinatal Patients: A Human-Centered Design Study

Christina N. Schmidt[1]; Benjamin S. Alpers[2]; Devika Patel[3]; Neeti Doshi[4]; Heather Briscoe[4]; Amanda Sammann[4]
[1]Massachusetts General Hospital and Brigham and Women's Hospital, Cambridge, MA; [2]The Better Lab, San Francisco, CA; [3]Pennsylvania State University College of Medicine, Hershey, PA; [4]University of California San Francisco, San Francisco, CA

4:00 PM - 6:00 PM

Objective: Designing novel solutions to address care fragmentation in the perinatal ecosystem requires rigorous evaluation of current workflows and engagement with the diverse network of stakeholders supporting patient care. Human-centered design (HCD) is an established methodology for identifying challenges in clinical workflows, with the goal of producing actionable insights to inform novel interventions. The objectives of this study were to use HCD methodologies to 1) understand the processes of transitioning perinatal care within a safety-net system, and 2) identify opportunities to improve care coordination for socially complex pregnant patients.
Study Design: We conducted semi-structured interviews with patients, clinical providers, and staff at community-based organizations (CBOs) working in a safety-net healthcare system. Interviews were analyzed using an HCD approach to inductive thematic analysis. We also completed an inventory of all questionnaires administered to patients by their perinatal care teams. Items were coded according to inductively generated themes for a descriptive analysis of item overlap.
Results: Fifteen patients, 21 clinical providers and 6 CBO staff participated in interviews. Six insights statements emerged: 1) the perinatal care system is resource rich but coordination is poor, 2) safety-net hospitals rely on CBOs to support patients but lack reliable communication systems with them 3) patient data protections complicate collaborative care planning, 4) poor communication around substance-use policies introduces bias in decision-making, 5) patients expect continuity of care and seeing new providers may engender mistrust. Eighteen perinatal questionnaires containing 833 items were coded into 21 unique themes, with 17 themes (81%) being duplicated between questionnaires.
Conclusion: Using an HCD approach, we identified key challenges in care coordination for socially complex perinatal patients. Interventions strengthening informational continuity between clinical and community-based providers offer promise for improved care delivery in safety-net systems.

1000 | Emergency Cervical Cerclage Versus Expectant Management in Women with Cervical Insufficiency Beyond 24 weeks

Christopher A. ENAKPENE[1]; Serin THOMAS[2]; Eric K. BRONI[3]; Brinkley COVER[4]; Erin ADAMS[4]; Omosiuwa ENAKPENE[5]; Sandra O. Anazor[6]; Michael GALLOWAY[7]
[1]Texas Tech University Health Sciences Center, Permian Basin, Midland-Odessa, TX; [2]Texas Tech University Health Sciences Center, Midland-Odessa, TX; [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [4]Texas Tech University Health Sciences Center, School of Medicine, Midland-Odessa, TX; [5]University of Michigan, Ann Arbor, MI; [6]Corewell Health West/Michigan State University, Grand Rapids, Michigan., Grand Rapids, MI; [7]Texas Tech University Health Sciences Center, Odessa, TX

4:00 PM - 6:00 PM

Objective: To determine whether cervical cerclage (CC) reduced the rate of preterm birth (sPTB), prolonged pregnancy (PP) latency and improved perinatal outcomes (PO) in women with cervical insufficiency (CI) $\geq$ 24 weeks compared to expectant management (EM).

Study Design: This was a prospective quasi-experimental study that compared CC vs EM in patients with CI $\geq$ 24 weeks (cervical dilatation $\pm$ exposed fetal membranes). Prospective data of the CC group was compared with historic data of similar characteristics of EM between 2022 to 2024 at an urban hospital in a 3:1 ratio. Both groups received Vaginal Progesterone, Betamethasone, Antibiotics and Indomethacin. Patient in the CC group were discharged home within 24 hours of surgery while EM group remained on admission until delivery. The outcomes were overall sPTB < 37 weeks, early and late sPTB (< 34 and 34 - 37 weeks), PO, NICU admission and duration. Baseline characteristic and PO were stratified and reported by intervention groups using Chi square and Kruskal Wallis. Multivariable and adjusted binomial and multinomial logistic regression models were used to assess rate of PTB between the two study groups. **(Table 2).**

Results: Of the 91 patients recruited, 67 had CC while 24 had EM. Baseline characteristics were similar. Neonates of women with CC were delivered at a later gestational age [38.2 wks vs 29.9 wks, p < 0.00 1], had higher birth weight [3170 g vs 2295 g, p < 0.001], lower NICU admission rate [18 (27.3%) vs 16 (66.7%), p = 0.001] and lower rate of severe neonatal complications [1 (6%) vs 6 (46.2%), p < 0.010] Table 1. Compared to women with EM, those with CC had 95% lower odds of PTB < 37 weeks [aOR; 0.05, (0.0.14 - 0.19), p < 0.001] and 97% lower risk of early PTB < 34 weeks [aRR; 0.03, (0.01 - 0.15), p < 0.001]. There was no difference in late PTB (34 - 37 weeks) between the groups [aRRR; 0.18, (0.25 - 1.25), p = 0.08] **Table 2.**

Conclusion: This study showed that compared to EM, CC in women with CI $\geq$ 24 weeks reduced the risks of sPTB, prolonged pregnancy latency and reduced NICU admission and severe neonatal complications rates.

Table 1: Comparison of Perinatal Outcomes between Emergency Cerclage and Expectant Management Groups ≥ 24 weeks

Perinatal Outcome	Expectant management	Rescue Cerclage	P value
Small for Gestational age	1 (4.35)	5 (7.69)	0.584

aOR, adjusted odds ratio; CI, confidence interval; aRRR, adjusted relative risk ratio.
[a]Models were adjusted for maternal age, ethnicity, BMI at initial prenatal visit, parity, gestational age at intervention, smoking in pregnancy, alcohol use in pregnancy and illicit drug use in pregnancy.

1001 | Detecting Maternal Mosaicism in Fetal Sex Chromosome Aneuploidy Screening

C.J. Battey[1]; J. Sherry Wang[1]; Kyle Trettin[1]; Ravi M. Patel[1]; Anu Srinivasan[1]; Janani Saikumar[1]; Divya Kushnoor[1]; Heather Labreche[1]; Carly Hammer[1]; Summer Pierson[1]; Manesha Putra[2]; Genevieve Gould[1]; Dale Muzzey[1]
[1]Myriad Genetics, Inc., Salt Lake City, UT; [2]University of Colorado Anschutz Medical Campus, Aurora, CO

4:00 PM - 6:00 PM

Objective: Sex chromosome anomalies (SCA) are a common class of fetal aneuploidy, but cell-free DNA (cfDNA) screening assays have relatively low positive predictive value (PPV) for SCA calls. False positives are caused by factors including statistical error, confined placental mosaicism, and maternal mosaicism. To compare the impact of these factors and improve SCA screening PPV, we developed a new "depth trajectory" method that identifies mosaic maternal aneuploidy by analyzing covariation in read depth and DNA fragment size.

Study Design: We screened 728 prenatal cfDNA samples for fetal SCA with a whole-genome sequencing (WGS) assay and a new targeted sequencing assay. The targeted assay uses *in silico* size selection to measure how chromosome dosage varies with fetal fraction within each sample's sequencing reads. Maternal mosaic loss of X is identified when X chromosome dosage is depressed but increases along with fetal fraction. The cohort included 25 patients screening positive for monosomy X and 36 patients screening positive for other SCAs on the WGS assay. Fetal diagnosis via amniocentesis or postnatal karyotype was obtained for 12 monosomy X screen-positive patients.

Results: 59 of 61 patients screening positive for fetal SCA in the WGS assay were also positive in the targeted assay prior to maternal anomaly calling. PPV of monosomy X calls in the WGS assay was 42% (5/12). One fetal mosaic true positive was not detected and 3 of 7 false positives were identified as maternal anomalies in the targeted assay, improving PPV to 50% (4/8). Remaining false positives had an average 61% degree of mosaicism in the targeted assay, consistent with placental mosaicism.

Conclusion: Depth trajectory analysis successfully identifies maternal X chromosome mosaicism and improves PPV in fetal sex chromosome anomaly screening. We observed high confirmation rates in re-tested samples, suggesting that statistical error is a relatively minor contributor to SCA false positives, which are primarily explained by confined placental mosaicism and maternal mosaicism.

1002 | Incidence of Recurrent Preterm Birth in the US after FDA Withdrawal of 17-OH-Progesterone

Claire H. Packer[1]; Taylor S. Freret[2]; Kaitlyn E. James[3]; Sarah E. Little[2]; Alexander Melamed[3]; Mark A. Clapp[3]
[1]Mass General Brigham, Boston, MA; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]Massachusetts General Hospital, Boston, MA

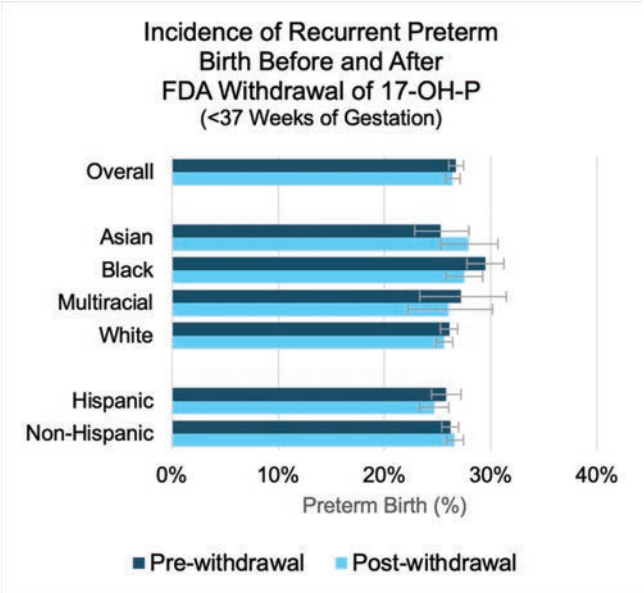
4:00 PM - 6:00 PM

Objective: For >10 years, 17-OH-progesterone (17-OH-P) was prescribed to reduce the risk of recurrent spontaneous preterm birth. In 2023, its FDA approval was withdrawn due to a lack of demonstrated efficacy. The objective of this study was to examine population changes in the incidence of recurrent preterm birth after the FDA withdrawal.

Study Design: We performed a pre-post study using cross-sectional US natality data. Patients with a history of preterm birth and who delivered a singleton, live birth after 20 weeks of gestation were included. FDA withdrawal of approval for 17-OH-P was in April 2023. The pre-period was from 09/2022-03/2023, and the post-period from 09/2023-03/2024; both periods were the same length and comprised the same calendar months. Births from 04/2023-08/2023 were excluded to avoid patients who potentially discontinued 17-OH-P mid-pregnancy. We examined the incidence of recurrent preterm birth < 37 and< 34 weeks of gestation; results were stratified by race and ethnicity and reported for groups with ≥100 individuals in the denominator. Chi-square tests were used for comparison.

Results: There were 16,088 deliveries in the pre-period and 16,534 in the post-period. There were no significant differences in the incidence of preterm birth < 37 weeks (26.7 vs. 26.4%, p = 0.54) or < 34 weeks (6.7 vs 6.7%, p = 1.00) between the pre- and post-periods. When stratified by race, there was no significant increase in preterm births in the post-period among any of the racial and ethnic groups (Figure).

Conclusion: When comparing the periods immediately before and after the FDA withdrawal of its approval for 17-OH-P, there were no apparent national differences in the incidences of recurrent preterm birth overall or among racial and ethnic groups. Future studies using individual patient-level data with more granular details on the etiologies for prior preterm births and accounting for other changes related to recurrent preterm birth management (e.g., vaginal progesterone use) will be important in understanding the population impacts of this major practice change.



1003 | Racial Disparities in Cesarean Deliveries without Trial of Labor: A Population-Based Analysis of Birth Timing

Clarice G. Zhou[1]; Christopher X. Hong[2]; Mariana Masteling[2]; Matthew K. Janssen[3]; Rebecca F. Hamm[4]
[1]New York University Langone Health, New York, NY; [2]University of Michigan, Ann Arbor, MI; [3]University of Pennsylvania, Pittsburgh, PA; [4]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA

4:00 PM - 6:00 PM

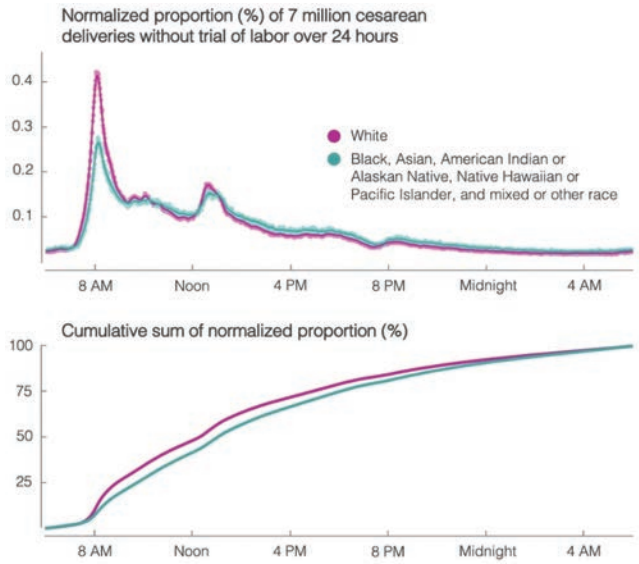
Objective: While racial disparities in obstetrics are multifactorial, differences in resource allocation may contribute to the disparity. Here, we assess racial differences in delivery timing for cesarean deliveries (CD) without a trial of labor (TOL).

Study Design: This retrospective population-based cohort used birth certificate data from the National Vital Statistics System from 2016-2021, which includes birth timing for CD in the US. Since the timing of planned CD may be more susceptible to external systemic influences, this analysis focuses on CD without TOL. We excluded CD with TOL and unknown delivery time. Maternal race was self-identified (White, Black, Asian, American Indian or Alaskan Native, Native Hawaiian or Pacific Islander, or mixed or other race) and categorized as White or Black, Indigenous, and People of Color (BIPOC). The number of CD without TOL at each minute was normalized relative to totals in each racial group to allow for balanced comparison. The cumulative sum in the proportion of CD was calculated starting from 6:00 a.m. Differences in cumulative sum of CD between races were analyzed with the Kolmogorov-Smirnov test.

Results: Among 7,045,802 patients who underwent a CD without TOL, 72% were categorized as White and 26.3% as BIPOC; less than 3% had unknown racial data. For both groups, the highest proportion of CD occurred around 8:00 a.m. followed by a second peak around 12:30 p.m. Differences in the cumulative sum distribution exist between racial groups ($p = 0.01$). The largest difference in the cumulative sum distribution between groups is observed at 10:10 a.m. between White and BIPOC patients; by this

time, CD without TOL occurred for 35% of White patients versus only 28% of BIPOC patients.

Conclusion: This population-based study reveals differences in the timing of CD without TOL between White and BIPOC patients, with White patients more likely to undergo CD earlier in the clinical workday. Future research should assess root causes, and whether disparities in resource allocation contribute to differences in obstetrical outcomes.



1004 | Early Placental Volume as a Biomarker for Maternal Vascular Malperfusion

Claudia J. Tawil[1]; Baris Oguz[2]; Gabriel A. Arenas[2]; Rebecca L. Linn[3]; Jasmine Steele[4]; Ipek Oguz[5]; Nadav Schwartz[1]

[1]University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA; [3]The Children's Hospital of Pennsylvania, Philadelphia, PA; [4]The Children's Hospital of Philadelphia, Philadelphia, PA; [5]Vanderbilt University, Nashville, TN

4:00 PM - 6:00 PM

Objective: Early placental volume (PV) is associated with fetal growth outcomes, but manual segmentation makes it clinically infeasible. Novel automated techniques have made 3D placental biometry more clinically practical; yet, it is unclear whether PV can distinguish constitutionally small fetuses from affected by placental insufficiency. Such a distinction is critical for developing targeted interventions and improving pregnancy outcomes. We sought to explore whether early PV, measured by an automated segmentation tool, is associated with placental pathology.

Study Design: In this prospective, longitudinal cohort study, 3DUS volumes of the placenta were obtained at 11-16 weeks (V1) and 18-24 weeks (V2). Automated segmentation tools developed in our lab were utilized to measure PV, which were normalized to gestational age. Placentas were examined by a trained placental pathologist blinded to the PVs. Outcomes included birth weight (BW), birth weight centile (BW%), placental weight (PW), placental weight z-score, and high grade maternal (MVM) or fetal (FVM) vascular malperfusion on the delivered placenta. Given the sample size, analyses were unadjusted.

Results: 72 subjects had a V1PV and available outcomes, 65 of which also had a V2PV. MVM and FVM was identified in 12.3% (n = 8) and 13.9% (n = 9) of placentas, respectively. V1PV (mean: 6.4±1.8 cc/wk) was significantly correlated with BW (mean: 3144.9±548g; p = 0.007) and BW %ile (mean: 42.8±25.6; p = 0.03). V1PV was significantly smaller in cases with MVM (mean: 5.3 vs 6.9cc, p = 0.039). V2PV (mean: 11.3±2.9 cc/wk) was significantly correlated with PW (mean: 463.7±98g; p = 0.02), PW z-score (mean: –0.5±1.3; p = 0.02), and showed a trend towards association with BW (p = 0.06) and MVM (p = 0.06). **Table**

Conclusion: Novel segmentation tools can measure PV in an automated fashion to generate a biomarker of fetal growth outcomes. Our results demonstrate that early PV may be used to identify placental maldevelopment in pregnancy, where early identification can significantly improve patients' counseling and clinical management.

Statistical significance of various factors associated with V1 and V2PV.

	Birth weight	BW %ile	PW	PW z-score	MVM		FVM	
					With	Without	With	Without
V1PV (cc/wk)	r = 0.32 p = 0.007	r = 0.26 p = 0.03	r = 0.15 p = 0.24	r = 0.08 p = 0.54	5.3	6.9 p = 0.039	5.8	6.6 p = 0.20
V2PV (cc/wk)	r = 0.22 p = 0.06	r = 0.18 p = 0.13	r = 0.3 p = 0.02	r = 0.29 p = 0.02	9.5	11.6 p = 0.06	11.7	11.2 p = 0.68

1005 | FGF2 Interferes with EGF/EGFR Pathway in Trophoblasts

Colleen Sinnott[1]; Olga Grechukhina[2]; Viktoriia Kolesnyk[2]; Yang Yang-Hartwich[2]

[1]Yale University, New Haven, CT; [2]Yale School of Medicine, New Haven, CT

4:00 PM - 6:00 PM

Objective: Trophoblast migration and invasion are critical to establishment of the healthy placenta, and dysregulation of these processes can result in placental disorders including placenta accreta spectrum (PAS) and preeclampsia (PEC) with high morbidity and mortality. We previously identified fibroblast growth factor-2 (FGF2) as a likely regulator of trophoblast migration. Further, we suggested that FGF2 may interact with epidermal growth factor (EGF) pathway, another signaling pathway that plays a key role in placenta biology. Here we aim to better characterize specific effects of FGF2 on EGF-mediated trophoblast function.

Study Design: Using immortalized human trophoblast cells (Sw.71), we performed transwell migration assay with human serum from healthy pregnant patients with and without a selective FGF2 neutralizing antibody. Next, trophoblasts were treated with either EGF alone or a combination of both EGF and FGF after which flow cytometry for surface expression of EGF receptor (EGFR) was performed. Western blot (WB) was then conducted to evaluate total EGFR expression after treatment with FGF2 and EGF individually and in combination.

Results: Blocking FGF2 in serum collected from healthy pregnant patients resulted in suppressed trophoblast migration. (Figure 1). Trophoblast exposure to EGF resulted in decrease in surface EGFR; however, combination treatment with FGF2 and EGF further decreased surface EGFR compared to treatment with EGF alone (Figure 2A). Similarly, EGF, but not FGF2, solo

treatment resulted in decreased total levels of EGFR protein demonstrated by WB (Figure 2B). Combined treatment with FGF2 and EGF resulted in total EGFR expression most similar to EGF treatment alone.

Conclusion: FGF2 is not only critical to trophoblast migration but may also play a role in regulating the EGF/EGFR pathway in trophoblasts. The decreased surface expression of EGFR after co-treatment with both EGF and FGF2 compared to EGF alone suggests that FGF2 may control cell-surface recycling of EGFR, leaving cells less able to respond to EGF signaling.

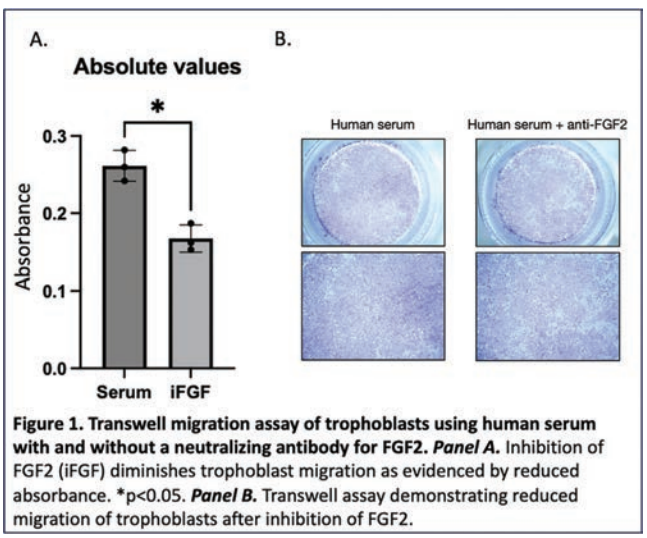

Figure 1. Transwell migration assay of trophoblasts using human serum with and without a neutralizing antibody for FGF2. *Panel A.* Inhibition of FGF2 (iFGF) diminishes trophoblast migration as evidenced by reduced absorbance. *p<0.05. ***Panel B.*** Transwell assay demonstrating reduced migration of trophoblasts after inhibition of FGF2.

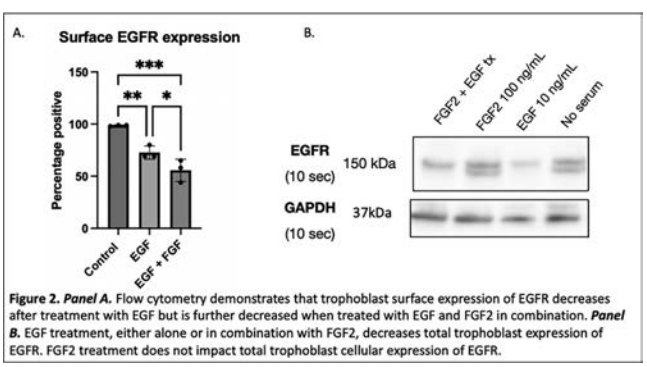

Figure 2. *Panel A.* Flow cytometry demonstrates that trophoblast surface expression of EGFR decreases after treatment with EGF but is further decreased when treated with EGF and FGF2 in combination. ***Panel B.*** EGF treatment, either alone or in combination with FGF2, decreases total trophoblast expression of EGFR. FGF2 treatment does not impact total trophoblast cellular expression of EGFR.

1006 | Equity and Perinatal Urine Drug Toxicology Testing by Hospital Location

Cresta W. Jones[1]; Savannah Maynard[1]; Caroline Brumley[1]; Samantha Considine[2]; Emily Biscaye[1]; Katelyn M. Tessier[3]
[1]*University of Minnesota Medical School, Minneapolis, MN;*
[2]*University of Minnesota Medical Center, Minneapolis, MN;*
[3]*University of Minnesota, Minneapolis, MN*

4:00 PM - 6:00 PM

Objective: To evaluate racial inequities in perinatal urine toxicology via urine drug screen (UDS) by hospital location.

Study Design: A retrospective cohort study was conducted examining data from pregnancy episodes for all live births occurring at three hospitals (urban vs. suburban vs. rural) within a single health system between January 1, 2019, and March 31, 2019. We assessed racial differences in urine toxicology testing via a UDS, as well as testing results. Data were compared by hospital location.

Results: Among 1368 patients across all hospital locations, 7.3% (n = 99) underwent a UDS before delivery, and 15.2% (n = 208) were tested at the time of delivery. There were significant associations between hospital location and testing rates, with the suburban hospital demonstrating the lowest rate compared to the urban and rural hospitals for testing both before delivery admission (1.9% vs 12.8% vs 14.7%, respectively; $p < 0.001$), and at delivery admission (11.9% vs 19.1% vs 18.4%, respectively; $p = 0.001$). There were no significant differences in the rates of UDS with substances detected between the hospital sites regardless of the timing of testing ($p = 0.305$ and $p = 0.386$). There were significant differences between UDS rates by identified patient race, and Black birthing patients were three times as likely as White birthing patients to undergo toxicology testing before delivery (15.4% vs 5.6%, $p < 0.001$) and twice as likely at delivery (25.8% vs 12.3%, $p < 0.001$).

Conclusion: While rates of perinatal substance use across racial groups are similar, Black birthing patients are more likely to undergo urine toxicology evaluation compared to their White birthing counterparts, and this appears to differ by hospital location. Policies and practices of perinatal urine drug testing warrant critical review to limit racial inequities in toxicology testing and to better support patients with perinatal substance use.

1007 | Practice Attitudes and Behaviors for Peripartum Management of Attention Deficit Hyperactivity Disorder (ADHD)

Cresta W. Jones[1]; Bukky Akingbola[2]; Jessica Makori[2]; Anwei Gwan[2]; Connor Demorest[3]; Katelyn M. Tessier[2]
[1]*University of Minnesota Medical School, Minneapolis, MN;*
[2]*University of Minnesota, Minneapolis, MN;* [3]*Masonic Cancer Center, University of Minesota, University of Minnesota/Minneapolis, MN*

4:00 PM - 6:00 PM

Objective: There is no current standard of care for managing attention deficit hyperactivity disorder (ADHD) in pregnancy. This study explores current practice in peripartum ADHD management among healthcare providers within a single academic health system.

Study Design: Prospective Observational - Over a 6 month period (December of 2023 to June of 2024), a 17-item electronic survey was administered to 198 active women's healthcare professionals within a single academic health system.

Results: A total of 75 respondents completed the survey (37.8% response rate). The average years in practice was 13.4 years, and most respondents (95%) had directly cared for a peripartum patient with ADHD. The majority of respondents (78.7%) were unsure if ADHD medications could be safely used during pregnancy/peripartum period. With regards to medication dose prior to attempting pregnancy, most (60%) recommend decreasing to the lowest effective dose, 14.7% recommend no change in medication and 5.3% recommend stopping ADHD medications prior to conception. During pregnancy, 62.7% advised patients to decrease to the lowest effective dose, 17.3% advised patients to discontinue ADHD medications, and only 12% advised patients to stay on their pre-pregnancy medication dose. For patients continuing ADHD medications during pregnancy, 89.3% of providers recommend

changes in obstetric care, including a detailed anatomic survey (62.7%), fetal growth ultrasound surveillance (57.5%), and/or third trimester antepartum surveillance (8%). In the postpartum period, there were significant variations in recommendations for medication treatment while breast/chest feeding.

Conclusion: There is significant variability among healthcare providers' recommendations in the management of perinatal ADHD. We call for a need to align provider behaviors through the development of evidence-based perinatal ADHD guidelines.

1008 | The Impact of Discrimination on Perceived Control Over Birth

Dana R. Canfield[1]; Marni B. Jacobs[2]; Emmanuel Elijah[3]; Karoline Gutierrez[4]; Minhazur R. Sarker[3]; Rachel L. Wiley[3]; Elizabeth Nicole Teal[3]; Cynthia Gyamfi-Bannerman[3]
[1]UC San Diego Health, San Diego, CA; [2]University of California, San Diego Health, San Diego, CA; [3]University of California, San Diego, San Diego, CA; [4]University of Miami, Miami, FL

4:00 PM - 6:00 PM

Objective: While studies have linked patient factors with perceived control over delivery, known as labor agentry, and discrimination to poor maternal outcomes, the impact of discrimination on labor agentry is unknown. We examined the association between discrimination, measured by the Everyday Discrimination Scale (EDS), and labor agentry, measured by the Labor Agentry Scale (LAS) a 29-item Likert-scale response survey in which a higher score corresponds with greater agentry.

Study Design: This a prospective cohort study in which patients were recruited at 27-34 weeks GA from high-risk obstetric clinics and completed surveys on health and lived experience, including the EDS. Following birth, they completed the LAS. The cohort was divided into two groups: those who reported experiencing discrimination (EDS≥1, n = 28, 47.5%) and those who did not (EDS = 0, n = 31, 52.5%). Plausible confounders were assessed (Table 1), and linear regression was used to estimate differences in LAS score based on reported discrimination, controlling for significant variables. Correlation analysis was also performed with EDS as a continuous measure calculated as frequency of reported discrimination.

Results: 59 patients were included. Patients experiencing discrimination were younger and more frequently preferred a non-English language. Mean unadjusted LAS was 166.8 (SD 32.9) for patients who did not experience discrimination and 161.1 (SD 23.2) for those who did. Age and preferred non-English language were included in the final model of discrimination and LAS. None of the factors in our final model were significantly associated with LAS (Table 2). There was a weak but significant negative correlation between EDS score and labor agentry, suggesting as frequency of discrimination increased, labor agentry decreased (ρ = -0.28, p 0.03).

Conclusion: Patients experiencing discrimination had slightly lower labor agentry when controlling for age and preferred language, with a weak but significant relationship noted between discrimination and agentry. Further studies with larger cohorts are needed to further investigate this relationship.

	Do Not Experience Discrimination (EDS=0) (n=28, 47.5%)	Experience Discrimination (EDS ≥1) (n=31, 52.5%)	p-value

1009 | Piperacillin-Tazobactam versus Ceftriaxone as Initial Antibiotic Treatment in 2nd Trimester Pregnancies Complicated by Acute Pyelonephritis

Daniel J. Martingano[1]; Amanda F. Francis Oladipo[2]; Marwah Al-Dulaimi[3]; Sandra Kumwong[4]; Andrea Ouyang[5]; Lauren Cue[6]; Ashley Nguyen[3]; Francis X. Martingano[7]; Shailini Singh[8]; Alexander Ulfers[9]; Mark Rebolos[3]; Kristin Cohen[10]; Donald Morrish[3]; Iffath A. Hoskins[11]
[1]St. John's Episcopal Hospital-South Shore and William Carey University College of Osteopathic Medicine, Far Rockaway, NY; [2]Hackensack University Medical Center, Hackensack, NJ; [3]St. John's Episcopal Hospital-South Shore, Far Rockaway, NY; [4]Touro College of Osteopathic Medicine-Harlem Campus, New York, NY; [5]William Carey University, Hattiesburg, MS; [6]Rutgers University and the Jersey City Medical Center, Jersey City, NJ; [7]NYU Grossman School of Medicine - NYU Brooklyn, New York, NY; [8]AtlantiCare Regional Medical Center, Pamona, NJ; [9]Walter Reed National Military Medical Center, Bethesda, MD; [10]RWJBarnabas Health - Trinitas Regional Medical Center, Elizabeth, NJ; [11]Albert Einstein College of Medicine - Montefiore Medical Center, New York, NY

4:00 PM - 6:00 PM

Objective: Acute pyelonephritis is one of the most common indications for antepartum hospitalization, yet the optimal antibacterial regimen for the treatment of acute pyelonephritis in pregnancy remains undefined. This study sought compare the effectiveness of piperacillin-tazobactam versus ceftriaxone as the initial antibiotic treatment in 2nd trimester pregnancies complicated by acute pyelonephritis.

Study Design: We conducted a multi-center, prospective observational study from 7/2022 to 7/2024 and included all pregnant women diagnosed with acute pyelonephritis in the 2nd trimester receiving initial antibiotic treatment with either piperacillin-tazobactam or ceftriaxone. Choice of regimen was determined by physician preference. Pyelonephritis diagnostic criteria included

presence of fever of 38.0°C, costovertebral angle tenderness, and urinalysis suggestive of urinary tract infection. Primary outcomes included inpatient length of stay (LOS), adult respiratory distress syndrome (ARDS), urosepsis, intensive care unit (ICU) admission and preterm labor. Patients were excluded if they received additional antibiotics before admission, had preexisting renal disease, or had an allergy to either medication.

Results: The study included 404 patients, with 235 receiving piperacillin-tazobactam and 169 receiving ceftriaxone. Baseline demographic factors were not significantly different. The causative uropathogen was not significantly different between treatment groups. Patients receiving piperacillin-tazobactam had lower rates of ICU admissions (5.1% v. 10.7% p = 0.003) and a shorter LOS (2.6 v. 3.1 days, p = 0.041) with a 44% (RR = 0.56, 95% CI 0.31-0.71, p = 0.004) and 17% (RR = 0.83, 95% CI 0.79-0.95, p = 0.001) decreased risk in confounder adjusted models, respectively. Patients receiving ceftriaxone had higher rates of ARDS (2.96% v. 0.85%, p< 0.001) with an 18% increased risk in adjusted models (RR = 1.18, 95%CI 1.10-1.32, p = 0.005).

Conclusion: Piperacillin-tazobactam is a reasonable choice for initial antibiotic treatment for 2nd trimester pregnancies complicated by acute pyelonephritis.

1010 | Adequacy of Chorionic Villus Samples in one- vs. Two-Pass Procedures

Daniela A. Febres-Cordero[1]; Rafaela Germano Toledo[1]; Julia Sroda Agudogo[1]; Annliz Macharia[1]; Anna M. Modest[1]; Yinka Oyelese[2]; Barbara O'Brien[1]

[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA

4:00 PM - 6:00 PM

Objective: At our center, when chorionic villus sampling (CVS) is performed, the initial pass sample adequacy is assessed immediately by an on-site cytogenetic lab. If the initial sample is inadequate, a second pass is done. Thus, a two-pass CVS procedure is a surrogate for specimen adequacy. CVS adequacy may be affected by body mass index (BMI), gestational age (GA), procedure route (transvaginal vs transabdominal), and provider experience. This study assesses risk factors for inadequate samples by comparing one-pass and two-pass CVS procedures.

Study Design: Retrospective cohort study of patients who underwent CVS at a single tertiary center in 2019-2023. Data was obtained via medical record review. Cases with an unknown number of placental entries were excluded. Comparisons were made between two groups: adequate villi (one-pass) and initially inadequate villi (two-pass). Factors compared were BMI, GA, genetic abnormality presence, placental location, route, needle size, and provider experience. Chi-square, Fisher's test for categorical data, and Wilcoxon rank sum for continuous data were used for analysis.

Results: Of the 408 CVS procedures that met inclusion criteria, 84% were successful after one pass. Maternal BMI was significantly higher in the two-pass than in the one-pass group (27.9 and 25.4, respectively, $P = 0.02$). There was no difference in GA, placental location, presence of genetic abnormalities, and number of fetuses (Table 1). Fellow years of experience was lower in the two-pass group (median 2.0 years, IQR 1.0-2.0) than the one-pass one (IQR 2.0-3.0). There was no difference across CVS route, needle size, or attending years of experience (Table 2).

Conclusion: Higher maternal BMI and fewer years of fellow experience were associated with a two-pass procedure, indicating sample inadequacy. Route of procedure, placental location, and genetic abnormalities were not associated with requiring a second pass. Rate of complications was low in both groups. This suggests that when on-site cytogenetics is unavailable, two-pass procedures should be considered for high maternal BMI and inexperienced operators.

Table 1. Patient and pregnancy characteristics with one-pass vs two-pass chorionic villous sampling procedure

Variables	Total (N=408)	One-Pass (N=342 (83.8%))	Two-Pass (N=66(19.3%))	*P-Value*

1011 | Low Dose Aspirin for Preeclampsia Risk Reduction: Do Patients Actually Take it?

Daniella Rogerson[1]; Marni B. Jacobs[2]; Omar Mesina[1]; Carolina Diaz Luévano[1]; Ayelet Ruppin-Pham[1]; Maryam Tarsa[3]; Ukachi N. Emeruwa[4]; Cynthia Gyamfi-Bannerman[4]; Elizabeth Nicole Teal[4]
[1]University of California San Diego Health, San Diego, CA; [2]University of California, San Diego Health, San Diego, CA; [3]University of California San Diego, San Diego, CA; [4]University of California, San Diego, San Diego, CA

4:00 PM - 6:00 PM

Objective: ACOG, SMFM, and USPSTF recommend low dose aspirin (LDA) in patients at high risk for preeclampsia (PreE). While there is increasing attention to LDA prescription, little is known about LDA uptake and adherence. This study examines LDA uptake and adherence among patients prescribed.

Study Design: This is a retrospective cohort study of patients who delivered at an academic medical center from 9/2022 to 7/2024 and were prescribed or recommended LDA for PreE risk reduction. LDA prescription/recommendation was ascertained through the electronic health record and chart review by a quality improvement nurse. Patients not prescribed LDA or for whom prescribing data was unavailable were excluded. The primary outcome was rate of LDA uptake. Secondary outcomes included LDA adherence and associations between sociodemographic characteristics and uptake. Chi-square and Student's t-tests were used to compare baseline characteristics and multivariable logistic regression determined strength of association.

Results: Among 1,715 patients prescribed LDA, 1,213 (70%) answered questions about LDA uptake and adherence at delivery admission: 953 (79%) reported taking LDA and 260 (21%) did not. Among those who took LDA, 307 (32%) had adherence data available: 246 (80%) reported taking LDA every day, 43 (14%) missed some doses, and 18 (6%) missed many doses. Patients who took LDA were older and had higher BMI than those who did not ($p > 0.05$, Table 1). Compared to White patients, patients who identified as Black and/or African American had lower odds of LDA uptake in an unadjusted analysis and when adjusting for maternal age and BMI (OR 0.55, 95% CI 0.34–0.87 and aOR 0.54, 95% CI 0.30–0.96, Table 2). There was no association between language or insurance and uptake.

Conclusion: Most patients prescribed LDA for PreE risk reduction took the medication and reported good adherence. However, Black patients indicated lower LDA uptake than White patients. Further studies examining LDA uptake/adherence are needed to understand the root causes of these disparities and identify solutions.

1012 | Induction Versus Expectant Management in Multiparous Low-Risk Women: Single Institution Impact of the ARRIVE Trial

Kathleen M. Pulice[1]; Shekinah Dosunmu[2]; Joanne N. Quiñones[2]; Meredith Rochon[2]; Amanda B. Flicker[2]; Travis Dayon[2]; George Angelakakis[3]; Janae Cornwall[3]; Ahsan Usmani[3]; Danielle Durie[2]
[1]Lehigh Valley Health Network, Macungie, PA; [2]Lehigh Valley Health Network, Allentown, PA; [3]University of South Florida Morsani College of Medicine, SELECT Program, Tampa, FL

4:00 PM - 6:00 PM

Objective: The ARRIVE trial found that elective induction of labor (eIOL) at 39 weeks in nulliparous persons compared to expectant management was associated with a lower rate of cesarean delivery (CD). The benefit of eIOL in a multiparous population is less certain. Our goal was to evaluate the performance of low-risk multiparous women undergoing eIOL at 39 weeks.

Study Design: Retrospective cohort study of all multiparous pregnant persons admitted for delivery ≥ 39w0d at a single academic community institution between 3/1/20-3/1/22, when we started offering eIOL. Those with singleton low risk pregnancies, without any clinical indication for delivery prior to 40w5d, were included. Maternal and neonatal outcomes of persons undergoing eIOL between 39w0d-39w4d were compared to women expectantly managed. The primary outcome was rate of CD. Secondary outcomes included select maternal outcomes and composite neonatal outcome (neonatal death and/or serious morbidity).

Results: 1141 multiparous persons with low-risk singleton gestations were identified, with 297 (26%) undergoing eIOL and 844 (74%) expectantly managed. Those undergoing eIOL delivered earlier (39.2 vs 40.0, p< 0.001) and were more likely to be obese (34.4 vs 23.7%, p< 0.001) and have diet controlled gestational diabetes (10.1 vs 6.4%, p = 0.04) (Table). The CD rate was similar between the eIOL and expectant management groups (2.7% vs 2.0%, p = 0.49). Elective IOL was associated with longer maternal but similar newborn lengths of stay compared to expectant management. The composite neonatal outcome occurred in significantly fewer neonates in the eIOL group compared to the expectant management group (4.0% vs 8.3%, p = 0.02), primarily due to decreased need for respiratory support in the eIOL group (1.7% vs. 4.5%, p = 0.03).

Conclusion: In our cohort of low-risk multiparous pregnant persons, eIOL at 39w0d-39w4d did not decrease CD rate but did decrease composite neonatal risk. Like the findings of ARRIVE trial in a nulliparous population, our findings suggest that eIOL at term for multiparous patients is safe and may have benefit.

1013 | The Association Between First Trimester Serum Creatinine and Pregnancy Outcomes in Patients with Chronic Hypertension

Danielle N. Olson[1]; Alyssa Wolfinger[2]; Kelly S. Gibson[2]
[1]MetroHealth Medical Center / Case Western Reserve University, Cleveland Heights, OH; [2]MetroHealth Medical Center / Case Western Reserve University, Cleveland, OH

4:00 PM - 6:00 PM

Objective: Pre-existing hypertension (HTN) and renal disease are known risk factors for adverse pregnancy outcomes, including pre-eclampsia (PreE). This study aimed to assess whether an elevated first trimester serum creatinine (sCr) in patients with chronic HTN, in the absence of pre-existing kidney disease, is associated with an increased risk of PreE.

Study Design: This was a retrospective cohort study at a single tertiary center from 1/2018 to 12/2022. Inclusion criteria were patients with HTN with a first trimester sCr result. Exclusion criteria were pre-existing kidney disease, significant proteinuria in the first trimester, acute illness during sCr evaluation, and conditions known to increase the risk for adverse pregnancy outcomes including pregestational diabetes, autoimmune disease, multiple gestation, history of renal surgery, transplantation, donation, and isolated renal agenesis. An elevated sCr was defined as >0.7 mg/dL. The primary outcome was the diagnosis of PreE. Secondary outcomes included assessment of first trimester sCr in patients diagnosed with PreE, gestational age at PreE diagnosis and at delivery, small for gestational age (SGA), and gestational diabetes (GDM). Wilcoxon rank sum tests and Chi-squared tests were used.

Results: 226 patients with normal sCr and 76 with elevated sCr were identified. 82/226 (36%) in the normal sCr group developed PreE, compared to 36/76 (47%) in the elevated sCr group (p = 0.11). First trimester sCr as a continuous variable was associated with an increased incidence of PreE diagnosis (p = 0.03). Gestational age at PreE diagnosis (35.2±3.4 v 35.1±3.6w, p = 0.845), gestational age at delivery (37.3±2.7 v 36.7±3.1w p = 0.045), SGA (27 v 32% p = 0.534), and GDM (15 v 20% p = 0.494) were not different between groups.

Conclusion: In the population studied, a first trimester sCr >0.7 mg/dL was not associated with an increased incidence of PreE, though this was associated with earlier gestational age at delivery. Patients who developed PreE had higher sCr in the first trimester on average than those who did not develop PreE.

Outcome	Normal serum creatinine, n = 226	Elevated serum creatinine, n = 76	p-value
Preeclampsia	82 (36%)	36 (45%)	0.115
Preeclampsia, severe	73 (32%)	34 (45%)	0.068

1014 | Adverse Perinatal Outcomes Based on Gestational Surrogacy Status in a Large Integrated Healthcare System

Fagen Xie[1]; Theresa M. Im[1]; Daniella Park[1]; Vicki Y. Chiu[1]; Michael J. Fassett[2]; Darios Getahun[1]
[1]Kaiser Permanente Southern California, Department of Research & Evaluation, Kaiser Permanente Southern California/Pasadena, CA; [2]Kaiser Permanente West Los Angeles Medical Center, Department of Obstetrics & Gynecology, Kaiser Permanente West Los Angeles Medical Center/Los Angeles, CA

4:00 PM - 6:00 PM

Objective: To examine adverse perinatal outcomes by gestational surrogacy status in a large integrated healthcare system in the United States.

Study Design: We performed a retrospective cohort study among pregnant individuals receiving obstetrical care at Kaiser Permanente (KP) Southern California (01/01/2008–12/31/2023). Unstructured clinical notes abstracted from electronic health records were used to determine surrogate pregnancy status via natural language processing (NLP) validated by manual chart reviews. Births at < 20 weeks gestation were excluded from all analyses. Adjusted risk ratios (aRR) and 95% confidence intervals (CI) derived from robust Poisson regression described the associations.

Results: Among 636,300 pregnancies during the study period, 1,109 (0.17%) were identified as surrogate pregnancies. Compared to those with non-surrogate pregnancy, people with gestational surrogacy were more likely to be older (32.4% versus 19.4%), non-Hispanic white (39.0% versus 23.8%), have privately funded KP membership (19.8% versus 7.6%), and have multiple gestations (15.8% versus 1.6%). They were also less likely to smoke (0.7% versus 2.4%) and consume alcohol (19.0% versus 27.1%) during pregnancy. Gestational surrogacy was associated with significantly increased risk of placenta previa (aRR: 1.74, 95% CI: 1.44-2.10), placental abruption (aRR: 2.25, 95% CI: 1.45-3.50) and preterm birth (aRR: 1.27, 95% CI: 1.13-1.43) while with significantly decreased risk of small for gestational age/intrauterine growth restriction (aRR: 0.80, 95% CI: 0.69-0.93), premature rupture of membranes (aRR: 0.72, 95% CI: 0.53-0.98), gestational diabetes (aRR: 0.84, 95% CI: 0.72-0.98) and chorioamnionitis (aRR: 0.58, 95% CI: 0.40-0.86) (Table).

Conclusion: This study successfully leveraged unstructured data to identify surrogate pregnancies via NLP in a large integrated healthcare system. Placenta previa, placental abruption, and preterm birth were found to be associated with gestational surrogate pregnancy. Identifying these risk factors can provide empirical evidence for predicting and preventing adverse perinatal outcomes.

Table: Association between gestational surrogacy status and adverse pregnancy outcomes

Adverse perinatal outcomes	Gestational surrogacy status: No N=635,191 (%)	Gestational surrogacy status: Yes N=1,109 (%)	[a]Adjusted Risk Ratio (95% Confidence Interval)	[b]P-value

SGA: Small for gestational age; IUGR: Intrauterine growth restriction
[a]Adjustments were made for maternal age, race/ethnicity, smoking during pregnancy, alcohol during pregnancy, pre-pregnancy body mass index, multi-gestation, and insurance type.
[b]P-values were from multivariable models used to estimate adjusted risk ratios.
[c]Applies only to live birth pregnancies.

1016 | How to Efficiently Recruit Participants in a Perinatal Cohort Study; CAN-B Cohort Strategies/Lessons Learned

Dhyana Kpegba[1]; Virginie Gillet[2]; Virginie Bouchard[2]; Claudia Lugo-Candelas[3]; Jonathan Posner[4]; Annie Ouellet[2]
[1]University of Sherbrooke, Sherbrooke, PQ; [2]Université de Sherbrooke, Sherbrooke, PQ; [3]Columbia University, New York, NY; [4]Duke University, Durham, NC

4:00 PM - 6:00 PM

Objective: Recruitment processes in perinatal cohort remain challenging, particularly when a specific population such as cannabis consumers is involved. The CAN-B study aims to determine the impact of prenatal cannabis exposure on fetal brain and infant neurodevelopment with longitudinal follow-up of mother/infant from pregnancy until 2y post-natal. Here we share our experience in finding the best recruitment strategy to meet our enrollment objective.

Study Design: From May 2022 to May 2024, at the routine 1st trimester scan at the obstetrical ultrasound unit of Sherbrooke University Hospital Center (CHUS), 4 recruitment strategies were successively tried: 1) study flyer given by care providers (May-September 2022), 2) by phone (October-November 2022), 3) study flyer given by care providers or part time in-person presentation of

the study by research team (December 2022-May 2023) and 4) full time in-person presentation of the study by research team (June 2023 to May 2024). Interest and enrollment rate were compared.
Results: 112 pregnant women were enrolled (71 cannabis users/41 controls). Strategy 4 triggered the highest basic interest to participate in a clinical research compared to the other strategies (87% vs < 64%) and yielded the highest enrollment rate (80%) compared to strategies 1(67%), 2 (40%) and 3 (70%). Ultimately, the last strategy with full time direct personalized approach allowed us to double our monthly enrollment rate of cannabis users. Same strategies performances were observed for the recruitment of controls.
Conclusion: Recruitment of cannabis users in the CAN-B cohort showed that low-cost passive strategies (e.g. flyers) or relying only on care providers appeared to be much less efficient and not cost-effective. Although costly, direct personal contact by research professional integrated into routine care is the best strategy to prioritize for recruiting pregnant women. This experience provides useful information for clinical researchers in designing perinatal cohorts.

1017 | Practice Patterns in the Administration of Late Preterm Antenatal Corticosteroids Among Twin Gestations

Diana S. Abbas[1]; Dana S. Berger[1]; Lindsay N. Marty[1]; Kate Tolleson[1]; Meghana A. Limaye[2]; Justin S. Brandt[2]
[1]NYU Grossman School of Medicine, New York, NY; [2]NYU Langone Health, New York, NY

4:00 PM - 6:00 PM
Objective: Predicting preterm delivery is challenging, especially among twin pregnancies. We sought to evaluate the odds of delivering twin pregnancies within 2-7 days of antenatal corticosteroid (ACS) administration in the late preterm period (optimally timed), by delivery indication.
Study Design: This is a retrospective cohort study of twin pregnancies at risk for late preterm delivery (Jan 2013-Dec 2022) performed at a large tertiary care health system. Patients were included if they had non-anomalous twin gestations and received at least one dose of ACS in the late preterm period (34 0/7- 36 6/7 weeks). They were excluded if they received ACS previously or had pre-gestational diabetes. The cohort was stratified into two exposure groups: patients at risk for spontaneous preterm birth (sPTB; preterm labor or preterm pre-labor rupture of membranes) and patients at risk for clinician initiated late PTB (i.e., hypertensive disorders of pregnancy). The primary outcome was optimally timed ACS administration. Secondary outcomes included median time from ACS administration to delivery, delivery at < 2 days and > 7 days, and PTB. Multivariable logistic regression was used to calculate odds ratios (aORs) of the primary and secondary outcomes, adjusted for potential confounders.
Results: Of 166 eligible patients, 30 (18.1%) delivered within 2-7 days. 86 (51.8%) were at risk for sPTB, and 80 (48.2%) were at risk for a clinician initiated late PTB. Group demographics are described in Table 1. Compared to patients at risk for sPTB, those with a clinician initiated late PTB were more likely to have optimally timed administration (4.6% vs 32.5%; aOR 9.2, 95% CI 3.2, 33. 9). Patients at risk for sPTB were more likely to deliver < 2 days (aOR 0.19, 95% CI 0.08, 0.42), with a shorter latency to delivery (7.0 vs 45.7 hours) (Table 2).
Conclusion: In this cohort of twin gestations at risk for late PTB, those at risk for clinician initiated late PTB were more likely to deliver within the optimal time period compared to those at risk for sPTB. Further study is warranted to evaluate factors associated with delivery timing.

Table 1
Demographics and Delivery Indication by Exposure Group

Characteristic	At risk for spontaneous late preterm birth (n=86)	At risk for clinician initiated late preterm birth (n=80)
Maternal Age, years	33 (29 - 36)	33 (30 - 36)

1018 | Risk for Adverse Perinatal Outcomes following Induction of Labor in Patients with Class III Obesity

Easha Patel[1]; Kirat Sandhu[1]; Cara D. Dolin[1]; Stacey Ehrenberg[1]; Maeve Hopkins[1]; Adina R. Kern-Goldberger[2]
[1]Cleveland Clinic Foundation, Cleveland, OH; [2]Cleveland Clinic Lerner College of Medicine, Cleveland, OH

4:00 PM - 6:00 PM

Objective: Maternal obesity is a known risk factor for adverse maternal and perinatal outcomes. This study evaluates risk for these pregnancy complications among patients with class 3 obesity undergoing induction of labor (IOL).

Study Design: This is a retrospective cohort study of nulliparous, singleton deliveries with BMI $\geq$ 40 following induction of labor $\geq$ 20 weeks at a multi-hospital academic health system from 1/1/2022-6/30/2024. The primary outcome was unplanned cesarean and secondary outcomes included severe maternal morbidity (SMM) without transfusion, postpartum hemorrhage, postpartum infection, postpartum length of stay $\geq$ 5 days, maternal readmission, and NICU admission. Maternal clinical characteristics and outcomes were extracted from the medical record and compared in univariable analyses. The association between class 3 obesity and primary and secondary outcomes was evaluated using a logistic regression model based on significance from univariable analyses.

Results: 6,533 nulliparous patients undergoing IOL were included, 3.4% of whom had class 3 obesity. Numerous comorbidities and outcomes were different based on class 3 obesity status, including significantly higher rates of pregestational and gestational diabetes and chronic and gestational hypertension, but not severe preeclampsia (Table 1). Unadjusted incidence of NICU admission was twofold higher for patients with class 3 obesity (16.8 v. 8.4%, $p < 0.01$). Adjusted analysis demonstrated significantly increased odds of cesarean in nulliparous patients undergoing IOL with class 3 obesity compared to those without (aOR 1.97, 95% CI 1.51–2.56, $p < 0.01$), but for none of the secondary outcomes other than hemorrhage, which had significantly lower odds in class 3 obesity (Table 2).

Conclusion: Nulliparous patients with class 3 obesity undergoing IOL have significantly higher risk of cesarean than those with lower BMI, but not for other adverse outcomes. Further study of predictors of successful vaginal delivery for patients with class 3 obesity is important.

Table 1. Demographics, Clinical Characteristics, and Obstetric Outcomes by Class 3 Obesity Status among Nulliparous Patients with Singleton Pregnancies undergoing Induction of Labor

	No Class 3 Obesity *N = 6,313*	Class 3 Obesity *N = 220*	P-value
Maternal age (median, IQR)	29 (25, 32)	29.5 (26, 33)	0.02

Table 2. Adjusted Odds of Primary and Secondary Outcomes in Patients with Class 3 Obesity Undergoing Induction of Labor

	Adjusted OR*	95% Confidence Interval	P Value
Cesarean delivery	1.97	1.51 – 2.56	< 0.01
Severe maternal morbidity without transfusion	1.22	0.67 – 2.22	0.52
Postpartum hemorrhage♦	0.47	0.30 – 0.74	< 0.01
Postpartum infection◇	1.81	0.70 – 4.72	0.22
Postpartum length of stay ≥ 5 days	0.83	0.34 – 2.02	0.68
Maternal readmission within 42 days	1.07	0.50 – 2.27	0.86
NICU admission	1.37	0.95 – 1.98	0.09

*Model adjusted for maternal race as a proxy for structural racism, chronic hypertension, gestational hypertension, severe preeclampsia, gestational and pre-gestational diabetes, modified OBCMI excluding BMI/hypertensive disorders/diabetes, gestational age, and need for cervical ripening
♦Defined as quantitative blood loss > 1000 mL.
◇Defined based on ICD-10 codes for postpartum infection and endometritis.

1019 | Mediastinal Shift Angle and its Association with Perinatal Mortality and Lung Volumes in CDH Fetuses

Edgar A. Hernandez-Andrade[1]; Donatella Gerulewicz Vannini[2]; Katrina S. Hughes[3]; Sami Backley[4]; Jerrie Refuerzo[1]; Jimmy Espinoza[4]; Eric P. Bergh[5]; Percy N. Pacora-Portella[6]; Gustavo Vilchez[7]; Ramesha Papanna[1]; Anthony Johnson[8]

[1]McGovern Medical School at UTHealth Houston, Houston, TX; [2]University of Texas Health Science Center in Houston, McGovern Medical School, Houston, TX; [3]McGovern Medical School. UThealth Houston, Houston, TX; [4]Division of Fetal Intervention, Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern Medical School at UTHealth Houston, Houston, TX; [5]UT Health, Houston, TX; [6]Division of Fetal Intervention, Dpt Obstetrics,Gynecol and Reprod Sciences, McGovern Medical School at UTHealth Houston, Houston, TX; [7]UTHealth Houston, Houston, TX; [8]McGovern Medical School University of Texas Health Science Center at Houston (UThealth), Houston, TX

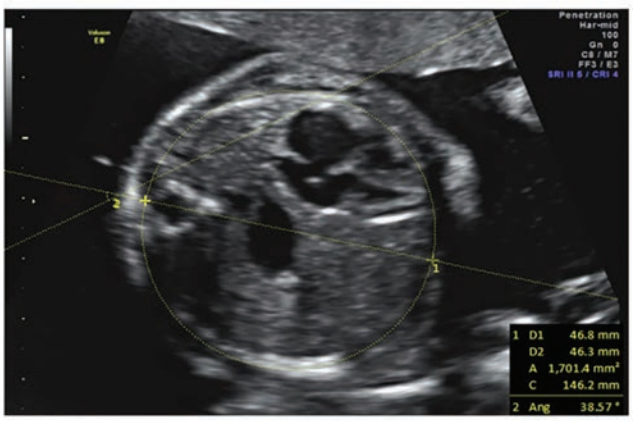
4:00 PM - 6:00 PM

Objective: The mediastinal shift angle (MSA) has been proposed as a potentially useful marker for the identification of CDH fetuses at risk of perinatal death. We aimed to evaluate the predictive performance of MSA for perinatal mortality in fetuses with isolated left CDH, particularly among those considered as mild and moderate with an O/E LHR (observed/expected lung-to-head ratio) >25%, and its correlation with other metrics of CDH severity.

Study Design: MSA was measured in a cross-sectional image of the fetal thorax in 84 fetuses with left CDH. MSA was obtained from two lines starting from a common point in the skin at the midline of the back of the spine, the first line dividing the thorax into two halves, and a second line directed to the lateral border of the right atrium (Fig 1). The MSA becomes wider as the right atrium is displaced towards the right side of the thorax. Additionally, the O/E LHR and MRI assessment of O/E total fetal lung volume (TFLV), and percentage of liver herniation (%LH) were evaluated. ROC analysis, prediction, and association with perinatal mortality and correlations with the mentioned predictors were evaluated

Results: Perinatal mortality was 31.3% (26/83). The areas under the ROC curve for perinatal mortality for MSA and O/E LHR were 0.694 and 0.753, respectively ($p = 0.2$). MSA best cut-off value was 35° with 77% sensitivity, and 38% 1-specificity; OR 6.68 (95% CI 2.2-21.3; $p < 0.001$), adjusted aOR 8.9 (95% CI 1.2-59.7; $p = 0.02$). Among fetuses with O/E LHR > 25% ($n = 60$) mortality was 21% ($n = 13$), MSA $\geq$ 35° showed an AUROC = 0.691 with 75% sensitivity and 36% 1-specificity, aOR 5.29 (1.47-19.01; $p = 0.01$). There was

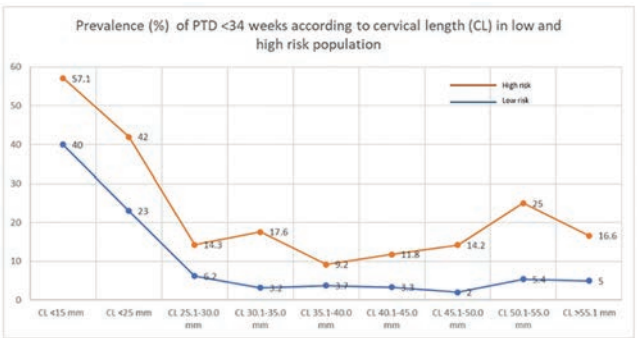
a significant correlation between MSA and O/E LHR (-0.48, p < 0.001), O/E TFLV (-0.36, p = 0.005), and %LH (0.43, p = 0.001).
Conclusion: The MSA angle is a technically simple and feasible metric to evaluate severity and risks for perinatal mortality in left-sided CDH cases. An MSA ≥ 35° can identify 77% of cases at increased risk of perinatal mortality. The prediction performance is similar among fetuses with moderate or mild CDH



1020 | Risk of Spontaneous PTB < 34 weeks Among Women with Mid-Trimester Cervical Length >25 mm

Edgar A. Hernandez-Andrade[1]; Donatella Gerulewicz Vannini[2]; Eleazar E. Soto[1]; Sean C. Blackwell[1]
[1]McGovern Medical School at UTHealth Houston, Houston, TX; [2]University of Texas Health Science Center in Houston, McGovern Medical School, Houston, TX

4:00 PM - 6:00 PM
Objective: There is a general assumption that the longer the cervix the lower the rate of spontaneous preterm birth (SPTB). This study aimed to test this hypothesis in low-risk and high-risk pregnant women with normal cervical length.
Study Design: Transvaginal cervical length (TVCL) was measured in 3,376 singleton pregnancies with no fetal anomalies at 17-24 weeks of gestation. Patients were grouped as low (LR) and high risk (HR) based on history of SPTB. TVCL measurements were analyzed as < 15 mm and < 25 mm, and then in groups of 5 mm from 25- 55 mm. SPTB was considered as ≤ 34 weeks of gestation not due to maternal or fetal indication such as placenta accreta, preeclampsia, or fetal growth restriction. Differences in the prevalence of SPTB among the CL groups and between LR and HR patients were evaluated.
Results: 2,863 (84.9%) patients were considered LR, and 513 (15.1%) HR. Short cervix (≤ 25 mm) was found in 3.0% of women (n = 103; LR n = 82 (2.8%); HR n = 21 (4.1%)). Prevalence of SPTB was 6.6% (n = 189; LR 4.0% n = 115, HR 14.4% n = 74; p< 0.001). Figure 1 shows the prevalence of SPTB ≤ 34 weeks according to the TVCL groups in LR and HR patients. The prevalence of SPTB was significantly higher in HR patients at any TVCL group than for LR patients. Among LR women, the risk of SPTB did not significantly change when TVCL was ≥ 30 mm, yet LR patients with TVCL between 25.1 and 30.0 mm had a higher risk of SPTB ≤ 34 weeks as compared to those with TVCL > 30.1 mm (p = 0.02). In HR patients the prevalence of SPTB did not significantly change when TVLC was >25 mm.
Conclusion: In our population, the risk of SPTB ≤ 34 weeks does not substantively increase once TVCL ≥ 30 mm for LR women and once > 25 mm in HR women. HR women had almost 3 times higher rate of SPTB than LR patients at any TVCL cut-off.



1021 | Are Standard Video Sweeps During Fetal Ultrasound Examination more Effective for Cardiac Screening?

Elena D'Alberti[1]; Olga Patey[2]; Lawrence Impey[2]; Christos Ioannou[2]; Angelo Cavallaro[2]; Aris T. Papageorghiou[2]
[1]Università di Roma Sapienza, Roma, Lazio; [2]University of Oxford, Oxford, England

4:00 PM - 6:00 PM
Objective: To compare workflow properties of standardized ultrasound video clips performed as sweeps from the four-chamber [4C] view to the three-vessel-trachea [3VT] view, to the still images and videos acquired during the routine fetal cardiac screening (FCS).
Study Design: An observational study was conducted at the John Radcliffe Hospital, Oxford. Singleton fetuses with normal cardiac anatomy at the routine 18^{+0} to 23^{+0} weeks anomaly scan were included. The available stored grey-scale images, videos and sweeps were extracted from scans performed by seven sonographers. We evaluated the number of records collected per fetus, time spent for data acquisition and the computer memory needed for storing these, comparing FCS and standardized sweeps. For the former, the order of view acquisition and the prevalence of cardiac workflow interrupted by extra-cardiac planes was also assessed.
Results: A total of 100 studies were included. FCS included solely still images in 17% of cases, but in 83% videos were used to complete cardiac assessment, mostly cine-4C alone or 4C and left ventricular outflow tract (LVOT) views. The mean number of images or videos in the FCS group were 10 ± 3, compared to 2 ± 1 in standardized sweeps. In 47% of cases, FCS data-acquisition was interrupted by extra-cardiac records, with a median amount of time spent in heart examination of 285 seconds (interquartile range (IQR) 94-726), compared to 4 seconds (IQR 3-8) needed to perform sweeps. Median memory required to store FCS data and sweeps were 167 MB (IQR 60-257) and 123 MB (IQR 76-165), respectively.
Conclusion: Standardized cardiac sweeps represented a more effective way to acquire and store data compared to the FCS; less time was spent on image acquisition, which was not interrupted by extra-cardiac views, and lower storage memory was required. Further studies are needed to assess the two methods, especially in the presence of fetal congenital heart defects.

1022 | Optimizing Timing of Intravenous Iron Therapy for Improved Outcomes in Pregnant Women with Iron-Deficiency Anemia

Ellen M. Murrin[1]; Olivia LeBeau[2]; Lillian Singer[2]; Mark Kassab[2]; Peyton Kalan[2]; McKenna Stidham[3]; Scott Sullivan[2]; G. Larry Maxwell[2]; George R. Saade[4]; Antonio F. Saad[5]
[1]Inova Fairfax Medical Campus, Falls Church, VA; [2]Inova Fairfax Medical Campus, Fairfax, VA; [3]University of Virginia College of Medicine, Charlottesville, VA; [4]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [5]Inova Health, Falls Church, VA

4:00 PM - 6:00 PM

Objective: To evaluate the efficacy and timing of intravenous (IV) iron therapy in improving hemoglobin (Hgb) levels and maternal and neonatal outcomes in pregnant women with iron-deficiency anemia (IDA).

Study Design: A retrospective cohort study was conducted on pregnant women with IDA who received outpatient IV iron therapy from January 2017- June 2024. Patients were divided into those who received their last IV iron dose >10 days (N = 331) or < 10 days (N = 82) before delivery. Primary outcomes included changes in Hgb levels, maternal composite outcomes (including postpartum hemorrhage and blood transfusion), and neonatal outcomes (such as NICU admission and low birth weight).

Results: Demographics and characteristics did not differ between groups. The type of IV iron used was primarily iron sucrose (>86.31%). The >10 days group showed a greater increase in Hgb levels post-infusion, with a median increase of 2.5 g/dL compared to 1.8 g/dL in the < 10 days group (p< 0.001). The maternal composite outcome rate was significantly lower in the >10 days group (7.14% vs. 14.63%, p = 0.03). Neonatal outcomes, including NICU admissions (7.46% vs. 8.54%, p = 0.7) and low birth weight (3.97% vs. 1.61%, p = 0.4), did not differ between the groups.

Conclusion: IV iron therapy improves hemoglobin levels in antenatal IDA. Administering the last dose of IV iron more than 10 days before delivery is associated with better maternal outcomes, suggesting that earlier treatment may reduce the risk of adverse pregnancy outcomes. Further studies are needed to refine treatment protocols and timing of administration to maximize benefits.

Table 1: Maternal and neonatal outcomes in women receiving last IV iron transfusion >10 days vs <10 days from delivery

Outcome	>10 days from delivery	<10 days from delivery	p-value
Hypertensive disorder	12 (3.57%)	4 (4.88%)	0.489
Preterm birth	9 (2.68%)	3 (3.66%)	0.705

Maternal Composite*	24 (7.14%)	12 (14.63%)	0.030
Hyperbilirubinemia	22 (6.5%)	2 (2.44%)	0.178
Intubation	6 (1.80%)	2 (2.44%)	0.303
NICU Admission	25 (7.46%)	7 (8.54%)	0.743
Birthweight (g)	3280 [1750-4375]	3297.5 [2190-4450]	0.852

*Postpartum hemorrhage, shock index > 1 at time of delivery, blood transfusion, ICU admission, or readmission within 6 weeks postpartum

1023 | Ureaplasma Colonization in Preterm Premature Rupture of Membranes: Implications for Latency Period and Neonatal Outcomes

Ellen M. Murrin[1]; Sebastian Nasrallah[2]; Helen Havens Howell[3]; Amber Bowman[3]; Antonio F. Saad[4]; Scott Sullivan[2]
[1]Inova Fairfax Medical Campus, Falls Church, VA; [2]Inova Fairfax Medical Campus, Fairfax, VA; [3]University of Virginia College of Medicine, Charlottesville, VA; [4]Inova Health, Falls Church, VA

4:00 PM - 6:00 PM

Objective: Ascending microbial invasion is thought to be responsible for many cases of preterm premature rupture of membranes (PPROM). Ureaplasma colonization has been observed in up to 65% of cases and may result in poorer neonatal outcomes. We aimed to assess the prevalence of vaginal colonization with Ureaplasma species in pregnancies complicated by PPROM and determine its correlation with the latency period and pregnancy outcomes.

Study Design: Demographics, pregnancy complications, treatment regimens, and outcomes were analyzed from 165 patients with PPROM and vaginal Ureaplasma testing from 2017-2024 at a tertiary care center. Chi-square, t-test, Wilcoxon rank sum tests, and logistic regression were used to assess Ureaplasma colonization effects.

Results: Ureaplasma was detected in 57.6% of PPROM patients. Baseline characteristics with significant variations between groups were adjusted for, including advanced maternal age, in vitro fertilization, history of cesarean section, cerclage, and mycoplasma positivity. There was no significant difference in latency periods between Ureaplasma-positive and negative groups (6 [2-12] vs. 5 [2-16] days, p = 0.9).

After adjusting for significant differences in characteristics, Ureaplasma colonization was associated with reduced odds of intubation (aOR 0.32, 95% CI 0.15–0.71) and surfactant use (aOR 0.34, 95% CI 0.14–0.79), but did not significantly affect the composite neonatal morbidity (aOR 0.82, 95% CI 0.32–2.10; Table 1). Incidence of preterm birth at < 34 weeks and < 28 weeks (Table 1) and maternal outcomes (Table 2) did not differ between groups after adjusting for characteristics differences.

Conclusion: Ureaplasma colonization was common in PPROM patients, however its presence did not significantly affect the latency period. It was associated with specific neonatal outcomes, such as a decreased requirement for neonatal respiratory support. This association suggests the need for further research into the effects of Ureaplasma in pregnancy and the interaction with microbial therapy.

Table 1: Neonatal outcomes comparing Ureaplasma-positive to Ureaplasma-negative PPROM patients

1024 | Comparing Inferior Vena Cava Collapsibility in Postpartum Patients with and without Severe Preeclampsia

Elsa Parra[1]; Kerri Brackney[2]; Lauren Piersall[2]; Michael VanDillen[2]; Paul J. Wendel[2]; Angela Nakahara[2]; Meyer L. Norman[2]; Patricia Goedecke[2]
[1]University of Tennessee Health Science Center Memphis, Memphis, TN; [2]University of Tennessee Health Science Center, Memphis, TN

4:00 PM - 6:00 PM

Objective: The aim of this study was to determine if there is a difference in the inferior vena cava collapsibility index (IVCCI) between postpartum patients with severe preeclampsia versus those without preeclampsia.

Study Design: This was a prospective cohort study conducted in an urban university teaching hospital from May 2024 to June 2024. Patients had singleton or twin gestations and were evaluated within 48 hours of delivery. Cases had severe features of preeclampsia and controls did not have preeclampsia. Patients who previously received furosemide, were hemodynamically unstable, or who had a postpartum hemorrhage were excluded. Inferior vena cava (IVC) diameter was measured at inspiration (IVCmin) and expiration (IVCmax) using transabdominal ultrasound with a curvilinear 1.5-5 Hz probe. The IVCCI was calculated ((IVCmax-IVCmin)/IVCmax). The primary outcome was the IVCCI in each group.

Results: Amongst cases, the median IVCCI was 0.27 (interquartile range = 0.14 to 0.37) while controls had a mean IVCCI of 0.28 (interquartile range = 0.19 to 0.37). There was no significant difference in the collapsibility index between those with severe preeclampsia and those without preeclampsia.

Conclusion: The IVCCI is an objective measure of intravascular volume. It was not shown to have a statistically significant difference between those with and without preeclampsia with severe features. A larger study cohort could establish a better understanding of IVC behavior in these two populations, and thus may provide a useful tool to guide fluid management and diuresis of postpartum patients with severe preeclampsia.

1027 | Should Fetuses with Growth Restriction at Term Undergo Trial of Labor?

Emily Schneider[1]; Dajana Alku[1]; Amberly Lao[1]; Delphina Maldonado[2]; Emma Walker[1]; Xiwei Yang[3]; Martin Chavez[4]; Hye Heo[2]
[1]NYU Grossman Long Island School of Medicine, Mineola, NY; [2]NYU Langone Hospital, Long Island, NY; [3]NYU Langone Hospital - Long Island, Mineola, NY; [4]NYU Langone Hospital, New York, NY

4:00 PM - 6:00 PM

Objective: To determine if trial of labor in term pregnancies with fetal growth restriction (FGR) impacts neonatal morbidity compared to planned Cesarean delivery.

Study Design: This is a single-site retrospective cohort study evaluating neonatal outcomes of singleton pregnancies with term FGR from 10/2019 to 02/2024 who underwent trial of labor (TOL) compared to planned Cesarean delivery (CD). Patients with fetal aneuploidy, major structural anomalies, or requiring emergent delivery prior to TOL were excluded. Patients were identified using a query within the obstetric ultrasound imaging program. FGR was defined as estimated fetal weight (EFW) or abdominal circumference (AC) < 10% for gestational age (GA). Maternal demographics, obstetric, and neonatal outcomes were obtained

by chart review. Variables were compared via Chi-square and Fisher's exact test, with significance of $p < 0.05$. Univariate logistic regression was used for the binary composite endpoint. The primary outcome was composite neonatal morbidity.

Results: There were 217 patients included for analysis; 178 (82.0%) underwent TOL and 39 (18.0%) planned CD. Of the TOL group, 140 (78.7%) had a vaginal delivery (VD) and 38 (21.3%) underwent CD. The TOL group was younger and had lower pre-pregnancy BMI. Baseline characteristics were otherwise similar (Table 1). There was no difference in composite neonatal morbidity between groups. Subgroup analyses also did not demonstrate a difference in composite neonatal morbidity based on planned mode of delivery (Table 2). Delivery complication rates were similar between groups.

Conclusion: In pregnancies with term FGR, there was no difference in composite neonatal morbidity in those undergoing TOL versus planned CD. Subgroup analyses for severe FGR, FGR based on AC < 10%, oligohydramnios, and abnormal fetal Dopplers showed no difference in composite neonatal morbidity. Of those with term FGR undergoing TOL, 78.7% had a VD without significantly increased neonatal morbidity or delivery complications. These findings support a trial of labor for patients with FGR at term.

Table 1. Demographics and clinical characteristics

	Planned CD n=39	TOL n=178	P value
Maternal age (yrs)	33.0 ± 5.0	30.6 ± 5.8	**0.017**

Abbreviations- CD: Cesarean delivery, TOL: Trial of labor, VD: Vaginal delivery, AFI: Amniotic fluid index, AC: Abdominal circumference, EFW: Estimated fetal weight, NICU: Neonatal intensive care unit
[a]Hypoglycemia: Capillary blood glucose <30 mg/dl within 24-hours after delivery, <45 mg/dl thereafter
[b]Fetal acidemia: umbilical artery pH <7.1
[c]Delivery complication: Postpartum hemorrhage, shoulder dystocia, operative VD, episiotomy, obstetric anal sphincter injury, intraoperative complication/injury, hysterectomy, intraamniotic infection, endometritis, surgical site infection, retained placenta, ICU admission, maternal death
[d]Nine of 20 patients (45%) with delivery complications underwent operative VD

1028 | The Association between PSV MCA and Perinatal Outcomes in Pregnancies Complicated by Small-for-Gestational-Age/Fetal-Growth-Restricted Fetuses

Misgav Rottenstreich[1]; Bryon DeFrance[2]; Jon F. Barrett[2]; Eran Ashwal[2]
[1]McMaster University, Hamilton, ON; [2]McMaster university, Hamilton, ON

4:00 PM - 6:00 PM

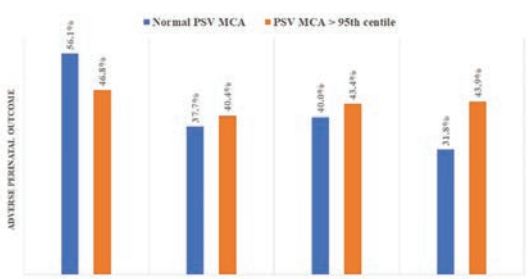
Objective: This study aimed to determine the relationship between middle cerebral artery (MCA) peak systolic velocity (PSV) and perinatal morbidity and mortality in SGA and FGR fetuses.

Study Design: A retrospective cohort study from a tertiary hospital including all singleton pregnancies without fetal genetic/structural anomalies and EFW and/or AC < 10th centile for gestational age (2017-2022). Only cases in which the umbilical artery (UA) and MCA were concurrently sampled within 14 days of birth were considered. The study compared cases with abnormal MCA PSV (> 95th centile for gestational age) to pregnancies with normal MCA PSV. The primary outcome was a composite adverse perinatal outcomes defined as either antenatal fetal death, cesarean birth due to fetal distress, 5-minute Apgar < 7, arterial cord < 7.1, prolonged NICU admission (>7 days), need for intubation, sepsis, necrotizing enterocolitis, and neonatal death. Multi variable logistic regressions were conducted, adjusting for relevant covariates.

Results: The study included 983 patients, among whom 98 (10%) had abnormal MCA PSV and 885 (90%) had a normal PSV MCA. Maternal sociodemographic characteristics were similar between the group. Cases with abnormal MCA PSV presented worse Doppler studies. Cases with abnormal MCA PSV delivered earlier than those with normal MCA PSV (33.9±4.5 vs. 36.1±3.3 wks; p< 0.001); nevertheless, the composite adverse perinatal outcomes did not differ between those with abnormal and normal PSV MCA (56.1% vs. 46.8%, p = 0.09). Subgroup analysis limited to cases with ultrasound assessment ≥ 32 weeks (n = 796); or those with normal MCA PI (≥ 5th centile; n = 708); or with normal CPR (≥ 5th centile; n = 621) presented similar composite adverse outcomes irrespective of MCA PSV status (Figure). Multivariate logistic regression controlling for MCA PI and UA PI failed to show a significant association between abnormal MCA PSV to the composite adverse outcome aOR 1.07; 95% CI 0.68-1.67.

Conclusion: In pregnancies complicated with SGA or FGR, abnormal MCA PSV, as a sole parameter, is not associated with adverse fetal/neonatal outcomes.

Figure 1 – The rate of adverse perinatal outcomes stratified by MCA PSV status in the entire cohort (p=0.09), those in which the most recent ultrasound was completed at or beyond 32 weeks (p=0.786), and those with normal MCA PI (p=0.744), and those with normal CPR PI (>5th centile) in the most recent ultrasound (p=0.283).



1029 | Unraveling Risk-Factors for Intrapartum Cesarean Section in Pregnancies with Fetal-Growth-Restriction Undergoing Labor Induction at Term

Misgav Rottenstreich[1]; Bryon DeFrance[2]; Jon F. Barrett[2]; Eran Ashwal[2]
[1]McMaster University, Hamilton, ON; [2]McMaster university, Hamilton, ON

4:00 PM - 6:00 PM

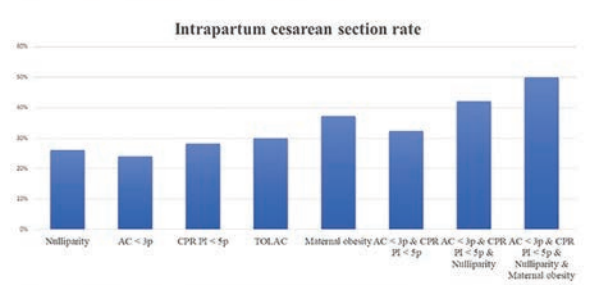
Objective: This study aimed to identify risk factors for intrapartum cesarean section in pregnancies complicated by fetal growth restriction undergoing labor induction at term.

Study Design: This case-control study included singleton pregnancies undergoing labor induction at term (≥37 weeks). All cases had estimated fetal weight (EFW) and/or abdominal circumference (AC) below the 10th centile for gestational age on the last sonographic assessment within 14 days of delivery. Pregnancies with known fetal genetic/structural abnormalities, previous ≥2 cesarean sections, or non-vertex presentation were excluded from the study. Perinatal and fetoplacental characteristics were compared between cases with successful vaginal delivery and those requiring intrapartum cesarean section (CS). Multivariable logistic regressions were conducted to identify independent variables associated with the need for intrapartum CS.

Results: A total of 405 eligible patients participated in the study, with 323 (79.8%) experiencing vaginal delivery, while 82 (20.2%) required intrapartum CS. Those undergoing CS exhibited higher rates of nulliparity and obesity. Gestational age at the most recent ultrasound assessment, mean EFW, and pulsatility index (PI) values of the umbilical artery and middle cerebral artery (MCA) were comparable between the groups. However, cases that underwent CS had a higher rate of fetal AC below the 3rd centile and abnormal cerebroplacental ratio PI. The gestational age at delivery did not differ significantly between the two groups. In the multivariate analysis (Table 2), maternal obesity, nulliparity, previous single CS, AC< 3rd centile, and abnormal cerebroplacental PI were identified as significant and independent predictors of intrapartu m CS. The predictive model demonstrated an area under the curve (AUC) of 0.714 (95% CI: 0.651-0.778); p< 0.001, indicating good discriminative ability.

Conclusion: Understanding maternal and fetoplacental characteristics can offer valuable insights into the success of vaginal delivery in pregnancies complicated by fetal growth impairment undergoing labor induction at term.

The rate of intrapartum cesarean section among pregnancies complicated by fetal growth restriction undergoing labor induction at term, stratified by the clinical status.



AC – abdominal circumference; CPR – cerebroplacental ratio; PI – pulsatility index; TOLAC – trial of labor after cesarean section

Predictors associated with intrapartum cesarean section among pregnancies complicated by fetal growth restriction undergoing labor induction at term – a multivariate analysis.

	Crude odds ratio (95% CI)	Adjusted odds ratio (95% CI)
Obesity (BMI ≥30 Kg/m²)	3.06 (1.77-5.28)	2.84 (1.60-5.03)
Nulliparity	2.40 (1.41-4.06)	2.99 (1.64-5.46)
Previous single cesarean section	1.74 (0.65-4.68)	3.19 (1.03-9.88)
Abdominal circumference < 3rd centile	1.69 (1.02-2.79)	1.94 (1.14-3.30)
Cerebroplacental ratio PI < 5th centile	1.96 (1.19-3.23)	1.81 (1.06-3.06)

BMI – body mass index; PI – pulsatility index

1030 | Prevalence of Cardiovascular-Kidney-Metabolic Syndrome in Reproductive-aged Women in the United States: NHANES 2011-2020

Eric K. BRONI[1]; Ebenezer Aryee[2]; Amber Lachaud[1]; Jennifer Lewey[1]; Lisa D. Levine[1]
[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Johns Hopkins School of Medicine, Baltimore, MD

4:00 PM - 6:00 PM

Objective: The AHA recently defined and staged cardiovascular kidney-metabolic (CKM) syndrome to highlight the multisystem consequences of poor CKM health, harmonize guidelines and provide opportunities for actionable preventive interventions before overt CVD. In the US, the components that comprise CKM (e.g., obesity, diabetes, hypertension) are potent risk factors for poor maternal and neonatal outcomes with a disproportionate burden among racial/ethnic minorities. However, population-level data on CKM syndrome in reproductive-aged women is scarce and is a critical next step in evaluating the association between CKM stages and overall pregnancy outcomes.

Study Design: We analyzed 2,347 non-pregnant, reproductive-aged women (≥ 20-49 years) from the National Health and Nutrition Examination Survey (NHANES) who had data on all CKM risk factors. We incorporated sampling weights into our analyses to account for the complex NHANES survey design. We reported prevalence estimates and standard errors of CKM syndrome stages (defined in Table) in the overall population, by race/ethnicity and across the study period (2011-2020).

Results: The mean age was 34.6 ± 7.7 yrs., with 57% non-Hispanic (NH) White, 19% Hispanic, 13% NH Black, 6% NH Asian, and 4% self-reported other races. Within the study period, 74.7% of participants had CKM syndrome [Stage 1: 37.3%, Stage 2: 35.7%, Stage 3: 0.3% and Stage 4: 1.97%], with notable variations over time. **(Table A & Figure A).** As noted in **Table B/Figure B**, NH Black women had the lowest prevalence of stage 0 CKM (13.2%) and the highest prevalence of stages ≥ 2 CKM (45.6%), followed by other races (40.8%) and Hispanic women (39.4%). Asian women had the lowest prevalence of stages ≥ 2 CKM (27.8%).

Conclusion: More than three-quarters of reproductive-aged women in the U.S. have at least stage 1 CKM with notable racial/ethnic disparities. Focusing health efforts on the prevention of these modifiable risk factors can undoubtedly improve health outcomes within this population. Studies evaluating the implications of these findings for overall pregnancy outcomes are urgently warranted.

A. Trends in the Prevalence of Stages of CKM Syndrome among Reproductive Aged Women in the United States: NHANES 2011-20

CKM Syndrome Stage	Overall (2011-2020)	2011-2012	2013-2014	2015 - 2016	2017-2020
			Prevalence (95% CI)		
Stage 0	25.33 (22.82 -28.02)	27.47 (22.04 -33.67)	24.62 (20.51 – 29.25)	22.26 (16.78 – 28.91)	26.52 (22.26 – 31.27)

4:00 PM - 6:00 PM

Objective: To identify the incidence and risk factors associated with elevated blood pressure at 6 weeks postpartum among women in Ghana, Kenya, India, Pakistan, and Zambia. Study Design: We report findings from the Pregnancy Risk, Infant Surveillance, and Measurement Alliance (PRISMA) prospective multi-country pregnancy cohort in Kenya, Ghana, Zambia, Pakistan, and India. Hypertension (HTN) is defined as blood pressure (BP) greater than 140/90. We excluded participants with known chronic hypertension or elevated BP prior to 20 gestational weeks. We used descriptive statistics to report the incidence of postpartum hypertension overall and by region. We performed multivariable Poisson regression with robust variance to describe the relationship between risk factors and postpartum hypertension with relative risks and 95% confidence intervals. Results: A total of 3858/4358 (89%) participants had at least 1 BP measured at the 6-week postpartum visit and were included in the analysis. The incidence of high BP postpartum differed by region, with 2.7% of participants in South Asia and 7.3% in Africa meeting criteria. Overall, 50/251 (19.9%) participants with hypertensive diseases of pregnancy had persistent elevated BP at 6 weeks postpartum, compared to 4% new onset high BP at 6 weeks postpartum among those who did not have any hypertensive disorders of pregnancy. Factors associated with high BP postpartum included maternal age (aRR 1.10, 95% CI 1.08, 1.13), early pregnancy BMI ≥ 30 (aRR 2.24, 95% CI 1.58, 3.18), and a diagnosis of gestational hypertension or preeclampsia during the current pregnancy (aRR 4.20, 95% CI 2.9, 5.9; aRR 4.49 95% CI 2.85, 7.07, respectively). Participants with HIV infection were less likely to have elevated blood pressure (aRR 0.46 95% CI 0.25, 0.83). Conclusion: This study demonstrates a high incidence of elevated blood pressure postpartum with notable differences by region. These findings underscore the need for robust follow-up at and beyond 6 weeks after delivery and linkages to primary care for women with persistent hypertension.

1032 | Shoulder Dystocia Resolution Utilizing < vs. > 3 Maneuvers and Associated Adverse Outcomes

Fabrizio Zullo[1]; Teresa C. Logue[2]; Daniele Di Mascio[3]; Giuseppe Rizzo[3]; Antonella Giancotti[3]; Hector M. Mendez-Figueroa[4]; Matthew K. Hoffman[2]; Anthony C. Sciscione[2]; Suneet P. Chauhan[5]

4:00 PM - 6:00 PM

Objective: Our objective was to examine the association between the use of < 3 versus ≥ 3 maneuvers to resolve SD and adverse outcomes.

Study Design: This was a secondary analysis of the Assessment of Perinatal EXcellence (APEX) study, a observational cohort of over 115,000 deliveries within 25 U.S. hospitals. We included women with singleton, vertex, non-anomalous gestations at ≥ 34 weeks who had SD, relieved with at least 1 maneuver. We excluded SD if no maneuvers were documented. We stratified the groups according to the number of maneuvers used to resolve the shoulder dystocia. The primary outcome was a neonatal composite outcome encompassing Apgar < 5 at 5', fetal fractures, intracranial hemorrhage, brachial plexus injury, facial nerve palsy, hypotension and neonatal death. Statistical analysis included Chi-square, Kruskal-Wallis, logistic and Poisson regressions with robust error variance for adjusted Incidence Rate Ratios, adjusting for BMI and maternal age.

Results: The overall rate of SD in APEX was 1.9% (2,138/118,422). Of 2,138 SD, 96% met the inclusion criteria for analysis. Three or more maneuvers were utilized in 19% (391/2,062) of SD. The composite outcome was higher with ≥ 3 maneuver (14.6%) vs < than 3 (5.7%; Fig 1). After adjustement the aIRR was 2.28 (95%CI 1.62, 3.20). Additionally, Apgar < 5 at 5' (aIRR 4.10 95% CI 1.18-14.25), fetal fractures (aIRR 2.58 95% CI 1,66-4.00), intracranial hemorrhage (aIRR 4.28 95%CI 1.06-17.19), brachial plexus injury (aIRR 2.58 95%CI 1.45-4.60) were significantly more likely when ≥ 3 vs < 3 maneuvers were used. No statistically significant differences were noted for rates of facial nerve palsy, hypotension requiring treatment and neonatal death and postpartum hemorrhage (Table 1).

Conclusion: Shoulder dystocia relieved by 3 or more maneuvers, compared to fewer, was associated with a 2.5-fold increased risk of composite neonatal adverse outcomes, albeit not postpartum hemorrhage.

Fig 1. Numbers of Maneuverers to Resolve Shoulder Dystocia and Composite Neonatal Adverse Outcomes

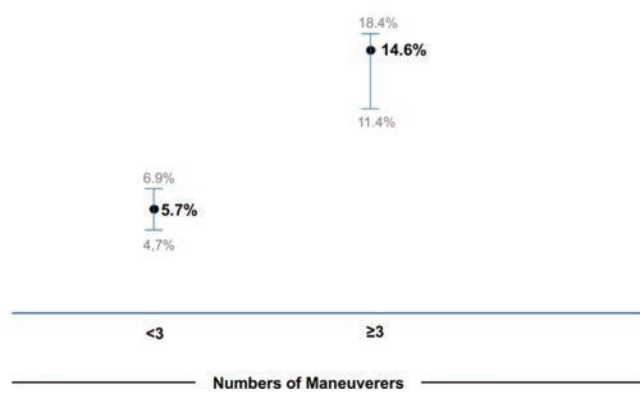

Table 1. Number of maneuvers used to relieve shoulder dystocia and outcomes

4:00 PM - 6:00 PM

Objective: To compare the fetal heart rate tracing (FHRT) and adverse outcomes among hypertensive and non-hypertensive women who delivered at term (≥ 37 wks).

Study Design: The inclusion criteria of the retrospective study were consecutive individuals with non-anomalous singletons who delivered at ≥ 37 wks over 15 months. The groups were stratified by the presence or absence of hypertensive disorder of pregnancy (HDP), defined as gestational and chronic hypertension. Using the ACOG guidelines, clinicians—blinded to maternal characteristics, BP status, and outcomes—interpreted the FHRT for the last 60 mins of labor. Composite neonatal and maternal adverse outcomes (CNAO, CMAO) were compared between the groups. Chi-square test was used to compare groups. Odds Ratios (OR) and adjusted OR were calculated using a multivariate binomial logistic regression model with permuted omnibus tests to identify confounding factors.

Results: Of the 5,160 deliveries during the study period, 3,166 (61%) met the inclusion criteria and among them 1,062 (33%) had HDP. Pregnancies complicated by HDP were significantly more likely to have minimal variability (p< 0.01). Decelerations occurred at similar rate. The rate of category I, II and III tracings were similar (Table 1). Cesarean delivery was comparable among the two groups after adjustment. CNAO of newborns of individuals with HDP (2.5%) was significantly higher than newborn of normotensive individuals (1.0%; aOR 2.32 95%CI 1.21–4.49). CMAO was significantly higher in the HDP (9.9%) than normotensive group (6.8%; aOR 1.56 95% CI 1.17–2.07); Table 2). Apgar score < 7 at 5 min and neonatal seizure were the only components of the CNAO that differed significantly.

Conclusion: Minimal variability was the only fetal heart rate characteristic which differed significantly among hypertensive

vs. normotensive individuals. Neonatal and maternal adverse outcomes were significantly higher in the hypertensive group. Intervention trials mitigating the increased likelihood of adverse outcomes among term individuals with hypertensive disorder are warranted.

Bolded if significantly different ($p<0.05$)
FHRT: fetal heart rate tracing.
* OR adjustment evaluated for: Nulliparous, Gestational age, BMI >30, Diabetes, Induction of labor, magnesium sulfate use, insurance, race, cervical ripening with cervidil, cook balloon, amniotomy, Maternal viral infection (HIV/Hepatitis). Multiple permutations of omnibus tests using binomial logistic regression were used to identify those with statistically significant contribution.
For Neonatal Composite: No co-variables were found to have significant model effect. Adjustment for all candidate variables is presented.
For Maternal Composite: Nulliparity, race, gestational age at delivery, and diabetes were significant co-variates ($P < 0.05$), and adjustment for these is presented.
For Cesarean Delivery rate: Nulliparous, Gestational age at delivery, diabetes, BMI > 30, amnioinfusion, magnesium sulfate use, induction of labor, cervidil, cook ballon, amniotomy, and tobacco use, had significant model effect as co-variates ($P < 0.05$) and adjustment for these is presented. After adjustment cesarean delivery rate was not significantly different due to hypertensive disorder.

1034 | Impact of Timing of Hysteroscopy for Retained Products of Conception on Subsequent Pregnancy Outcomes

Gal Bachar[1]; Efrat Leibowitz[2]; Ron Beloosesky[2]; Naphtali Justman[1]; Dana Vitner[1]; Yaniv Zipori[1]; Zeev Weiner[2]; Nizar Khatib[2]

[1]Rambam Medical Center, Haifa, Hefa; [2]Rambam Medical Health Center, Haifa, Hefa

4:00 PM - 6:00 PM

Objective: Retained products of conception (RPOC) occur in ~3% of deliveries and can have significant adverse effects on women's health. Hysteroscopy removes RPOC but has its own possible side effects. On the other hand, delayed treatment may damage the endometrium. Prolonged RPOC can lead to infection and inflammation, potentially affects future pregnancy outcomes. We studied outcomes for women with suspected RPOC, comparing hysteroscopy performed within 8 weeks versus more than 8 weeks postpartum.

Study Design: Our 2010-2023 retrospective dataset included information on women who had suspected RPOC and who underwent hysteroscopy at a tertiary medical health center. Women with a documented subsequent live birth following hysteroscopy were categorized based on timing: Group 1 (hysteroscopy within 8 weeks) and Group 2 (hysteroscopy beyond 8 weeks). We compared maternal characteristics, hysteroscopic findings, subsequent delivery details and neonatal outcomes between the two groups. The primary outcome was gestational age at delivery for the subsequent pregnancy. Secondary outcomes included various maternal and neonatal complications.

Results: Both groups had similar baseline characteristics. There were no significant differences in most aspects of the first delivery course, including mode of delivery. Indications for hysteroscopy were similar between groups, with retained placental tissue being the most common finding.

Regarding subsequent pregnancies following hysteroscopy, time to conception, gestational age at delivery, pregnancy complications including hypertensive disease, and most delivery outcomes were all similar between the two groups. Neonatal outcomes were also comparable.

Conclusion: The timing of hysteroscopy for RPOC following delivery - whether within 8 weeks or more than 8 weeks postpartum - appears to have minimal impact on subsequent pregnancy outcomes. Therefore, a wait-and-see approach might be recommended at least for two months after delivery. However, further investigation with a larger sample size is needed to confirm these findings.

1035 | Vaginal Compared with Oral Misoprostol Induction for Individuals with Morbid Obesity

Gayathri D. Vadlamudi[1]; Donald D. McIntire[2]; Emily H. Adhikari[2]

[1]UT Southwestern Medical Center, Dallas, TX; [2]University of Texas Southwestern Medical Center, Dallas, TX

4:00 PM - 6:00 PM

Objective: To characterize labor progress in term individuals with morbid obesity undergoing induction using vaginal compared with oral misoprostol

Study Design: We conducted a secondary analysis of a cluster randomized controlled trial comparing oral or vaginal misoprostol regimens for term labor induction among individuals with intact membranes and cervical dilation ≤ 2cm. Pregnant persons with BMI ≥ 40kg/m2 at delivery were included. Weekly randomization was assigned to either oral (100 μg every 4 hours for up to two doses) or vaginal (25 μg every 3 hours for up to five doses) misoprostol, followed by a standardized oxytocin protocol. We recorded cervical exams at misoprostol administrations, oxytocin initiation, and prior to delivery. We compared labor progress and duration, need for oxytocin, and delivery and neonatal outcomes using generalized estimating equations to account for clustering. Outcomes were stratified by parity. Labor curves were constructed using a mixed effects repeated measures model.

Results: Of 491 patients, 264(53.8%) received vaginal and 227(46.2%) oral misoprostol. There were no significant demographic differences. Route of administration was not associated with a difference in time (hours) to delivery (22.9±0.74 vaginal vs 22.3±0.78 oral). Among 165(66.2%) vaginal and 137(62.8%) oral misoprostol recipients who reached the second stage of labor, length of first stage did not differ (20.6±0.81h vs 20.5±0.89h). Need for oxytocin was lower with vaginal misoprostol (188(71.2%) vs 194(85.5%). There were no significant differences in vaginal delivery or other maternal and neonatal outcomes including umbilical cord pH < 7.0 and neonatal intubation. Associations between route of misoprostol and outcomes were similar after stratification by parity. Rate of cervical dilation did not differ by route of administration.

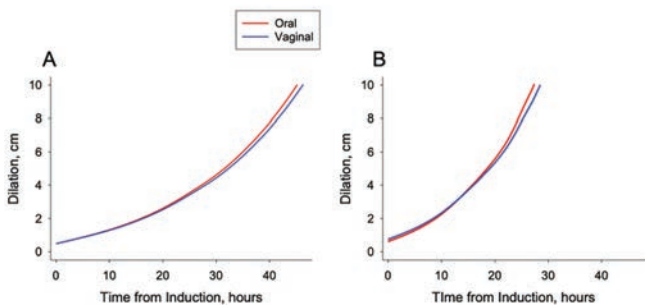
Conclusion: In patients with morbid obesity undergoing term induction, route of misoprostol does not impact time to delivery or vaginal delivery rates.

Table 1: Characteristics of induction in patients with BMI ≥ 40 kg/m² undergoing induction with vaginal vs oral misoprostol

Outcome	Vaginal misoprostol, n = 264	Oral misoprostol, n = 227	Mean difference or OR (95% CI)
Time to delivery, hours	22.9 ± 0.74	22.3 ± 0.78	0.57 (-1.54, 2.69)
Need for oxytocin	188 (71.2)	194 (85.5)	0.42 (0.27, 0.66)
Number who reached complete cervical dilation	165 (66.2)	137 (62.8)	1.09 (0.76, 1.58)
Length of first stage, hours*	20.6 ± 0.81	20.5 ± 0.89	0.05 (-2.31, 2.40)
Vaginal delivery	183 (69.3)	153 (67.4)	1.09 (0.75, 1.60)

Data shown as n (%) or mean ± SD as appropriate. Effect size shown as mean difference for continuous and OR (odds ratio) for categorical outcomes. *Measured for those who reached complete cervical dilation.

Figure 1: Rate of cervical dilation did not differ among patients with BMI ≥ 40 kg/m2 undergoing term induction with oral vs vaginal misoprostol and standardized oxytocin protocol, stratified by parity. A) nulliparous, B) multiparous.



1036 | Characterizing Vaginal Misoprostol Induction in Individuals with Morbid Obesity

Gayathri D. Vadlamudi[1]; Donald D. McIntire[2]; Emily H. Adhikari[2]
[1]UT Southwestern Medical Center, Dallas, TX; [2]University of Texas Southwestern Medical Center, Dallas, TX

4:00 PM - 6:00 PM

Objective: To compare labor progression in individuals with body mass index < 40 vs ≥ 40 kg/m2 undergoing induction at term

Study Design: This was a secondary analysis of the vaginal misoprostol arm of a cluster randomized controlled trial comparing vaginal to oral misoprostol induction. This analysis included patients ≥ 37 weeks, with cervical dilation ≤ 2 cm who underwent induction using a standardized protocol. Vaginal misoprostol was given in 25 μg doses every three hours for up to five doses, followed by a standardized high-dose oxytocin protocol. We compared characteristics of labor progression among individuals with BMI < 40 and ≥ 40kg/m2 including labor duration, number of misoprostol doses, and obstetric and neonatal outcomes. Data was analyzed using generalized estimating equations to account for clustering. Effect sizes were presented as odds ratios and mean differences in duration with 95% confidence intervals.

Results: From May 2021 to September 2022, 1322 patients received vaginal misoprostol, among whom 1058(80.0%) had BMI < 40 kg/m2 and 264(20.0%) had BMI ≥ 40kg/m2. Baseline differences between the two groups are shown in Table 1. Cervical dilation at the start of induction was lower in patients with BMI ≥ 40, and these individuals required more doses of misoprostol during induction (Table 2). Inductions in this group had longer durations of oxytocin use (13.8 ± 9.2 vs 11.1 ± 8.0 h), length of first stage of labor (20.6 ± 11.1 vs 18.0 ± 9.4 h), and time to delivery (22.9 ± 12.1 vs 19.0 ± 10.3), with lower rates of vaginal delivery (69.3 vs 80.2%). Patients with morbid obesity were more likely to have excess blood loss (22.3 vs 15.5%) and develop wound infection (1.5 vs 0.4%).

Conclusion: Following term labor induction with vaginal misoprostol, morbid obesity is associated with longer labor duration, lower vaginal delivery frequency, and increased obstetric morbidity. Whether alternative labor induction protocols in morbidly obese patients improve these outcomes requires additional study.

1037 | Recurrent Pregnancy Loss as an Independent Risk Factor for Celiac Disease of The Offspring

Gil Gutvirtz[1]; Gali Pariente[2]; Tamar Wainstock[2]; Eyal Sheiner[2]
[1]Soroka University Medical Center, Metar, HaDarom; [2]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom

4:00 PM - 6:00 PM

Objective: Celiac disease is a common immune-mediated inflammatory disease that mainly develops in genetically predisposed individuals. However, it is still unclear what predisposes some to develop the disease but not others. Women with a history of recurrent pregnancy losses (RPL) may harbor a genetic disposition for inflammatory responses causing pregnancy losses and this genetic trait may pass to their offspring. We sought to investigate whether offspring of women with RPL are at an increased risk to develop celiac disease.

Study Design: A population-based cohort study was conducted to evaluate the risk to develop celiac disease in offspring (up to the age of 18 years) born to mothers with and without a history of RPL. Only singleton deliveries were included. Data for the diagnosis of celiac disease of the offspring was extracted from community-based clinics and/or hospitalization records. Kaplan-Meier survival curve was used to compare the incidence of celiac disease between the study groups. A cox regression model was used to control for confounders.

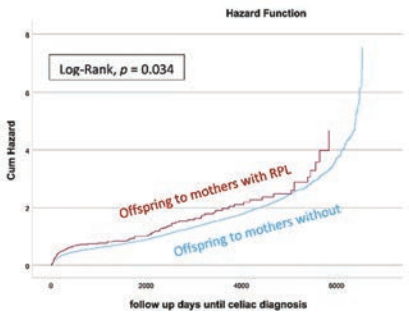
Results: During the 30 years (1991-2021) study period, 356,356 singleton deliveries occurred; 14,235 deliveries (4%) were in women with a history of RPL. Children in this group had higher rates of celiac disease as compared to children born to mothers without a history of RPL (**Figure**). The Kaplan-Meier survival curve illustrated higher incidence of celiac disease in offspring with maternal history of RPL (**Figure**). Using a Cox regression model, adjusting for maternal celiac disease, maternal age and gestational age at birth, maternal history of RPL was independently associated with celiac disease of the offspring (adjusted HR = 1.22, 95% CI 1.1-1.5; P = 0.04).

Conclusion: Maternal history of RPL is an independent risk factor for celiac disease in the offspring.

The association between RPL and celiac disease of the offspring: Univariate analysis, Kaplan-Meier survival curve and results from a Cox regression model

	History of RPL	No RPL	Odds Ratio	95%CI	Adjusted* HR	95%CI	*p* value
Celiac disease	107 (0.8%)	1,854 (0.5%)	1.39	1.1 – 1.7	1.22	1.1 – 1.5	0.04

* Adjusted for maternal celiac disease, maternal age and gestational age



1038 | Maternal Vaginal Colonization with Group-B Streptococcus During Labor and Long-Term Cardiovascular Morbidity of the Offspring

Gil Gutvirtz[1]; Tamar Wainstock[2]; Eyal Sheiner[2]
[1]Soroka University Medical Center, Metar, HaDarom; [2]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom

4:00 PM - 6:00 PM

Objective: Group B Streptococcus (GBS) is a Gram-positive bacteria that commonly colonizes the gastrointestinal and genital tracts of pregnant women. Vertical transmission to the neonate may occur during labor. While early onset GBS infection usually manifests with sepsis, pneumonia or meningitis, cardiac complications such as endocarditis, myocarditis and pericarditis have also been reported. This study was aimed to investigate whether an association exists between maternal vaginal GBS and offspring long-term cardiovascular morbidity

Study Design: A retrospective population-based cohort analysis of singleton vaginal deliveries between the years 2002-2021 at a tertiary medical center was performed. Long-term cardiovascular morbidity of children who were exposed to maternal positive GBS was compared with children to mothers with negative or unknown GBS status. Data for long-term cardiovascular morbidity of the offspring was extracted from community-based clinics and hospitalization records. A Kaplan-Meier survival curve was constructed to compare long-term cumulative cardiovascular morbidity, and a Cox regression model was used to adjust for possible confounders

Results: The analysis included 146,103 singleton vaginal deliveries that occurred during the study period. Of them, 2,225 (1.5%) mothers were identified with positive GBS status. The cumulative incidence of long-term cardiovascular morbidity was comparable between maternal GBS exposed offspring and those with negative or unknown maternal GBS status (**Figure**). The Cox regression model, adjusting for various confounders including gestational and maternal age, hypertensive disorders, diabetes mellitus and ethnicity, found that maternal vaginal GBS colonization was not associated with long-term cardiovascular morbidity of the offspring (adjusted HR = 0.88; 95% CI 0.55-1.42, P = 0.608, **Table**)

Conclusion: Maternal vaginal colonization with GBS during vaginal delivery is not associated with long-term cardiovascular morbidity of the offspring

Figure. Kaplan-Meier survival curve demonstrating the cumulative incidence of cardiovascular morbidity among study groups

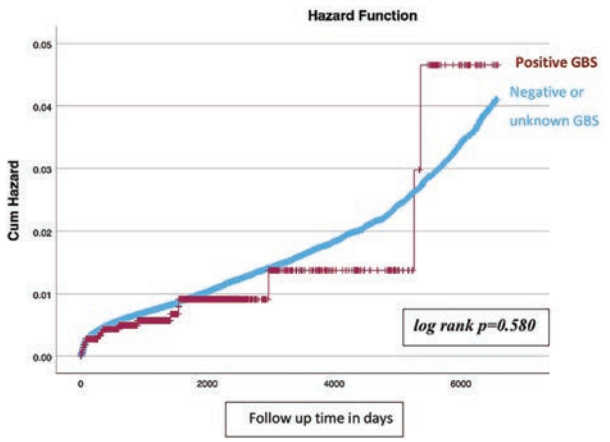


Table. Cox regression model for the association between maternal vaginal colonization of GBS and offspring long-term cardiovascular morbidity

	aHR	95%CI	p value
Positive GBS status	0.88	0.55 - 1.42	0.608

1039 | Pulse Pressure does not Predict Response to Treatment of Severe Hypertension in Preeclampsia

Gillian Piltch[1]; Rachel P. Gerber[2]; Chisom Chigozie-Nwosu[3]; Burton Rochelson[2]; Matthew J. Blitz[2]; Evelina Grayver[2]; Alejandro D. Alvarez[2]; David Krantz[2]; Caroline Pessel[2]
[1]Northwell, Astoria, NY; [2]Northwell, New Hyde Park, NY; [3]Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY

4:00 PM - 6:00 PM

Objective: To evaluate pulse pressure as a predictor of response to treatment of severe hypertension in preeclampsia.

Study Design: Multicenter retrospective cohort study of pregnant or postpartum people who received treatment with immediate release nifedipine or intravenous labetalol or hydralazine for severe hypertension due to preeclampsia with severe features from 2017-2022. Primary outcomes were time to resolution of severe hypertension and resolution of severe hypertension within 30 minutes. Secondary outcomes were number of fast-acting antihypertensive doses and of distinct ACOG-defined medication algorithms needed for resolution of severe hypertension. Log-rank tests, likelihood ratio tests, and t-tests were performed with $p < 0.05$ considered statistically significant.

Results: 1191 people met inclusion criteria. Range in pulse pressure of the severe blood pressure immediately prior to

fast-acting antihypertensive administration was 24-132 mmHg and in time to resolution of severe hypertension was 10-295 minutes. There was no relationship between pulse pressure of the severe blood pressure immediately prior to treatment (Figure 1) or change in pulse pressure between the two severe blood pressures prompting treatment (Figure 2) and time to resolution of severe hypertension. Pulse pressure was not predictive of resolution of severe hypertension within 30 minutes ($p = 0.10$). Subgroup analysis stratified by first fast-acting antihypertensive administered demonstrated no relationship between pulse pressure and resolution within 30 minutes among those who received immediate release nifedipine ($p = 0.23$) or intravenous labetalol ($p = 0.48$) or hydralazine ($p = 0.45$). There was no association between pulse pressure and number of doses of fast-acting antihypertensives ($p = 0.74$) needed for resolution. There was a wider range in pulse pressures that included narrower pulse pressures among people who required one medication compared to those who needed more than one ($p< 0.01$) for resolution.

Conclusion: Pulse pressure was not predictive of time to resolution of severe hypertension in preeclampsia with severe features.

4:00 PM - 6:00 PM

Objective: The safety & efficacy of vaccination against COVID-19 during pregnancy is crucial for not only current maternal and fetal health, but public health policy and management with future pandemics. To date, many meta-analyses on the safety and efficacy of COVID-19 vaccine were published with conflicting results; we aimed to correct this crucial knowledge gap with the current study.

Study Design: We conducted a systematic search of PubMed, Scopus, Web of Science, and Embase from 01/01/2021 to 09/13/2023. We included 23 meta-analyses inclusive of over 200 studies and 1,300,000 gravidae with or without documented evidence of COVID-19 vaccination. Meta-analyses were performed using R to aggregate effect sizes, utilizing random-effects models. Heterogeneity was evaluated using the I^2 statistic, and publication bias was assessed with Egger's test. PROSPERO registration: CRD42024519174.

Results: COVID vaccination during pregnancy reduced maternal COVID-19 infection rates (Risk Ratio [RR] 0.41, 95% CI 0.30-0.57), stillbirth (RR 0.75, 95% CI 0.58-0.98), PTB ≤37 wks (RR 0.92, 95% CI 0.86-0.99), congenital malformations (RR 0.83, 95% CI 0.70-0.98), SGA neonates (RR 0.94, 95% CI 0.91-0.98), and NICU admission (RR 0.91, 95% CI 0.85-0.97). No significant risk differences were observed among other outcomes, with the exception of a marginal increased risk of Cesarean delivery (RR 1.07, 95% CI 1.01-1.12; Table 1, Figure 1).

Conclusion: With the conduct of an umbrella review of comprehensive meta-analyses and including over 1.3M patients, we demonstrate significant benefit towards vaccination at no increased risk. The quantifiable benefits may aid shared

decision-making and public health communications in this and future pandemics.

1041 | Prenatal Aortic Coarctation Sign Screening Using Automatic AI-Assisted Vessel Diameter Measurement

Guillaume Corda[1]; Remi Besson[1]; Nikola Matevski[1]; Guy Vaksmann[2]; Julien Stirnemann[3]; Yves Ville[4]

[1]Sonio, Paris, Ile-de-France; [2]Cabinet Vendôme, Lille, Nord-Pas-de-Calais; [3]Hôpital Necker Enfants Malades, Paris, Ile-de-France; [4]University and Necker-Enfants Malades Hospital, Paris, Ile-de-France

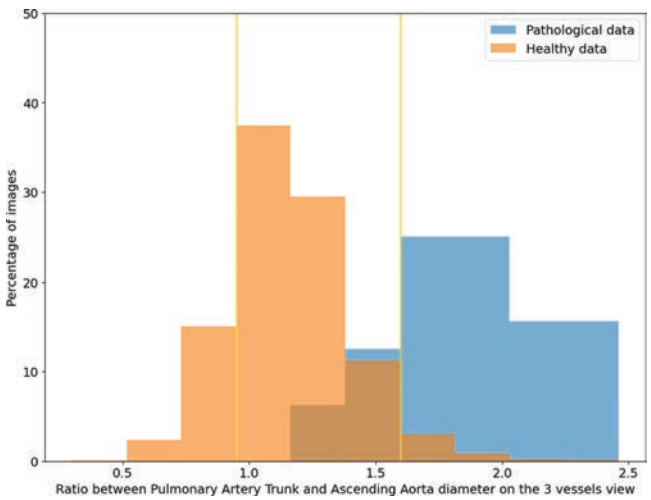
4:00 PM - 6:00 PM

Objective: Aortic coarctation (AoC) is a congenital heart defect characterized by hypoplasia of the aortic arch visible on the 3-vessel view (3VV). This study aims to (i) develop a pipeline using artificial intelligence (AI) for automatic vessel diameter measurement, (ii) assess whether vessel diameter is a reliable predictor of AoC prenatally.

Study Design: An AI software (under development, not yet FDA approved) trained on thousands of annotated images from US and European sites is used for the automatic detection and segmentation of the pulmonary artery (PA) and aorta (Ao) on 2D 3VV images. Post-processing algorithms are applied to achieve automatic and standardized diameter measurements. The model's performance is assessed on a test set of images on which the models were not trained, consisting of 2548 non-pathological images and 32 images from studies where AoC was diagnosed prenatally by a multidisciplinary team (Hôpital Necker, Paris).

Results: The models demonstrated high accuracy in vessel diameter measurement. The sign used for AoC screening is the diameter ratio of the PA to that of the Ao. With a ratio greater than 1.6, an AoC should be suspected. This ratio is calculated over the entire test set for the two populations, and a shift is observed (Figure 1). For healthy data, the mean ratio is 1.2±0.3 mm, while for the pathological data, the mean ratio is 1.8±0.3 mm. Our method achieves a sensitivity of 71.9% and a specificity of 87.8% for AoC sign screening.

Conclusion: This study validates AI's potential for automatic AoC sign screening. It offers a fast and reliable alternative to manual measurement methods. However, the AP/Ao ratio alone has limitations for screening CoA prenatally. Other indicators should be investigated. This study used cases detected prenatally, introducing a bias. Future work will look at cases that were diagnosed postnatally.



1042 | Direct Dispensation of Prenatal Supplements with Iron Among Pregnant People: a Cost-Effectiveness Analysis

Helen Samuel[1]; Megha Arora[2]; Ashley E. Benson[2]; Aaron B. Caughey[2]

[1]Oregon Health and Science University, Springfield, VA; [2]Oregon Health & Science University, Portland, OR

4:00 PM - 6:00 PM

Objective: Postpartum transfusion is a leading cause of severe maternal morbidity in the United States, with pregnant individuals with iron deficiency and/or iron deficiency anemia (IDA) at increased risk. Despite early detection and treatment recommendations to reduce prenatal iron deficiency and IDA, effective strategies to overcome barriers to medication and supplement access are less clear, and iron supplement adherence remains suboptimal during pregnancy. This study compares the cost effectiveness of directly providing versus recommending prenatal iron.

Study Design: A decision-analytic model was constructed in TreeAge to compare directly dispensing prenatal iron supplements versus the standard protocol of recommending prenatal iron supplements in a theoretical cohort of 1,514,784 pregnant

individuals enrolled in Medicare annually. Probabilities, utilities, and costs were derived from the literature. Outcomes included costs, quality-adjusted life years (QALY), preterm deliveries, neurodevelopmental disabilities, maternal postpartum anemia, and postpartum transfusion for acute blood loss. We defined our cost-effective threshold as 100,000 USD per QALY.

Results: Directly dispensing prenatal iron supplements resulted in 62,600 fewer preterm deliveries, 52 fewer cases of neurodevelopmental disability, 75,683 fewer cases of maternal postpartum anemia, and 54,010 fewer postpartum blood transfusions (Table 1) within our theoretical cohort. This intervention resulted in an estimated 187,475 additional QALYs and cost savings of $62,187,202,377 annually. Given the increase in QALYs and cost savings, directly dispensing prenatal iron was a dominant strategy.

Conclusion: In this study, directly dispensing prenatal iron supplements to Medicaid-enrolled pregnant individuals was a cost-effective strategy associated with reduced rates of adverse perinatal outcomes. These findings support the implementation of iron supplement provision at point of care prenatally to improve adherence, maternal and child health outcomes, and reduce healthcare expenditures.

Table 1. Outcomes associated with directly dispensing versus recommending prenatal iron in a theoretical cohort of 1,514,784 Medicaid-enrolled pregnant individuals.

	Directly Dispensed Prenatal Iron	Recommending Prenatal Iron	Differences
Preterm delivery	92,401	155,001	-62,600
Neurodevelopmental disability	353	405	-52
Maternal Postpartum Anemia	545,347	621,030	-75,683
Acute Blood Loss Transfusions at Postpartum	773,062	827,072	-54,010
Cost (USD)	$28,386,003,406	$905,732,057,844	-$62,187,202,377
Effectiveness (QALYs)	84,833,163	84,645,688	187,475

1043 | Increased Risk of Major Fetal Anomalies in Cases of Severe Placenta Accreta Spectrum

Helena C. Bartels[1]; Jennifer M Walsh[2]; Donal O'Brien[2]; Jennifer Donnelly[3]; Stephen Carroll[2]; Heather Hughes[2]; Barbara Cathcart[2]; Rhona Mahony[2]; Paul Downey[2]; Fionnuala M. M. McAuliffe[4]; Siobhan Corcoran[2]

4:00 PM - 6:00 PM

Objective: To evaluate the incidence of congenital fetal anomaly in pregnancies with placenta accreta spectrum (PAS).

Study Design: This is a prospective cohort study of PAS cases from January 2018–July 2024. Consecutive patients with clinically and histopathologically confirmed PAS were included. Ultrasound assessments were performed by fetal-medicine specialists in a tertiary referral centre for PAS.

Results: 73 participants with a mean age of 36.0±3.6 met inclusion criteria. In seven cases (9.5%), a major fetal congenital anomaly in a euploid fetus was diagnosed, compared to a background rate of 3%. The anomalies diagnosed were as follows: two major cardiac anomalies (hypoplastic left heart, right heart), two tracheoesophageal fistula, one severe ventriculomegaly, one giant omphalocele with hydrops, and one congenital diaphragmatic hernia. No case was associated with an underlying genetic diagnosis. In each case, clinical PAS findings were on the severe end of spectrum, with low implantation in early pregnancy which evolved to intraoperative topography consistent with type 2L (low lateral parametrial involvement) and 3 (low anterior cervical).

Conclusion: Severe PAS may be associated with a higher rate of fetal congenital anomaly, which in our cohort were major single structural anomalies without genetic associations. PAS cases associated with congenital fetal anomalies were lateral and cervical defects on the severe end of the spectrum. These structural defects suggest fetal insult in early pregnancy from 5-9 weeks gestation. It is possible early implantation within a previous uterine scar results in vascular disruption of embryonic development and the subsequent development of structural fetal anomaly. These cases present significant clinical challenges and warrant specialist multi-disciplinary care to include neonatology and paediatric surgery to ensure safe delivery timing to optimise maternal health and fetal outcomes. PAS cases should have a detailed fetal medicine assessment in view of the higher incidence of fetal anomalies.

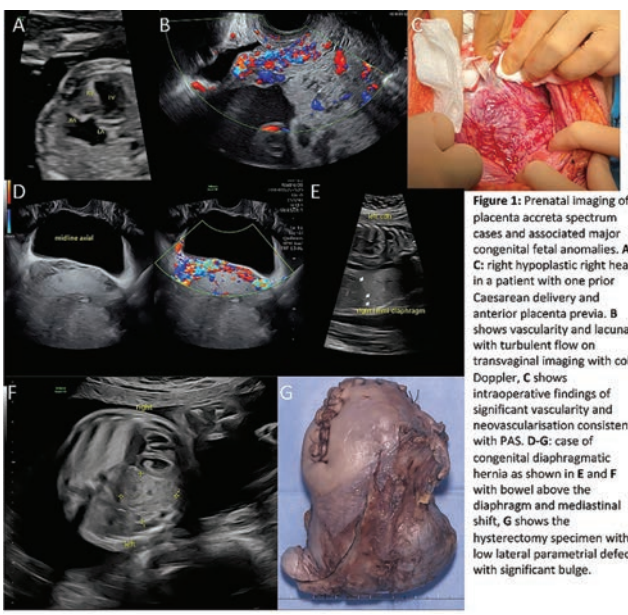

Figure 1: Prenatal imaging of placenta accreta spectrum cases and associated major congenital fetal anomalies. **A-C:** right hypoplastic right heart in a patient with one prior Caesarean delivery and anterior placenta previa. **B** shows vascularity and lacunae with turbulent flow on transvaginal imaging with color Doppler, **C** shows intraoperative findings of significant vascularity and neovascularisation consistent with PAS. **D-G:** case of congenital diaphragmatic hernia as shown in **E** and **F** with bowel above the diaphragm and mediastinal shift, **G** shows the hysterectomy specimen with a low lateral parametrial defect with significant bulge.

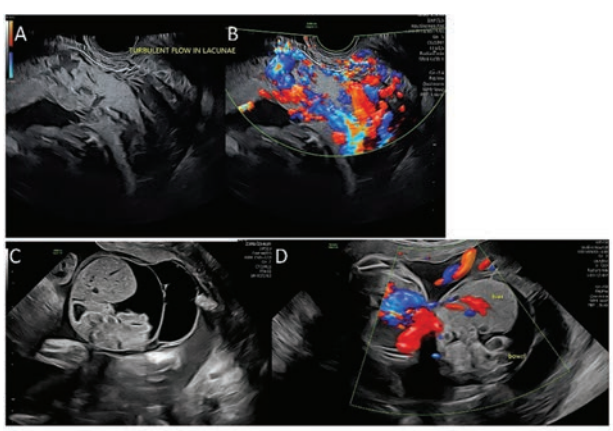

Figure 2: Prenatal imaging of placenta accreta spectrum cases and associated major congenital fetal anomalies. **A/B** anterior placenta previa a patient with one prior Caesarean delivery, with transvaginal imaging showing multiple lacunae with turbulent flow and no discernible myometrium with color Doppler in **B**, associated with a fetus with giant omphalocele and hydrops as seen in **C** and **D**.

1044 | Assessing the Impact of Early Pregnancy Air Travel on First Trimester Miscarriage Rates

Hila Shalev-Ram[1]; Shai Ram[2]; bitya Nehuf[3]; Netanella Miller[4]; Gal cohen[5]; Ron Sconman[6]; Gil Shechter Maor[7]; Tal Biron-Shental[1]
[1]Meir Medical Center, Meir Medical Center, HaMerkaz; [2]ICHILOV, Tel Aviv, HaMerkaz; [3]Jerusalem University, Jerusalem, Yerushalayim; [4]Department of Obstetrics and Gynecology Meir Medical Center, Kfar Saba, HaMerkaz; [5]Meir Hospital, Meir Hospital, HaMerkaz; [6]Department of Obstetrics and Gynecology Meir Medical Center, Kfar Saba, Yerushalayim; [7]Meir Medical Center, Kfar Saba, HaMerkaz

4:00 PM - 6:00 PM

Objective: Our study aimed to investigate the potential association between air travel and spontaneous abortions in the general population, addressing the limited and conflicting data currently available on this subject.

Study Design: We conducted an observational retrospective study using a large dataset comprising 469,976 live births and 76,556 spontaneous abortions from 2010 to 2019. We compared singleton pregnancies that resulted in live births with those that ended in spontaneous abortion in the first trimester, focusing on air travel during the first trimester (4w0d - 13w6d) as the independent variable. The primary outcome was spontaneous abortion. A logistic regression model was used to analyze the association between the outcome and the exposure. Adjusted odds ratios (aOR) and 95% confidence intervals (CI) were reported.

Results: In this study, 427,727 live births (97.2%) and 12,263 (2.8%) spontaneous abortions were recorded. Women who experienced spontaneous abortions exhibited a higher incidence of air travel, with 0.11% having traveled compared to only 0.04% among those who delivered live births (P< 0.001). After adjusting for confounding factors (as detailed in Table 1), the odds ratio for spontaneous abortion was 5.20 (95% CI 4.38-6.33) for those who traveled by air during early pregnancy.

Conclusion: Our study suggests that air travel during early pregnancy is associated with a higher risk of spontaneous abortion.

Table 1. Characteristics of study populations (N = 439,990)

This table presents the demographic and clinical characteristics of the study population, comparing deliveries and spontaneous abortions.

	Deliveries	Spontaneous Abortions	P-value
	N= 427,727 (97.2%)	N= 12,263 (2.8%)	
Maternal age, mean (SD)			
<25	60,169 (14.1%)	1511 (12.3%)	<0.001
25-29	112,960 (26.4%)	3025 (24.7%)	<0.001
30-35	135,499 (31.7%)	3,913 (31.9%)	0.596
>35	119,099 (27.8%)	3,814 (31.1%)	<0.001
BMI, mean (SD)			
<20	41,910 (9.8%)	1,561 (12.7%)	<0.001
20-25	125,715 (29.4%)	4,743 (38.7%)	<0.001
26-30	75,783 (17.7%)	2,744 (22.4%)	<0.001
>30	40,564 (9.5%)	1,259 (10.3%)	0.004
Smoking, n (%)	20,196 (4.7%)	928 (7.6%)	<0.001
Socioeconomic state (SES), mean (SD)	5.9 (2.1)	6.2 (2.0)	<0.001
Chronic hypertension, n (%)	2,660 (0.6)	89 (0.7)	0.167
Pregestational diabetes type 1, n (%)	474 (0.1%)	16 (0.1%)	0.613
Pregestational diabetes type 2, n (%)	854 (0.2%)	37 (0.3%)	0.014
Fertility treatments (IVF), n (%)	24,072 (5.6%)	637 (5.2)	0.042
End of pregnancy week (SD)	40.3 (1.9)	10.3 (2.8)	<0.001
Previous abortion	38,844 (9.1%)	1578 (12.9%)	<0.001
Number of flights, n (%)	17,109 (0.04%)	1294 (0.11%)	<0.001

Continuous variables are presented as mean ± SD and categorical variables as n (%).

*SES levels range between 1 (lowest) to 10 (highest)

Table 2: Multivariable logistic regression analysis: Factors associated with spontaneous abortion.

Variable	Adjusted Odds Ratio (aOR)	95% Confidence Interval	P-value
Air travel during pregnancy	5.20	4.38-6.33	0.008
Past spontaneous abortion	1.36	1.29-1.44	<0.001
Age < 25	1.02	0.96-1.09	0.427
Age 25-29	0.99	0.94-1.04	0.802
Age 30-35	Reference		
Age > 35	1.10	1.05-1.15	<0.001
Religiosity	1.06	1.00-1.12	0.045
BMI < 20	1.68	1.58-1.78	<0.001
BMI 20-25	Reference		
BMI 25-29	1.71	1.64-1.78	<0.001
BMI >30	1.45	1.36-1.55	<0.001
Smoking	1.47	1.37-1.58	<0.001
Socioeconomic state (SES)*	1.07	1.06-1.08	<0.001
Pregestational diabetes type 2	1.40	0.8-2.45	0.224
Fertility treatments (IVF)	0.75	0.69-0.82	<0.001

Factors were included in the multivariable regression model were independent variables found significantly different between groups in the univariate analysis or considered to potentially impact spontaneous abortion. Results are reported as adjusted odds ratios and 95% confidence intervals.

*SES levels range between 1 (lowest) to 10 (highest)

1045 | Utilizing the PEN-FAST Scoring Tool in Pregnant Patients for Syphilis Management Complicated by Penicillin Allergy

Hope Brandon[1]; Noelle Leung[2]
[1]University of Kentucky College of Pharmacy, Lexington, KY; [2]University of Kentucky HealthCare, Lexington, KY

4:00 PM - 6:00 PM

Objective: Assess the PEN-FAST scoring tool in conjunction with direct oral challenge to expedite appropriate syphilis treatment in pregnant patients reporting a penicillin allergy without increasing incidence of penicillin-related adverse reactions.

Study Design: This was a single center, retrospective, case cohort study of pregnant patients with confirmed Syphilis requiring treatment and a reported penicillin allergy between August 2022 through August 2023.

Results: There were six patients included in analysis. Three patients had a PEN-FAST score of zero, two of whom had direct de-labeling of the penicillin allergy while one patient had an oral challenge followed by allergy de-labeling. Three patients had a PEN-FAST score of three. One of these patients had a successful oral challenge with subsequent penicillin allergy de-labeling, one patient received an IV test dose followed by a continuous penicillin infusion and subsequent penicillin allergy de-labeling, and one patient required admission to the intensive care unit for desensitization. All patients were successfully treated for syphilis with penicillin without adverse drug reactions, with only one requiring desensitization. Overall, four out of six patients had their penicillin allergy successfully de-labeled as one patient had a true allergy and one declined de-label. Patients with a documented penicillin allergy had a significant delay in time to treatment compared to patients without a documented penicillin allergy presenting with syphilis during the same time period.

Conclusion: Overall, the PEN-FAST assessment was an efficient and safe tool for stratifying risk of penicillin allergies within this cohort of patients. The clinical impact of this assessment includes decreased utilization of healthcare resources and improved time to treatment for pregnant patients with syphilis. The PEN-FAST

scoring tool in combination with direct oral challenge when needed, resulted in the safe, effective, and timely treatment of six pregnant patients with syphilis.

1046 | Disposition Index as a Predictor of Diabetes Development in Women with Gestational Diabetes

Hiroshi Yamashita[1]; Harumi Kanzawa[1]; Ichiro Yasuhi[2]
[1]NHO Nagasaki Medical Center, Omura City, Nagasaki; [2]NHO Nagasaki Medical Center, Omura-City, Nagasaki

4:00 PM - 6:00 PM

Objective: Gestational diabetes mellitus (GDM) increases the risk of developing type 2 diabetes mellitus (DM) postpartum. The disposition index (DI), reflecting pancreatic beta-cell function in response to insulin resistance, is a potent predictor of diabetes development outside pregnancy. This study aimed to evaluate the utility of early postnatal DI in predicting DM development within three years postpartum in women with GDM.

Study Design: This prospective cohort study included singleton pregnant Japanese women diagnosed with GDM during pregnancy. An oral glucose tolerance test (OGTT) was conducted at 6 to 9 weeks postpartum and repeated every 6 to 12 months. The primary outcome was the development of DM within three years postpartum. Using early postpartum OGTT results, we calculated the Matsuda index (MI) and AUCins/AUCglu (area under the curve of insulin/glucose) over 120 minutes as indices of insulin sensitivity and secretion, respectively, and DI (MI x AUCins/AUCglu). We examined the association between DI and DM development, adjusting for potential confounders including age, family history of DM, insulin treatment during pregnancy, obesity, and breastfeeding.

Results: Among 363 women with GDM (mean age 34 ± 5 years, prepregnancy BMI 23.7 ± 5.0), 14 developed DM (3.9%). DI was significantly lower in the DM group compared to the non-DM group (1.17 ± 0.30 vs. 1.83 ± 0.65, $p < 0.01$). A low DI was significantly associated with DM development (**Figure**). Women with a DI less than 1.58, derived from the receiver operating characteristic curve, had significantly higher odds of developing DM (crude odds ratio 20.6, adjusted odds ratio 12.5; 95% confidence intervals 4.0-376.3 and 2.3-234.6, respectively). Neither MI nor AUCins/AUCglu was significantly associated with DM development.

Conclusion: In Japanese women with GDM, early postnatal DI is a significant predictor of DM development within three years postpartum. Women who developed DM already had impaired beta-cell response to insulin resistance during the early postpartum period.

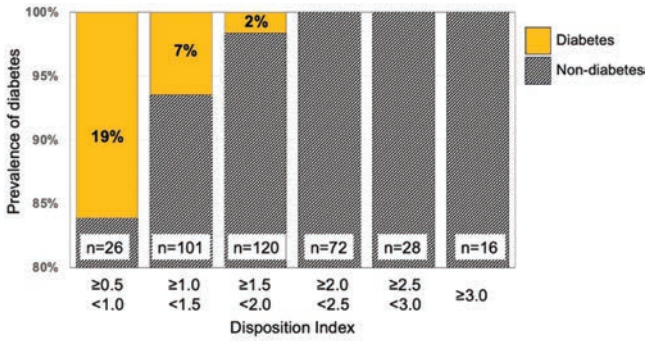

Figure. Association between the disposition index at the 1st postpartum OGTT and the prevalence of diabetes during three years after delivery

1047 | Association between Psychopharmacotherapy and Excessive Gestational Weight Gain

Insaf Kouba[1]; Frank I. Jackson[2]; Nathan A. Keller[2]; Luis A. Bracero[2]; Matthew J. Blitz[2]
[1]Northwell, St. Petersburg, FL; [2]Northwell, New Hyde Park, NY

4:00 PM - 6:00 PM

Objective: To determine the relationship between use of medications to treat mood disorders (psychopharmacotherapy, PPT) and excessive gestational weight gain (EGWG).

Study Design: This retrospective cohort study included all pregnant patients who delivered live, term, singleton newborns at seven hospitals within a large health system in New York from 2019-2023. Patients with missing GWG data were excluded. The primary exposure was prenatal exposure to PPT (yes/no), which included selective serotonin reuptake inhibitors (SSRIs), serotonin-norepinephrine reuptake inhibitors (SNRIs), dopamine-norepinephrine reuptake inhibitors (DNRIs), benzodiazepines, and others. The primary outcome was EGWG (yes/no), defined as weight gain exceeding the upper limit recommended by the Institute of Medicine based on pre-pregnancy BMI. Multiple logistic regression was performed to evaluate the association between PPT and EGWG, adjusting for covariate factors.

Results: A total of 87,385 pregnancies were included for analysis and EGWG occurred in 49.50% (n = 43,261). Patients with mental health conditions had EGWG more often than patients without such conditions (49.3% vs. 54.3%, respectively; aOR 1.26, 95% CI 1.10-1.45). Among the individual PPT categories, only SSRI monotherapy was associated with increased odds of EGWG (aOR 1.21, 95% CI 1.09-1.33) compared to patients without a mental health disorder. Patients taking two medications had higher odds of EGWG (aOR 1.62, 95% CI 1.23-2.16) than those taking one medication (aOR 1.11, 95% CI 1.03-1.20). Regression results are shown in Figure.

Conclusion: Pregnant patients with mental health disorders are at higher risk for EGWG, especially those treated with SSRIs and those receiving multiple PPT medications. Our findings suggest that the type of PPT affects GWG, underscoring the need for tailored management strategies to mitigate excessive weight gain in these patients

1048 | Patient-reported Outcomes of Iron-Deficiency Anemia Treatment in Pregnancy: a Mixed Methods Analysis

Irogue I. Igbinosa[1]; Ijeoma Iweakogwu[1]; Elizabeth B. Sherwin[1]; Sabrina Montgomery[2]; Caroline Berube[1]; Deirdre J. Lyell[1]
[1]Stanford University, Palo Alto, CA; [2]Charles R. Drew University of Medicine and Science, College of Medicine, Inglewood, CA

4:00 PM - 6:00 PM

Objective: Iron deficiency anemia (IDA) in pregnancy is common, yet patient-reported outcomes on IDA treatment are limited. Our objective is to determine whether intravenous iron, compared with oral iron, improves patient-reported outcomes in the treatment of iron-deficiency anemia (IDA) in pregnancy.

Study Design: We conducted a randomized controlled trial of pregnant patients with laboratory-confirmed IDA comparing IV ferumoxytol to oral ferrous sulfate. We assessed patient-reported outcomes with a modified short-form validated survey and free text feedback using a mixed methods approach. We compared the changes in survey domain scores (scale of 0-100) in general health, physical functioning, role limitations due to physical health, and energy/fatigue from study initiation to 4 weeks between treatment groups. We analyzed free-text responses with inductive thematic analysis and compared qualitative themes with quantitative results. Adverse side effects were monitored by survey and a Data Safety Monitoring Board.

Results: Among the 61/80 (76% of the total study) participants who responded to the 4-week survey, participants in the IV ferumoxytol group noted improvements in energy/fatigue, with a median increase of 10 points over 4 weeks compared to no change in the oral ferrous sulfate group (p = 0.018) (Table 1). There were no changes in general health, physical functioning, or role limitations due to physical health at 4 weeks post-treatment in either study group. Thematic analysis of free text responses revealed that patients generally favored IV iron (preferred IV treatment despite randomization, more energy and effectiveness, and fewer side effects) and desired anemia management (follow-up of their hemoglobin levels) (Table 2). Analysis of quantitative and qualitative data reinforced patient preference for IV iron. There were no serious adverse events during the study period.

Conclusion: IV iron significantly improved patient-reported outcomes in quality of life, specifically more energy and less fatigue, compared to oral ferrous sulfate.

Table 1: Median Survey Domain Changes

Median survey domain changes from pre-treatment to 4 weeks post-treatment

Domain[1]	N	Oral iron, N = 34[2]	IV iron (ferumoxytol), N = 29[2]	p-value[3]
Energy/fatigue	60	0 (-10, 10)	10 (0, 30)	0.018
General health	61	0 (-13, 0)	0 (-13, 0)	0.56
Physical functioning	60	-10 (-20, 0)	0 (-20, 10)	0.21
Role limitations due to physical health	58	0 (0, 25)	0 (0, 50)	0.99
Energy/fatigue	60	0 (-10, 10)	10 (0, 30)	0.018

[1]*Possible range -100 to 100. Zero indicates no change and positive number indicates an improvement in the domain.*
[2]*Median* (Q1, Q3)

Table 2. Overarching Themes of Experience with Treatment of Iron Deficiency Anemia In Pregnancy

Themes	Experience with IV Ferumoxytol	Experience of Oral Ferrous Sulfate
Preferred treatment despite randomization	"I preferred infusion because I did not have to worry about taking oral medication." "One-time thing I had to do."	"The [oral iron] treatment worked, although I would have preferred an infusion...instead of remembering to take pills." "I prefer [oral iron] because I am afraid of intravenous meds."
Energy	"Following the infusion, my mom observed a noticeable transformation... I appeared revitalized with a healthy flush to my cheeks."	"I did not feel results when taking oral iron as prescribed. I was usually weak and little to no energy."
Perceived effectiveness of treatment	"I felt like the treatment had faster results and lasted longer."	"I am happy my iron rose to sufficient levels by delivery, but it did take my body time to adjust..."
Patient reported side effects	"[IV iron] didn't cause constipation which is already so hard when pregnant to keep the bowel movements regular."	"The oral iron has been particularly bad because it seems to make me nausea [nauseated] and makes my heart burn worse."
Patient desire for anemia management	"My hemoglobin increased by a lot with the IV and I appreciated that. Postpartum hemoglobin was good too."	"I'm very satisfied since they were testing my blood count every four weeks to see if taking oral iron makes a big difference."

1049 | Relationship Between Patient Trust and Adverse Perinatal Outcomes Among Black and White Pregnant Patients

Jacklyn M. Locklear[1]; Madison Lanza, N/A[2]; Ateshi Bhatt[3]; Briasha Jones[3]; Emily Rebowe[3]; Annie Talbot[4]; Andrew G. Chapple[4]; Jill M. Maples[5]; Alicia Mastronardi[6]; Neelima Sukhavasi[4]; Elizabeth F. Sutton[3]; Kaitlyn Taylor[7]
[1]University of Tennessee Graduate School of Medicine, Department of OB/GYN, Knoxville, TN; [2]LSU Health Science Center, Baton rouge, LA; [3]Woman's Hospital, Baton Rouge, LA; [4]LSU Health Science Center, New Orleans, LA; [5]University of Tennessee Health Science Center, College of Medicine, Knoxville, TN; [6]University of Tennessee Graduate School of Medicine, Department of OB/Gyn, Knoxville, TN; [7]UAMS, UAMS/Little Rock, AR

4:00 PM - 6:00 PM

Objective: To evaluate trust in physicians among different self-reported patient races and evaluate if trust was a contributing factor to adverse perinatal outcomes by evaluating the interplay of trust, patient race and a severe maternal morbidity composite.

Study Design: The 10-item Wake Forest Physician Trust Scale (WFPTS) was administered to pregnant individuals from July 2021- January 2022 (score 10-50; higher scores indicating higher trust) in an academic, primarily Medicaid-funded, OB/GYN practice in Baton Rouge, Louisiana. The survey also included demographic information including self-reported race, household income, and education. Pregnancy and delivery data were abstracted from medical records and coded into a binary adverse perinatal outcome. The composite outcome included any of the following events: transfusion, hospital readmission, intensive care unit admission, non-live birth, PPROM, and pre-term birth.

Categorical variables were compared using Fisher exact tests and continuous variables using Wilcoxon rank sum tests. Logistic and Quasi-Poisson regressions were used to adjust for confounding effects.

Results: Average WFPTS score was 40.1±4.7, indicating moderate-high trust. There was no difference in trust scores between Black patients compared to all other races (40.5±4.5 vs 39.4±4.9, p = 0.116), which held after confounding adjustment for income, age, and education. The adverse perinatal outcome composite occurred in 19% (n = 37) of the study cohort. There were no significant associations between the composite adverse outcome and patient race (aOR 1.65, 95% CI 0.64-4.28, p = 0.301) or trust score (aOR 1.03, 95% CI 0.95-1.12, p = 0.451).

Conclusion: This study showed high levels of trust in physicians across all racial groups. Neither trust score nor race was related to adverse perinatal outcomes in our cohort.

Figure 1. Total Trust Score by Patient Race, P-value = 0.116

1050 | Obesity Remains Associated with Cesarean Delivery Despite Combined Cervical Ripening

Jacqueline J. Thompson[1]; Lisa D. Levine[2]; Celeste Durnwald[1]; Rebecca F. Hamm[2]

[1]*Hospital of University of Pennsylvania, Philadelphia, PA;* [2]*University of Pennsylvania Perelman School of Medicine, Philadelphia, PA*

4:00 PM - 6:00 PM

Objective: Prior studies demonstrate that patients with obesity have increased risk of cesarean delivery (CD) and longer inductions of labor (IOL), however few studies have evaluated this in the context of combination cervical ripening methods.

Study Design: This is a secondary analysis of prospective cohort study of term, singletons with intact membranes and unfavorable cervix undergoing standardized IOL at 2 sites from 2018-2022. This analysis included only IOLs who utilized combined cervical ripening (Foley + either misoprostol or oxytocin concomitantly). Patients were stratified by BMI (< 35 vs. ≥35kg/m2). Primary outcomes included CD and labor length. Poisson regression with robust error variance was used to calculate adjusted relative risks (aRR) for CD. Time-to-event regression analyses for labor length, censored for CD, was modeled with a Cox proportional hazard model. Secondary outcomes included time Foley in, time utilizing misoprostol if applicable, dilation at and time to amniotomy, and maximum dose of oxytocin.

Results: 4,263 patients were included (BMI< 35 = 2,819, ≥35 = 1,444). BMI groups differed by hospital site, race, insurance, parity, diagnosis of diabetes and hypertension, modified Bishop score, maternal age, gestational age, and IOL indication. Even when controlling for differences between groups, patients with BMI ≥35 had a 64% higher risk of CD than those with BMI< 35 (24.0% v. 15.3%; aRR1.64[1.41-1.90]. BMI ≥35 was not associated with differences in length of labor (HR 1.11[0.96-1.29]). While patients with obesity had a similar time utilizing Foley and misoprostol, they had longer time to and were less dilated at amniotomy. Higher maximum oxytocin doses were also utilized in those with BMI > = 35.

Conclusion: Even in the setting of combined cervical ripening methods, patients with BMI ≥35 are at increased risk of CD, although there is no difference in labor length. As our data is indicative of lower success of ripening with BMI > = 35, innovative solutions for IOL are needed to improve CD rate for patients with obesity.

Table 1: Demographic and clinical characteristics by patient BMI

1051 | Maximum Oxytocin Dose in Labor Induction and Associated Pregnancy Outcomes in Nulliparous Individuals

Jae Baek[1]; Marissa J. Berry[1]; Patrick Schneider[2]; Maged M. Costantine[1]; William A. Grobman[1]; Heather A. Frey[1]
[1]The Ohio State University, Columbus, OH; [2]The Ohio State University, Wexner Medical Center, Columbus, OH

4:00 PM - 6:00 PM

Objective: Oxytocin is often used for induction of labor (IOL) with a lack of evidence-based guidelines on its maximum dose. In some institutions, 20 milliunits/minute (mU/min) is used as a maximum dose due to concerns about adverse outcomes at higher rates. We sought to evaluate the relationship between the maximum dose of oxytocin with maternal and neonatal outcomes in low-risk nulliparous individuals.

Study Design: This secondary analysis of the MFMU ARRIVE trial included nulliparous individuals who underwent IOL. The primary exposure was maximum oxytocin dose categorized as ≤ 20 or > 20 mU/min. Logistic regression was used to adjust for gestational age, body mass index, induction without medical indication, Bishop score on admission, and hypertensive disorders of pregnancy.

Results: Of the 3,565 participants included in this secondary analysis, 2,673 (75%) were exposed to a maximum dose of oxytocin of ≤ 20 mU/min and 892 (25%) were exposed to a maximum dose of > 20 mU/min. Those who were exposed to > 20 mU/min of oxytocin had a greater median BMI (p< 0.001) and a lower Bishop score on admission (p< 0.001) (Table 1). Duration from initiation of oxytocin to delivery was longer in the higher-dose group compared to the lower-dose group (median[IQR] ≤ 20 mU/min: 12.1[8.2-17] vs. > 20 mU/min: 21.2 [15.9-257] hours; p< 0.001). Individuals exposed to < 20 mU/min of oxytocin had higher rates of cesarean delivery (adjusted odds ratio [aOR] 1.23, 85%CI 1.01-1.48), cesarean deliver for labor dystocia (aOR 1.63, 95%CI 1.28-2.07), and postpartum hemorrhage (aOR 1.51, 95%CI 1.09-2.09) (Table 2). There was no difference in rates of cesarean delivery for non-reassuring fetal status (aOR 0.80, 95%CI 0.62-1.03), NICU admissions (aOR 1.03 95%CI 0.82-1.30), or neonatal adverse outcomes (aOR 0.97, 95%CI 0.68-1.39).

Conclusion: This analysis showed no difference in rates of cesarean delivery for non-reassuring fetal status or adverse neonatal outcomes at oxytocin rates > 20 mU/min, suggesting that 20 mU/min should not be used as a maximum dose during IOL of nulliparous individuals.

Table 1. Characteristics of the study population

	Maximum oxytocin dose ≤20 mU/minute N=2,673	Maximum oxytocin dose >20 mU/minute N=892	P
Gestational age (weeks)	39.4 (39.1-39.9)	39.4 (39.3-39.9)	0.76

With vaginal delivery	11.5 (8-16)	19.3 (14.4-24.5)	<0.001

Data represented as median (interquartile range) or n (%). BMI: body mass index; PROM: premature rupture of membranes.

Table 2. Maternal and neonatal outcomes by maximum oxytocin dosage.

	Maximum oxytocin dose ≤20 mU/minute N=2,673	Maximum oxytocin dose >20 mU/minute N=892	aOR (95%CI)
Cesarean delivery	589 (22.0)	258 (28.9)	1.23 (1.01-1.48)
Cesarean (dystocia)	259 (9.7)	144 (16.1)	1.63 (1.28-2.07)
Cesarean (non-reassuring fetal status)	322 (12.1)	105 (11.8)	0.80 (0.62-1.03)
Postpartum hemorrhage	123 (4.6)	65 (7.3)	1.51 (1.09-2.09)
Chorioamnionitis	370 (13.8)	137 (15.4)	1.03 (0.82-1.29)
Neonatal composite	134 (5.0)	47 (5.3)	0.97 (0.68-1.39)
NICU admission	333 (12.5)	127 (14.2)	1.03 (0.82-1.30)

Data represented as n (%) and adjusted odds ratio (95%CI). Outcomes were adjusted for by gestational age, body mass index, elective induction, Bishop score on admission, and hypertensive disorders of pregnancy. Neonatal composite consists of any perinatal death, need for respiratory support within 72 hours of life, 5-minute APGAR score of ≤3, hypoxic-ischemic encephalopathy, seizure, confirmed sepsis or pneumonia, meconium aspiration syndrome, birth trauma, intracranial or subgaleal hemorrhage, or hypotension requiring vasopressors. NICU: neonatal intensive care unit.

1052 | Assessment of Disparities in Cerclage Placement Among Individuals with a History of Preterm Birth

Jamie Green; Sarah H. Abelman; Frank I. Jackson; Nathan A. Keller; Julie Chen; Luis A. Bracero; Matthew J. Blitz
Northwell, New Hyde Park, NY

4:00 PM - 6:00 PM

Objective: To evaluate the association between rates of cerclage placement and race and ethnicity group, primary language, and insurance type among patients with a history of preterm birth.

Study Design: This was a retrospective cohort study within a large healthcare system in New York. Patients with were included who had screening cervical length measurements between 16 weeks 0 days and 23 weeks 6 days of gestation and a history of preterm birth due to any indication. Multivariate logistic regression was used to compare rates of cerclage placement by race and ethnicity group, English as primary language, Medicaid insurance, and the presence of a very short cervix < 10mm. All statistical analyses were performed in R 4.3.1.

Results: A total of 3,988 pregnancies in patients with a history of preterm birth were included. A cerclage was placed during 1228 (30.8%) of these pregnancies, and not in the remaining

2760 (69.2%). There were no significant differences in the rates of cerclage placement based on race and ethnicity groups, primary language, or insurance type. Very short cervical length (< 10mm) was associated with a significantly higher rate of cerclage placement (aOR 4.04, 95% CI 2.97-5.51).

Conclusion: Systemic disparities in rates of cerclage placement among patients with a history of preterm birth on the basis of race and ethnicity group, primary language, and insurance type were not identified in this cohort. Patients with a history of preterm birth and a cervical length < 10mm have increased odds of receiving a cerclage.

Chart 1- Incidence of Cerclage Placement by Race/Ethnicity, Language, Insurance and Presence of Cervix <10mm

1053 | Migrating while Pregnant: A Qualitative Study of Immigration and Obstetric Health

Jecca R. Steinberg[1]; Hebron Kelecha[1]; Madeline F. Perry[1]; Allie Valenzuela[1]; Nivedita Potapragada[1]; Erica O'Neill[2]; Ashish Premkumar[3]; Lynn M. Yee[1]

[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Stroger Hospital Cook County, Chicago, IL; [3]Pritzker School of Medicine, University of Chicago, Chicago, IL

4:00 PM - 6:00 PM

Objective: The recent influx of migrants to select regions of the United States (US) has reshaped the demographic landscape and need for social and health services. We aimed to understand the experiences of pregnant people during immigration and in the domestic migration system.

Study Design: This qualitative study applied inductive methods to explore the perspectives of pregnant and postpartum migrants in Chicago, Illinois, a sanctuary city and frequent destination for migrants transported from Texas. To design interviews, we engaged with patients, advocates, physicians, nurses, and social workers through community-based participatory methods. Participants were recruited from a public hospital prenatal clinic and completed validated demographic surveys and semi-structured interviews in Spanish or English. We applied iterative coding of transcripts to develop a codebook, evaluate interrater reliability (Cohen's kappa >0.85), and analyze themes.

Results: Of 12 participants (ages 19-39), 11 identified as Latine and one as Black. Six were in the third trimester, 5 in the second and 1 postpartum. Half had attended or completed university prior to migration. Most were publicly insured (7/12) and the remainder were uninsured (5/12). Participants migrated from Venezuela, Colombia, and Sierra Leone. Interviews revealed that pregnant people face a number of health-harming migration-related circumstances, including: (1) unique obstetric health challenges during migration; (2) significant food insecurity; (3) hazardous conditions in shelters; (4) family separation; (5) limited access to income during pregnancy (largely due to the physically demanding nature of work in the informal sector); and (6) limited access to legal support (Table). When pregnant migrants faced hardship, scarce options were available to improve their circumstances and health.

Conclusion: Pregnant individuals migrating to the US face unique challenges that may negatively influence obstetric health. The current system for migrant support struggles to provide basic obstetric necessities, such as adequate safety, nutrition, or sanitation measures.

Table. Refugee experiences in pregnancy: Themes and representative quotations

Unique obstetric health challenges during migration
"I was pregnant, so, we couldn't run, so, the Immigration official came and said: "Stop now, stop, stop." Because everyone was running away, because the normal thing was to run away, but in our condition, we could not run, because they were going to trap us anyway, and I could also fall. So we stopped and I felt like they were furious about the fact that they could not catch [the other migrants]. They took it out on us. Then, they unloaded on us, beat my husband, pushed us, and knocked my children onto the ground." "It affected me physically because I had an infection, urine infection, and vaginal infection. I had very low hemoglobin...After all that we walked; I had very swollen feet. Contractions even started before."
Significant food insecurity
"I'm currently living in a [refugee] shelter, they give breakfast, lunch, dinner there...it is actually very little amount for my pregnancy. And there are times when I do feel dizzy and I know it is from the poor diet, but we have no income [to buy more food] because we are just beginning our legal immigration process." "I experienced stress while living in the shelter because of concerns about food. During my pregnancy, I lost a significant amount of weight. I am underweight; I did not eat well… That's because the shelter only gave us cookies and juice. There was food available outside, but let's say it was pretty costly."
Hazardous conditions in shelters
"The truth is that I am very concerned about the overcrowding [in the refugee shelter]... there are so many people. There are people who cough, there are people who have a rash on their skin, like rubeola...So that's dangerous too...You have to share the area and if someone coughs...It is difficult to protect my children or protect myself like this, in terms of health." "Well, it affected me during pregnancy because I think around 300 or 400 women were using the bathrooms. I got a lot of infections because I was pregnant."
Family separation
"It was not very good, because they had [my spouse] at one shelter and me at another one. And more than anything, we would live in a friend's car, sleep there, and everything."
Limited access to income during pregnancy
"At the beginning, I had to work in family houses…Because my belly had already grown more, I didn't have the same strength or the same as someone would say…In other words, I no longer performed at the job like in the beginning when I had a tiny belly." "I want to work but don't feel well at some jobs. I used to work making tortillas, but the machine, the assembly line—well, the smell made me dizzy. I fainted once, so I stopped working there. I'm interested in finding a cleaning job, even if it's a modest job, but opportunities in this area are limited."
Limited access to legal support
"I have an appointment for June next year. They haven't told me anything; I don't know. I think I have to wait for the appointment to find out how my process is going…I haven't spoken to a lawyer before; they only gave me my parole and scheduled a date for next year."

1054 | Postpartum Hospital use in the 90 days after Delivery

Jecca R. Steinberg; Mahika Gopalka; Samanvi Kanugula; Lynn M. Yee; Joe M. Feinglass
Northwestern University Feinberg School of Medicine, Chicago, IL

4:00 PM - 6:00 PM

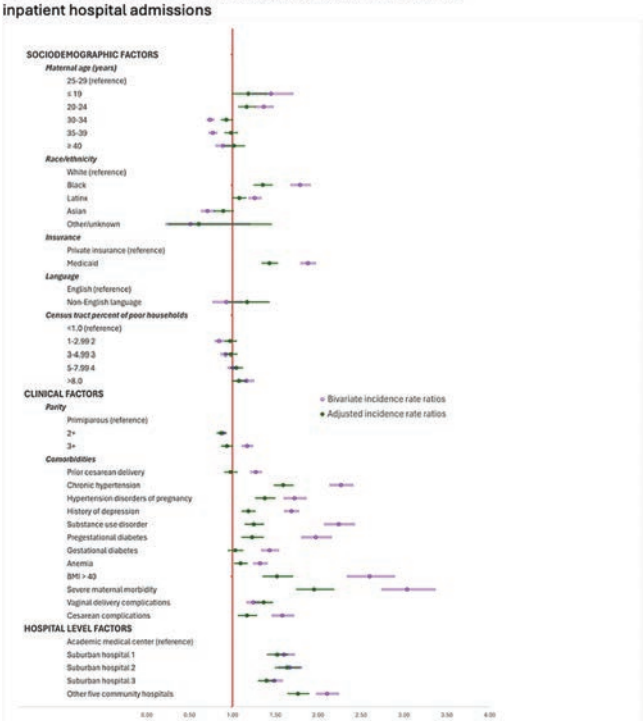
Objective: We aimed to perform a health system-wide analysis of sociodemographic, clinical, and hospital-level factors associated with 90-day postpartum emergency department (ED) visits and inpatient hospital admissions.

Study Design: This cross-sectional study of all 90-day postpartum hospital ED visits and inpatient admissions ("90-day readmission") in a nine-hospital Midwest health system included all births from 1/2018-6/2023. We applied a multilevel eco-social framework to examine associations between factors in three domains and 90-day readmission. Exposure variables included sociodemographic (age, race/ethnicity, insurance, language, census zip code percent poor households), clinical (body mass index [BMI], severe maternal morbidity during delivery admission [SMM], and other comorbidities), and hospital-level factors. We applied bivariate and adjusted Poisson regression analyses.

Results: Of 104,076 deliveries, 6,879 (6.6%) were followed by 90-day readmission. In bivariate analysis, chronic hypertension, substance use disorder, BMI ≥40, and SMM demonstrated the strongest association with 90-day readmission (Figure). After adjusting for all factors under investigation, of sociodemographic factors, Medicaid insurance (adjusted incidence rate ratio [aIRR] 1.43; 95% confidence interval [CI] 1.34-1.45) and Black race (aIRR 1.35; CI 1.25-1.46) were associated with the greatest 90-day readmission risk. SMM remained most strongly associated with 90-day readmission of any factor (aIRR 1.95; 95% CI 1.75-2.18). Chronic hypertension (aIRR 1.59; CI 1.49-1.70) and BMI ≥40 (aIRR 1.52; CI 1.36-1.70) both had elevated 90-day readmission risk. Primiparity and all other medical comorbidities had relatively weaker associations (Figure). At the hospital level, delivery at a suburban or community hospital was associated with greater 90-day readmission risk than delivery at the academic medical center.

Conclusion: In this health system-wide analysis, 90-day readmission is driven by a combination of sociodemographic, clinical, and hospital-level factors, underscoring the need for a comprehensive mitigation strategy.

Figure. Association of clinical, sociodemographic and hospital level factors with 90-day postpartum emergency department visits and inpatient hospital admissions



1055 | Frequency and Type of Chromosome Abnormalities in Stillbirths: Insights from More Than 4000 Cases

Vivienne Souter[1]; Katrina Merrion[1]; Madeleine Armer-Cabral[1]; Katherine Howard[1]; Melda Balcioglu[1]; Kathryn J. Gray[2]; Peter Benn[3]
[1]Natera, Inc., San Carlos, CA; [2]University of Washington, Seattle, WA; [3]UCONN Health, Farmington, CT

4:00 PM - 6:00 PM

Objective: Approximately 1 in 166 pregnancies in the US result in stillbirth (fetal demise ≥20 weeks' gestation) and only a minority have a postmortem examination or genetic evaluation. Our objective was to evaluate chromosomal abnormalities detected by single nucleotide polymorphism (SNP)-based chromosomal microarray (CMA) in products of conception (POC) from a large cohort of stillbirths.

Study Design: Retrospective review of 4,990 fresh POC specimens from singleton pregnancies at ≥ 20 weeks' gestation evaluated 2010-2022. Known pregnancy terminations and livebirths were excluded (278 cases). Illumina CytoSNP-12b SNP-based CMA was used to detect maternal cell contamination (MCC), aneuploidy, triploidy, copy number variants (CNVs), uniparental disomy (UPD), mosaicism, and parental origin of abnormalities.

Results: Of 4,712 samples, 244 (5.2%) had MCC and 37 (0.8%) had an inconclusive result leaving 4,431 samples for analysis. Of these, 517 (11.7%) were abnormal (Table). Median maternal age was 30 and 31 years for normal and abnormal cases, respectively, and median gestational age was 25 and 24 weeks. The percentage of abnormal results increased with maternal age ($p < 0.001$) but not gestational age ($p = 0.34$). Triploidy was not observed after 31 weeks' gestation. Common autosomal trisomies (T21, T18, T13) were present in 3.9%; monosomy X, 2.6%; CNVs with one or more

regions involved, 3.2%; triploidy, 1.0%; and single chromosome UPD, 0.2% (Table).

Conclusion: Here we report a large dataset of CMA analyses in stillbirth. CMA was successfully performed in approximately 95% of cases (MCC explained most of those without a result). More than 1 in 10 cases had an abnormal finding with a spectrum of abnormalities intermediate between those seen in livebirths and those present in early gestation miscarriages. Many of the findings had implications for future **r**eproductive risk. CMA was useful across all maternal ages and all gestational ages at the time of stillbirth.

Table. Abnormalities detected by CMA in 4,431 stillbirths

Abnormality	Non-mosaic (N)	Mosaic (N)	With additional abnormality (N)	Total (N)	Total (% of all cases)
Common autosomal trisomy					
Trisomy 21	97	1	1	99	2.23%
Trisomy 18	41	2	0	43	0.97%
Trisomy 13	24	1	1	26	0.59%
Other autosomal trisomy	27	8	0	35	0.79%
Diandric triploidy (molar)	11	0	1	12	0.27%
Digynic triploidy	30	0	0	30	0.68%
Triploidy (parental origin unknown)	3	0	0	3	0.07%
Monosomy X	113	1	0	114	2.57%
Other sex chromosome abnormality	3	2	0	5	0.11%
CNV	109	7	7	123	2.78%
Possible unbalanced translocation	11	0	0	11	0.25%
Single chromosome UPD	9	0	0	9	0.20%
Multiple abnormalities	7	0	0	7	0.16%
All abnormal results	**485**	**22**	**10**	**517**	**11.67%**

Total sample sizes = 4,431 stillbirths. CNV = copy number variant; UPD = uniparental disomy

1056 | Perinatal Outcomes in Patients with Diagnosed and Undiagnosed Depression

Jessica Britt[1]; Moonseong Heo[2]; Lu Zhang[2]; Amy Crockett[3]
[1]Prisma Health, Prisma Health, SC; [2]Clemson University, Clemson, SC; [3]Prisma Health and University of South Carolina School of Medicine, Greenville, SC

4:00 PM - 6:00 PM

Objective: Each year in the US, 20% of pregnant people suffer from perinatal mental health conditions; up to 75% never receive treatment. The adverse impact of undiagnosed depression is likely underestimated. We aimed to examine the association between diagnosed and undiagnosed depression and birth outcomes.

Study Design: This is a secondary analysis of the CRADLE randomized clinical trial which compared birth outcomes in group vs. individual prenatal care. Patients were included if they completed the Center for Epidemiological Studies-Depression (CES-D) tool and birth outcome data were available. A CES-D score ≥23 was considered positive, and the clinical team was blinded to results. Clinically diagnosed depression (CD) was identified via chart review. Providers used patient history or the Edinburgh Postnatal Depression tool if CD was suspected; universal screening was not being utilized at the time. Patients were classified based on CD during pregnancy and CES-D scores: 1) no depression (no CD and negative CES-D; CON); 2) depression (CD with any CES-D score; DIAG); 3) undiagnosed depression (no CD but positive CES-D; CESD+). The primary outcome was preterm birth (< 37 weeks). Secondary outcomes were low birthweight (< 2,500g), NICU admission, and APGAR < 7 at 1 and 5 minutes. Multivariable logistic regression was performed with CON as the reference and adjustments for race, maternal age, nulliparity, and pregnancy intention.

Results: 1765 patients were included: 1380 (78%) in the CON group, 202 (12%) in DIAG, and 184 (10%) in CESD+. CESD+ patients were more likely to be younger, Black, nulliparous, and have an unintended pregnancy (Table 1). CESD+ patients had increased odds of preterm birth (OR 2.50, 95% CI 1.53-4.10) compared to CON. CESD+ patients had increased odds of all secondary outcomes compared to CON while DIAG had increased odds of low birthweight and NICU admission (Table 2).

Conclusion: Diagnosed and undiagnosed depression is associated with adverse birth outcomes. Increased screening efforts using validated instruments during pregnancy are warranted and may help improve racial equity.

Table 1: Comparison of baseline characteristics between groups.

1057 | Healthy Placental or Umbilical Cord Stem Cell Extracellular Vesicles Restore Preeclamptic Cells to Normal Function

Jessica Greenberg[1]; Shauna F. Williams[2]; Lauren Sherman[3]; Pranela Rameshwar[3]; Bobak Shadpoor[3]
[1]Rutgers New Jersey Medical School, South Orange, NJ; [2]Rutgers New Jersey Medical School, Newark, NJ; [3]Rutgers, Rutgers, NJ

4:00 PM - 6:00 PM

Objective: Preeclampsia (PE) contributes to pregnancy-related morbidity and mortality, with inflammation a critical factor in PE pathophysiology. Healthy placenta mesenchymal stem cells (P-MSC) mitigate inflammation. Our group reported on PE P-MSC dysfunction, characterized by decreased anti-inflammatory licensing, cell cycle dysregulation, and reduced immune suppressive cytokine production. Aspirin (ASA) treatment remedied these via epigenetic reprogramming. This study hypothesized extracellular vesicles (EV) from healthy P-MSCs or umbilical cord (UC) blood could reset PE P-MSCs to a healthy phenotype, improving cell cycle dysregulation and anti-inflammatory capacity.

Study Design: P- and UC-MSCs were isolated from healthy and PE pregnancies at delivery. EVs from healthy MSCs were isolated by differential ultracentrifugation and quantified. PE P-MSCs were exposed to EVs or treated with 1mM ASA for 48h. P-MSCs were added as third-party cells in mixed lymphocyte reaction (MLR) to assess anti-inflammatory capacity. Treated P-MSCs were analyzed for the epigene regulator TDG and cell cycle linked CDK4, p21, and p53 proteins.
Results: EV- and ASA-treated PE P-MSC suppressed MLR to levels of healthy P-MSCs. While ASA increased p21, p53, and TDG, and decreased CDK4, EV treatment decreased their expression. Of note, p53 and TDG remained elevated as compared to healthy P-MSCs while p21 was decreased.
Conclusion: PE P-MSC can be restored towards healthy anti-inflammatory function. The healthy EVs reduced PE-MSC cell cycle with evidence of changes in DNA methylation regulation. These findings are consistent with MSCs exhibiting tissue maintenance during insult. In total, healthy P-MSC EVs may restore the function of PE P-MSCs, as well as other insults during pregnancy. These findings suggest off-the-shelf availability of EVs to treat PE. Combined with prior data on ASA restoring MSC function, this study furthers our understanding of possible methods to reduce PE via anti-inflammatory modality.

1058 | Development and Validation of Ensemble Model for Fetal Birthweight Prediction in Third-Trimester Pregnant Women

Jing Gao[1]; Zhongzhou Xiao[2]; Jie Xu[2]; Weiwei Cheng[3]
[1]International Peace Maternity and Child Health Hospital, Shanghai, Shanghai; [2]Shanghai Artificial Intelligence Laboratory, Shanghai, Shanghai; [3]International Peace Maternal and Child Health Hospital, Shanghai, Shanghai

4:00 PM - 6:00 PM
Objective: On the basis of clinical big data, we aim to develop a machine learning (ML) model for accurate prediction of birth weight in the third trimester of pregnancy, which can help reduce adverse maternal and fetal outcomes.
Study Design: From 1 January 2018 to 31 December 2019, a retrospective cohort study involving 16655 singleton live births without congenital anomalies (> 28 weeks of gestation) was conducted in a tertiary first-class hospital in Shanghai. The initial set of data was divided into a train set for algorithm development and a test set on which the algorithm was divided in a ratio of 4:1. We extracted maternal and neonatal delivery outcomes, as well as parental demographics, obstetric clinical data, and sonographic fetal biometry, from electronic medical records. Five basic machine learning algorithms, including Ridge, SVM, Random Forest, XGBoost, and Multi-Layer Perceptron, were used to develop the prediction model, which was then averaged into an ensemble learning model. The models were compared using accuracy, mean squared error, root mean squared error, and mean absolute error.
Results: Train and test sets contained a total of 13324 and 3331 cases, respectively. From a total of 59 variables, we selected 17 variables that were readily available for the "few feature model" which achieve high predictive power with an accuracy of 81.84% and significantly exceeds ultrasound formula methods. In addition, our model maintained superior performance for low birth weight and macrosomic fetal populations.
Conclusion: Our research investigated an innovative artificial intelligence model for predicting fetal birthweight and maximizing healthcare resource utilization. In the era of big data, our model improves maternal and fetal outcomes and promotes precision medicine.

1059 | Increased BMI Associated with Decreased Breastfeeding Initiation in Million Veteran Program Participants

Joanna Lankester[1]; Rodrigo Guarischi-Sousa[2]; Austin T. Hilliard[2]; Labiba Shere[2]; Marya Husary[2]; Susan Crowe[3]; Philip S. Tsao[2]; David H. Rehkopf[3]; Themistocles L. Assimes[2]
[1]Palo Alto Veterans Affairs/Stanford University, Palo Alto, CA; [2]Palo Alto Veterans Affairs, Palo Alto, CA; [3]Stanford University, Stanford, CA

4:00 PM - 6:00 PM
Objective: Breastfeeding has been associated with maternal and infant health benefits but has been inversely associated with body mass index (BMI) prepartum. Breastfeeding and BMI are both linked to socioeconomic factors. The objective of this study was

to disentangle the underlying biological association between BMI and breastfeeding initiation using a genetic predictor of BMI.
Study Design: Data from parous female participants with available breastfeeding information from the Million Veteran Program cohort was included (n = 20,375). BMI at enrollment and earliest BMI available were extracted, and polygenic scores (PGS) for BMI were calculated. We modeled breastfeeding for one month or more as a function of BMI at enrollment; earliest BMI where available pre-pregnancy; and PGS for BMI. We conducted Mendelian randomization for breastfeeding initiation using PGS as an instrumental variable.
Results: A higher BMI predicted a lower likelihood of breastfeeding for one month or more in all analyses. A +5 kg/m^2 BMI pre-pregnancy was associated with a 24% reduced odds of breastfeeding, and a +5 kg/m^2 genetically predicted BMI was associated with a 17% reduced odds of breastfeeding.
Conclusion: BMI predicts a lower likelihood of breastfeeding for one month or longer. The impact of breastfeeding on later BMI is an important future direction of research. Given the high success of breastfeeding initiation regardless of BMI in supportive environments as well as potential health benefits, patients with elevated BMI may benefit from additional postpartum breastfeeding support.

Observational analysis predicting breastfeeding initiation as a function of earliest prepartum body mass index (BMI). Odds ratio (OR) and 95% confidence interval for analyses: (a) by quartile (Q1 - lowest value, Q4 - highest value; Q1 is reference with OR=1) and (b) continuous (OR per +5 kg/m^2).

Covariates	Q2	Q3	Q4	Continuous
None (univariate)	0.91 (0.52,1.58)	0.63 (0.34,1.17)	0.37 (0.16,0.84)	0.72 (0.56,0.92)
age at earliest BMI measurement + race/ethnicity + education level + income level + smoking status	0.87 (0.48,1.55)	0.74 (0.38,1.43)	0.37 (0.15,0.94)	0.76 (0.58,0.99)
age at earliest BMI measurement + race/ethnicity + education level + income level + smoking status + married/partnered status + number of births	0.87 (0.48,1.58)	0.87 (0.44,1.72)	0.34 (0.13,0.87)	0.76 (0.58,1.00)

1060 | Concordance of Maternal GBS DNA-PCR Rectovaginal test at 36 weeks and Maternal/Neonatal Testing at Delivery

Amanda Peña[1]; Meredith Rochon[1]; Guillermo De La Vega[1]; Kara Madey[2]; Kyle Shaak[3]; Joanne N. Quiñones[1]
[1]Lehigh Valley Health Network, Allentown, PA; [2]University of South Florida Morsani College of Medicine, Tampa, FL; [3]Network Office of Research and Innovation, Lehigh Valley Health Network, Allentown, PA

4:00 PM - 6:00 PM
Objective: GBS is an important cause of neonatal infectious morbidity. Universal GBS screening via rectovaginal test in the late third trimester, with intrapartum antibiotic prophylaxis if GBS positive, decreases the risk of neonatal GBS infection. The effectiveness of this strategy depends on the predictive nature of this result, and GBS point-of-care (POC) testing at the time of delivery admission has been proposed as a possible strategy to further decrease neonatal risk. The goal of this study was to determine discordance between a negative GBS test at 36 weeks and at the time of delivery using GBS DNA-PCR.
Study Design: Prospective pilot study of pregnant persons with a negative GBS DNA-PCR rectovaginal test on routine screen at 36 weeks intending to deliver vaginally at the study institution from 3/2023-4/2024. On admission for delivery, repeat maternal rectovaginal GBS DNA-PCR was performed; immediately after delivery, GBS DNA-PCR testing was performed on the placenta and neonatal ear. Results were not disclosed to the clinical team and intrapartum/neonatal care was otherwise routine. Primary outcome was GBS positive rate. Planned sample size was 60. Study supported by an institutional grant.
Results: 39 patients were enrolled; 9 did not complete the study (tests not performed as planned, subject withdrew or delivered elsewhere) for 30 completed subjects. Recruitment was terminated early due to slow enrollment. Most subjects were White (80.0%), non-Hispanic (86.7%), and multiparous (60.0%), Table. Mean gestational age at delivery was 40.3±0.68 wks and 93.3% delivered vaginally. Of the 90 GBS DNA-PCR study tests performed, 2/90 (2.2%) were positive in 2 different patients–1 maternal rectovaginal and 1 neonatal ear–for a GBS positive rate of any result in 2/30 (6.7%) patients. There were no cases of neonatal GBS sepsis.
Conclusion: Maternal and neonatal GBS DNA-PCR testing results done at 36 weeks and at the time of delivery are highly concordant. Our findings suggest that the addition of GBS POC testing at the time of delivery admission is likely low yield and would add additional cost.

Table. Characteristics and outcomes of GBS concordance study population	
Baseline Characteristics	
Age at delivery, years	30.6 ± 4.4

1061 | How does Needing an Interpreter Affect Outcomes among Primarily Non-English Speaking Patients?

Jocelyn Reckford[1]; Nandini Raghuraman[1]; Antonina I. Frolova[2]; Amanda C. Zofkie[1]; Sherri Jackson[1]; Katherine H. Bligard[1]; Jeannie C. Kelly[1]
[1]Washington University School of Medicine in St. Louis, St. Louis, MO; [2]Washington University School of Medicine, St. Louis, MO

4:00 PM - 6:00 PM

Objective: The need for interpreter services has been linked to poor health outcomes but remains understudied in the obstetric population. We sought to compare outcomes among patients whose primary language was not English between those who used an interpreter and those who did not.

Study Design: We performed a retrospective cohort study of all patients delivering at an urban tertiary care center between 2021-2023 who self-reported their primary language as anything other than English. Patients were dichotomized between those who used an interpreter versus those who did not; all patients with non-English as a primary language are offered interpreter services. Our primary outcomes were mode of delivery, gestational age at delivery, and low birth weight (LBW, < 2500g); secondary outcomes included postpartum hemorrhage (PPH), shoulder dystocia, APGAR at 5 minutes, and perineal lacerations. Mann-Whitney U, chi-square, fisher exact, and multivariable logistic regression were performed appropriately.

Results: 767 patients reported a primary language other than English; 396 (51.6%) did not use an interpreter and 371 (48.4%) did. There were lower rates of Hispanic ethnicity (28% vs 43%, p< 0.001) and gestational hypertension (11% vs 16%, p = 0.010), and higher rates of pre-existing diabetes (4.3% vs 1.3%, p = 0.035) among patients who used interpreters, as well as differences in self-reported race between groups (Table 1). There were no differences in age, parity, BMI, or rates of chronic hypertension. Gestational age at delivery and LBW did not differ between cohorts (Table 2); most patients delivered at term with birthweights >2500g. However, there were increased odds of cesarean (aOR 1.08, 95% CI 1.02-1.14) and PPH (aOR 1.61, 95% 1.43-1.82) in the cohort who used an interpreter.

Conclusion: For delivering patients whose primary language was not English, needing an institutional interpreter was associated with a higher risk of cesarean delivery and PPH. These results suggest that language barriers in the labor unit are an important target to improve outcomes, especially for those who require an interpreter.

1062 | Routine Genetic Carrier Screening Practices During Prenatal Care and Perceptions Regarding Expanded Carrier Screening

Joseph Levy[1]; Carolyn Chatterton[2]; Melissa Hicks[3]; Devika Maulik[1]
[1]University of Missouri-Kansas City, Kansas City, MO; [2]Detroit Medical Center/Wayne State University, Detroit, MI; [3]Detroit Medical Center / Wayne State University, Detroit, MI

4:00 PM - 6:00 PM

Objective: The American College of Obstetricians and Gynecologists (ACOG) and the American College of Medical Genetics

(ACMG) disagree on prenatal genetic carrier screening (GCS) guidelines. ACOG recommends routine screening for 2 genes plus risk based screening, while ACMG recommends screening for genes with a ≥1/200 carrier frequency. We sought to understand current GCS practices, and perceptions of expanded genetic carrier screening (EGCS).

Study Design: An electronic survey was distributed to obstetrical providers, including Ob/Gyns, midwives, and medical students. For statistical analysis, logistic regression was used.

Results: 210 responses were recorded from 37 states. The majority of responses were from providers in Michigan (20%, n = 42), in an urban setting (49.5%, n = 104), and practicing as Ob/Gyn physicians (81.9%, n = 172) or Maternal Fetal Medicine physicians (14.8%, n = 31). For a low risk prenatal patient, providers reported screening for a wide range of genes (1-445 genes, Fig. 1). Most reported screening for 14 genes (n = 49, 23.3%), followed by 4 genes (n = 33, 15.7%). A minority of providers deviate from this practice, with some (4.6%) basing the gene number on patient preferences, while others (5.7%) routinely screen for >100 genes; furthermore, 12.9% of providers were unsure of the number screened (Fig. 1). Overall, 62.4% (n = 131) of respondents support expanding ACOG recommendations for routine GCS for low risk PNC. Increased provider comfort level for counseling patients on GCS results was significantly associated with increased support for EGCS (p = 0.02) (Fig. 2). Perceived barriers to integrating EGCS include concerns about patient cost, a lack of appropriate pre and post-test counseling, and clinic logistics.

Conclusion: There is significant heterogeneity in current GCS practices among obstetrical providers. The majority of respondents support an updated ACOG practice guideline for EGCS. Given the rapidly changing landscape of genetic technology and reproductive choice, increased provider education is paramount to overcome potential barriers to implementing EGCS and achieving equitable PNC.

Figure 1: Number of Genes Routinely Screened in a Low Risk Patient During Prenatal Care

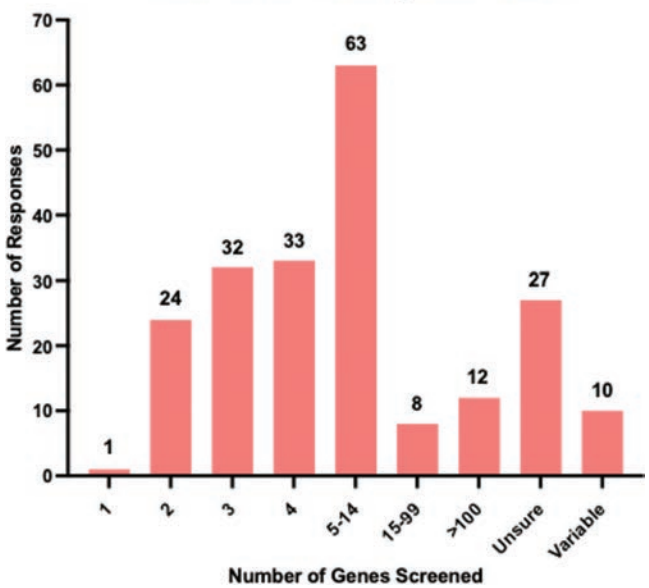

Figure 2: Relationship between provider comfort level with counseling patients about GCS results and support for updated ACOG recommendations

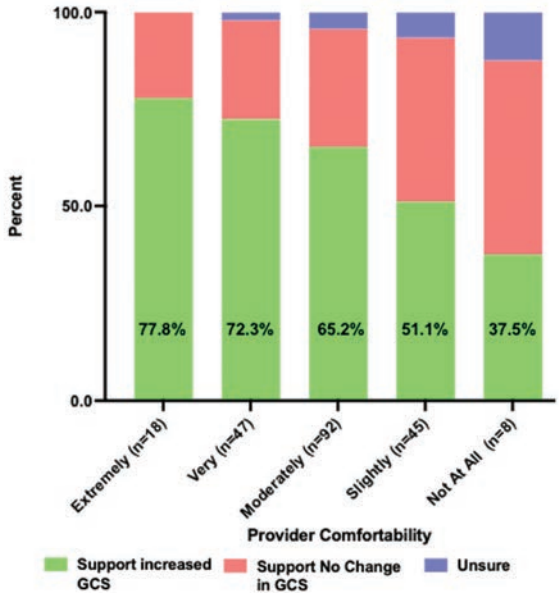

1063 | Risk Of Severe Maternal Morbidity and Mortality Among Pregnant Patients with Chronic Kidney Disease

Joyce H. Xu[1]; Isabella Toledo[2]; Emily A. DeFranco[3]; Carri Warshak[1]; Heather N. Czarny[1]; Robert M. Rossi[1]

[1]*University of Cincinnati College of Medicine, Cincinnati, OH;* [2]*Indiana University School of Medicine, Indianapolis, IN;* [3]*Department of Obstetrics and Gynecology, University of Kentucky, Lexington, KY*

4:00 PM - 6:00 PM

Objective: Chronic kidney disease (CKD) is a significant cause of adverse obstetric outcomes, yet few studies assess the risk of severe maternal morbidity (SMM) among those with CKD. We evaluated the prevalence and association of CKD with SMM.

Study Design: This was a population-based, retrospective cohort study of U.S. delivery hospitalizations from 2010-2020 utilizing the National Inpatient Sample database. Patients were identified as having a delivery hospitalization, CKD, and SMM using International Classification Diagnoses codes (9th and 10th edition). The primary outcome of SMM was defined by the Centers for Disease Control and Prevention criteria. Multivariate logistic regression analyses were used to estimate adjusted relative risks (aRR) and 95% confidence intervals (CI). Subgroup analyses were performed by CKD subtype, stage, race and ethnicity, and individual SMM indicators.

Results: Among 38,374,326 parturients, 77,210 (0.2%) had CKD. CKD was associated with an increased risk of SMM (aRR 7.2, 95% CI 6.7-7.6) and maternal death (aRR 4.6, 95% CI 3.2-6.4). Increased risk of SMM was associated with all CKD subtypes, stages, and a history of renal transplant. Those with CKD were at the highest risk for acute renal failure (aRR 24.4, 95% CI 22.2-26.8) and sepsis (aRR 9.3, 95% CI 7.9-11.0) (Table 1). Black individuals had a higher adjusted population attributable fraction between SMM and CKD (3.8%, 95% CI 3.5-4.1). Maternal death was significantly associated with diabetic nephropathy, renovascular, and obstructive or unspecified CKD (aRR 7.3-14.1), as well as CKD

stages 3-5 (aRR 15.5-32.6). The risk of SMM and maternal death was similar in those with a history of renal transplant and those with stage 1 CKD (Figure 1). The number needed to treat with renal transplant to prevent one SMM event or maternal death in those with stages 3-5 CKD was 2.6 (95% CI 2.4-2.9) and 45.0 (95% CI 31.0-82.0), respectively.

Conclusion: CKD in pregnancy was significantly associated with SMM, mortality, and other adverse perinatal outcomes, warranting close surveillance and multidisciplinary management throughout pregnancy.

Table 1. Incidence of Severe Maternal Morbidity at Delivery Hospitalization in Individuals with Chronic Kidney Disease in the United States, 2010–2020 (n=38,374,325)

SMM Indicators	CKD (n=77,210)	No CKD (n=38,297,116)	Relative Risk (95% CI)
Composite SMM	10,728 (13.9)	272,481 (0.7)	7.2 (6.7-7.6)
Transfusion SMM	12,873 (16.7)	659,511 (1.7)	4.5 (4.3-4.8)
Maternal death	342 (0.44)	2,734 (0.007)	4.6 (3.2-6.4)
Cardiovascular SMM per 10,000 delivery hospitalizations			
Acute myocardial infarction	175 (22.72)	1,354 (0.35)	2.3 (1.5-3.5)
Aneurysm*	30 (3.94)	1,108 (0.29)	1.1 (0.5-2.6)
Cardiac arrest/ventricular fibrillation	249 (32.23)	3,262 (0.85)	2.2 (1.6-3.3)
Conversion of cardiac rhythm	259 (33.53)	2,974 (0.78)	2.7 (1.8-4.0)
Heart failure/arrest during surgery*	74 (9.63)	2,294 (0.60)	2.5 (1.3-4.7)
Puerperal cerebrovascular disorders	382 (49.48)	12,398 (3.24)	2.1 (1.6-2.8)
Renal SMM per 10,000 delivery hospitalizations			
Acute renal failure	7,135 (924.1)	34,235 (8.94)	24.4 (22.2-26.8)
Respiratory SMM per 10,000 delivery hospitalizations			
Acute respiratory distress syndrome	2,290 (296.6)	31,650 (8.26)	4.3 (3.7-5.0)
Pulmonary edema / Acute heart failure	2,941 (380.87)	23,871 (6.23)	3.9 (3.4-4.6)
Pre-eclampsia Related SMM per 10,000 delivery hospitalizations			
Eclampsia	214 (27.67)	27,771 (7.25)	1.5 (1.1-2.0)
Infectious SMM per 10,000 delivery hospitalizations			
Sepsis	1,508 (195.33)	23,159 (6.05)	9.3 (7.9-11.0)
Shock	1,893 (245.22)	20,774 (5.42)	6.3 (5.4-7.4)
Hemorrhagic SMM per 10,000 delivery hospitalizations			
Disseminated intravascular coagulation	1,311 (169.79)	97,655 (25.50)	2.7 (2.4-3.1)
Blood transfusion	5,006 (648.41)	446,117 (116.49)	2.2 (2.1-2.4)
Thromboembolic SMM per 10,000 delivery hospitalizations			
Sickle cell disease with crisis*	65 (8.36)	4,225 (1.10)	1.8 (1.0-3.2)
Amniotic fluid embolism*	46 (5.90)	1,579 (0.41)	3.3 (1.6-6.9)
Air and thrombotic embolism	265 (34.31)	8,917 (2.33)	2.9 (2.1-4.0)
Morbidity-Associated Procedures per 10,000 delivery hospitalizations			
Severe anesthesia complications*	34 (4.39)	3,876 (1.01)	1.5 (0.7-3.2)
Hysterectomy	792 (102.60)	41,014 (10.71)	3.7 (3.0-4.4)
Temporary tracheostomy	125 (16.24)	533 (0.14)	7.5 (4.0-14.1)
Ventilation	1,017 (131.74)	18,102 (4.73)	2.7 (2.2-3.4)

Data are displayed in the table as n (%) or relative risk (95% confidence interval)
CKD: chronic kidney disease; SMM: severe maternal morbidity; transfusion SMM: severe maternal morbidity including transfusion codes
Model adjusted for advanced maternal age, race, government insurance, class III obesity (BMI > 40), social determinants of health, tobacco use, anemia, chronic hypertension, severe preeclampsia, chronic cardiac disease, pregestational diabetes, and mode of delivery.
*Model adjusted for mode of delivery, preeclampsia, and cardiac disease only due to rarity of events

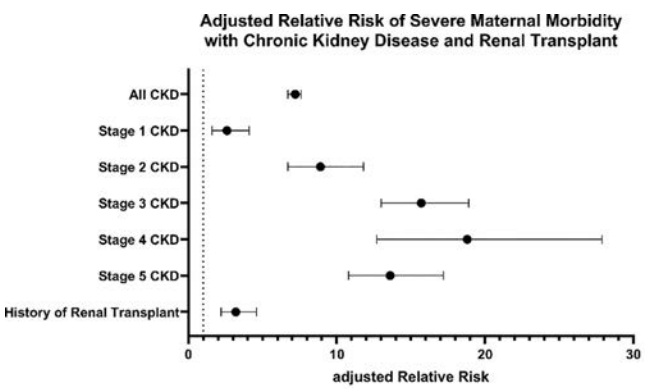

Figure 1. Adjusted Relative Risk of Severe Maternal Morbidity (SMM) by Chronic Kidney Disease (CKD) Stage and History of Renal Transplant in the United States, 2010-2020. Referent group is those without CKD diagnosis (dotted line). Error bars present 95% confidence intervals. SMM events include those defined by the Center for Disease Control and Prevention (acute myocardial infarction, aneurysm, cardiac arrest or ventricular fibrillation, conversion of cardiac rhythm, heart failure or arrest during surgery, puerperal cerebrovascular disorders, pulmonary edema or acute heart failure, acute renal failure, adult respiratory distress syndrome, temporary tracheostomy, ventilation, severe anesthesia complications, eclampsia, sepsis, shock, disseminated intravascular coagulation, air and thrombotic embolism, sickle cell disease with crisis, amniotic fluid embolism, and hysterectomy) but excludes transfusion.

1064 | Effect of Intraoperative Sublingual Nitroglycerin on Active Segment Uterine Incision Rate in Preterm Cesarean Delivery

Judy Jiang[1]; Alexandra L. Berra[2]; Megan Breen[3]; Brittany Butler[4]; Anna Rybinska-Campbell[5]; Angela Ranzini[6]
[1]Case Western Reserve University/Metrohealth, Cleveland, OH; [2]Case Western Reserve University Metrohealth Medical Center, Cleveland, OH; [3]Ohio State University, OH; [4]Saint Peter's University Hospital, Saint Peter's University Hospital, NJ; [5]Metrohealth, Cleveland, OH; [6]The MetroHealth System, Cleveland, OH

4:00 PM - 6:00 PM

Objective: Active segment uterine incisions, including classical, T-shaped and high transverse incisions are often performed during preterm cesarean deliveries (CD). These uterine incisions increase the risk of maternal morbidity with longer operative time, increased blood loss, and rate of uterine dehiscence in future pregnancies compared to lower segment uterine incisions. Patients with uterine incisions in the active segment are also not candidates for future trials of labor. Nitroglycerin is known to cause uterine relaxation and has been used in cases of uterine inversion and Bandl's rings. Our primary aim was to determine if intraoperative sublingual nitroglycerin is associated with decreased active segment uterine incision rate in patients undergoing CD prior to 30 weeks of gestation. Secondary outcomes included maternal blood loss, umbilical artery pH, and five minute APGAR scores.

Study Design: In this case control study, patients with singleton pregnancy between 22 weeks 0 days and 29 weeks 6 days of gestation undergoing CD at two community-based hospitals were compared between the years of 2017 and 2023. Maternal and neonatal variables were collected and analyzed using equality of means, Mann-Whitney U tests as appropriate.

Results: Patients who received nitroglycerin (n = 26) were compared with patients at the same week of gestation who did not receive nitroglycerin (n = 26) during cesarean delivery. The rate of active segment uterine incision was lower in the group that received nitroglycerin intraoperatively (26.9%) compared to the group that did not (61.5% p = 0.012). Quantitative blood loss (QBL) was significantly decreased in patients who received nitroglycerin with a mean QBL of 583mL compared to 794mL in patients who did not (p = 0.002). Neonatal outcomes including umbilical artery pH and APGAR scores were not found to be significantly different between the two groups.

Conclusion: Intraoperative nitroglycerin administration was associated with a lower rate of active segment uterine incision in patients undergoing CD and decreased maternal blood loss. Neonatal outcomes were similar between groups.

1065 | Factors Associated with Exclusive Formula Feeding in Individuals with History of Diabetes in Pregnancy

Julia Sroda Agudogo[1]; Krysten North[2]; Chloe Zera[1]; Stephen Wagner[1]; Anna M. Modest[1]
[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA

4:00 PM - 6:00 PM

Objective: Infants of those with diabetes are less likely to be breastfed despite unique benefits in this population. Knowledge of factors associated with exclusive formula feeding (EFF) would enable identification of patients at high-risk of lactation difficulties. Our objective was to investigate factors associated with EFF in those with pregestational diabetes (PGDM) or gestational diabetes (GDM).

Study Design: The United States Vital Statistics Birth Certificate data was utilized in this retrospective cohort study. Singleton pregnancies with PGDM or GDM from 2016-2022 were included. Pregnancies with missing infant feeding and diabetes data were excluded. We evaluated EFF risk at hospital discharge across multiple maternal and neonatal characteristics and morbidity within both groups. Composite maternal morbidity included admission to ICU, blood transfusion, clinical chorioamnionitis/fever, uterine rupture, unplanned hysterectomy, and perineal laceration. Composite neonatal morbidity included admission to NICU, APGAR score < 5 at 5 min, assisted ventilation > 6 hours and neonatal seizure.

Results: Of the 1,796,752 births included, 227,948 (12.7%) had PGDM and 1,568,804 (87.3%) had GDM. Demographic factors associated with EFF included racial minorities especially non-Hispanic Black, education less than college level, single marital status, lack of prenatal care, smoking in pregnancy, underweight, overweight and obesity within both groups (Table 1). EFF was more likely after caesarean delivery and operative vaginal delivery compared to vaginal delivery within both groups (Table 2). Composite maternal morbidity, ICU admission and transfusion were associated with increased EFF, while clinical chorioamnionitis/fever was not associated with increased EFF within both groups. EFF was more likely within the setting of composite neonatal morbidity or preterm delivery within both groups (Table 2).

Conclusion: This study demonstrates that several maternal and neonatal risk factors are associated with EFF among those with PGDM or GDM. There is a need for enhanced breastfeeding support in this vulnerable population.

Table 1: Risk of exclusive formula feeding (EFF) by patient demographics

Characteristic	Risk ratio (95% confidence interval) Pregestational Diabetes (n=227,948)	Gestational Diabetes (n=1,568,804)

1066 | First Trimester Combined Screening for Preterm Preeclampsia using the Fetal Medicine Foundation Competing Risks Model

Juliana Martins[1]; Elizabeth Miller[2]; Michael Bittner[2]; Daniel L. Rolnik[3]; Tetsuya Kawakita[4]

[1]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medial School at Old Dominion University, Virginia Beach, VA; [2]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medial School at Old Dominion University, Norfolk, VA; [3]Monash University, Melbourne, South Australia; [4]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA

4:00 PM - 6:00 PM

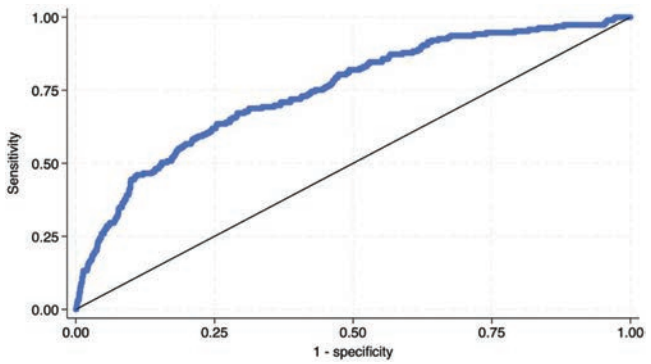
Objective: To assess the performance of first trimester combined screening using the Fetal Medicine Foundation (FMF) model for the prediction of preterm preeclampsia in a U.S. population.

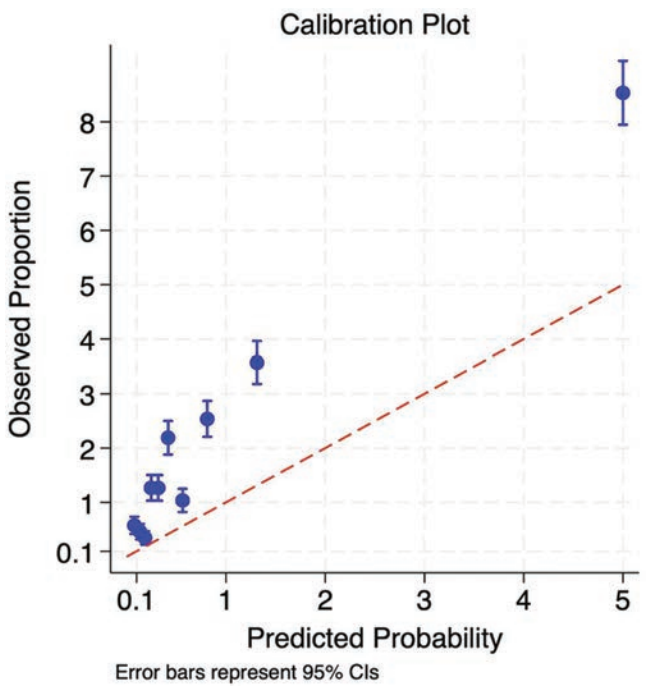
Study Design: This was a secondary analysis of the Nulliparous Pregnancy Outcomes Study: Monitoring Mothers-to-be database. Diagnoses of chromosomal or structural fetal abnormality, miscarriage, or fetal death before 24 weeks of gestation, and those missing information regarding gestational age at delivery or preeclampsia were excluded. Variables in the FMF risk calculation included maternal factors, mean arterial pressure, biochemical markers, and uterine artery pulsatility index. We assessed the model performance using the area under the curve (AUC) of the receiver operating characteristic (ROC) curve using a bootstrap method. The optimal cutoff point was determined using Liu's method and calculated sensitivity, specificity, positive and negative predictive values (PPV, NPV), positive and negative likelihood ratio (LHR), and odds ratio (OR). Goodness of fit was evaluated by calibration plot.

Results: The study analyzed 8,675 nulliparous women, among whom 2.18% had preterm preeclampsia. The ROC curve (Figure 1) revealed an AUC of 0.75, with a 95% confidence interval (CI)

of 0.71 to 0.78 at the optimal cutoff point of 0.7%. Sensitivity of the model was 64.0% (95% CI 56.7–70.9), and specificity was 72.5% (95% CI 71.5–73.4). The PPV was 4.9% (95% CI 4.1–5.9), whereas NPV was 98.9% (95% CI 98.6–99.1). The positive LHR was 2.3 (95% CI 2.1–2.6), and the negative LHR was 0.5 (95% CI 0.4–0.6). OR for predicting preterm preeclampsia was 4.7 (95% CI 3.5–6.3). Overall, the FMF model underestimated the risk of preterm preeclampsia as shown by calibration plot (Figure 2).

Conclusion: The FMF combined screening algorithm demonstrates a moderate ability to predict preterm preeclampsia in a U.S. nulliparous population, indicating a fair discriminative power. Ongoing prospective studies aim to validate this model across diverse populations, potentially leading to more tailored and effective pre-eclampsia prediction.





1067 | Association of CDC Social Vulnerability Index and Adequate Prenatal Care

Julie Robin Dean[1]; Anna P. Staniczenko[1]; Kristin M. Voegtline[2]; Charlene Thomas[2]; Steven Yen[2]; Evan Sholle[2]; Lauren M. Osborne[2]; Heather S. Lipkind[2]; Moeun Son[2]

[1]Weill Cornell Medical College, New York, NY; [2]Weill Cornell Medicine, New York, NY

4:00 PM - 6:00 PM

Objective: Disparities in prenatal care (PNC) access are a major public health issue. We aimed to evaluate the association between the CDC Social Vulnerability Index (SVI) and receipt of adequate prenatal care.

Study Design: This was a retrospective case control study of patients delivered at 3 hospitals within a New York City health system from 1/1/22 to 5/31/24 who had at least 1 completed PNC visit at < 20 weeks' gestation at an affiliated clinic. Data were extracted from the electronic medical record. Outcomes were based on the distribution of the number of outpatient PNC visit encounters among the cohort: inadequate PNC was defined as ≤8 visits (≤25th percentile) and adequate PNC was defined as >8 visits. The exposure of interest was CDC-defined SVI, which was calculated using a validated technique for geocoding patient addresses: FIPS codes were generated for the census tract and block group of each patient's home address to generate overall SVI and SVI theme scores. SVI scores were converted into categorical variables by quartiles signifying low to high social vulnerability. Other sociodemographic, medical, and obstetric factors were examined. Univariate and multivariate logistic regression models were performed.

Results: Compared to those with adequate PNC, those with inadequate PNC were more often Black, Hispanic, non-married, and < 21 years old. Among the SVI quartiles, high vulnerability SVI had the greatest number of patients with inadequate PNC (40.0%). Compared to those with low SVI, patients with mid-high and high SVI had the lowest odds of adequate PNC (respectively: OR = 0.84, 95% CI 0.73, 0.96; OR = 0.67, 95% CI 0.58, 0.77). Of the SVI themes, socioeconomic status and household composition had the strongest associations with inadequate PNC.

Conclusion: Social vulnerability is associated with adequacy of prenatal care. The CDC's SVI may be a useful tool to identify patients at risk of receiving inadequate prenatal care and linking them to appropriate resources.

Table 1. Frequency and odds of adequate prenatal care by CDC Social Vulnerability Index (SVI)

Characteristic	Number of patients (n, %)		Odds of adequate prenatal care (OR [95% CI])	Adjusted odds of adequate prenatal care* (aOR [95% CI])
	Adequate prenatal care (>8 visits) n=18,243	Inadequate prenatal care (≤8 visits) n=3,004	n=21,132	n=21,132

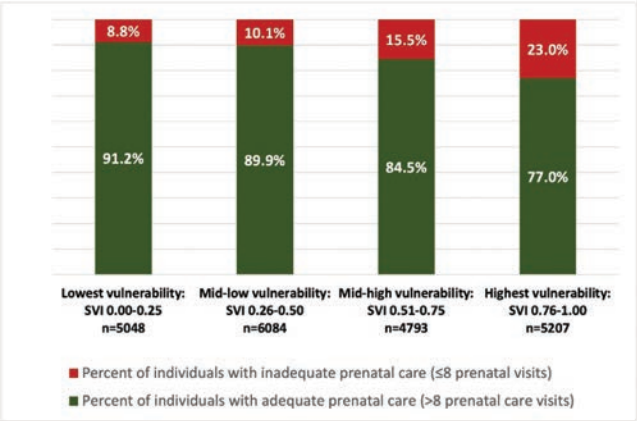
SVI=social vulnerability index, OR=odds ratio, CI=confidence interval, aOR=adjusted odds ratio

^The Centers for Disease Control and Prevention Social Vulnerability Index (SVI) uses 16 U.S. census variables from the 5-year American Community Survey; these variables are grouped into four themes (socioeconomic status, household characteristics, racial and ethnic minority status, housing type and transportation) and then combined into a single measure of overall social vulnerability.

*Adjusted for factors that were significantly associated with adequate prenatal care in univariate analyses: maternal age, marital status, preferred language, employment status, delivery hospital, number of OB providers seen during prenatal care, antepartum admission, GA at first visit, multifetal gestation, BMI>30, in vitro fertilization pregnancy, pregestational diabetes, and gestational diabetes. Race, ethnicity, insurance status, and SVI themes, although associated with adequate prenatal care, were not included in multivariate model due to high collinearity.

**Those with unknown SVI were excluded from univariate and multivariate analyses.

Figure 1. Distribution of prenatal care adequacy based on CDC Social Vulnerability Index (SVI)



1068 | Maternal Serum Leptin Level in Early-and mid-Gestation as a Possible Marker of Fetal Adiposity

Junko Tamai[1]; Satoru Ikenoue[1]; Keisuke Akita[1]; Naotsugu Ishikawa[1]; Yasuhiko Ogata[1]; Kaoru Kajikawa[1]; Yuka Fukuma[1]; Yuya Tanaka[1]; Toshimitsu Otani[2]; Yoshifumi Kasuga[1]; Mamoru Tanaka[1]

[1]Keio University School of Medicine, Shinjuku-ku, Tokyo; [2]Keio University School of Medicine, Nakano-ku, Tokyo

4:00 PM - 6:00 PM

Objective: Newborns exhibit substantial variation in fat mass accretion, which extend into infancy and metabolic dysregulation in later life. Leptin is one of the adipokines related with lipid metabolism, which affects birth weight and infant adiposity. However, the association between maternal serum leptin and fetal fat deposition remains unclear. This study aimed to investigate the association of maternal serum leptin in early- and mid-gestation with fetal adiposity across gestation.

Study Design: A prospective cohort study was conducted in 95 singleton uncomplicated pregnancies. Maternal blood sample was obtained at 10 and 24 weeks' gestation. Serum leptin level was log transformed to be normally distributed. Fetal ultrasonography was performed at 24, 30 and 36 weeks' gestation. Estimated fetal adiposity (EFA) was calculated as the average of standardized z scores of arm percentage fat area, thigh percentage fat area and anterior abdominal wall thickness as previously reported. The association between maternal serum leptin and EFA was examined using Pearson product moment correlation. Multiple linear regression was conducted to quantify the association between maternal serum leptin and EFA with adjustment for potential confounding factors including maternal age, parity, pre-pregnancy body mass index, gestational weight gain, and infant sex.

Results: Maternal serum leptin was 20.0 ± 11.9 (mean ± S.D.) and 22.8 ± 14.6 ng/ml at 10 and 24 weeks, respectively. Maternal leptin levels were not associated with EFA at 24 and 30 weeks. Maternal leptin at 10 weeks ($r = 0.298$, $p = 0.005$) and 24 weeks ($r = 0.361$, $p < 0.001$) were associated with EFA at 36 weeks. After controlling for the covariates, leptin at 10 weeks (standardized $B = 0.317$, $p = 0.028$) and 24 weeks (standardized $B = 0.413$, $p = 0.004$) significantly correlated with EFA at 36 weeks.

Conclusion: Maternal serum leptin level in early- and mid-gestation is associated with fetal fat deposition in late gestation. Maternal serum leptin could be a marker for identifying increased adiposity during intrauterine life.

1069 | Association of Cord Blood Cytokine Levels with Fetal Adiposity Across Gestation

Junko Tamai[1]; Satoru Ikenoue[1]; Keisuke Akita[1]; Naotsugu Ishikawa[1]; Yasuhiko Ogata[1]; Kaoru Kajikawa[1]; Yuka Fukuma[1]; Yuya Tanaka[1]; Toshimitsu Otani[2]; Yoshifumi Kasuga[1]; Mamoru Tanaka[1]

[1]Keio University School of Medicine, Shinjuku-ku, Tokyo; [2]Keio University School of Medicine, Nakano-ku, Tokyo

4:00 PM - 6:00 PM

Objective: Recent clinical and experimental evidence have shown that the origins of obesity (i.e., increased adiposity) can be, in part, traced back to intrauterine life. However, the determinants of fetal fat deposition have yet to be elucidated. This study aimed to investigate the association between cord blood cytokines related with lipid metabolism (leptin, adiponectin, insulin-like growth factor-1 [IGF-1]) and fetal adiposity across gestation.

Study Design: A prospective study was conducted in a cohort of 91 singleton pregnancies. Fetal 3D ultrasonography was performed at 24, 30, and 36 weeks' gestation. Estimated fetal adiposity (EFA) was calculated by integrating measurements of cross-sectional arm and thigh percentage fat area and anterior abdominal wall thickness as previously reported. Serum cytokine levels and C-peptide immunoreactivity (CPR) of the umbilical cord (as a proxy for fetal insulin resistance) were evaluated in the cord blood sample obtained at delivery. The associations between cord blood cytokine levels and EFA at 24, 30 and 36 weeks were determined by multiple linear regression adjusted for potential covariates including maternal age, parity, pre-pregnancy BMI, gestational weight gain, fetal sex, and gestational age at assessments.

Results: Serum leptin, adiponectin and IGF-1 of the umbilical cord was 8.5 ± 6.4 ng/ml (mean ± S.D.), 23.0 ± 6.7 μg/ml and 52.1 ± 19.0 ng/ml, respectively. After adjusting for the covariates, leptin was not associated with EFA at 24 and 30 weeks, but significantly correlated with EFA at 36 weeks (standardized $B = 0.299$, $p = 0.008$). Leptin was also positively correlated with CPR in the umbilical cord ($p = 0.024$). Cord adiponectin and IGF-1 were not associated with EFA across gestation.

Conclusion: Cord blood leptin level was associated with fetal adiposity in late gestation. Considering the effect of leptin on fetal insulin resistance and lipid metabolism, increased leptin level potentially be one of the serum biomarkers of increased fetal adiposity, which leads to infant obesity and metabolic dysfunction in later life.

1070 | Non-Mother Birthing Identities and Risk of Hospitalization for Psychiatric Diagnoses Before and After Delivery Hospitalizations

Justin S. Brandt[1]; Rebecca J. Baer[2]; Scott P. Oltman[2]; Diana S. Abbas[3]; Marra Ackerman[1]; Allison Deutch[1]; Dana R. Gossett[1]; Laura L. Jelliffe-Pawlowski[1]

[1]NYU Langone Health, New York, NY; [2]University of California San Francisco School of Medicine, San Francisco, CA; [3]NYU Grossman School of Medicine, New York, NY

4:00 PM - 6:00 PM

Objective: To understand the impact of pregnancy on depression and other psychiatric illnesses for transgender and gender diverse people, we evaluated the risk of hospitalization for psychiatric diagnoses among non-mother birthing people in the year before and after delivery hospitalizations.

Study Design: We performed a cross-sectional study of singleton live births in California (2019-2021). Birth certificates were linked to hospital discharge records for birthing people for the year before and after delivery hospitalizations. Birthing parent identity was based on birth certificates, in which birthing people self-identify as mother, father, or parent. The primary outcome was hospital admission with psychiatric diagnoses, as determined by ICD-10 codes. Risk of hospitalization with psychiatric diagnoses was calculated for non-mother versus mother birthing people in the year before or after delivery hospitalization using Poisson regression models.

Results: There were 1,298,307 singleton live births in California from 2019-2021, including 1,065,714 hospital records linked with birthing person identities. 898 (0.08%) people had non-mother birthing identities (n = 515 fathers, n = 383 parents), of whom 143 (15.9%) had psychiatric diagnoses compared to 127,545 (12.0%) birthing mothers. In the year prior to delivery hospitalization, 41 (4.6%) non-mother birthing people were hospitalized with psychiatric diagnoses compared to 30 (3.3%) non-mother birthing people in the year postpartum. Compared to mother birthing people, non-mother birthing people were at increased risk for these hospitalizations in the year before (RR 1.22, 95% CI 0.90, 1.66) and after (RR 1.52, 95% CI 1.06, 2.17) delivery hospitalizations. Characterization of medical engagement is described in the Table.

Conclusion: In this study, non-mother birthing people were at increased risk for hospitalization with psychiatric diagnoses in the year after delivery hospitalizations, but the absolute number of postpartum hospitalizations with psychiatric diagnoses was lower. Further study is needed to understand the impact of pregnancy on this risk.

Table
Relationship between hospital admissions with psychiatric diagnoses in the year *before* and *after* delivery hospitalizations, by birthing parent identity

	Mother	Non-Mother[a]	RR (95% CI)
All births	1,064,816	898	
Year before delivery			
No admission	96.3	95.4	*Reference*
Any admission	3.7	4.6	1.22 (0.90, 1.66)
Admission without psychiatric health diagnosis[b]	3.2	3.6	1.12 (0.79, 1.58)
Admission with psychiatric diagnosis	0.5	[c]	1.98 (1.03, 3.81)
Admission with substance use diagnosis	0.3	[c]	[d]
Year after delivery			
No admission	97.8	96.7	*Reference*
Any admission	2.2	3.3	1.52 (1.06, 2.17)
Admission without psychiatric health diagnosis	1.8	2.5	1.40 (0.92, 2.12)
Admission with psychiatric health diagnosis	0.2	[c]	[d]
Admission with substance use diagnosis	0.4	[c]	2.05 (1.02, 4.10)

Data listed as percentages. RR: relative risk; CI: confidence interval.
[a]Non-mother birthing identities include 'father' and 'parent' identities as self-identified on California birth certificates.
[b]Mental health diagnoses derived from ICD-10 codes for suicidal behavior, major depression, postpartum depression, anxiety, bipolar disorder, schizophrenia, substance use disorder, and other mental health diagnosis.
[c]Not displayed when n<11.
[d]Not calculated when n<5.

1071 | Non-Mother Birthing People and the Risk of Ischemic Placental Disease, Severe Morbidity, and Preterm Birth

Justin S. Brandt[1]; Rebecca J. Baer[2]; Scott P. Oltman[2]; Diana S. Abbas[3]; Marra Ackerman[1]; Allison Deutch[1]; Dana R. Gossett[1]; Laura L. Jelliffe-Pawlowski[1]
[1]NYU Langone Health, New York, NY; [2]University of California San Francisco School of Medicine, San Francisco, CA; [3]NYU Grossman School of Medicine, New York, NY

4:00 PM - 6:00 PM

Objective: To evaluate the risk of ischemic placental disease (IPD), severe morbidity (SM), and preterm delivery (PTD) among individuals who identify as non-mother birthing people, presumably transgender men and gender diverse people assigned female sex at birth.

Study Design: We performed a cross-sectional study of singleton live births in California (2019-2021). Birth certificates were linked to hospital discharge and neonatal records. Birthing parent identity was based on birth certificates, in which birthing people self-identify as mother, father, or parent. The primary outcomes were IPD (hypertensive disorders of pregnancy, placental abruption, and small for gestational age birth), composite SM based on the CDC definition, and PTD < 37 weeks gestation. Outcomes were determined by ICD-10 codes. The risk of outcomes was calculated for non-mother versus mother birthing people using Poisson regression models.

Results: There were 1,298,307 singleton live births in California from 2019-2021, including 1,065,714 linked hospital and neonatal records with birthing person identities. 898 (0.08%) people had non-mother birthing identities, of whom 9.2% were age >40 years, 24.9% had BMI >30 kg/m^2, 13.1% had pregestational diabetes, and 2.2% had chronic hypertension. Compared to mother birthing people, non-mother birthing people had similar rates of adequate prenatal care as defined by Kotelchuck (71.9% vs. 70.1%), but higher rates of cesarean delivery (30.9% vs. 24.9%) and pregnancies conceived with assisted reproduction (17.3% vs. 1.7%). The risk of IPD was similar between the groups, but the risks of SM (RR 1.69, 95% CI 1.20, 2.38) and preterm birth (RR 1.30, 95% CI 1.07, 1.58) were increased among non-mother birthing people. The risks are further described in the Table.

Conclusion: In this study of singleton live births in California, non-mother birthing people had similar rates of adequate prenatal care, but were at increased risk for SM and PTD, though not at increased risk for IPD, compared to mother birthing people. These disparate risks may reflect the impact of minority stress and warrant further evaluation.

Table
Risk of ischemic placental disease, severe morbidity, and preterm birth, by birthing person identity

	Mother	Non-Mother[a]	RR (95% CI)
	n (%)	n (%)

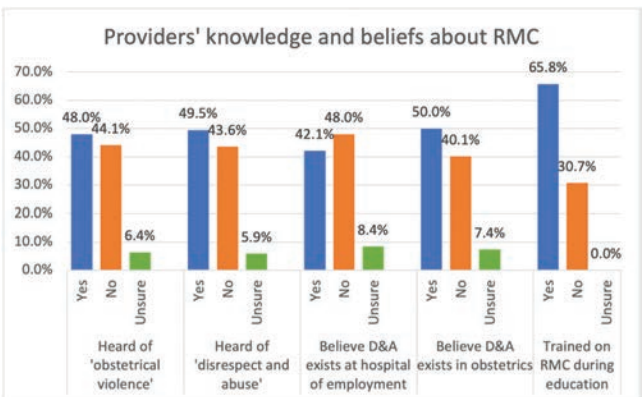
[b]Severe morbidity based on the CDC definition using birth certificate indications and ICD-10 codes.
[c]Not displayed when n<11.

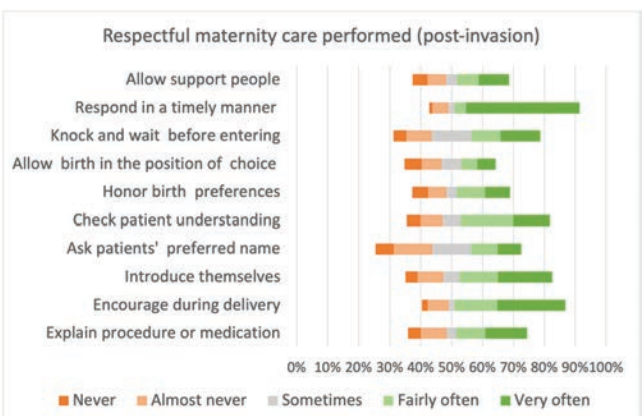
1072 | Respectful Maternity Care in Ukraine During a Time of War

Volodymyr V. Artyomenko[1]; Annekathryn Goodman[2]; Igor Shpak[3]; Mary Greenwald[4]; Marcella Regina Cardoso[4]; Katherine D. Fachon[4]; Christina M. Duzyj[2]
[1]Odesa National Medical University, Odesa, Odes'ka Oblast'; [2]Massachusetts General Hospital, Boston, MA; [3]Maternity Hospital No 5, Odesa, Odes'ka Oblast'; [4]Strength and Serenity Initiative Against Gender-Based Violence, Massachusetts General Hospital, Boston, MA

4:00 PM - 6:00 PM

Objective: Respectful maternity care (RMC) is a fundamental right of birthing people. Our objectives were: to measure the proportion of obstetric providers at an Odesa Maternity Hospital reporting disrespect and abuse (D&A) during childbirth; to identify challenges to RMC; and to assess perceptions of the impact of war on RMC.
Study Design: This is a cross-sectional study consisting of a quantitative survey distributed to physicians, nurses, midwives, and other personnel at Odesa City Maternity Hospital № 5. The survey included 90 questions assessing prevalence and types of disrespect. Topics covered included: RMC practices performed; disrespectful behaviors witnessed; the impact of war on the provision of RMC; Perceived Stress Scale and Post-Traumatic Stress Scale; perspectives on patient autonomy and decision-making. Results were compared with a survey administered in a Boston maternity unit.
Results: 202 Providers responded: 89 nurses and junior nurses, 28 midwives, 84 physicians, and 1 unknown provider. 49.5% were familiar with the term "disrespect and abuse," compared with 82.6% in Boston; and 50.0% believed D&A exists in the obstetrics field, compared with 84.8% in Boston. The most reported types of disrespect were scolding or blaming (58.4% compared with 63% in Boston), asking private questions in the presence of others (42.1% vs 58.7%) and uncomfortable vaginal examinations (39.6% vs. 65.2%). The most common types of discriminatory care witnessed were discrimination based on social status (38.6% vs. 28.3%) and ability to pay "pocket money" (37.1%).
Conclusion: This study provides insights into the provision of maternity care under conditions of duress, and highlights challenges faced under the strains of conflict. These efforts aim to identify gaps in education and training around RMC in order to enhance maternal healthcare delivery in conflict-affected regions, fostering a more supportive and respectful environment for providers and patients.





1073 | Short-Interval Births Among Adolescents who Received Immediate Postpartum Long-Acting Reversible Contraception

Katherine B. Kaak[1]; Alicia Mastronardi[2]; Jill M. Maples[3]; Kimberly B. Fortner[4]; Lilyan Starkey[1]; William L. Riley[4]; Rebecca Purvis[5]; Megan L. Young[6]; Nikki B. Zite[4]
[1]University of Tennessee at Knoxville, Knoxville, TN; [2]University of Tennessee Graduate School of Medicine, Department of OB/Gyn, Knoxville, TN; [3]University of Tennessee Health Science Center, College of Medicine, Knoxville, TN; [4]University of Tennessee Graduate School of Medicine, Knoxville, TN; [5]University of Tennessee Medical Center Knoxville, Knoxville, TN; [6]University of Tennessee Medical Center, Center for Women and Infants, Knoxville, TN

4:00 PM - 6:00 PM

Objective: Adolescent pregnancy is linked to adverse maternal and neonatal outcomes and is associated with short interval birth, further exacerbating these risks. Contraceptive counseling and access can decrease rates of short-interval birth, especially in this high-risk population. Tennessee faces high rates of both adolescent pregnancies and SIB, with 32.5% of pregnancies following a prior live birth having <18 months of birth spacing (2018-2020 average). In 2018, a statewide quality improvement project introduced immediate postpartum long-acting reversible contraception (IPP LARC) for publicly insured recipients. This study aims to assess SIB rates among adolescents who received IPP LARC.

Study Design: This retrospective study utilized billing data for publicly insured adolescents (≤20 years old) giving birth from January 2018-December 2019. These data were matched by SSN, date of birth, and mother's name with statewide birth certificate records from January 2015-December 2021. SIB was defined as two births ≤24 months apart. Among multiparous patients, SIB prior to and after receiving IPP LARC was assessed.

Results: We identified 267 adolescent deliveries. IPP arm implants were inserted more often than intrauterine devices (IUDs) (65.5% vs 34.5%) (Figure1) in these adolescents. Of the 267, 62.0% (n = 165) were primiparous (Table 1). Among multiparous patients (n = 101), 56.4% (n = 57) had a SIB prior to IPP LARC placement. The median number of previous live births among multiparous was 1.0 (IQR:1,2). Among the multiparous patients with a prior SIB, 90.7% (49) did not have another SIB post LARC. Among the entire cohort, 8.2% (n = 22) of deliveries had a SIB after IPP LARC placement.

Conclusion: Adolescents electing IPP LARC had low subsequent SIB rates. Addressing adolescent pregnancy is a public health priority, and, although secondary prevention, access to desired IPP LARC is a strategy to decrease repeat adolescent pregnancies and short interval births.

Figure 1: Type of Immediate Postpartum LARC Chosen by Adolescents

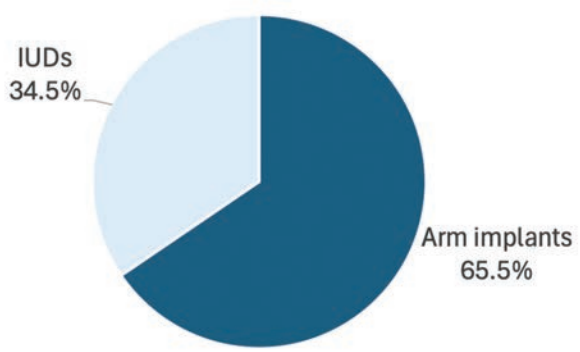


Table 1. Demographics of adolescents receiving IPP LARC

	Number of adolescents (N=267) (%)
Age	
14-16	32 (11.9)
17-18	72 (27.0)
19-20	163 (61.0)
Primiparous	154 (57.7)
Patient Predominant Race Reported	
White	128 (47.9)
Black	93 (34.8)
Other Race	45 (17.3)
Hispanic	47 (17.6)
Previous live birth	102 (38.2)
Short-Interval Birth After IPP LARC Receipt	22 (8.2)
Public Insurance	251 (94.0)
Primary Language Not English	33 (12.4)

1074 | Impact of Socioeconomic Disadvantage on Adolescent Pregnancy

Katherine B. Kaak[1]; Alicia Mastronardi[2]; Jill M. Maples[3]; Destiny Pearson[1]; Zachary J. Shelton[2]; Kimberly B. Fortner[4]; William L. Riley[4]; Rebecca Purvis[5]; William S. Havron, IV[4]; Nikki B. Zite[4]
[1]University of Tennessee at Knoxville, Knoxville, TN; [2]University of Tennessee Graduate School of Medicine, Department of OB/Gyn, Knoxville, TN; [3]University of Tennessee Health Science Center, College of Medicine, Knoxville, TN; [4]University of Tennessee Graduate School of Medicine, Knoxville, TN; [5]University of Tennessee Medical Center Knoxville, Knoxville, TN

4:00 PM - 6:00 PM

Objective: Adolescent pregnancy is associated with adverse maternal and neonatal outcomes, less prenatal care, and lower school attendance. In Tennessee, the adolescent birth rate is higher than the national average (23.7/1,000 vs 16.7/1,000). The Area Deprivation Index (ADI), ranging from 1-100, assesses neighborhood-level disadvantages, with higher values indicating greater deprivation. This study explores the relationship between adolescent pregnancy, ADI scores, and pregnancy outcomes.

Study Design: This retrospective cohort study analyzed adolescent patients (age ≤20) delivering at a regional academic medical center from March 2018-June 2023. Data was extracted from

electronic medical records. Each patient's address was used to determine their Area Deprivation Index (ADI) score, categorized into quintiles representing increasing deprivation (1 to 100), with scores of 61 or higher considered high risk. Chi-square tests were used to evaluate associations within the dataset.

Results: Of 22,086 deliveries, 1,281 (5.8%) were to patients ≤20 years of age. The mean ADI score in this adolescent cohort was 73.4 and 78.8% had ADI 61 or greater (Figure 1). No statistically significant differences were found in patients with higher ADI scores in adequacy of prenatal care obtained, low birth weight full-term infants, illicit drug use, or hypertensive disorders. Reported marijuana use was significantly lower (p =.007) in patients with higher ADI scores (Table 1). During this time, 60 adolescents had an additional birth while under the age of 20 and 85.0% of those had a high-risk ADI. Nearly 1 in 4 (23.3%) of the births to adolescent patients were pre-term.

Conclusion: Although nearly 4 of 5 adolescents giving birth at our center were from high-risk zip codes, risk factors and outcomes did not statistically differ based on ADI score. Further research should look more into these at-risk teens, focusing on patients with the highest burden of disadvantages.

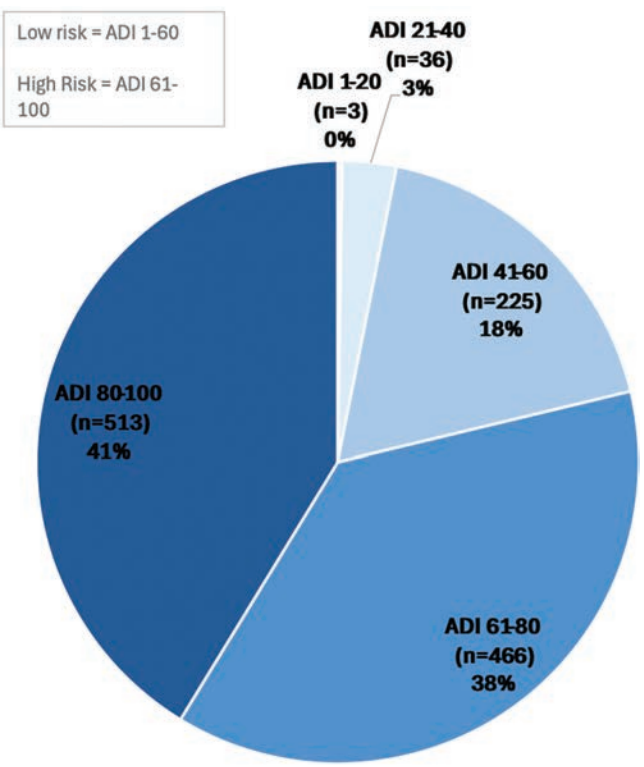

Figure 1: Area Deprivation Index (ADI) Quintiles of Pregnant Adolescents

Table 1: Pregnancy Risks and Outcomes by ADI Score			
	Low Risk = ADI 1-60 (n=264)	High Risk = ADI 61-100 (n=979)	p-value
Late/Limited/No Prental Care**	25 (9.5%)	113 (11.5%)	0.458
Preterm Delivery	47 (17.8%)	169 (17.3%)	0.231
Low Birth Weight Infant	9 (5.0%)	34 (4.7%)	0.900
Gestational Hypertension	28 (10.6%)	101 (10.4%)	0.866
Marijuana Use	66 (25.2%)	173 (17.8%)	*0.007
Tobacco Use	20 (7.7%)	111 (11.6%)	0.077
Chi-squared tests were used to compare groups.			
*P-value of <0.05 was used to signal significance.			
**Late prenatal care defines as starting after 18 weeks gestation. Limited prenatal care defined as fewer visits than recommended based on gestational age. No prenatal care was designated if they had no prental visits prior to their encounter for delivery			

1075 | Remote 3D LiDAR Imaging to Estimate Fundal Height: A Feasibility Study

Katherine J. Kissler[1]; Shalom Darmanjian[2]; Quentin Noirhomme[2]
[1]*University of Colorado Anschutz Medical Campus, Aurora, CO;* [2]*Bloomlife, San Francisco, CA*

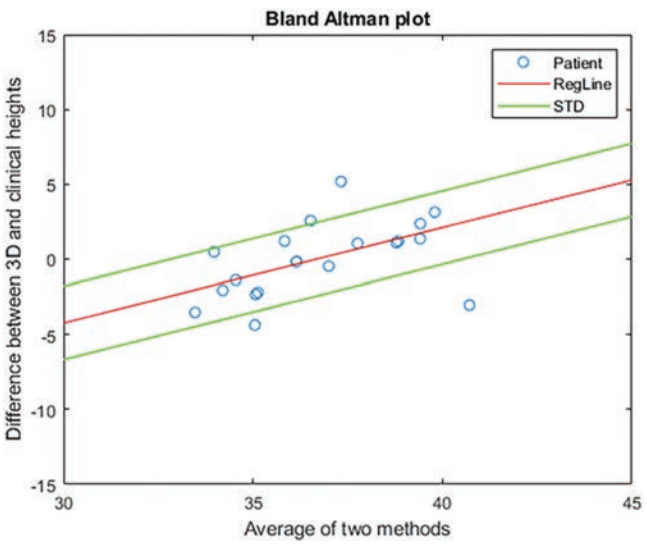
4:00 PM - 6:00 PM

Objective: Prenatal care is increasingly offered virtually to expand access to care. However, estimation of fetal growth is limited during virtual appointments jeopardizing safety and quality of care. The purpose of this feasibility study was to evaluate accuracy of term fundal height estimation using 3D LiDAR (Light Detection and Ranging) technology to create accurate 3D images of the gravid abdomen using an Apple iPad. Development of this technology would allow patients to remotely share a 3D image during a virtual visit to allow for accurate physical exam including fundal height estimate.

Study Design: In this retrospective feasibility study, we compared fundal height measurements calculated remotely from 3D LiDAR images to those measured in-person by research nurses using a measuring tape at term in (N = 20) low risk pregnant patients. The 3D LiDAR image was captured on the same day as the physical measurement by the nurse using an Apple iPad with the Polycam app. Participants with incomplete data or inadequate imaging of the fundus and pubis were excluded. Fundal heights were calculated by first mapping fiducial markers along the midline from pubis to the fundus then summing the distances calculated between the 3D surface markers. Fundal heights measured using the 3D LiDAR images were detrended with linear regression and a Bland-Altman Plot was created to evaluate agreement.

Results: Fundal heights measured via 3D LiDAR imaging ranged from 36.68 to 40.21 cm (mean = 38.53) and by the nurses from 35.50 to 44.00 cm (mean = 38.53). The mean absolute error (MAE) before detrending was 1.97±2.44cm. Post detrending MAE was 1.01±1.57cm with the limits of agreement (95% CI, ±3.09cm).

Conclusion: 3D LiDAR imaging shows promising preliminary results for accurately measuring fundal heights at term and may provide a clinically useful alternative for estimating fetal growth for patients receiving care remotely. Follow-up studies are needed to extend these findings to earlier gestations, explore usability of the app during remote visits, and identify additional obstetric applications of 3D abdominal imaging.



1077 | Impact of Prenatal Care on Perinatal Outcomes in Individuals with Opioid Use

Kristin C. Prewitt; Alyssa R. Hersh; Bharti Garg; Ximena A. Levander; Bradley M. Buchheit; Aaron B. Caughey
Oregon Health & Science University, Portland, OR

4:00 PM - 6:00 PM

Objective: Prenatal opioid use is associated with maternal and neonatal morbidity and mortality, yet only half of individuals are connected to treatment due to barriers accessing care. The objective of this study is to assess how the number of prenatal care attendance affects perinatal outcomes in individuals with opioid use.

Study Design: We conducted a retrospective cohort of singleton, non-anomalous births between 23-42 weeks gestation using California linked vital statistics and hospital discharge data (2008-2020). Opioid-related diagnosis was identified using ICD-9/ICD-10 codes. Prenatal visit number grouping (≥5 visits and < 5 visits) was determined based on WHO recommendations for minimum visits to mitigate adverse perinatal outcomes. Chi-squared and multivariable logistic regression were utilized for statistical analyses.

Results: There were 8,799 individuals with opioid use in pregnancy that met inclusion criteria, with the majority attending ≥5 prenatal care visits (80.34%). Attendance at < 5 prenatal care visits was associated with adverse maternal outcomes, including a higher rate of placental abruption (6.2% vs 2.7%; aOR 1.87, 95% CI: 1.42-2.47), preterm premature rupture of membranes (8.0% vs 3.8%; aOR 1.91, 95% CI: 1.50-2.43), preterm delivery < 37 weeks (33.0% vs 14.2%; aOR 2.69, 95% CI: 2.34-3.08), and severe maternal morbidity (6.5% vs 2.8%; aOR 2.31, 95% CI: 1.77-3.02). Neonatal outcomes were also worse in those with fewer prenatal visits, including higher rates of respiratory distress (4.6% vs 2.6%; aOR 1.78, 95% CI: 1.31-2.42), neonatal withdrawal (37.6% vs. 29.4%, aOR 1.42, 95% CI: 1.26-1.61), and NICU admission (58.4% vs 41.9%; aOR 1.76, 95% CI: 1.57-1.99).

Conclusion: We found that lower prenatal care attendance among individuals with an opioid-related diagnosis is associated with worse maternal and neonatal outcomes. Although our study is limited by the ability to control for pharmacotherapy, addressing barriers to prenatal care among those with opioid use may impact maternal and neonatal morbidity and mortality.

Table 1. Maternal outcomes among patients with opioid use during pregnancy by number of prenatal care visits attended

	≥5 visits (n=7,069)	<5 visits (n=1,730)	p	aOR (95% CI)
Hypertensive disorders	779 (11.0%)	223 (12.9%)	0.021	1.24 (1.03-1.48)
Preterm premature rupture of membranes	268 (3.8%)	139 (8.0%)	<0.001	1.91 (1.50-2.43)
Placental abruption	188 (2.7%)	107 (6.2%)	<0.001	1.87 (1.42-2.47)
Preterm delivery				
<37 weeks	1,001 (14.2%)	571 (33.0%)	<0.001	2.69 (2.34-3.08)
<32 weeks	100 (1.4%)	84 (4.9%)	<0.001	2.77 (1.95-3.94)
Cesarean delivery (CD)				
Nulliparous	880 (35.1%)	119 (24.4%)	<0.001	0.53 (0.41-0.69)
Multiparous without prior CD	467 (15.2%)	131 (15.3%)	0.615	0.94 (0.74-1.19)
Multiparous with prior CD	1,372 (92.5%)	318 (87.1%)	0.057	0.66 (0.43-1.01)
Operative vaginal delivery*	370 (8.5%)	108 (9.4%)	0.602	1.07 (0.83-1.39)
Severe maternal morbidity	199 (2.8%)	112 (6.5%)	<0.001	2.31 (1.77-3.02)
Non-transfusion severe maternal morbidity	81(1.2%)	41(2.4%)	0.022	1.67 (1.08-2.60)

Analyses adjusted for race/ethnicity, age, education, body mass index, insurance type, parity, chronic hypertension, pre-existing diabetes, mental health conditions, and polysubstance use (nicotine, alcohol, amphetamines, cocaine)
**Among vaginal deliveries*

Table 2. Neonatal outcomes among patients with opioid use during pregnancy by number of prenatal care visits attended

	≥5 visits (n=7,069)	<5 visits (n=1,730)	p	aOR (95% CI)
Small for gestational age	1,076 (15.2%)	299 (17.3%)	0.580	1.05 (0.89-1.22)
APGAR <7 at 5 minutes	158 (2.3%)	78 (4.6%)	<0.001	1.93 (1.4-2.65)
Respiratory distress syndrome	186 (2.6%)	79 (4.6%)	<0.001	1.78 (1.31-2.42)
Neonatal withdrawal syndrome	2,063 (29.4%)	639 (37.6%)	<0.001	1.42 (1.26-1.61)
Neonatal ICU admission	2,962 (41.9%)	1,010 (58.4%)	<0.001	1.76 (1.57-1.99)
Neonatal death	16 (0.23%)	20 (1.2%)	<0.001	3.77 (1.72-8.25)
Infant death	44 (0.6%)	29 (1.7%)	0.006	2.12 (1.24-3.65)

Analyses adjusted for race/ethnicity, age, education, body mass index, insurance type, parity, chronic hypertension, pre-existing diabetes, mental health conditions, and polysubstance use (nicotine, alcohol, amphetamines, cocaine)

1078 | Impact of Changing Medicaid Coverage for Methadone on Opioid Use Disorder Treatment in Pregnancy

Kristin C. Prewitt[1]; Megan Fuerst[1]; Ximena A. Levander[1]; Maria I. Rodriguez[2]
[1]Oregon Health & Science University, Portland, OR; [2]Oregon Health & Science Unviersity, Portland, OR

4:00 PM - 6:00 PM

Objective: Driven by synthetic opioids, overdose is the leading cause of maternal mortality. Pregnancy increases difficulty in accessing treatment. The purpose of this study was to assess how Medicaid coverage for methadone affected treatment for opioid use disorder in pregnancy.

Study Design: This is a cross-sectional study using linked South Carolina claims and birth certificate data (2015 to 2022) of live births with a diagnosis of opioid use disorder (OUD) in pregnancy. We divided our population into 2 cohorts: 1) before and 2) after the state's Medicaid approval for methadone coverage on January 1st 2019. Our primary outcome was receipt of medication for OUD (MOUD) during pregnancy or within the first 60 days postpartum. Using standard bi-variate tests, we compared the pre- and post-policy rates of Methadone of MOUD as well as demographic factors between each group.

Results: In total, 2,633 patients with OUD were included in our study. Of these, 1181 delivered prior to Medicaid approval of methadone and 1,452 were in the post-approval cohort. Following Medicaid approval for methadone, there was a statistically significant increase in the number of methadone prescriptions within the Medicaid population ($p< 0.001$) and a near significant increase of individuals receiving methadone as MOUD (5.1% vs 9.1%, $p = 0.06$). There was a statistically significant increase in those receiving any MOUD post-coverage (34.8% vs 47.2%, $p < 0.001$). Those who did not receive Methadone or any MOUD were more likely to be under the age of 25 (57.2%) and live in a rural county (59.9%).

Conclusion: Our results show that changing Medicaid coverage for methadone increases overall treatment for OUD in pregnancy. However, there continue to be gaps in treatment connections for individuals < 25 years of age and from rural counties. As the opioid epidemic increases, improving access to medication coverage for OUD and focusing efforts on younger, more rural areas may impact OUD treatment in pregnancy, and subsequently, maternal mortality.

Table 1. Prescriptions of MOUD related to Medicaid approval for methadone coverage

Number (N) of prescriptions pre/post methadone approval by Medicaid in South Carolina among those with OUD			
	Pre-Medicaid Methadone Approval (pre 1/1/19) (N=3816)	**Post-Methadone Approval (1/2/19 and beyond) (N=11,338)**	**p-value***
Methadone	1323 (34.5%)	5210 (45.9%)	<0.001
Buprenorphine	3624 (95.0%)	9136 (80.6%)	<0.001
Naltrexone	51 (1.3%)	91(0.8%)	0.0012
Proportion of individuals with OUD receiving MOUD during pregnancy or within 60 days postpartum pre-and post (N=2,633)			
	Pre-Medicaid Methadone Approval (pre 1/1/19) (N=1,181)	**Post-Methadone Approval (1/2/19 and beyond) (N=1,452)**	**p-value***
Methadone	60 (5.1%)	131 (9.0%)	0.06
Buprenorphine	331 (28.0%)	525 (36.2%)	0.19
Naltrexone	22 (1.9%)	30 (7.3%)	0.57
Any MOUD	411 (34.8%)	686 (47.2%)	<0.001

**Chi-squared test*

Table 2. Demographics of those receiving methadone following Medicaid approval of methadone (N=1452)

	Methadone (N=131)	**Any MOUD (N=686)**	**No MOUD (N=876)**	**p-value****
Age < 25	22 (16.8%)	124 (18.1%)	501 (57.2%)	<0.001

1079 | Inequities in Breastfeeding Patterns Among Patients with HDP at a Southwestern Safety net Hospital

Kristin Hinsen[1]; Fiona LaRoc[1]; Christina Yarrington[2]
[1]School of Medicine Health Sciences Center, University of New Mexico, Albuquerque, NM; [2]University of New Mexico, Albuquerque, NM

4:00 PM - 6:00 PM

Objective: Breastfeeding reduces lifelong cardiovascular (CV) risk, particularly in those with a hypertensive disorder of pregnancy (HDP). American Indian (AI) patients experience inequities in both preeclampsia and chronic CV disease. This study investigated newborn feeding differences among women with HDP in a cohort with a representative AI population.

Study Design: This retrospective cohort study analyzed patients with chronic hypertension or HDP using a quality improvement data set. Cases with uncertain diagnoses underwent direct chart review. The primary outcome was exclusive formula feeding (FF). Demographics included race, ethnicity, insurance type, cesarean delivery (CD), and selected comorbidities. Univariate and multivariable analysis used t-tests, chi-square, and logistic regression as appropriate, with a significance level of $p< 0.05$.

Results: Data were analyzed from 975 patients: 198 non-Hispanic white (NHW), 494 Hispanic (H), 178 AI, and 37 non-Hispanic Black (NHB). FF was higher (44%) and exclusive breastfeeding (EB) lower (16%) among AI patients compared to other groups ($p< 0.001$). Univariate analysis revealed increased odds of FF among patients with CD (OR 2.1 [1.6-2.9]), antihypertensive use (3.5 [2.5-4.8]), transfusion (2.2 [1.4-3.5]), and preterm birth (PTB) (13.7 [9.2-20.4]). AI patients were more likely to have diabetes (2.9 [1.8-4.7]), PTB (3.3 [2.0-5.5]), and require antihypertensives (1.8 [1.1-2.9]). FF rates were high (>60%) in PTB cases across all groups. Multivariable analysis showed 80% increased odds of FF among AI patients compared to NHW, controlling for DM, CD, and HTN medications. Among term deliveries and controlling for the above, AI patients had higher odds of FF (aOR 1.9 [1.2-3.0]) as well as lower odds of EB (aOR 0.35 [0.21-0.59]) compared to NHW.

Conclusion: These findings demonstrate a higher rate of FF among AI patients compared to NHW, indicating a potential contributor of inequities in subsequent CV disease. Future educational and quality improvement measures should seek to optimize rates of breastfeeding in this high-risk population.

1080 | Racial Disparities in Maternal Mortality before, during, and after the COVID-19 Pandemic in the US

Kyosuke Kamijo[1]; Lindsay S. Robbins[2]; George R. Saade[2]; Tetsuya Kawakita[2]
[1]Department of Obstetrics and Gynecology Nagano Prefectural Shinshu Medical Center, Suzaka, Nagano; [2]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA

4:00 PM - 6:00 PM

Objective: To evaluate racial disparities in maternal mortality before, during, and after the Coronavirus Disease 2019 (COVID-19) pandemic.

Study Design: We conducted difference-in-differences (DID) analyses using the Centers for Disease Control and Prevention's

WONDER database. Data on the number of births and maternal mortality were aggregated into monthly intervals. We compared changes in maternal mortality during pregnancy and up to 1 year after delivery per 100,000 births between White and Black or African Americans before (Jan 2018–Mar 2020), during (Apr 2020–Mar 2022), and after (Apr 2022–Jun 2024) the COVID-19 pandemic. Predicted incidence of maternal mortality and DID with 95% confidence intervals (95% CI) were calculated using negative binomial regression models with interactions between race and periods.

Results: There were 3,694,282 Black individuals and 17,284,929 White individuals who gave birth during that period, with 2,513 (68 per 100,000) and 4,547 (26 per 100,000) death, respectively (**Figure 1**). Mortality per 100,000 from before COVID-19 to during COVID-19 increased by 29.4 (95% CI: 19.8-39.1) for Black and 11.8 (95% CI: 8.2-15.4) for White individuals, with a DID of 17.6 (95% CI: 7.3-28.0) in favor of White (Table 1). Mortality per 100,000 from before COVID-19 to after COVID-19 increased by 9.5 (95% CI: 3.2-15.9) for Black and 1.6 (95% CI: -0.4-3.7) for White with a DID of 7.9 (95% CI: 1.2-14.6), suggesting that Black-White disparity worsened after COVID-19 pandemic.

Conclusion: The findings highlight that racial disparity in maternal mortality, which disproportionately affects Black individuals, was further exacerbated by the COVID-19 pandemic. The gap in maternal mortality between Black and White individuals increased post-pandemic, underscoring the need for targeted interventions to address systemic inequities in maternal healthcare.

Figure 1. Charts showing monthly changes in maternal mortality among Black and White, Jan 2018 to Jun 2024. Dashed lines represent before (Jan 2018–Mar 2020), during (Apr 2020–Mar 2022), and after (Apr 2022–Jun 2024) the COVID-19 pandemic. Each line represents the predicted incidence of maternal mortality (blue is Black and red is White).

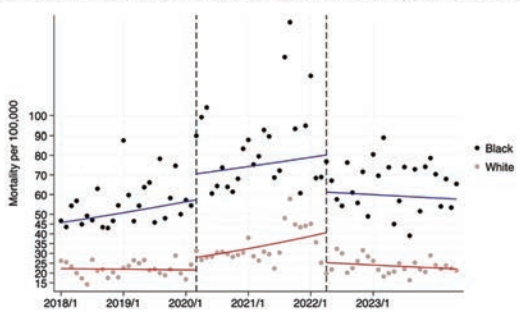

Table 1. Maternal mortality during pregnancy and up to 1 year post-delivery (per 100,000 births).

	Black	White	Difference
Before COVID-19	55.3 (50.9-59.6)	21.9 (20.6-23.3)	33.3 (28.8-37.9)[a]
During COVID-19	84.7 (76.0-93.4)	33.7 (30.4-37.1)	51.0 (41.7-60.2)[a]
After COVID-19	64.8 (60.1-69.5)	23.6 (22.0-25.1)	41.2 (36.3-46.2)[a]
Difference between before COVID-19 and during COVID-19	29.4 (19.8-39.1)	11.8 (8.2-15.4)	17.6 (7.3-28.0)[b]
Difference between before COVID-19 and after COVID-19	9.5 (3.2-15.9)	1.6 (-0.4- 3.7)	7.9 (1.2-14.6)[b]

a Difference between Black and White individuals

b Difference-in-Difference between Black and White individuals

Data is given as count (95% confidence interval).

1081 | An Increased Postpartum Visit Model vs. the Usual Postpartum Visit Model: A Cost-Effectiveness Analysis

Lamia K. Hauter[1]; James Cahill[1]; Sarah K. Dzubay[2]; Megha Arora[2]; Ava D. Mandelbaum[2]; Aaron B. Caughey[2]

[1]Oregon Health & Science University School of Medicine, Portland, OR; [2]Oregon Health & Science University, Portland, OR

4:00 PM - 6:00 PM

Objective: The postpartum (PP) period is crucial for the health of both mothers and infants, necessitating comprehensive care. Traditional obstetrics care includes a routine postpartum follow-up visit at perhaps 2 to 6 weeks postpartum, but there is growing interest in exploring alternatives. A recent model which utilized Certified Nurse Midwives (CNMs) to provide more frequent PP visits was found to reduce both visits to the Emergency Department as well as hospital readmissions. The current study models the outcomes, costs, and cost-effectiveness of more frequent postpartum care versus a traditional obstetric care approach.

Study Design: A decision-analytic model was created using TreeAgePro software to compare outcomes between using the frequent PP visit model versus the standard approach for postpartum follow-up visits. Our theoretical cohort was 2,356,883, the approximate number of postpartum individuals following low-risk vaginal deliveries annually in the US. Outcomes were emergency department visits, hospital readmissions, costs, and quality-adjusted life years (QALYs). All probabilities were derived from literature. The willingness to pay threshold was $100,000/QALY.

Results: In our cohort, the higher frequency care model was associated with 68,350 fewer emergency department visits (129,629 vs 197,978) and 683 fewer hospital readmissions (1296 vs 1980) (Table 1). There were $1,487,263,566 of increased costs with the higher frequency of visits model and it increased QALYs by 1217 (by 63,878,707 vs 63,877,490). The increased frequency model was not cost-effective with an ICER of $1,222,097/QALY. However, the model becomes cost effective when the costs were varied down to 50% or less of baseline assumed cost of 6 postpartum visits.

Conclusion: The model of more frequent postpartum visits led to fewer ED visits and hospitalizations, but ultimately was not cost-effective. Whether the benefits from this high-frequency visit model would be realized from a virtual visit approach which would reduce costs should be investigated.

Table 1. Outcomes of using the Certified Nurse-Midwife (CNM) Model compared to an Obstetrics (OB) model for postpartum follow-up visits in a cohort of 2,356,883 individuals.

Outcomes	CNM Model	OB Model	Difference*
Emergency department visits	129,629	197,978	68,349
Hospital Readmissions	1296	1980	- 684
Cost (in USD millions)	$2,135,283,478	$648,019,911	$1,487,263,567
QALYs (effectiveness)	63,878,707	63,877,490	1217
Incremental Cost Effectiveness Ratio (ICER)	$1,222,097/QALY		

USD, United States Dollar; QALYs, quality-adjusted life years

1082 | Impact of Patient-Directed Financial Penalties on Appointment Non-Adherence Rates in an Academic Maternal-Fetal Medicine Clinic

Lauren A. Forbes[1]; Matvey Karpov[1]; Peter Takacs[1]; Tetsuya Kawakita[2]

[1]Eastern Virginia Medical School, Norfolk, VA; [2]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA

4:00 PM - 6:00 PM

Objective: To examine the impact of patient-directed financial penalties on appointment non-adherence rates within a single

academic institution's maternal-fetal medicine (MFM) outpatient clinic.

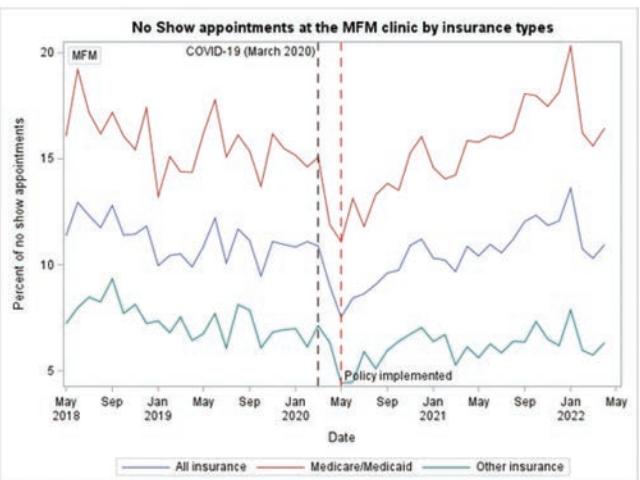
Study Design: This retrospective policy effectiveness study included administrative data from all appointments at Eastern Virginia Medical School's MFM outpatient clinics from May 1, 2018 to April 30, 2022. The institution-wide patient-directed financial penalty for appointment non-adherence was implemented on May 1, 2020. Institutional Review Board approval was waived for this study. An interrupted time series analysis (ITS) stratified by patient insurance type was performed after adjusting the model for the effect of COVID-19.

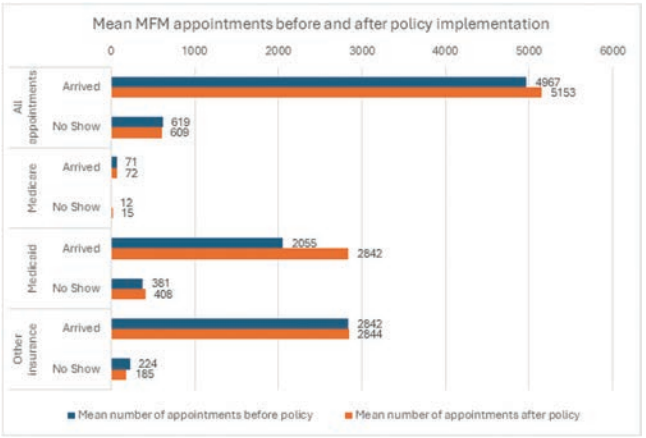
Results: There were 272,335 appointments; 29,452 (10.8%) were not attended. Pre-implementation mean (standard deviation) per month was 5,586 (466) appointments with11.1% (0.99%) non-adherence rate. Post-implementation was 5,762 (429) appointments with 10.6% (1.36%) non-adherence rate. Publically insured patients had a higher non-adherence rate (pre-: 15.60% (1.56%); post-: 15.46% (2.13%)).

Adjusted ITS models observed a statistically significant immediate (1.47% fewer appointments; p = 0.01) and sustained (0.09% additional appointments; p = 0.02) effect on number of non-adherent appointments per month.

Stratified by insurance, non-publically insured patients observed a significant immeidate effect (1.66% fewer appointments; p = 0.02). Publicly insured patients observed a significant sustained effect (0.18% additional appointments; p< 0.01).

Conclusion: A clinically significant reduction in appointment non-adherence was not observed in a single academic center's MFM outpatient clinic after institutional implementation of patient-directed financial penalties for appointment non-adherence. Patient-directed financial penalties for appointment non-adherence may not be an effective strategy for decreasing appointment non-adherence rates. The impact may differ based on patient insurance type.





1084 | Childhood Sexual Abuse Impacts 2nd Trimester Blood Pressure Nadir

Lauren Holt[1]; Mariana Rocha[1]; Natalie Poliektov[2]; Kaitlyn Stanhope[3]; Vasiliki Michopoulos[1]; Suchitra Chandrasekaran[4]

[1]Emory University School of Medicine, Atlanta, GA; [2]Emory University School of Medicine, Department of Gynecology and Obstetrics, Atlanta, GA; [3]Rollins School of Public Health, Atlanta, GA; [4]Emory University, Atlanta, GA

4:00 PM - 6:00 PM

Objective: Childhood trauma (CT) impacts health in adulthood with increased risks of hypertensive disease. Relationships between CT & maternal blood pressure (BP) during pregnancy are less clear. Using the Childhood Trauma Questionnaire (CTQ), we sought to assess relationships between CT & BP in each trimester (TRI) & BP nadir in the 2nd TRI.

Study Design: We performed a prospective longitudinal cohort study investigating associations between trauma & pregnancy outcomes at an urban safety net hospital. Participants who self-identified as Black completed the CTQ, a validated measure of 5 trauma domains in 1st TRI. CT was determined by CTQ total score: ≥35 with CT, < 35 no CT. Systolic (SBP) and diastolic (DBP) pressures were recorded in each TRI. SBP/DBP nadir was calculated (2nd TRI SBP/DBP–1st TRI SBP/DBP) & compared between subjects with & without CT. Continuous variables were compared using Student T-tests or Rank Sum Tests. Categorical variables were compared using Chi-Square tests. Multivariable linear regression was performed controlling for age, race, 1st TRI body mass index, & chronic hypertension.

Results: Of N = 335, 34.3% & 65.6% had no CT & CT exposure respectively (Table 1). There were no differences in 1st, 2nd or 3rd TRI SBP/DBP or 2nd TRI SBP/DBP nadir between groups (Table 2). CT scores were further subtyped into 3 groups: sexual abuse (SA), physical abuse (PA) and emotional abuse (EA). SA scores were associated with lower 1st TRI SBP (β = -0.06, 95% CI -0.14-0.01, p = 0.09). No significant differences in 1st TRI SBP were seen in those with PA or EA. Those with SA had a lower 2nd trimester SBP nadir compared to those without SA (-1.7±10.5 vs -6.3±11.2, p = 0.04).

Conclusion: CT is a concerning problem affecting many reproductive aged individuals. Using the detailed CTQ, our data innovatively demonstrates SA in childhood may mitigate vascular relaxation between 1st & 2nd TRI, a time where vascular relaxation is physiologically necessary. Future studies need to evaluate

mechanisms driving the relationship between CT subtypes & gestational vascular dysregulation.

1085 | Neighborhood Deprivation as a Predictor of Congenital Syphilis

Le'Nisha Williams[1]; Mariella Gastanaduy[2]; James D. Toppin[3]; Frank B. Williams[1]
[1]Ochsner Clinic Foundation, New Orleans, LA; [2]Ochsner Clinic, New Orleans, LA; [3]Ochsner Health, New Orleans, LA

4:00 PM - 6:00 PM

Objective: In the US, congenital syphilis (CS) has increased 464% since 2001, a trend that has been even more pronounced in Louisiana, a place with both high socioeconomic deprivation at the individual and neighborhood levels. Area Deprivation Index (ADI) is a geographic measure of socioeconomic disadvantage that quantifies neighborhood-level limitations to material resources. High ADI is associated with a range of adverse health outcomes. We hypothesize that high ADI is a predictor of CS.

Study Design: We performed a retrospective cohort study of patients between 18-45 years old with at least one prenatal visit and delivery within a single large health system in Louisiana between 2015-2023. Incomplete charts and those without any prenatal syphilis testing were excluded. Patients were stratified as high ADI if their home address census block ranked above the 75th percentile; controls were those below the highest quartile. CS was defined by Centers for Disease Control case criteria. Baseline and pregnancy characteristics were compared using chi square or Wilcoxon Ranked-Sum test where appropriate. Outcomes were compared by regression analysis controlling for individual level socioeconomic deprivation (indicated by public insurance) generating odds ratio and 95% confidence intervals.

Results: Among 56,654 pregnancies meeting inclusion criteria, 17,335 patients (30.5%) resided in high deprivation neighborhoods. High ADI residence was associated with younger age, Black race & public insurance (Table). Among 49 positive CS cases, 37 (75.5%, Table) occurred among patients in high ADI census blocks, corresponding with a congenital syphilis rate of 214 per 100,000 live births compared to 30 per 100,000 live births among non-high ADI pregnancies (aOR 5.1, 95% CI 2.7–9.8). When analyzed in a continuous fashion, there is a positive correlation between CS and high ADI, with each increasing decile representing an 80% increased risk for CS.

Conclusion: High neighborhood deprivation was highly associated with congenital syphilis even when controlling for individual-level socioeconomic deprivation.

Table. Baseline characteristics of pregnancies by high Area Deprivation Index (ADI) status, defined as >75%

	Non-High ADI		High ADI

1086 | Displaying 1-year Versus Lifetime Pay-offs In the Perinatal Decision Analyses

Lihong Mo[1]; Nithya Sivakumar[1]; Herman L. Hedriana[1]; Jeffrey Hoch[2]
[1]UC Davis Health, Sacramento, CA; [2]UC Davis, Sacramento, CA

4:00 PM - 6:00 PM

Objective: When the interests of maternal and fetal patients do not align, pregnancy presents a unique challenge to health economic evaluations. The common practice on perinatal topics has been combining all health pay-offs during the lifetime for both mothers and babies in the equation. However, using lifetime evaluation may not truly reflect the complicated decision-making considerations in real-life practice. The objective of this study is to construct a decision tree to compare immediate delivery and expectant management in a hypothetical clinical scenario to compare the preferred decision when 1-year versus lifetime pay-offs are used.

Study Design: This is a decision analysis in a hypothetical clinical situation when choosing immediate delivery or expectant management is an equipoise. Key assumptions are 1) only one maternal complication is included, its probability is 10% when seeking immediate delivery, while increases to 20% if pregnancy is prolonged for a week, and 25% if prolonged for two weeks; 2) neonatal demise, a short-term complication (i.e. respiratory distress syndrome), and a long-term complication (i.e. developmental delay) are considered for neonatal outcomes.

The probabilities of neonatal complications are derived from literature. Quality Adjusted Life Week (QALW) was calculated as a product of utility and duration.

Results: When maternal complication lasts lifetime, preferred strategies between the 1-year or lifetime evaluation differ at or before 31 weeks. At and after 32 weeks, both evaluation methods favor immediate delivery due to maternal benefits (Table 1). However, when maternal complication is presumed as short-term only, preferred strategies between the 1-year and lifetime evaluation differ almost throughout the span of gestational age.

Conclusion: Choosing between immediate delivery versus expectant management is a complicated decision that requires balancing the maternal and neonatal risks and benefits. Our study supports individualized consideration when the risk of maternal complication is high, and the impact is long lasting.

Table 1. Comparison of Quality Adjusted Life Week (QALW) of Mother and Baby in a Hypothetical Clinical Situation When Maternal Complication Is Long-term *

		1 year		Lifetime	
		Delivery	Expectant	Delivery	Expectant
28 weeks	Mother	51 (↑1)	50	1529 (↑31)	1498
	Baby	44	45 (↑1)	3462	3469 (↑7)
29 weeks	Mother	51 (↑1)	50	1529 (↑31)	1498
	Baby	45	46 (↑1)	3469	3511 (↑42)
30 weeks	Mother	51 (↑1)	50	1529 (↑31)	1498
	Baby	46	46	3511	3549 (↑38)
31 weeks	Mother	51 (↑1)	50	1529 (↑31)	1498
	Baby	46	49 (↑3)	3549	3557 (↑8)
32 weeks	Mother	51 (↑1)	50	1529 (↑31)	1498
	Baby	49	49	3557	3557
33 weeks	Mother	51 (↑1)	50	1529 (↑31)	1498
	Baby	49	50 (↑1)	3557	3586 (↑29)
34 weeks	Mother	51 (↑1)	50	1529 (↑31)	1498
	Baby	50	51 (↑1)	3586	3605 (↑19)
35 weeks	Mother	51 (↑1)	50	1529 (↑31)	1498
	Baby	51	51	3605	3610 (↑5)
36 weeks	Mother	51 (↑1)	50	1529 (↑31)	1498
	Baby	51	52 (↑1)	3610	3623 (↑13)
37 weeks	Mother	51 (↑1)	50	1529 (↑31)	1498
	Baby	52	52	3623	3623
38 weeks	Mother	51 (↑1)	50	1529 (↑31)	1498
	Baby	52	52	3623	3628 (↑5)

(↑#) means the QALW is higher by # of weeks in this strategy compared to the other strategy.
The highlight in green indicates this is the preferred strategy when considering both maternal and baby's QALW.
* Model assumptions: 1) pregnancy is presumed to extend by one week if expectantly managed; 2) life expectancy is presumed 30 years for mother after the delivery, and 70 years for baby; 3) only one maternal complication with a utility of 0.8 is considered; 4) the probability of the maternal complication when seeking immediate delivery is presumed at 10%, while in the expectant management arm, it increases to 20% if pregnancy is prolonged for a week, and 25% if pregnancy is prolonged for two weeks; 5) maternal complication lasts lifetime; 6) baby demise, a short-term complication (i.e. respiratory distress syndrome, utility of 0.8), and a long-term complication (i.e. developmental delay, utility of 0.6) are considered for fetal or neonatal outcomes.

Table 2. Comparison of Quality Adjusted Life Week (QALW) of Mother and Baby in a Hypothetical Clinical Situation When Maternal Complication Is Short-term *

		1 year		Lifetime	
		Delivery	Expectant	Delivery	Expectant
28 weeks	Mother	51 (↑1)	50	1559 (↑1)	1558
	Baby	44	45 (↑1)	3462	3469 (↑7)
29 weeks	Mother	51 (↑1)	50	1559 (↑1)	1558
	Baby	45	46 (↑1)	3469	3511 (↑42)
30 weeks	Mother	51 (↑1)	50	1559 (↑1)	1558
	Baby	46	46	3511	3549 (↑38)

4:00 PM - 6:00 PM

Objective: Pregnancy is a physiologic high-volume state. Physiologic electrocardiogram (ECG) changes in pregnancy have been reported but not well characterized. We hypothesize that certain ECG features are more likely to be present in pregnant compared to non-pregnant individuals, reflecting physiologic cardiac volume and compliance changes. The objective of this study is to evaluate ECG changes in normal pregnancies by trimester compared to women who are not pregnant.

Study Design: This is an analysis of a database that includes 22,034 ECGs on 7,298 individual patients from 18-50 years of age who were pregnant at least once between 2011 to 2024 in a single tertiary medical center. Univariate and multiple generalized linear mixed effect models were performed to evaluate associations between four ECG features (QRS interval, QTc interval, PR interval, and heart rate) in pregnancy and by trimester compared to those in women who were not pregnant or within 6 months postpartum.

Results: After excluding patients with pre-existing cardiac morbidity, or affected hypertensive disorders of pregnancy, 5,574 ECGs from 2,988 patients were included: 3,423 of ECGs (61%) were obtained outside of pregnancy or the 6 months postpartum period, 2,151 (39%) of ECGs during pregnancy or postpartum. Shorter QRS duration, QTc interval, PR interval, and higher heart rate were associated the pregnancy or 2 weeks postpartum state (Table 1). The shorter QRS duration, PR interval, and higher heart rate were associated with the second, third trimester, and two weeks postpartum, and these changes resolved within 6 months postpartum (Table 2).

Conclusion: Four ECG features were found to be associate with pregnancy. The association is present particularly in the 2nd and 3rd trimester when cardiovascular changes are most pronounced. Future research includes extracting subtle patterns beyond well characterized ECG features to further investigate associations with normal pregnancy and to evaluate how they can be used to predict pathologic cardiovascular changes associated with pregnancy and postpartum.

Table 1. Adjusted Odds of ECG Features Associated with Pregnancy Compared to State Outside of Pregnancy or Postpartum*

Features	OR (95%CI)
QRS Duration**	0.72 (0.6, 0.85)
QTc Interval**	0.93 (0.87, 0.98)
PR Interval**	0.79 (0.73, 0.85)
Heart Rate**	1.55 (1.42, 1.7)

All Odds ratio (OR) have p-value < 0.001
*Multivariate logistic regression was performed to adjust for other ECG features listed in the table.
** Rescaling was performed via dividing by 10.
95%CI= 95% confidence interval.

Table 2: ECG Features Associated with Trimesters Compared to State Outside of Pregnancy or Postpartum*

	QRS Duration Estimates (95%CI)	QTc Interval Estimates (95%CI)	PR Interval Estimates (95%CI)	Heart Rate Estimates (95%CI)
Trimester 1	-0.05 (-0.16, 0.05)	-0.05 (-0.32, 0.23)	-0.16 (-0.34, 0.03)	0.08 (-0.12, 0.27)
Trimester 2	**-0.14 (-0.23, -0.05)**	**0.27 (0.04, 0.51)**	**-0.33 (-0.49, -0.17)**	**0.43 (0.26, 0.6)**
Trimester 3	**-0.25 (-0.34, -0.17)**	0.05 (-0.16, 0.26)	**-0.73 (-0.88, -0.58)**	**1.18 (1.03, 1.33)**
Within 2 Weeks Postpartum	**-0.18 (-0.32, -0.04)**	**-0.72 (-1.09, -0.35)**	**-0.37 (-0.61, -0.12)**	**0.73 (0.47, 0.99)**
Between 2 Weeks to 6 Months Postpartum	0.16 (0, 0.31)	0.18 (-0.23, 0.58)	-0.03 (-0.29, 0.23)	0.19 (-0.09, 0.47)

*Multiple generalized linear mixed effect models with a random effect for pregnancy identifier were fit to adjust for other ECG features listed in the table
** Rescaling was performed via dividing by 10
Bolded estimates and 95%CI (95% confidence interval) have p-value < 0.05.

1088 | Trends in Uterine Rupture and Perinatal Outcome Among Individuals Undertaking Trial of Labor After Cesarean

Lillian H. Goodman[1]; Amanda A. Allshouse[1]; Torri D. Metz[1]; Ann M. Bruno[2]
[1]University of Utah, Salt Lake City, UT; [2]University of Utah Health, Salt Lake City, UT

4:00 PM - 6:00 PM

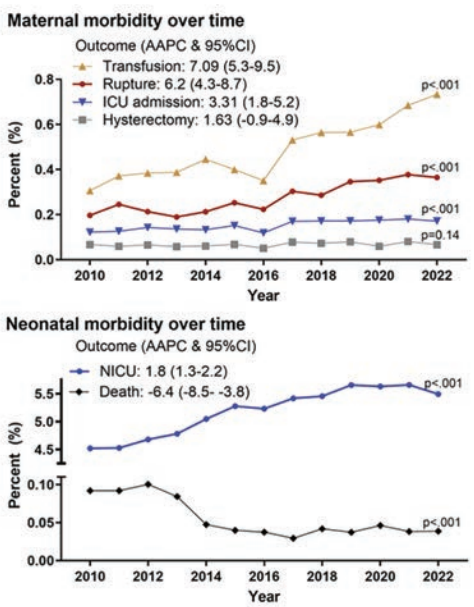
Objective: ACOG endorses trial of labor after cesarean (TOLAC) as a reasonable alternative to repeat cesarean delivery (CD). Concordantly, national rates of TOLAC have increased but the risk of uterine rupture remains a serious complication. We aimed to evaluate U.S. trends in uterine rupture and perinatal outcomes among individuals undertaking TOLAC from 2010 to 2022.

Study Design: This was a population-level retrospective cohort study using natality files in the National Vital Statistics System (NVSS) from 2010-2022. We included individuals with singleton, cephalic, term pregnancies undertaking TOLAC with 1 or 2 prior CD. The primary outcome was uterine rupture. Secondary outcomes included unplanned hysterectomy, blood transfusion, maternal or neonatal ICU admission, and neonatal death. Baseline characteristics were compared among those with and without uterine rupture. Temporal trends in outcomes were characterized using JoinPoint regression with average annual percentage change (AAPC) and 95% CI reported. Log binomial modeling estimated changes in maternal outcomes by 1-year increments adjusting for confounding.

Results: Of 1,016,073 deliveries included, uterine rupture occurred in 2,888 (0.28%). Those with uterine rupture were more likely to be older, have gestational diabetes, and be diagnosed with a hypertensive disorder of pregnancy. Rates of uterine rupture, transfusion, and maternal and neonatal ICU admission increased over time, while rates of hysterectomy were not significantly different over time and rates of neonatal death declined (Figure). In adjusted modeling, each 1-year increment remained significantly associated with higher rates of uterine rupture, transfusion, and admission to ICU but absolute rates remained low (Table).

Conclusion: While national rates of uterine rupture increased over time, uterine rupture continues to be rare. Counseling regarding mode of delivery among those with a prior CD should continue to weigh maternal and neonatal outcomes.

Figure. Trends in uterine rupture and perinatal outcomes among those undertaking trial of labor after cesarean (TOLAC) from 2010 to 2022



Average Annual Percentage Change (AAPC) with 95% confidence interval (CI) from joinpoint analysis. Maternal outcomes with zero joinpoints (i.e., linear), neonatal death estimated with two joinpoints, and NICU admission with one joinpoint. Intensive care unit (ICU), neonatal intensive care unit (NICU)

Table. Unadjusted and adjusted estimate of uterine rupture and perinatal outcomes over time among individuals undertaking trial of labor after cesarean (TOLAC)

	Incidence			AAPC*	
Outcomes	2010-14 (n=301,030)	2015-19 (n=438,407)	2020-22 (n=275,784)	Unadjusted	Adjusted†
Maternal					
Uterine rupture	637 (0.21)	1,244 (0.28)	1,007 (0.37)	6.25 (5.14-7.38)	4.28 (3.13-5.44)
Unplanned hysterectomy	187 (0.06)	308 (0.07)	191 (0.07)	1.58 (-0.54-3.75)	0.14 (-2.08-2.41)
Blood transfusion	1162 (0.39)	2,126 (0.48)	1,859 (0.67)	7.17 (6.31-8.02)	5.99 (5.11-6.90)
ICU admission	400 (0.13)	690 (0.16)	485 (0.18)	3.32 (1.89-4.79)	2.09 (0.58-3.62)
Neonatal					
Neonatal death	244 (0.1)	163 (0.0)	113 (0.0)	–	–
NICU admission	14,250 (4.7)	23,712 (5.4)	15,417 (5.6)	–	–

Data are n (%). Intensive care unit (ICU), neonatal intensive care unit (NICU), confidence interval (CI)
*Average Annual Percent Change (AAPC) estimate from log binomial regression of outcome difference for 1-year difference, estimate transformed as 100*exp(B)-1. Year parameterized linearly for maternal endpoints is a validated assumption per joinpoint analysis; data do not support assumption of linearity for neonatal outcomes and therefore estimates are not provided.
†Adjusted model includes maternal age, delivery weight, tobacco use, interval since last delivery, induction of labor, augmentation of labor, year of delivery.

1089 | Maternal Cytokine Expression in Mice with Gestational Breast Cancer

Lizelle Comfort[1]; Mackenzie Callaway[2]; Clarissa Bonanno[1]; Christine Metz[3]; Camila dos Santos[2]; Burton Rochelson[1]
[1]Northwell, New Hyde Park, NY; [2]Cold Spring Harbor Laboratory, Cold Spring Harbor, NY; [3]Feinstein Institutes for Medical Research, Manhasset, NY

4:00 PM - 6:00 PM

Objective: Immunosuppressive cytokines are implicated in both cancer progression and prenatal health outcomes. This study aims to examine cytokine levels in the plasma of tumor-bearing pregnant mice using a murine model of gestational breast cancer.

Study Design: On estrous day 11, nulliparous female BALB/c mice were either injected with 20K 4T1 MCherry tumor cells in PBS (20uL) a model for triple-negative breast cancer, or PBS (20uL) injected into the right 4th mammary duct (5 per group). These nulliparous BALB/c female mice were bred with BALB/c males (N = 10). Mice were euthanized on gestational day 19: pup numbers and fetal weights were recorded and maternal blood was collected. Isolated serum was frozen and analyzed using a cytokine array (Proteome Profiler Mouse Array Kit).

Results: Three of 5 mice injected with tumor cells and 1 of 5 mice injected with PBS were pregnant at time of specimen collection. Mice injected with tumor cells developed small but grossly visible mammary tumors. The mouse injected with PBS had 5 pups weighing ~1.3g/pup, whereas mice injected with tumor cells had 1-6 pups weighing ~1.2g/pup. Cytokine array demonstrated absence of pro-inflammatory cytokines in both serum samples and similar expression of CXCL13 and GM-CSF. However, tumor-injected serum demonstrated decreased IL-10, an anti-inflammatory cytokine implicated in tumorigenesis and pregnancy outcomes (4.27 units control to tumor-injected serum expression), IL-3, and IL-4 (3.95 and 2.09 units control to tumor-injected, respectively), regulators of adaptive immunity.

Conclusion: There does not appear to be a difference in pro-inflammatory cytokine expression in serum of pregnant tumor-affected mice; however, there is decreased anti-inflammatory cytokine expression among individual markers. This was a pilot analysis on a small sample size; we plan to perform cytokine analysis on a larger murine sample size, to validate findings in the pregnant human population, and to examine murine cytokine expression of amniotic fluid and pups in this gestational breast cancer model.

1090 | Prevalence of and Factors Associated with Iron Deficiency at the time of Delivery

Logan Mauney[1]; Ashley Parker[2]; Kathleen J. Koenigs[2]; Pichliya Liang[1]; Sarah N. Bernstein[3]; Mark A. Clapp[1]
[1]Massachusetts General Hospital, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Massachusetts General Hospital, Division of Maternal Fetal Medicine, Boston, MA

4:00 PM - 6:00 PM

Objective: Iron deficiency (ID) and iron deficiency anemia (IDA), the end-stage manifestation of ID are associated with maternal and fetal morbidity in pregnancy and postpartum. While pregnant individuals are screened for anemia, there is no consensus on the role of routine ID screening. Our study sought to assess the prevalence of ID and IDA at the time of delivery.

Study Design: This pilot, single-site, prospective cohort study recruited patients with singleton pregnancies at ≥ 36 weeks of gestation during routine prenatal care visits. Patients who had received IV iron during the pregnancy were excluded. Participants completed surveys about their use of iron supplementation during pregnancy and had iron studies and hemoglobin measured on admission for delivery. We report the prevalence of ID and IDA by varying definitions: ferritin < 30 ng/mL, transferrin saturation (TSAT) < 20%, or either criterion; anemia was defined as Hgb < 11 g/dL. Patient characteristics and the rates of anemia were compared among those with and without ID by ferritin criteria.

Results: Of 92 patients included, 45 (49%) had ferritin < 30 ng/mL, 52 (57%) had TSAT < 20%, and 60 (65%) had either (Figure 1). 10 patients (11%) had anemia, of which 8 (80%) had ferritin < 30 ng/mL. Patients with ID were more likely to be multiparous (60% vs. 36%, p = 0.04) and have higher BMI at delivery (median (IQR) 32.0 (28.5-34.3) vs. 29.2 (27.3-31.7), p = 0.02; Table 1). 13% of the subjects self-identified as Asian; none had ID. Although the rates of anemia in the 3rd trimester were similar, 19 patients without ID (40%) vs. 5 with ID (11%) reported taking an iron (p = 0.001). On admission, 8 (18%) with ID and 2 (4%) without ID were anemic (p = 0.048).

Conclusion: ID was highly prevalent at the time of delivery, exceeding previously published estimates, and associated with anemia. Further research is needed to evaluate the impact of ID at delivery as well as the treatment of ID with and without anemia on perinatal outcomes.

Table 1: Characteristics of patients with and without iron deficiency at delivery

Characteristics	Iron Deficiency N=45	No Iron Deficiency N=47	P-value
Maternal age, years	34.6 (4.9)	33.6 (3.6)	0.28
Self-reported race			
American Indian or Alaska Native	1 (2%)	0	<0.001
Asian	0	12 (26%)

1091 | Patient-Reported unmet Health-Related Social Needs in Patients with and without Preterm Birth

Logan Mauney[1]; Jonathan Y. Siden[2]; Kaitlyn E. James[1]; Chengbo Zeng[3]; Sarah N. Bernstein[4]
[1]Massachusetts General Hospital, Boston, MA; [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA; [3]Brigham & Women's Hospital, Boston, MA; [4]Massachusetts General Hospital, Division of Maternal Fetal Medicine, Boston, MA

4:00 PM - 6:00 PM

Objective: Preterm birth (PTB) is the leading cause of infant mortality and has been linked to social determinants of health (SDOH) such as economic stability, social and community context, and limited healthcare access. There is little evidence on the impact of unmet health-related social needs (HRSNs), the patient-level manifestations of these SDOH, on birth outcomes.

We sought to characterize the impact of patient-reported HRSNs on PTB.

Study Design: Retrospective cohort study of pregnant patients who completed a screen at least once in pregnancy for HRSNs in a regional health-care system from 5/2020 to 3/2024. HRSNs in the domains of education, employment, family care, food, housing, medication affordability, transportation, and household utilities affordability were identified through a validated screening tool. The primary outcome was birth before 37 weeks' gestation. Generalized estimating equations were generated to determine adjusted odds ratios (aOR) for the association between preterm birth and HRSN domains. Models were adjusted for advanced maternal age, nulliparity, hypertensive disorders of pregnancy, pre-existing diabetes mellitus, and pregravid body mass index.

Results: There were 2,055 pregnancies screened for HRSNs that met inclusion criteria, of whom 156 (7.6%) had a PTB. Patients with a PTB were significantly more likely to report food insecurity (14.1% vs 8.2%; aOR 2.09 95% CI 1.22-3.59) and unemployment (19.2% vs 11.2%; aOR 1.74 95%CI 1.07-2.81). The presence of ≥ 2 or ≥ 3 HRSNs was associated with increased odds of PTB: ≥ 2 HRSNs aOR 1.68 (95% CI 1.12-2.52); ≥ 3 HRSNs aOR 1.81 (95% CI 1.11- 2.95). Other HRSNs represented in the cohort were not significantly associated with risk of PTB.

Conclusion: Patient-reported food insecurity and unemployment are independently associated with PTB. Further, HRSNs in 2 or more of any domains have nearly the same impact. Future research is needed to understand the mechanisms of these associations to inform critically needed patient and policy level interventions to reduce PTB.

TABLE 1: Rates of preterm birth by health-related social needs

	Term birth (n=1,899)	Preterm birth (n=156)
Patient Factors		
Maternal age at delivery (mean, SD)	32.6 (5.2)	33.8 (5.4)
Nulliparity	1033 (54.4%)	79 (50.6%)
Hypertensive disorders of pregnancy*	355 (18.7%)	56 (35.9%)
Pre-existing diabetes mellitus	25 (1.3%)	6 (3.8%)
Pregravid BMI (mean, SD)	26.6 (6.6)	27.7 (7.0)
HRSNs		
Transportation	66 (3.5%)	7 (4.5%)
Utilities	105 (5.5%)	10 (6.4%)

1092 | State Partisan Divide and Intimate Partner Violence before and during Pregnancy

Madeline F. Perry; Joe M. Feinglass; Lynn M. Yee
Northwestern University Feinberg School of Medicine, Chicago, IL

4:00 PM - 6:00 PM

Objective: Pregnancy is a high-risk period for intimate partner violence (IPV), with greater risk for adverse pregnancy outcomes among people who experience IPV. Our objective was to evaluate the association between a state's percent vote for Donald Trump in the 2020 presidential election and statewide IPV rates before and during pregnancy reported by birthing people.

Study Design: Data from 2016-2020 from 44 states using the Pregnancy Risk Assessment Monitoring System (PRAMS) were linked to the state percent vote for Trump in the 2020 election. PRAMS surveys postpartum people two to four months after delivery. The survey asks participants if their current or past husband/partner "push, hit, slap[ped], kick[ed], choke[d], or physically hurt [them] in any way" in the 12 months before pregnancy and/or during pregnancy. Respondents who answered "yes" to either question were defined as reporting IPV. Our main outcome was the mean state-reported prevalence of IPV in the 12 months before or during pregnancy. Multivariable Poisson regression estimated the association between the 2020 state percent vote for Trump and the mean IPV rate reported, controlling for individual-level sociodemographic variables. Sensitivity analysis with 2016 election data was performed.

Results: Among 190,800 respondents representing an estimated population of 9,762,956, 3.1% of respondents reported experiencing IPV before or during pregnancy. There was a significant positive association ($r = 0.62$, $p < 0.001$) between mean state IPV rate and state percent vote for Trump in 2020 (Figure). After adjusting for respondent sociodemographic factors, each 10-point increase in the state percent vote for Trump was associated with a nine percent greater likelihood of reporting IPV before or during pregnancy (aIRR 1.09, 95% CI 1.05, 1.13; Table). Findings were similar for 2016 election data (aIRR 1.08, 95% CI 1.04, 1.13).

Conclusion: Political and cultural environments are potential contributing factors to IPV prevalence before and during pregnancy. The state percent vote for Trump may be a signal of a greater prevalence or toleration of abusive behavior.

1093 | Exposed Fetal Membranes Prior to Physical Examination-Indicated Cervical Cerclage and Time to Delivery

Mallory Vial[1]; Baha M. Sibai[2]; Emily Hyde[3]; Khalil M. Chahine[4]; Nahla Daye[1]; Sami Backley[5]; Sean C. Blackwell[2]; Ahmed Zaki Moustafa[6]

[1]University of Texas Health Science Center at Houston, Houston, TX; [2]McGovern Medical School at UTHealth Houston, Houston, TX; [3]UT Houston, Houston, TX; [4]McGovern Medical School at UTHealth, Houston, TX; [5]Division of Fetal Intervention, Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern Medical School at UTHealth Houston, Houston, TX; [6]Division of Maternal-Fetal Medicine, Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern Medical School at UTHealth Houston, University of Texas - Houston, TX

4:00 PM - 6:00 PM

Objective: Physical examination-indicated cerclage (PEIC) is considered in the setting of painless cervical dilation with or without exposed fetal membranes. We hypothesize that exposed fetal membranes is a poor prognostic sign and associated with shortened latency from cerclage to delivery.

Study Design: This is a retrospective cohort study of all singleton pregnancies that underwent PEIC at a Level IV center between January 2015 and March 2024. Patients with no delivery records available for review were excluded. We compared demographic and clinical characteristics, latency from cerclage to delivery, and perinatal outcomes among patients with and without exposed fetal membranes at the time of surgery.

Results: Ninety-three cases of PEIC were analyzed: 56 (60%) had exposed fetal membranes and 37 (40%) did not. There were no significant differences in the distribution of age, race, parity, or medical comorbidities between groups. Latency period was significantly shortened in patients with exposed membranes compared to patients without (median 5 vs 16 weeks, P = 0.008) (Figure 1). Exposed membranes was associated with higher rates of preterm birth at < 24, < 28, < 32, and < 37 weeks gestation respectively (32 vs 11%, P = 0.02; 55 vs 22%, P = 0.001; 57 vs 27%, P = 0.004; and 73 vs 46%, P = 0.01). Exposed membranes was also associated with higher rates of prelabor premature rupture of membranes (PPROM) and intraamniotic infection (IAI) (27 vs 8%, P = 0.008; 12 vs 2%, P = 0.04) (Table 1).

Conclusion: Sixty percent of patients with PEIC had exposed fetal membranes at the time of cerclage placement. Patients with exposed membranes had shortened latency periods and higher rates of preterm delivery < 24, < 28, < 32, and < 37 weeks. These data will inform provider counseling and patient expectations when considering PEIC.

1094 | The Accuracy of Crown-Rump Length Measurements: Comparison of 5-7 with 8-10 Gestational Weeks

Manal Massalha[1]; Maria Abbas[2]; Etty Daniel-Spiegel[2]; Enav Yefet[3]; Zohar Nachum[1]
[1]Emak Medical Center, Afula, HaZafon; [2]Emek Medical Center, Emek Medical Center, Afula, HaZafon; [3]Tzafon Medical Center, Poriya, HaZafon

4:00 PM - 6:00 PM

Objective: The International Society of Ultrasound in Obstetrics and Gynecology recommends for dating to use ultrasound (US) measurements at 8-13gestational weeks (GW), and to change the dating if the difference from the last menstrual period (LMP) is of 6d or more. We aimed to evaluate the accuracy of the crown-rump length (CRL) at an earlier stage of 5-7GW compared with 8-10GWand to estimate if 5d difference justifies dating correction.

Study Design: A retrospective cohort study was conducted. Data was retrieved from the medical records of women treated in the assisted reproductive technology (ART) clinic between 2016-2023 at Emek Medical Center, Afula, Israel. The LMP was calculated from embryo age and the date of transfer. The study and control groups included women who conceived by ART a singleton pregnancy and performed an US exam at 5+5-7+6 or/and 8-10+6GW, respectively. Transvaginal US was performed using the Voluson E10 BT20 device by experienced technicians at the US unit. Women with severe chronic diseases (e.g. chronic hypertension, pre-gestational diabetes, autoimmune diseases and heart or renal diseases) were excluded. The primary outcome was the accuracy of the CRL values at a range of ±4d according to Hadlock at 5+5(CRL = 2mm)-7+6 compared with 8-10+6(CRL = 42mm)GW. Assuming that 20% of the US CRL measurements at 5+7-7+6GW will differ at least 5d from the calculated GW compared with 10% of the measurements at 8-10+6GW, a sample size of 400 pregnancies was required ($\alpha = 0.05$, power = 80%).

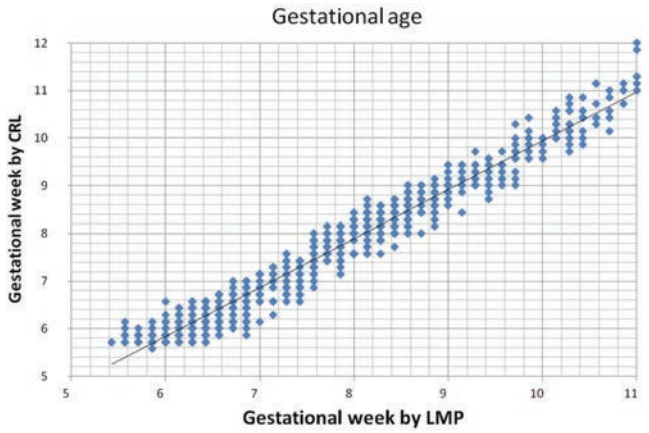
Results: Included in the study 443 women, who performed 1045 US exams (mean 2.4/woman). The study and control groups performed 575 and 470 exams, respectively, and the accuracy of CRL measurements of ±4d within the LMP was 96% and 99%, respectively (P = 0.02). High rate of accuracy of 95-100% was found throughout all GWs (Table and Figure).

Conclusion: Although the control group performed slightly better, the early 5+5-7+6GW group has a high accuracy of CRL measurements and can be used for dating. We recommend dating correction if a 5d difference or more is found using transvaginal US exam during 5+5-10+6GW.

Table: accuracy of CRL measurements by early gestational weeks

GW \ Accuracy	±3 days	±4 days
5+5 – 7+6 (N=575)	506 (88%)	552 (96%)
8+0 – 10+6 (N=470)	445 (95%)	463 (99%)
P value	0.0002	0.02
5+5 – 5+6 (N=42)	42 (100%)	42 (100%)
6+0 – 6+6 (N=351)	307 (87%)	337 (96%)
7+0 – 7+6 (N=182)	157 (86%)	173 (95%)
8+0 – 8+6 (N=328)	317 (97%)	324 (99%)
9+0 – 9+6 (N=83)	75 (90%)	80 (96%)
10+0 – 10+6 (N=59)	53 (90%)	59 (100%)

CRL = crown-rump length, GW = gestational week



1095 | Intellectual Disability as a risk Factor for Adverse Outcomes Among Pregnant People with Diabetes

Manasa G. Rao[1]; Timothy Wen[2]; Mary E. D'Alton[1]; Alexander M. Friedman[3]; Noelia Zork[3]
[1]Columbia University Medical Center, New York, NY; [2]University of California, San Diego, Irvine, CA; [3]Columbia University Irving Medical Center, New York, NY

4:00 PM - 6:00 PM

Objective: Intellectual and developmental disabilities (IDD) are associated with increased risk of adverse pregnancy outcomes and the proportion of pregnant patients with a IDD diagnosis has increased over time. Diabetes mellitus (DM) requires more intensive antenatal care including frequent glucose monitoring, medication adherence and titration, and frequent visits. It is unclear whether IDD is an independent risk factor for adverse outcomes among pregnancies with DM. The purpose of this analysis was to evaluate whether IDD was associated with adverse outcomes among deliveries complicated by DM.

Study Design: Delivery hospitalizations to patients with pregestational and gestational DM aged 15-54 were analyzed using the 2000-2021 Nationwide Inpatient Sample. The primary exposure of interest was IDD defined using ICD9/ICD10 codes. Temporal trends in proportion of deliveries with IDD and DM were analyzed with joint point regression to determine average annual percent change (AAPC) with 95% confidence intervals. The association between hospital, demographic, and a range of adverse outcomes were analyzed with logistic regression models.

Results: 2389 (0.04%) deliveries of 6,012,324 with DM diagnosis had an associated IDD diagnosis. Deliveries to patients with both DM and IDD increased from 2 per 10,000 in 2000 to 7 per 10,000 in 2021 (AAPC 7.8, 6.4-10.3, p< 0.01). More patients with IDD had pregestational DM (30.2% vs 13.5%). In adjusted analyses, patients with IDD had increased odds of diabetic ketoacidosis (aOR 2.66, 1.06-6.69), preterm birth < 37 weeks (aOR 1.46, 1.10-1.92), cesarean delivery (aOR 1.30, 1.05-1.60), non-transfusion severe maternal morbidity (aOR 2.06, 1.26-3.32), hypertensive disorders of pregnancy (aOR 1.29, 1.03-1.63), and stillbirth (aOR 1.94, 1.07-3.5). Odds of shoulder dystocia did not differ between the groups.

Conclusion: Among deliveries with DM, the proportion of IDD increased over time. IDD is associated with increased risk of adverse outcomes among deliveries with DM. Additional

resources and surveillance may be warranted for patients with IDD and DM to optimize outcomes.

Table. Odds of adverse outcomes related to diabetes in pregnancy

	Intellectual and Developmental Disability*				Unadjusted model		Adjusted model	
	Absent		Present					
	N	%	N	%	OR	95% CI	aOR	95% CI

1096 | Race and Temporal Temperature Measurement in Intraamniotic Infection

Maria A. Phillis[1]; Peyton Johnston[1]; Esha Ghosalkar[2]; David N. Hackney[1]
[1]*University Hospitals Cleveland Medical Center, Cleveland, OH;* [2]*Case Western Reserve University, Cleveland, OH*

4:00 PM - 6:00 PM

Objective: Temperature is underestimated in Black versus White inpatients when temporal thermometers are used. There is no data on racial differences in temporal temperature measurements in obstetrical patients in assessment of Intraamniotic infection (IAI). Our aim was to analyze intrapartum temporal temperature readings in self-identified Black versus White patients with IAI. We hypothesized that Black patients would have significantly lower max temperature (Tmax) when measured temporally and this may result in delay of diagnosis or antibiotics, higher stage or grade of chorioamnionitis on pathology or neonatal and maternal morbidity.

Study Design: We conducted a single institution retrospective cohort study of self-identified Black and White patients at term with clinical IAI or histopathological diagnosis of chorioamnionitis from 2021-2022. Primary outcomes were differences in Tmax in Black versus White patients with clinically diagnosed IAI and Tmax differences in Black versus White patients with histopathological chorioamnionitis. All temperatures were measured with temporal thermometers. Secondary outcomes included differences in stage and grade of chorioamnionitis, timing of diagnosis and antibiotics, and neonatal and maternal complications.

Results: 459 patients were identified that met the inclusion and exclusion criteria, 285 (62.1%) Black patients and 174 (37.9%) White patients, with Black patients more likely to be diagnosed with IAI. Black patients were younger, more often multiparous, with higher BMIs and a higher likelihood of hypertensive diseases. There was no difference in primary outcome of Tmax by race. Black patients with a clinical diagnosis of IAI were more likely to undergo cesarean delivery. Infants of White patients with a histopathological diagnosis of chorioamnionitis were more likely to be admitted to the NICU.

Conclusion: Temporal thermometer measurements were not statistically significant by race. However there were disparities in cesarean delivery rates and NICU admissions.

1098 | Risk Factors for Unplanned Cesarean Delivery Among Pregnancies with Preexisting Diabetes

Marie-Julie Trahan[1]; Qi Yan[2]; Noelia Zork[2]; On behalf of the MOMPOD Consortium
[1]*Columbia University, New York, NY;* [2]*Columbia University Irving Medical Center, New York, NY*

4:00 PM - 6:00 PM

Objective: Diabetes in pregnancy is associated with an increased risk of cesarean delivery (CD). While CD risk factors among pregnancies with gestational diabetes (GDM) are well defined, such as nulliparity, body mass index, gestational weight gain, and insulin use, it is unclear whether these same risk factors apply to pregnancies with preexisting diabetes. The objective of this study was to identify risk factors for unplanned CD among pregnancies with Type 2 diabetes (T2D) or early GDM.

Study Design: This was a secondary analysis of the Metformin Plus Insulin for Preexisting Diabetes or Gestational Diabetes in Early Pregnancy (MOMPOD) randomized controlled trial. Participants with T2D or early GDM were included if they had a trial of labor. Baseline and pregnancy characteristics were compared between those with a vaginal delivery (VD) and those with an unplanned CD using descriptive and logistic regression analyses, controlling for potential confounders.

Results: Of 405 participants, 144 (36%) had an unplanned CD and 261 (64%) had a VD. There were no differences in diabetes type, metformin use, or neonatal birthweight between groups. Compared to those with a VD, participants with an unplanned CD had greater median gestational weight gain [11.6 pounds (interquartile range (IQR) 6.8-15.4) vs. 10 pounds (IQR 4.4-14.9), $p = 0.019$], enrollment HbA1c $\geq$ 6.5% (69% vs. 56%, $p = 0.0239$), third trimester HbA1c $\geq$ 6.5% (39% vs. 25%, $p = 0.0459$), and median glucose levels in labor [130.0 mg/dL (IQR 112.0-161.5) vs. 121.0 mg/dL (IQR 100.0-144.0), $p = 0.0025$]. There was no difference in median third trimester HbA1c. In multivariate adjusted analysis, only median enrollment HbA1c (mean gestational age 11.2 weeks) was associated with CD [7.3% for CD vs. 6.85% for VD, $p = 0.0107$; aOR 1.21 (95% confidence interval 1.03, 1.42)].

Conclusion: Higher first trimester HbA1c is associated with CD in patients with T2D or early GDM attempting VD. Preconception counseling should focus on improved glycemic control prior to and in early pregnancy as a potential strategy to reduce risk of unplanned CD for pregnant individuals with preexisting diabetes.

Birthweight (grams) (median, IQR)	3198 (2693-3524)	3216 (2880-3586)	0.4324

IQR: interquartile range; SD: standard deviation

Table 2. Logistic regression analyses

Exposures*	Unplanned CD (n=144)	VD (n=261)	Adjusted p-value	Adjusted OR (95% CI)
HbA1c at enrollment (%) (median, IQR)	7.3 (6.2-9.4)	6.85 (5.9-8.5)	0.0185	1.21 (1.03, 1.42)
HbA1c at enrollment ≥6.5% (n, %)	87 (68.49%)	133 (56.37%)	0.0523	1.96 (0.99, 3.87)
HbA1c in 3rd trimester ≥6.5% (n, %)	26 (39.39%)	29 (25.22%)	0.0612	2.40 (0.96, 6.00)
Gestational weight gain (pounds) (median, IQR)	11.55 (6.81-15.43)	9.95 (4.38-14.88)	0.926	1.00 (0.98, 1.03)
Induction (n, %)	127 (88.19%)	197 (75.50%)	0.1835	1.67 (0.78, 3.57)
Highest glucose level in labor (mg/dL) (median, IQR)	130.0 (112.0-161.5)	121.0 (100.0-144.0)	0.0083	1.01 (1.00, 1.01)

**Logistic regression was performed to test the association between unplanned cesarean delivery and each of the six exposures, with adjustment for nulliparity, Hispanic origin, marital status, preexisting hypertension requiring daily medication, preeclampsia, and cigarette use in pregnancy. Characteristics were considered potential confounders if they were significantly different between CD and VD groups.*
CD: cesarean delivery; IQR: interquartile range; OR: odds ratio; VD: vaginal delivery

1099 | Anal Sphincter Injury After Vacuum-Assisted Delivery- is Avoiding Episiotomy Still Safe?

Matan Anteby[1]; Tally Pinchas-Cohen[1]; Asnat Groutz[1]; Ronen Gold[1]; Anat Lavie[2]; Yariv Yogev[3]; Yoav Baruch[1]
[1]Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv University, Israel, Tel Aviv, Tel Aviv; [2]Tel Aviv Sourasky Medical Center, Tel Aviv Sourasky Medical Center, Tel Aviv; [3]Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv University, Tel Aviv Sourasky Medical Center, Tel Aviv

4:00 PM - 6:00 PM

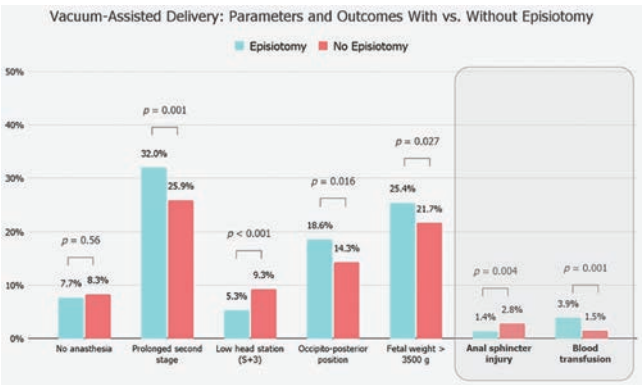
Objective: To assess whether avoiding episiotomy during vacuum-assisted deliveries (VAD) affects the incidence of anal sphincter injury (OASI) in primiparous women.

Study Design: A retrospective cohort study of all primiparous patients who had a VAD at a university-affiliated tertiary center (2011-2022). In our institution, during VAD, a mediolateral episiotomy is performed at the attending physician's discretion. We compared outcomes between VADs with and without episiotomy. Baseline characteristics were evaluated along with various VAD parameters. The primary outcome was OASI, with secondary outcomes including other maternal adverse events.

Results: Out of 157,282 deliveries, 10,400 (6.6%) were VADs, and 7,951 met the inclusion criteria. Among these, 7,201 (90.6%) had episiotomies, and 750 (9.4%) did not. Baseline maternal characteristics were similar between the groups. Those who had episiotomy had a higher rate of prolonged second stage of labor (PSS) (32% vs. 25.9%, p = 0.001), higher rates of occipitoposterior position (OP) (18.6% vs. 14.3%, p = 0.016) and more advanced head station (+3 under ischial spine in 5.3% vs. 9.3%, p< 0.001), as compared to no episiotomy. Newborns weighing >3500 grams were more common in the episiotomy group (25.4% vs. 21.7%, p = 0.027).

Despite these known risk factors for OASI, the incidence of OASI was higher in the no-episiotomy group (2.8% vs. 1.4%, p = 0.004). Multivariable analysis confirmed that episiotomy had a protective effect against OASI [aOR 0.433 (0.258-0.728), p = 0.002]. Prolonged second stage [aOR 1.98 (1.32-2.94), p< 0.001] and higher birthweight [aOR 1.86 (1.09-3.17), p = 0.022] also correlated with a higher risk of OASI. The number needed to treat (NNT) to prevent one OASI with episiotomy was 71, reduced to 42 for PSS, 33 for OP, and 22 for newborns >3500 g. Other maternal adverse outcomes were similar, except for a higher postpartum blood transfusion rate in the episiotomy group (3.9% vs. 1.5%, p = 0.008).

Conclusion: Avoiding routine episiotomy during VAD in primiparous women is associated with a higher OASI rate, particularly in those with PSS, OP, or larger newborns.



1100 | Normotensive vs. Hypertensive HELLP Syndrome: Should We Expect Different Outcomes?

Matan Anteby[1]; Keren Or Wertheimer[1]; Liran Hiersch[2]; Yariv Yogev[3]
[1]Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv University, Israel, Tel Aviv, Tel Aviv; [2]Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv University, Israel, Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv; [3]Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv University, Tel Aviv Sourasky Medical Center, Tel Aviv

4:00 PM - 6:00 PM

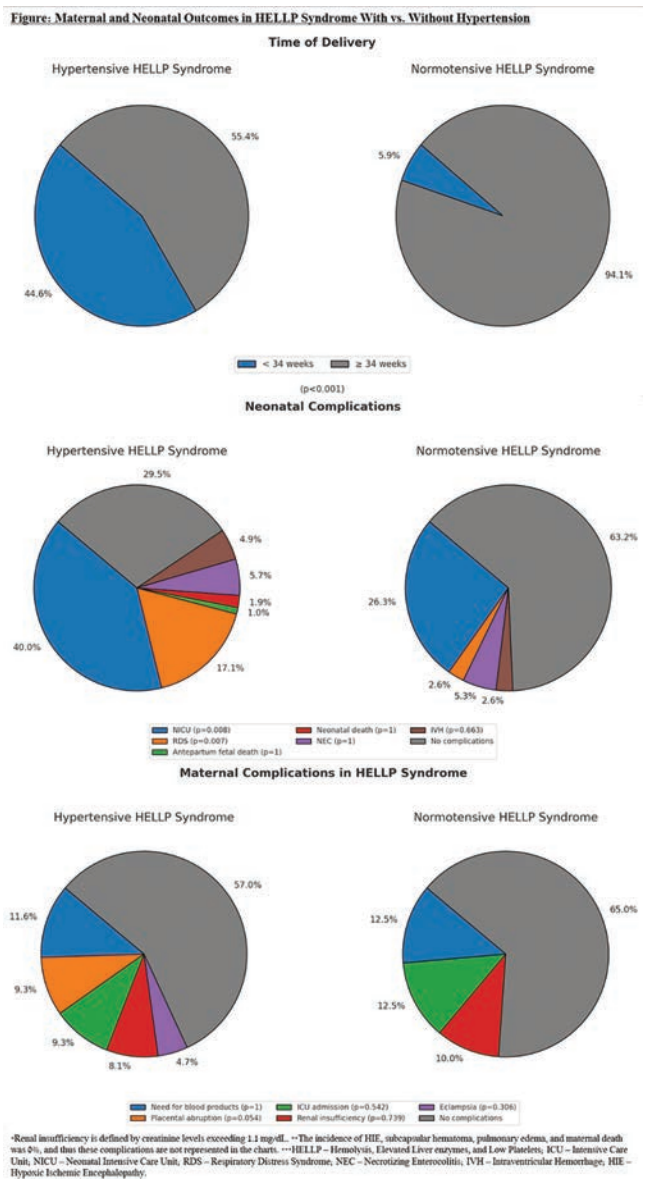
Objective: To compare maternal and neonatal outcomes between women with hemolysis, elevated liver enzymes, and low platelet (HELLP) syndrome with and without associated hypertension, focusing on differences in presentation, disease severity, and associated complications.

Study Design: A retrospective cohort study of singleton deliveries diagnosed with HELLP syndrome at a tertiary university-affiliated hospital (1.2011-3.2023). Cases were categorized into normotensive HELLP and hypertensive HELLP. We collected and compared data on maternal demographics, clinical presentation, laboratory findings, delivery outcomes, and neonatal complications.

Results: Among 157,282 deliveries, 118 met the full criteria for HELLP syndrome: 74 (68.5%) hypertensive and 34 (31.5%) normotensive. Normotensive HELLP cases were diagnosed at a significantly later gestational age (37.5 ± 3.0 vs. 34.5 ± 4.4

weeks, p< 0.001). Only 2 women (5.9%) with normotensive HELLP delivered < 34 weeks, compared to 33 (44.6%) with hypertensive HELLP (p< 0.001) (figure). Proteinuria was less common in normotensive cases (58.8% vs. 87.8%, p< 0.001). Laboratory parameters, including hemoglobin, platelet count, creatinine, liver function tests, and hemolysis parameters, did not differ significantly between the groups. Neonates in the normotensive group had significantly higher mean birth weights (2574.6 ± 746.2 vs. 1947 ± 816.6 grams, p< 0.001), fewer NICU admissions (29.4% vs. 56.8%, p = 0.008), and lower rates of respiratory distress syndrome (2.9% vs. 24.3%, p = 0.007) (figure). Maternal complications related to HELLP syndrome did not differ significantly between normotensive and hypertensive cases (figure).

Conclusion: Normotensive HELLP syndrome appears to be a less severe form of HELLP syndrome, presenting at a later gestational age. Despite differences in neonatal outcomes, maternal adverse outcomes remain comparable to those in hypertensive HELLP syndrome. This suggests that normotensive HELLP should be managed with the same caution as hypertensive HELLP to ensure optimal maternal and neonatal outcomes.



•Renal insufficiency is defined by creatinine levels exceeding 1.1 mg/dL. ••The incidence of HIE, subcapsular hematoma, pulmonary edema, and maternal death was 0%, and thus these complications are not represented in the charts. •••HELLP – Hemolysis, Elevated Liver enzymes, and Low Platelets; ICU – Intensive Care Unit, NICU – Neonatal Intensive Care Unit, RDS – Respiratory Distress Syndrome, NEC – Necrotizing Enterocolitis, IVH – Intraventricular Hemorrhage, HIE – Hypoxic Ischemic Encephalopathy.

1101 | Optimizing Induction: Shortened Balloon Protocols for Better Outcomes

Matthew D. Mitts[1]; Kamran Hessami[1]; Meija Caldwell[1]; Christina M. Ackerman-Banks[1]; Karin A. Fox[2]

[1]Baylor College of Medicine, Houston, TX; [2]University of Texas Medical Branch, Galveston, TX

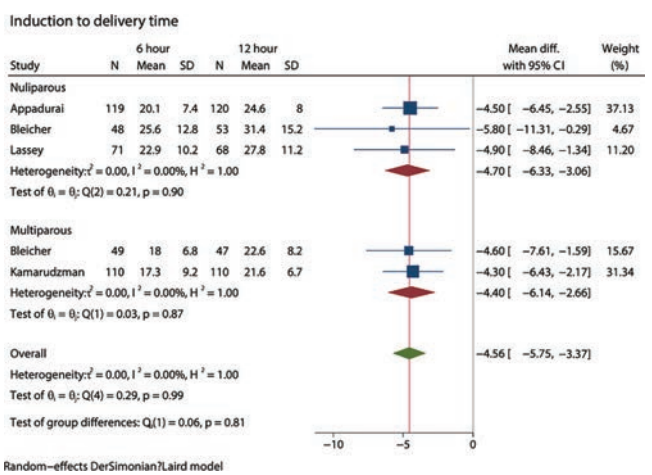
4:00 PM - 6:00 PM

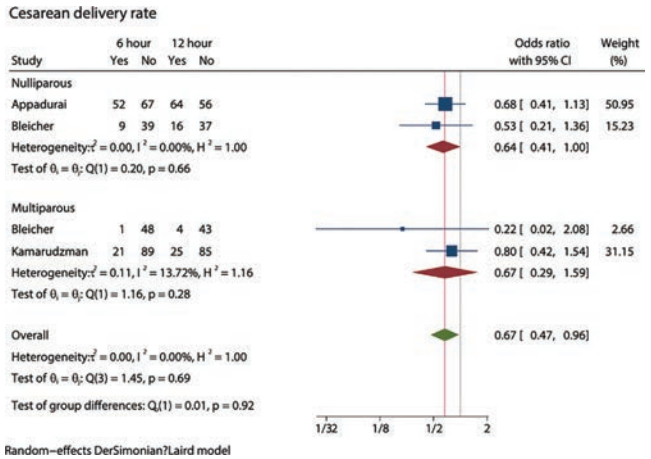
Objective: The optimal timing of mechanical balloon induction remains controversial. This meta-analysis compares the effectiveness of 6-hour versus 12-hour mechanical balloon induction protocols in reducing delivery time in term pregnancies.

Study Design: A comprehensive literature search was conducted using terms related to mechanical balloon induction. Randomized controlled trials (RCTs) comparing 6-hour and 12-hour induction protocols with various types of balloon catheters (single and double balloon) were included. The primary outcome was the interval time to delivery, defined as the time from the start of the induction process to delivery. The secondary outcomes were cesarean delivery rate (CD), operative vaginal delivery rate, time on oxytocin, and delta bishop score. The random-effects model was used to pool the odds ratios (ORs) and the corresponding 95% confidence intervals (CIs).

Results: Four RCTs were included in the meta-analysis, encompassing a total of 972 participants. Overall, patients with a 6-hour balloon induction delivered 4.5 hours sooner compared to those with a 12-hour balloon (mean difference -4.56, CI [-5.75,-3.37], P< 0.001). The risk of cesarean delivery was 1.5 times higher for patients with a 12-hour balloon compared to those with a 6-hour balloon (OR 0.67, 95% CI [0.47, 0.96], P = 0.028). Additionally, the risk of cesarean delivery due to non-reassuring fetal heart tones (NRFHTs) was 1.7 times higher in the 12-hour group (OR 0.59, 95% CI [0.36, 0.96], P = 0.030). No significant differences were found in the rate of operative vaginal delivery, time on oxytocin, change in Bishop score, or starting and post-intervention Bishop scores between the two groups.

Conclusion: A 6-hour mechanical balloon induction protocol significantly reduces the interval to delivery and the risk of cesarean delivery, particularly due to NRFHTs, compared to a 12-hour protocol. These findings support the use of a shorter induction interval for improved maternal and fetal outcomes in term pregnancies.





1102 | Neonatal Outcomes of Gastroschisis Births by mode of Delivery in the United States

Matthew H. Mossayebi[1]; Jennifer E. Powel[2]; Rodney A. McLaren, Jr., Jr.[3]; Zubair H. Aghai[4]; Virali Patel[4]; Mariella F. Toro[4]; Huda B. Al-Kouatly[3]
[1]Brigham and Women's Hospital, Boston, MA; [2]Hackensack Meridian Jersey Shore University Medical Center, Neptune, NJ; [3]Thomas Jefferson University Hospital, Philadelphia, PA; [4]Sidney Kimmel Medical College at Thomas Jefferson University, Philadelphia, PA

4:00 PM - 6:00 PM

Objective: Although trial of labor (TOL) versus planned caesarean delivery (CD) has been hypothesized to influence clinical outcomes in neonates with gastroschisis, this clinical decision remains controversial. We assessed neonatal outcomes in newborns with gastroschisis based on delivery mode in a contemporary United States cohort.

Study Design: We conducted a retrospective cohort study using population-based data from the US Natality Database on live singleton births complicated by gastroschisis from 2017 to 2022. Data was stratified by TOL versus CD. A sub-group analysis for term versus preterm neonates was performed. Cases with CD after failed TOL were included in the TOL group. Our primary outcome was composite adverse neonatal outcome, including chorioamnionitis, 5-minute Apgar score < 3, assisted ventilation use > 6 hours, surfactant use, neonatal seizures, and neonatal death. Patient characteristics were compared and logistic regression was performed to estimate adjusted odds ratios (aORs) for adverse outcomes accounting for gestational age (GA) at birth and birthweight.

Results: Of 17,104,917 births, 3,543 (0.021%) were complicated by gastroschisis. TOL was attempted in 2,433 (68.7%), while 1,110 (31.3%) reported planned CD. Compared to the planned CD group, those undergoing TOL had lower rates of preterm birth, delivered at later GA, and had higher birthweights (Table 1). TOL was associated with lower odds of composite adverse neonatal outcome (25.5% vs 31.4%, aOR 0.79). TOL was also associated with lower odds of NICU admission (aOR 0.53) and immediate ventilation use (aOR 0.73), and higher odds of chorioamnionitis (OR 2.12) and infant transfer to a higher-level care facility (OR 1.23) (Table 2). Similar results were observed after stratification for term versus preterm neonates.

Conclusion: TOL was associated with lower composite adverse neonatal outcome compared to planned CD among pregnancies complicated by gastroschisis. This study is limited by variables of antenatal morbidity, such as fetal growth restriction and size of gastroschisis.

Table 1. Patient Characteristics

Characteristics	Trial of Labor N=2,433	Planned Cesarean Delivery N=1,110	P-value

1103 | Antenatal Ultrasound Predictors of Genitourinary Injury in Cesarean Hysterectomy for Placenta Accreta Spectrum

Matthew D. Mitts[1]; Kamran Hessami[1]; Yamely H. Mendez[1]; Christina C. Reed[2]; Arthur Ladron De Guevara[1]; Keneshia Lane[1]; Kayla E. Ireland[3]; Georgia A. McCann[3]; Claire Hoppenot[1]; Amir A. Shamshirsaz[1]; Hendrik A. Lombaard[4]; Michael A. Belfort[5]; Jessian L. Munoz[1]
[1]Baylor College of Medicine, Houston, TX; [2]Baylor College of Medicine at Texas Children's Pavilion for Women, Houston, TX; [3]University of Texas Health Science Center at San Antonio, San Antonio, TX; [4]Texas Children's Hospital, Houston, TX; [5]Texas Children's Hospital and Baylor College of Medicine, Houston, TX

4:00 PM - 6:00 PM

Objective: Placenta accreta spectrum (PAS) is a complex obstetric condition associated with maternal morbidity. Urologic injuries complicate 20-30% of PAS deliveries during cesarean hysterectomy. This study aimed to evaluate ultrasonographic predictors of genitourinary (GU) injury during Cesarean Hysterectomy for PAS from multiple referral centers.

Study Design: We conducted a multicenter, retrospective analysis of singleton pregnancies with pathology-confirmed PAS (accreta, increta, or percreta). Ultrasonographic variables assessed included placental location, presence of previa or low-lying

placenta, presence of lacunae, loss of retroplacental clear zone, lower segment hypervascularity, bladder and uterine bulge, myometrial thinning, abnormal uterine-bladder interface, and suspected depth of invasion. The primary outcome was the occurrence of any GU injury (ureteral or bladder) during cesarean hysterectomy. Comparisons were made using Fisher's Exact test, and odd ratios were established using logistic regression.

Results: Among 358 patients included in the study, 59 (16%) experienced GU injury during surgery. Patients with GU injury were significantly more likely to have had antenatal suspicion of percreta based on ultrasound findings (OR 2.89, 95% CI: 1.56–5.35) and to have complete placenta previa (OR 3.26, 95% CI: 1.71–6.21), as seen in Table 1. Conversely, posterior placental location was associated with a lower risk of GU injury (OR 0.31, 95% CI: 0.11–0.89). None of the six ultrasonographic markers independently predicted GU injury.

Conclusion: Antenatal suspicion of percreta and complete placenta previa significantly increase the risk of GU injury during Cesarean Hysterectomy for PAS. Conversely, posterior placental location appears to be associated with a lower risk of such injuries. Individual ultrasonographic markers alone do not reliably predict GU injury at the time of cesarean hysterectomy; thus, multimodal imaging may be important for patient counseling and surgical preparation.

Table 1: Ultrasound Predictors and Genitourinary Injury

US Predictor		Odds Ratio	95% Confidence Interval	P-value
Placenta Previa		3.84	1.57 to 11.34	**<0.01**
Lacunae		1.43	0.78 to 2.69	0.25
Turbulent Flow		0.80	0.15 to 2.82	1.0
Loss of Retroplacental Space		1.32	0.67 to 2.47	0.36
Hypervascularity		1.48	0.81 to 2.71	0.20
Bladder Bulge		0.75	0.22 to 2.05	0.65
Uterine Bulge		0.86	0.38 to 1.80	0.73
Myometrial Thinning		0.63	0.27 to 1.35	0.24
Abnormal Bladder Interface		1.44	0.62 to 3.11	0.32
Feeder Vessels		0.72	0.08 to 3.25	1.0
Placental Location		-	-	**<0.01**
	n			-
Anterior	211	0.67	0.39 to 1.18	-

1104 | Azithromycin Utilization and Maternal Outcomes in Patients with Intrapartum Cesarean Birth, 2016-2020

Maura Jones Pullins[1]; Marie-Louise Meng[2]; Jerome J. Federspiel[2]; Kim Boggess[3]; Matthew Fuller[4]; Johanna Quist-Nelson[1]

[1]University of North Carolina, Chapel Hill, NC; [2]Duke University School of Medicine, Durham, NC; [3]University of North Carolina at Chapel HIll, Chapel Hill, NC; [4]Duke University, Durham, NC

4:00 PM - 6:00 PM

Objective: In 2016, the Cesarean Section Optimal Antibiotic Prophylaxis (C/SOAP) study demonstrated perioperative azithromycin at time of labored cesarean delivery reduced infection by 50% (12% to 6%). We examined national trends in perioperative azithromycin use following C/SOAP. We also evaluated association between azithyromicin use and maternal sepsis and death.

Study Design: This retrospective cohort study used the Premier Healthcare Database to identify births from 2016-2020 in patients aged 12 to 55, at > 24 weeks' gestation, with a singleton pregnancy and intrapartum cesarean or cesarean after rupture of membranes. Those with chorioamnionitis prior to delivery were excluded. The primary outcome was azithromycin use. Secondary outcomes were a composite endpoint of infectious and surgical wound complications, endometritis, necrotizing fasciitis, abscess, septic pelvic thrombophlebitis, sepsis, pyelonephritis, pneumonia, meningitis and death during delivery hospitalization or the following 30 days.

Results: From 2016 to 2020, there were 1,528,602 cesarean deliveries, of which 531,709 met inclusion criteria. Azithromycin recipients were more likely than Azithyromicin non-recipients to have diabetes, hypertension, and tobacco use disorder. Azithromycin use increased from < 1% to nearly 40% from 2016-2020 (Figure). Utilization was highest in hospitals with > 500 beds compared to hospitals with < 100 beds (41.4% vs 4.7% $p < 0.001$). Despite increasing azithromycin use, the composite outcome was higher among patients receiving Azithyromicin, as was endometritis, length of stay, and home health use (Table).

Conclusion: After C/SOAP, the uptake of azithromycin was rapid and faster in larger hospitals. Further implementation should focus on smaller rural hospitals where uptake remains low, which may reflect limited financial resources, or capacity for implementation. Given outcomes assessment was limited to inpatient encounters and this cohort was not randomized, we encourage caution when evaluating associations between azithromycin exposure and outcomes.

Figure 1. Azithromycin utilization trends for intrapartum cesarean birth by hospital size, 2016-2020

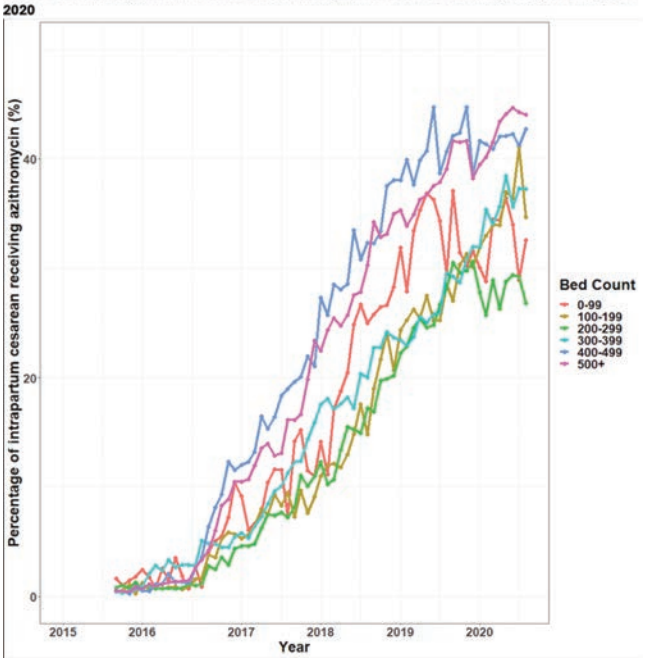

Table : Postoperative outcomes among patients with intrapartum cesarean

	Received Azithromycin Intraoperatively?			
	Overall (N=531,709)	No (N=435,392)	Yes (N=96,317)	p
Infectious complication composite*	8,737 (1.6%)	6,893 (1.6%)	1,844 (1.9%)	<0.001
Surgical Wound Complication	3,237 (0.6%)	2,681 (0.6%)	556 (0.6%)	0.165

4:00 PM - 6:00 PM

Objective: To investigate short-term maternal and neonatal outcomes in individuals with twin pregnancies and two prior CDs undergoing TOLAC.

Study Design: A cross-sectional study of live birth data was conducted between 2014-2021 in the United States. Individuals with twins and two prior CDs undergoing TOLAC were included. Comparison groups included those with: (1) twins and two prior CDs undergoing elective CD, (2) twins and one prior CD undergoing TOLAC, and (3) singletons and two prior CDs undergoing TOLAC. The primary outcomes were composite measures of maternal and neonatal morbidity. Maternal outcomes included chorioamnionitis, transfusion, hysterectomy, uterine rupture, ICU admission, and vaginal birth after cesarean (VBAC). Neonatal outcomes included 5-min Apgar ≤ 3, assisted ventilation, NICU admission, surfactant or antibiotic use, and seizures.Univariable and multivariable analyses were conducted with P value < 0.05 considered significant after Bonferroni adjustment.

Results: A total of 92,665 pregnant individuals and 106,361 neonates were isolated. VBAC was achieved in 37.8% (239/632) of individuals with twins and two prior CDs attempting TOLAC compared to 61.5% (2,271/3,693) in twins and one prior CD and 58% (45,834/78,969) in singletons and two prior CDs undergoing TOLAC ($P< 0.001$). Both composite maternal and neonatal morbidity were not significantly different between individuals with twin pregnancies and two prior CDs attempting TOLAC and other twin groups. None of the 632 individuals with twins and two prior CDs attempting TOLAC had a uterine rupture. Following adjustments with covariates, the odds of VBAC were more than twice as great in those with twins with one prior CD (aOR: 2.41; 95% CI: 2.01-2.90) and those with singletons with two prior CDs (aOR: 2.23; 95% CI: 1.88-2.65) compared to individuals with twins and two prior CDs.

Conclusion: In twin pregnancies with two prior CDs, although the chance of VBAC was 37.8%, there was no significant difference in adverse maternal or neonatal outcomes.

1106 | Role of Prenatal Care in Modifying the Risk of NAS Among Mothers with OUD

Megha Arora; Bharti Garg; Aaron B. Caughey
Oregon Health & Science University, Portland, OR

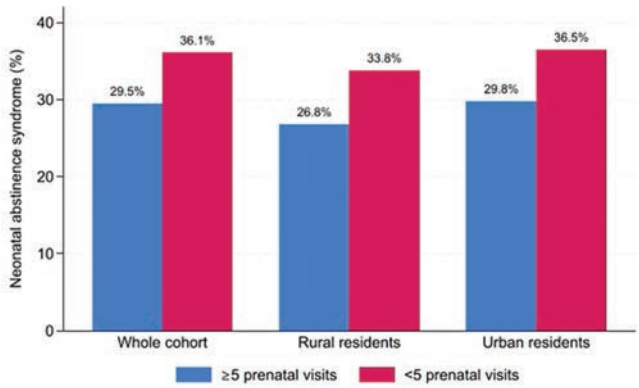
4:00 PM - 6:00 PM

Objective: To examine the risk of neonatal abstinence syndrome (NAS) among mothers with opioid use disorder with low and high engagement with prenatal care.

Study Design: We conducted a retrospective cohort study of births in the state of California from 2008-2020 among individuals with opioid use disorder to compare rates of NAS between those with < 5 prenatal visits and ≥5 prenatal visits. NOWs rates were assessed in the overall cohort then stratified by urban/rural residence. We performed multivariable logistic regression controlling for age, race/ethnicity, education, pre-pregnancy BMI, parity, and insurance status to estimate adjusted odds ratios (aOR) and 95% confidence intervals.

Results: In the cohort of 10,654 individuals with opioid use disorder, 2,147 (20.15%) attended < 5 prenatal visits and 8,507 (79.85%) attended ≥5 prenatal visits. There was lower prenatal care attendance among individuals aged 20-34, those with public insurance, and those with high school education or less. In the overall cohort, the adjusted odds of NAS was significantly higher among individuals with < 5 prenatal visits (aOR = 1.29; 95% CI 1.15-1.44). Similar significant results were found in rural residents; however, the results were not statistically significant in urban residents.

Conclusion: Our study found that among pregnant individuals with opioid use disorder, those with lower prenatal care had a higher risk of NAS in the infant. Close follow up of pregnant individuals with opioid use disorder through prenatal visits may reduce the burden of NAS among neonates.



1107 | What to Expect when you're Expecting: Impact of Physician and Patient factors on Predicted Delivery

Melissa S. Wong[1]; So Yung Choi[1]; Karla Gonzalez[1]; Samira Torna[1]; Matthew Wells[1]; Alex A. T. Bui[2]; Kimberly D. Gregory[3]
[1]Cedars-Sinai Medical Center, Los Angeles, CA; [2]Medical & Imaging Informatics Group, University of California, Los Angeles, Los Angeles, CA; [3]Cedars Sinai Medical Center, Los Angeles, CA

4:00 PM - 6:00 PM

Objective: The cesarean delivery rate continues to rise, and it is critical to understand how physician perceptions of likely mode of delivery influence the delivery outcome. The aim of this study was to perform an early, intrapartum assessment of physician's predictions of their patient's likelihood of vaginal delivery (VD) and to identify which physician and patient factors affect these predictions.

Study Design: We prospectively assessed physician prediction of anticipated mode of delivery for patients presenting to labor and delivery for planned vaginal delivery. At 4 hours, physicians were sent a single-item REDCap survey, "On a scale of 1-10 (where 10 = the highest), what is your patient's likelihood of a vaginal delivery?" and the value was converted to a probability (0-1.0).
We chart abstracted patient demographics and outcomes and obtained physician demographics through publicly available sources. We used linear mixed models to assess differences in predictions by patient and physician characteristics, and performed subgroup analysis for nulliparous, term, singleton vertex (NTSV) patients.

Results: We received 203 physician responses from 46 physicians. Table 1 lists physician and patient demographics. The median prediction was 0.9. Physicians predicted a lower likelihood of VD for patients with obesity and a higher likelihood of VD for multiparas. (Table 2)
The NTSV subgroup was 111 patients delivered by 39 physicians. Physician and patient characteristics were similar to the overall population. The median prediction was 0.8. Physicians predicted a lower likelihood of VD for patients age ≥ 35 and for BMI ≥30 and a higher likelihood of VD for Asian patients. There were no differences in predictions by physician demographics (age, gender, language, practice duration).

Conclusion: Numerous patient factors influence physician's perception of the probability of a VD. Given that we anticipate the physician's early perception impacts the eventual outcome (anchoring bias), future research will focus on the importance of

early recognition to determine strategies to mitigate those without causal association.

1108 | Physician vs. Partometer: a Machine Learning Model Predicts mode of Delivery as well as Physicians

Melissa S. Wong[1]; So Yung Choi[1]; Karla Gonzalez[1]; Samira Torna[1]; Matthew Wells[1]; Alex A. T. Bui[2]; Kimberly D. Gregory[3]
[1]Cedars-Sinai Medical Center, Los Angeles, CA; [2]Medical & Imaging Informatics Group, University of California, Los Angeles, Los Angeles, CA; [3]Cedars Sinai Medical Center, Los Angeles, CA

4:00 PM - 6:00 PM

Objective: Performance of predictive machine learning (ML) models has rarely been assessed against clinician intuition. The Partometer is a validated ML model which uses data from the electronic health record to generate ongoing predictions of a patient's likelihood of vaginal delivery (VD). The aim of this study is to compare calibration and accuracy of the Partometer in predicting VD compared to the physician.

Study Design: This was a prospective study of all patients presenting for a planned VD. At 4 hours, we conducted two concurrent assessments: 1) to the patient's physician "on a scale of 1-10 (ordinal; 10 = highest), what is your patient's likelihood of a vaginal delivery?"; 2) we queried the Partometer on the same continuous scale.

Patient information was chart abstracted; physician characteristics were obtained from public sources. We assessed calibration by fitting a linear mixed model for difference in Brier scores with random intercept to account for the predictions made by the same physician. For accuracy, we used >6 as predicting a VD (i.e., if the prediction was >6 and a VD occurred, this was a true positive). We stratified by patient characteristics. Subgroup analysis was performed among patients who were nulliparous, term, singleton vertex (NTSV).

Results: There were 203 predictions from 46 clinicians. The Partometer was equally well calibrated (Partometer 0.11 +/- 0.18, physician 0.12 +/- 0.22) and accurate (85.7% [80.1-90.2] vs. 80.8% [74.7-86.0]) as physicians in predicting VD. The findings persisted after adjustment for patient and clinician characteristics. On demographic-adjusted analysis, both the Partometer and physicians were less well calibrated for patients who were non-Hispanic Black, with obesity, or nulliparous. For the NTSV subgroup, predictions on subjects age ≥35 were less well calibrated by both Partometer and physicians. Differences in calibration were found in the NTSV subgroup among the clinicians < 40 years old and/or < 10 years of practice.

Conclusion: ML model to predict mode of delivery was as well calibrated and accurate as physicians' own predictions of their patients.

1109 | Proinflammatory Omega-6 and Arachidonic Acid are Increased in Breast Milk of Mothers with Overweight/Obesity

Michael G. Ross; MacKenzie Cervantes; Guang Han; Lihiri Bora; Mina Desai
The Lundquist Institute at Harbor-UCLA Medical Center, Torrance, CA

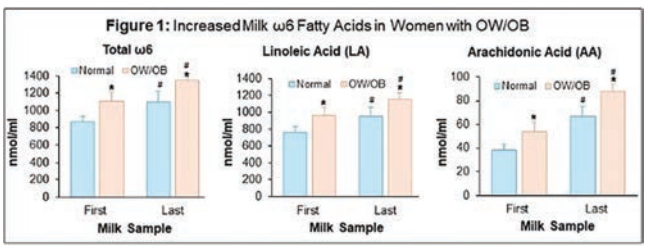
4:00 PM - 6:00 PM

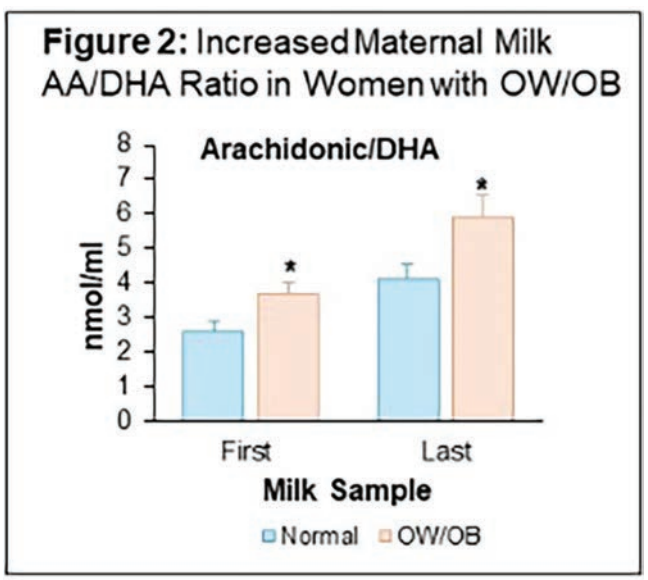
Objective: Human milk composition varies depending on maternal diet, duration of nursing, time of day and maternal body habitus. Among the critical milk components, essential polyunsaturated fatty acids (PUFA omega-6 and omega-3) must be supplied to the newborn for brain growth and development. Western diets have led to an increase in maternal consumption of omega-6 linoleic acid (LA) and a decrease in omega-3 α-linolenic acid (ALA) PUFA. Through the elongation and desaturation process, LA is converted to arachidonic acid (AA) and ALA to docosahexaenoic acid (DHA). While AA and DHA are important for brain development, an excessive amount of total omega-6 (ω6), AA and a higher AA/DHA ratio are associated with accelerated weight gain in infants, increased oxidative stress, inflammation and cognitive impairment. As women with OW/OB have increased total milk fat content, we sought to determine the influence of maternal body mass index (BMI) on specific PUFA levels.

Study Design: We studied women who delivered singleton, term neonates and were exclusive breastfeeding at 7-9 weeks postpartum. Among both normal weight (BMI 18.5-24.9 kg/m^2) and women with overweight and obesity (OW/OB; BMI$\geq$25 kg/m^2), continuous milk samples (10ml) from foremilk to hindmilk were obtained via pump until the breast was emptied. First and last pumped milk samples were analyzed. Milk and maternal plasma lipidomics were undertaken (Lipidyzer Platform).

Results: In women with OW/OB, breast milk total ω6, LA and AA levels were significantly increased in both the first (foremilk) and last (hindmilk) samples as compared to normal weight (Fig 1). Importantly, the AA/DHA ratio was significantly increased in foremilk and hindmilk of women with OW/OB (Fig 2).

Conclusion: The increased ω6, LA and AA levels including an increased AA/DHA ratio in the breast milk of women with OW/OB has a potential risk for infant obesity, inflammation and adverse cognitive/behavioral outcomes. Novel strategies to optimize milk AA/DHA are urgently needed during pregnancy and lactation, particularly in women with obesity.





1110 | Metformin Inhibits Insulin-induced Mammary Lipid Synthesis: Development of Personalized Human Milk to Prevent Childhood Obesity

Mina Desai[1]; Guang Han[1]; Krishna Rao[2]; Michael G. Ross[1]
[1]*The Lundquist Institute at Harbor-UCLA Medical Center, Torrance, CA;* [2]*Southern Illinois University School of Medicine, Springfield, IL*

4:00 PM - 6:00 PM

Objective: Infants born to obese mothers are at increased risk of childhood obesity due to in-utero programming and accelerated infant weight gain. The increased fat/calorie content of milk of mothers with obesity suggests that the maternal metabolic milieu, including increased serum insulin, alters breast lipid synthesis. We utilized a 3-D immortalized human mammary epithelial cell (MEC) culture to examine the effects of exogenous insulin on lipid synthesis. We further hypothesized that Metformin would prevent insulin-induced milk lipid synthesis.

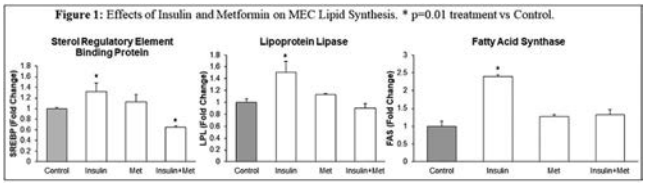
Study Design: MECs were cultured on cell inserts which separate the basolateral chamber containing "serum" from the apical chamber of milk production. Insulin (5 ng/ml), with and without

Metformin (5 μmol/L), was added to the lactogenic medium within the basolateral chamber. After 48h, MECs were analyzed for protein expression (Western Blot) of lipogenic transcription factor (sterol regulatory element-binding protein, SREBP), and enzymes involved in triglyceride uptake (lipoprotein lipase, LPL) and fatty acid synthesis (fatty acid synthase, FAS). Treated vs. untreated MECs were compared by ANOVA with Dunnett's post-hoc test. Values are fold change (mean ± SEM) of N = 4 independent cultures.

Results: In response to insulin, cellular MECs demonstrated activation of the lipid synthesis pathway as evident by increased protein expression of SREBP1 including its downstream target enzymes LPL and FAS. Metformin treatment normalized the insulin-induced upregulation of MEC lipid synthesis (Fig 1).

Conclusion: The increased fat/caloric content of milk of obese mothers is a result, in part, of insulin-enhanced mammary lipid synthesis. Consistent with hepatic effects, Metformin reduces insulin-mediated lipogenesis. These findings suggest that excess human milk lipid synthesis may be normalized by maternal diet or pharmacologic interventions which reduce serum insulin. The extension of personalized human milk from the low birth weight to macrosomic infants may prevent excess infant weight gain resulting from high caloric breast milk.

Figure 1: Effects of Insulin and Metformin on MEC Lipid Synthesis. * p=0.01 treatment vs Control.



1111 | Effect of the COVID-19 Pandemic on Sterilization Rates based on Location in Wisconsin

Michelle P. Lin[1]; Jacqueline M. Powell[1]; Megan Knutson Sinaise[1]; Janine S. Rhoades[1]; Ronald E. Gangnon[2]; Kara K. Hoppe[1]

[1]University of Wisconsin School of Medicine and Public Health, Madison, WI; [2]University of Wisconsin Department of Population Health Sciences, Madison, WI

4:00 PM - 6:00 PM

Objective: The COVID-19 pandemic placed significant demands on healthcare infrastructure, and medical resources were preferentially allocated to emergent or urgent services. This study aims to examine the effect of the COVID-19 pandemic on the rate of immediate and 3-month postpartum (PP) sterilization procedures in Wisconsin (WI) based on geographic location.

Study Design: A retrospective cohort of all births from 3/1/2017 to 3/31/2023 in WI was constructed using WI Hospital Association coding data. Pre-COVID was defined as 3/1/2017 - 2/29/2020 and post-COVID was defined as 3/1/2020 - 3/31/2023. Generalized additive logistic regression models were constructed for the rate of sterilization at birth and at 3 months PP as a function of geographic location (ZIP code). Statistical analyses were performed using the mgcv package in R.

Results: There were 334,408 births – 172,752 pre pandemic and 161,656 during/post pandemic. There were 15,534 sterilization events at the time of birth (4.6%)–8,263 (4.8%) pre pandemic and 7,271 (4.5%) during/post pandemic (RR 0.94, 95% CI 0.91-0.97, p = 0.0002). There was very strong evidence (p< 0.0001) of geographic variation in the impact of the pandemic on the rate of immediate sterilization. There were nominally significant (p< 0.05) elevations in the rate of immediate sterilization for zip codes in northern and western WI and nominally significant reductions in the rate of immediate sterilization for zip codes in northwest, west central, and south central WI. Similar relationships were seen at 3 months PP.

Conclusion: The COVID-19 pandemic demonstrated a significant decrease in rates of immediate to 3-month PP sterilization procedures in WI. There was strong evidence of geographic variation in the pandemic's impact on the sterilization rate statewide. The findings of this study indicate a shift in rate of sterilization during a pandemic, which demonstrates the need for development of provisions or alternatives to permanent sterilization to allow for optimal family planning and contraceptive choice for PP patients during times of healthcare crises or when access to care is limited.

1112 | Impact of a Statewide Quality Collaborative on Screening and Referral for Perinatal Substance Use Disorders

Michelle R. Petrich[1]; Alison Williams[2]; Josh Grotzinger[3]; Katie Brassfield[3]; Niraj R. Chavan[4]
[1]Saint Louis University School of Medicine, Saint Louis University / St. Louis, MO; [2]Missouri Hospital Association, Missouri Hopsital Association / Jefferson City, MO; [3]Missouri Hospital Association, Missouri Hospital Association / Jefferson City, MO; [4]Saint Louis University School of Medicine, St. Louis, MO

4:00 PM - 6:00 PM

Objective: To evaluate the effectiveness of a statewide quality improvement (QI) collaborative for increasing the adoption of Screening, Brief Intervention, and Referral to Treatment (SBIRT) in pregnant persons with substance use disorder (SUD).

Study Design: We evaluated the impact of a statewide perinatal collaborative aimed at increasing the adoption of SBIRT through implementation of the Alliance for Innovation in Maternal Health (AIM) patient safety bundle on caring for pregnant and postpartum people with substance use disorder (SUD). We evaluated changes in average rates of SBIRT and bundle implementation through hospital-level chart reviews, aggregate data submission, structure measure surveys, and engagement metrics over a 2-year period from January 2022 to December 2023. QI metrics for the collaborative, including process, outcome and structure measures were defined in alignment with the AIM bundle. Hospitals with data from the initial (Jan 1 - Mar 31, 2022) and final (Oct 1–Dec 31, 2023) phase of the project were included. All study variables were coded as nominal data and analyzed using Chi-square tests; statistical significance was set at $p \leq .05$.

Results: Ten hospitals met criteria for inclusion in this QI initiative review and were evaluated for SBIRT adoption before and after implementation of the patient safety bundle. There were no significant differences among sites with regards to geographic location or obstetric bed size. Evaluation of screening patterns demonstrated a significant increase in rates of SUD screening (59.4% to 90.1%, $p < .001$) after bundle implementation (Figures 1 and 2). Rates of referral for SUD treatment (77.8% to 83.8%, $p = .21$) and counseling about medications for opioid use disorder (MOUD) (84.5% to 89%, $p = .31$) were also noted to increase over the 2-year implementation period, however–this did not reach statistical significance (Figure 1).

Conclusion: Adoption of a structured patient safety bundle implemented through a statewide quality collaborative has the potential to increase screening and timely referrals for enhancing care delivery in patients with perinatal SUD.

1113 | Magnesium Sulfate Infusion During Delivery Hospitalization is not Independently Associated with Postpartum Hemorrhage

Molly McAdow[1]; Jennifer F. Culhane[1]; Kathryn M. McKenney[2]; Moeun Son[3]; Heather Burris[4]; Sara Handley[5]; Jay Greenspan[6]; Kevin Dysart[6]
[1]Yale School of Medicine, New Haven, CT; [2]University of Colorado, Denver, CO; [3]Weill Cornell Medicine, New York, NY; [4]Children's Hospital of Philadelphia, Philadelphia, PA; [5]Children's Hospital of Pennsylvania, Philadelphia, PA; [6]Nemours Children's Hospital, Wilmington, DE

4:00 PM - 6:00 PM

Objective: To determine whether intravenous (IV) magnesium sulfate (Mg) use is associated with postpartum hemorrhage (PPH) and peripartum hysterectomy (hyst).

Study Design: This retrospective cross-sectional study utilizes Epic Systems' Cosmos research platform, a US-based electronic health record database with de-identified patient-level data. All deliveries from 2017-2023 without International Classification of Diseases (ICD)-10 codes for placenta accreta spectrum were included. The exposure was IV Mg use based on the medication

administration record. The outcome of PPH was defined by ICD-10 code plus red blood cell transfusion, procedure code for hemorrhage treatment, or receipt of methergine or carboprost. The outcome of hyst was based on Current Procedural Terminology codes. The associations of IV Mg and the outcomes of (1) PPH and (2) hyst were examined using bivariate and multivariate analyses. In addition, these associations were examined stratified by gestational age at delivery (< 32 vs >32 weeks' gestation).

Results: PPH was significantly associated with all listed covariates in bivariate tests (Table 1). Patients receiving IV Mg were significantly more likely to have PPH [OR 2.55 (95% CI: 2.48-2.61)], which was slightly attenuated after adjustment [aOR 2.01 (95% CI 1.95-2.08)]. Among patients with PPH, IV Mg was associated with higher odds of hyst in both models [OR 4.22 (95% CI 3.64-4.88); aOR 7.72 (95% CI 6.38-9.30)]. In stratified analyses, after adjustment, patients who delivered >32 weeks and received IV Mg had even higher odds of PPH [aOR 8.40 (95% CI 6.90-10.21)] (Table 2). There was no significant association among those who delivered < 32 weeks after adjusting for potential confounders.

Conclusion: IV Mg use was significantly associated with increased risk of PPH but only among those patients who delivered >32 weeks' gestation. Since IV Mg is administered primarily for eclampsia risk reduction and not for fetal neuroprotection after this gestational age threshold, our findings suggest that severe preeclampsia may drive the association between Mg and hemorrhage. Further exploration is needed.

Darnell Medical Center, Fort Cavazos, TX; [6]Geisel School of Medicine at Dartmouth, Hanover, NH

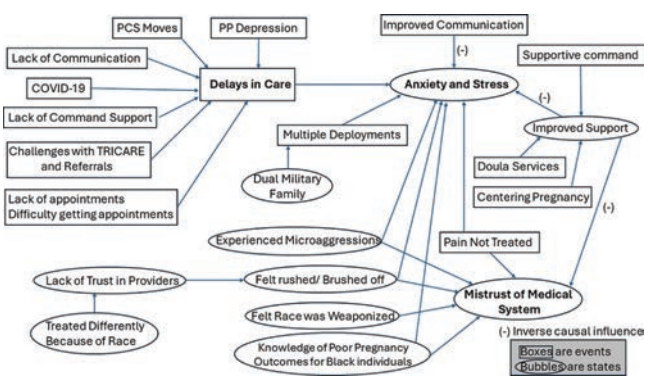
4:00 PM - 6:00 PM

Objective: Persistent healthcare disparities exist within the Military Health System (MHS). The objective of this study was to use qualitative interviews to assess the intersection of operational and cultural experiences of military service with the lived experience of individuals on their use and experience of health care.

Study Design: This is an IRB approved qualitative study of the perinatal birthing experience of servicemembers and TRICARE beneficiaries. Thirty semi-structured interviews were conducted with individuals who delivered an infant within the last five years. Causation coding and deductive methods were used to generate a variable list of antecedent variables, mediating variables and outcomes. Themes were organized into causal chains based on participant stories. A causal network was developed using cross-case mapping to generate a thematic narrative from a systematic comparison of within-case causal networks.

Results: A complex detailed causal network was developed, depicting structural and social factors affecting birth experiences. Such causal relationships impact individual experiences to varying degrees. Antecedent variables included experiences of dismissal, lack of support, concerns about the pregnancy, knowledge of poor outcomes, family experiences, and systemic issues. Mediating variables included delays in care, lack of command support, fragmented care, microaggressions and fear of medications and interventions. Outcomes included mistrust of the medical system, fear and anxiety, early cessation of human milk feeding and decreased military retention.

Conclusion: Comprehensive and logical pathways illustrate challenges faced by birthing individuals in the MHS. Outcomes including mistrust, fear and anxiety and early cessation of human milk feeding are mediated by healthcare experiences and concerns.



1115 | Fertility Treatments Resulting in Twin Pregnancy and the Risk for Childhood inFectious Disease

Moran Shahar[1]; Gil Gutvirtz[2]; Tamar Wainstock[1]; Eyal Sheiner[1]
[1]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom; [2]Soroka University Medical Center, Metar, HaDarom

4:00 PM - 6:00 PM

Objective: Recent research suggests that singleton pregnancies achieved using fertility treatment are at an increased risk for long-term infectious morbidity of the offspring as compared with spontaneous singleton pregnancies. Scarce data exists regarding twins. We investigated the risk of long-term infectious morbidity among twins born following fertility treatments.

Study Design: A population-based retrospective cohort study of all twin deliveries born between the years 1991-2021 at a tertiary center. Twins born using fertility treatments including ovulation induction (OI) and in-*vitro* fertilization (IVF) were compared with twins born following spontaneous pregnancies. The long-term infectious morbidity was compared based on data from community clinics visits and hospitalizations of offspring up to the age of 18 involving an infectious morbidity. The diagnoses of infectious morbidities were based on ICD-9 codes used in the clinics and hospital wards. A Kaplan–Meier survival curve was used to compare the cumulative incidence of infectious morbidities and a Cox proportional hazards model was constructed to control for confounders.

Results: A total of 7790 twins met the inclusion criteria: 2076 twins (26.6%) were born following fertility treatments, among them 696 (8.9%) were born using OI and 1380 (17.7%) following IVF. The total infectious morbidity rate was significantly higher in twins born following fertility treatments as compared with twins from spontaneous pregnancies (73.3% for OI, 71.1% for IVF and 64.1% for spontaneous twins, $p< 0.001$). Likewise, the cumulative incidence of infectious morbidity over time was higher for twins born following fertility treatments (**Figure**). In the Cox regression model, controlling for maternal and gestational age, hypertensive disorders, diabetes mellitus and ethnicity, fertility treatments resulting in twin pregnancy were found to be an independent risk factor for long-term infectious morbidity of the offspring (**Table**).

Conclusion: In our cohort, twins born following fertility treatments were found to be at higher risk for long-term infectious morbidity.

Figure. Kaplan-Meier survival curve demonstrating the cumulative incidence of infectious morbidity among study groups

Maternal age	0.99	0.99 - 1.01	0.399
Gestational age	1.00	0.98 - 1.00	0.399
Hypertension	1.05	0.96 - 1.15	0.238
Diabetes mellitus	0.99	0.90 - 1.08	0.814
Ethnicity	0.87	0.82 - 0.92	<0.001

1116 | Does Maternal Age at First Pregnancy Affect Long-Term Endocrine Morbidity of the Mother?

Moran Shahar[1]; Eyal Sheiner[1]; Ruslan Sergienko[2]; Naama Steiner[1]; Tamar Wainstock[1]; Gil Gutvirtz[3]; Roy Kessous[4]
[1]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom; [2]Ben-Gurion University of the Negev, Beer Sheva, HaDarom; [3]Soroka University Medical Center, Metar, HaDarom; [4]Soroka, Beer-Sheva, HaDarom

4:00 PM - 6:00 PM

Objective: Pregnancies of women of advanced maternal age are associated with various pregnancy and perinatal complications for the mother and the offspring. However, the long-term outcomes of the mothers were scarcely investigated. Our aim was to investigate the association between maternal age at first pregnancy and long-term endocrine morbidity of the mother

Study Design: In a population-based cohort study, long-term endocrine morbidity of mothers who delivered between 1991-2021 in a regional tertiary medical center was analyzed. Mothers were stratified by 4 age groups (< 30,30-35,35-40, >40). Endocrine morbidity was assessed according to a predefined set of ICD-9 codes and extracted from endocrine-related hospitalization files of the mothers. A Kaplan-Meier survival curve was used to assess cumulative incidence of endocrine morbidity and a Cox proportional hazards model was constructed to control for

confounders, comparing the groups of maternal age over 30 to a reference group of women under 30 in their first pregnancy

Results: During the study period 73258 women were included, of which 67365 (92.0%) women had their first delivery prior to 30 years of age, 4571 (6.2%) were between the ages 30-35, 1069 (1.5%) between the ages 35-40 and 253 (0.3%) were older than 40 years. The total endocrine-related hospitalization rate increased as maternal age increased among the 4 study groups (15.1%, 15.2%, 17.8% and 18.6%, respectively, $p = 0.004$). Likewise, the cumulative incidence of endocrine morbidity over time was higher for women as they were older in their first pregnancy (**Figure**). The Cox regression model, controlling for fertility treatments and ethnicity, found a 'dose dependent' effect as maternal age in the first pregnancy was an independent risk factor for long-term endocrine morbidity of the mother as compared with the reference group of women under 30 years old (**Table**)

Conclusion: As women delay their first pregnancy to an older age, they have higher long-term endocrine morbidity later in life. The risk tends to increase in a dose-dependent manner for women over the age of 30 and is highest for women over 40.

Figure. Kaplan-Meier survival curve demonstrating the cumulative incidence of endocrine morbidity among study groups divided by maternal age in the first pregnancy.

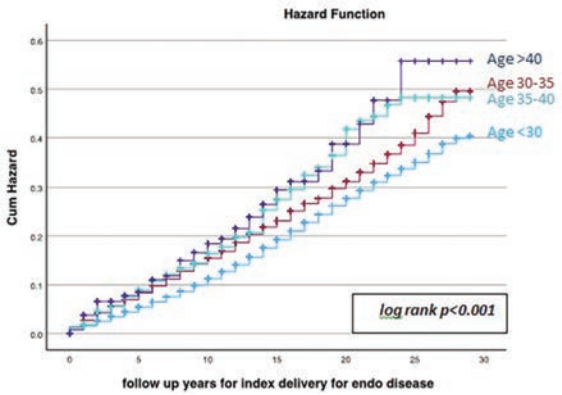

Table. Cox regression model for the association between maternal age in the first pregnancy and the mother's long-term endocrine morbidity

	aHR	95%CI	p value
Maternal age < 30 years	1 (Reference)		
30-35 vs. under 30	1.35	1.25 – 1.46	<0.001
35-40 vs. under 30	1.44	1.25 – 1.67	<0.001

1117 | Lactated Ringer's versus Normal Saline for Initial Fluid Resuscitation in Pregnant Patients with Diabetic Ketoacidosis

Morgan A. Scaglione[1]; Melissa J. Cazzell[1]; Margaret Mlynarczyk[2]; Jerri A. Waller[2]; Rebecca Horgan[2]; Alfred Z. Abuhamad[2]; George R. Saade[2]; Marwan Ma'Ayeh[2]
[1]Macon & Joan Brock Virginia Health Sciences, Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [2]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA

4:00 PM - 6:00 PM

Objective: Prior studies examining diabetic ketoacidosis (DKA) outside of pregnancy show a shorter time to resolution of the anion gap when utilizing Lactated Ringer's (LR) compared to normal saline (NS) for fluid resuscitation. Our objective was to evaluate this evidence.

Study Design: This was a retrospective cohort study of pregnant individuals who present with DKA. The primary outcome was time to anion gap closure. Secondary outcomes included intensive care unit admission, total insulin infusion received, and total crystalloid volume. Continuous variables were tested for normality using the Shapiro-Wilk test, and compared using Student t-test or Mann-Whitney-U test as appropriate. Categorical variables were compared using Fisher's exact or Chi Squared test.

Results: 156 patients were included, 43 (28%) treated with LR and 113 with NS. Baseline characteristics were similar between groups. Median time to anion gap closure was shorter in the LR group (8.8 hours vs 13.2 hours, p = 0.003). Those who received LR also required less insulin from admission to anion gap closure (median 25.4 units vs 41 units, p = 0.005). Volume of crystalloid required to close the anion gap did not differ between groups.

Conclusion: The use of lactated ringers as the crystalloid solution with volume resuscitation in DKA is associated with a shorter time to anion gap closure.

1118 | Outcomes of Patients with Euglycemic Versus Hyperglycemic Diabetic Ketoacidosis During Pregnancy

Morgan A. Scaglione[1]; Melissa J. Cazzell[1]; Margaret Mlynarczyk[2]; Jerri A. Waller[2]; Rebecca Horgan[2]; Alfred Z. Abuhamad[2]; George R. Saade[2]; Marwan Ma'Ayeh[2]
[1]Macon & Joan Brock Virginia Health Sciences, Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [2]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA

4:00 PM - 6:00 PM

Objective: Euglycemic diabetic ketoacidosis (DKA) is uncommon in the adult non-pregnant diabetic population, but is more common in pregnancy. Our objective was to evaluate the outcomes of DKA admissions in pregnant patients with euglycemic versus hyperglycemic DKA.

Study Design: This was a retrospective cohort study of individuals with diabetes admitted with DKA during pregnancy. They were classified as euglycemic if their admission blood glucose was < 250 mg/dL. The primary outcome was the duration of time between diagnosis of anion gap metabolic acidosis and anion gap closure. Secondary outcomes included admission to the intensive care unit, total insulin received between diagnosis of DKA and anion gap closure, and total crystalloid volume. For continuous variables, normality testing was done using the Shapiro-Wilk test and data compared using Student t-test or Mann-Whitney-U test as appropriate. Categorical variables were compared using Fisher's exact or Chi Squared test.

Results: Euglycemic DKA was present in 78 (50%) of 156 included individuals with DKA. Those with euglycemic DKA had a lower blood glucose, beta-hydroxybutyrate, hemoglobin A1c, and anion gap compared to those with hyperglycemic DKA. Time between diagnosis of DKA and anion gap closure was longer in those with euglycemic DKA (median 14.8 hours vs 11.6 hours), however volume of crystalloid and amount of insulin did not differ between the groups.

Conclusion: Euglycemic DKA is associated with a longer time to anion gap closure despite a lower admission anion gap and beta-hydroxybutyrate level.

4:00 PM - 6:00 PM

Objective: United States Preventive Services Task Force (TF) guidelines recommend using risk-factors for preeclampsia (PE) in order to offer low-dose aspirin (LDA) to reduce risk. However, the predictive value is unclear. We sought to prospectively evaluate the performance and utilization of TF in predicting PE and to determine if LDA was recommended based on TF in a diverse population.

Study Design: People with a singleton pregnancy enrolled in an IRB-approved prospective, observational, cohort study < 22 weeks gestation between July 2020 - June 2023. Enrollment occurred at one of 12 clinical centers or via direct-to-participant-recruitment across the United States. Data was obtained from medical records review including TF risk-factors and if LDA had been recommended (Table 1). All PE cases were adjudicated by trained MFMs.

Results: The study enrolled 5,652 diverse participants (Table 1). Using TF recommendations for prediction of PE the sensitivity is 74% and the specificity is 48%. When including one or more moderate risk-factors the sensitivity increases to 97% and the specificity drops to 12%. 2,440 (43%) received a LDA recommendation. Of those with at least one high-risk factor, 82% had LDA recommended while in those with one or more moderate risk-factors, 37.4% received LDA recommendation (Fig 1a). 3,974 (70.3%) were in the TF's moderate risk-factors only category. For those with any risk factor, LDA was more likely to have been recommended in those who later developed PE vs those who didn't (Fig 1b).

Conclusion: TF had poor performance as a predictive screening tool for PE in the group with moderate risk factors. There was also low compliance with LDA recommendations suggesting non-adherence to TF, practice variation, or incomplete documentation. The higher rate of PE in those recommended LDA may reflect provider identification of a higher risk subgroup, non-adherence with taking aspirin, or failure of LDA to reduce PE in certain subgroups. These data highlight the opportunity and urgent need to develop better risk assessment tools based on objective biology rather than based on clinical risk factors.

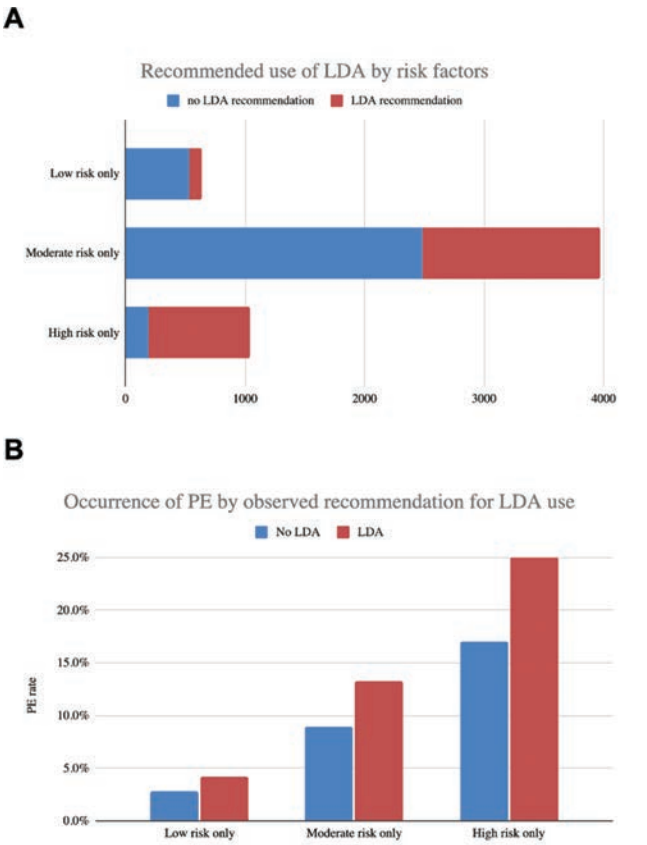

Figure 1. Recommendation of LDA and occurrence of PE. A) LDA recommendation by USPSTF risk factor. B) Rate of PE by risk group and LDA recommendation

Table 1: Screening test performance of USPSTF guidelines for preeclampsia risk prediction and resulting utilization of low-dose aspirin prophylaxis. ***LDA "recommended" if 1+ high risk factors and/or 2+ moderate risk factors. LDA to be "considered" if 1+ moderate risk factors***

1120 | Time Interval from Antenatal Corticosteroid Administration to Delivery and Severe Neonatal Morbidity

Moti Gulersen[1]; Frank I. Jackson[2]; Ashley N. Battarbee[3]; Vincenzo Berghella[1]; Matthew J. Blitz[2]

[1]Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA; [2]Northwell, New Hyde Park, NY; [3]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL

4:00 PM - 6:00 PM

Objective: To evaluate the association between time interval from ACS administration to delivery and severe neonatal morbidity (SNM) among periviable, early, and late preterm births

Study Design: Retrospective cohort of singleton preterm births (PTBs) between 22 0/7-36 6/7 weeks' gestational age (GA) at 2 tertiary academic medical centers from 2019-2022. All patients exposed to ACS prior to delivery were eligible for inclusion. Patients who had neonates that were not actively resuscitated, intrauterine fetal demise, and missing data were excluded. The primary outcome was SNM, a standardized composite neonatal adverse outcome indicator which includes diagnoses and procedures from the neonatal intensive care unit indicative of severe morbidity. Baseline characteristics and outcomes were compared by time interval from the first dose of ACS administration to

delivery in 3 groups: < 2, 2-7, and >7 days. Multivariate logistic regression was performed to evaluate the association between the ACS timing and SNM within planned stratification by GA if there was evidence of interaction. Models were adjusted for potential confounders, and delivery within 2-7 days was as the reference group. Data were presented as adjusted odds ratios (aOR) with 95% confidence intervals (CI).

Results: Of the 2,367 patients included, 518 (21.9%) delivered after 2-7 days of ACS administration, 1,215 (51.3%) at < 2 days after ACS and 634 (26.8%) at >7 days after ACS. An interaction was noted between GA and time interval from ACS to delivery, where time interval from ACS to delivery was associated with more benefit in reducing SNM at earlier GA ($P < 0.001$). There was no association between ACS timing and SNM in PTBs occurring between 22 0/7-33 6/7 weeks (Table). Among late PTBs, ACS exposure < 2 days before delivery was associated with an increased risk of SNM (Table).

Conclusion: The likelihood of ACS administration occurring within 2-7 days of PTBs is low. ACS exposure < 2 days before delivery in the late preterm period was associated with an increased risk of SNM. Optimizing timing of ACS in the late preterm period requires further study.

Table. The association between time interval from antenatal corticosteroid administration to delivery and severe neonatal morbidity

Gestational age at delivery	Time interval from ACS administration to delivery	Severe neonatal morbidity*	aOR** with 95% CI
22 0/7 – 25 6/7 weeks	< 2 days	24/33 (72.7)	1.00 (0.27-3.74)
	2-7 days	26/36 (72.2)	Reference
	> 7 days	10/14 (71.4)	0.86 (0.17- 4.47)
26 0/7 – 29 6/7 weeks	< 2 days	72/86 (83.7)	0.60 (0.23-1.52)
	2-7 days	78/88 (88.6)	Reference
	> 7 days	73/87 (83.9)	0.65 (0.23-1.84)
30 0/7 – 33 6/7 weeks	< 2 days	189/275 (68.7)	1.46 (0.98- 2.17)
	2-7 days	141/224 (62.9)	Reference
	> 7 days	117/179 (65.4)	0.95 (0.59-1.53)
34 0/7 – 36 6/7 weeks***	< 2 days	189/821 (23.0)	1.89 (1.14-3.25)
	2-7 days	40/170 (23.5)	Reference
	> 7 days	110/354 (31.1)	1.02 (0.63-1.67)

Data are presented as number (percentage).
*Composite of ≥ 1 of the following: neonatal resuscitation, continuous positive airway pressure, respiratory distress syndrome, mechanical ventilation, any body cavity surgical procedure, blood transfusion, Intraventricular hemorrhage, sepsis, pneumothorax, chest tube insertion, pneumonia, bronchopulmonary dysplasia, necrotizing enterocolitis, periventricular leukomalacia, hypoxic ischemic encephalopathy, cerebral infarction, exchange transfusion, retinopathy of prematurity, seizures, brachial plexus injury, neonatal death within 28 days of birth or before discharge from hospital.
**Models adjusted for maternal age, race/ethnicity, body mass index, nulliparity, pregestational diabetes, chronic hypertension.
***Patients with pregestational diabetes were excluded from this analysis.

1121 | Trends in Previable Antenatal Corticosteroid Administration Among Singletons After Implementation of a Practice Advisory

Moti Gulersen[1]; Erez Lenchner[2]; Marlee Hirsch[3]; Rodney A. McLaren, Jr., Jr.[4]; Huda B. Al-Kouatly[4]; Vincenzo Berghella[1]; Eran Bornstein[5]
[1]Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA; [2]New York University Rory Meyers College of Nursing, New York, NY; [3]Northwell Lenox Hill Hospital, Lenox Hill Hospital, NY; [4]Thomas Jefferson University Hospital, Philadelphia, PA; [5]Northwell Lenox Hill Hospital, New Hyde Park, NY

4:00 PM - 6:00 PM

Objective: We aimed to evaluate national trends in antenatal corticosteroid administration among previable singletons after implementation of a practice advisory by the American College of Obstetricians and Gynecologists (ACOG) recommending consideration of ACS use as early as 22 0/7 weeks of gestation.

Study Design: Retrospective analysis of the United States Centers for Disease Control and Prevention Natality Live Birth Database (2016-2022). All patients with in-hospital, non-anomalous, singleton previable live births (20 0/7-23 6/7 weeks' gestation) were eligible for inclusion. Cases where ACS exposure was unknown were excluded. Rates of ACS exposure among all births were compared before and after ACOG's practice advisory published online in September, 2021 using Pearson's chi-squared test. September to December 2021 was considered an implementation period and therefore excluded from the analysis. Statistical significance was set at $P < 0.05$.

Results: A total of 33,570 previable live births comprised the study cohort. There was a significant increase in rates of ACS administration among singletons after ACOG's practice advisory compared to before (1,304/4,827 [27.0%] vs. 6,014/28,743 [20.9%], $P < 0.001$). Rates of ACS exposure stratified by gestational age before and after ACOG's practice advisory are displayed in the Table. Trends in ACS exposure over time among births occurring before and after ACOG's practice advisory is illustrated in the Figure.

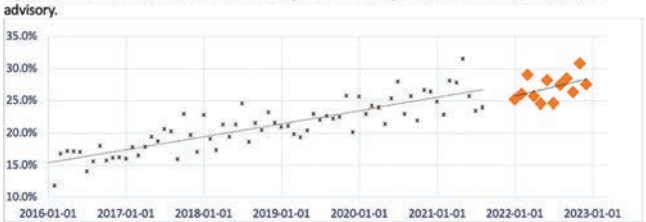
Conclusion: Data from this large cohort demonstrates the immediate impact ACOG's practice advisory had on administering previable ACS in singleton gestations. A significant increase in ACS exposure occurred at all previable gestational ages. Future research evaluating the impact of this practice change on neonatal outcomes during this time period is needed.

Table. Rates of ACS exposure stratified by gestational age before and after ACOG's practice advisory.

Gestational age	ACS exposure before practice advisory	ACS exposure after practice advisory	*P* value
20 0/7-20 6/7 weeks	77/4,524 (1.7)	17/771 (2.2)	<0.001
21 0/7-21 6/7 weeks	138/5,562 (2.5)	36/927 (3.9)	
22 0/7-22 6/7 weeks	1,143/7,304 (15.6)	337/1,201 (28.1)	
23 0/7-23 6/7 weeks	4,656/11,353 (41.0)	914/1,928 (47.4)	

Data are presented as number (percentage).

Figure. Trends in ACS exposure over time among births occurring before and after ACOG's practice advisory.



1123 | Survey of Individuals with HDP on Cardiovascular Disease Risk Awareness and Prevention Perspectives

Nadine Sunji[1]; Natalia Tovar[1]; Kathryn E. Flynn[1]; Alisse Hauspurg[2]; Anna Palatnik[1]
[1]Medical College of Wisconsin, Milwaukee, WI; [2]Alpert Medical School of Brown University, Providence, RI

4:00 PM - 6:00 PM

Objective: To survey individuals with hypertensive disorders of pregnancy (HDP) on their knowledge of cardiovascular disease (CVD) risk and their views on prevention and treatment.

Study Design: A 22-question prospective survey on postpartum HDP management preferences and future cardiovascular risk was administered to postpartum individuals with HDP (gestational hypertension or preeclampsia) during postpartum days 1-4 before hospital discharge. The survey was validated through six cognitive interviews with HDP individuals.

Results: Of 185 individuals with HDP that were approached, 158 (85.4%) completed the survey with their characteristics described in Table 1. Regarding short-term risks, 57% thought that the risk of developing severe-range blood pressures (BPs) is the highest during labor admission with 29% estimating the risk to be highest during the first week postpartum. Many individuals were aware of the risk of stroke, severe hypertension, kidney problems, and other CVD during the first 6 weeks postpartum. When asked about treatment for high BPs in the first 6 weeks after delivery, 29% prefer to start with daily exercise, 52% prefer to start with eating healthier with limited salt intake, and only 19% prefer to start with an antihypertensive medication. If exercise and diet were unsuccessful, 61% stated they will consider medications. Table 2 describes participants' perspectives on facilitators and barriers to starting antihypertensive medications postpartum. 92% reported that doing physical activity regularly and eating healthy may prevent hypertension. 74% thought that eating healthy and engaging in physical activity are easy to do after delivery, and 72% were planning to pursue these activities to lower the risk of hypertension. When asked about future risk of CVD, 40% reported they are well or very well informed on future risk of CVD; however, 74% underestimated the future risk to be ≤10%.
Conclusion: Most individuals with HDP recognized short-term risks and preferred lifestyle changes over medication initially. However, despite 40% feeling well-informed, many underestimated their long-term CVD risk.

Table 2. Survey responses

What do you think will happen to your blood pressure readings once you are discharged home after delivering your baby?	
My blood pressure will *go back to what it was* before pregnancy.	136 (87.2)
My blood pressure will *go lower than what it was* before pregnancy.	12 (7.7)
My blood pressure will *remain high like it was* during my pregnancy / during delivery.	8 (5.1)
Out of the following options, when do you think your risk of developing severely high blood pressure (160/110 or higher) is the highest?	
During labor	71 (46.1)
In the hospital after delivery	16 (10.4)
Within the first week after delivery	45 (29.2)
Within the first month after delivery	22 (14.3)
In the first 6 weeks after delivery, people with gestational hypertension or preeclampsia are at increased risk of developing…	
Heart attack	84 (56.4)
Stroke	97 (65.1)
Hospital readmission	106 (71.1)
Very high blood pressures	126 (84.6)
Kidney problems	77 (51.7)
Heart failure	59 (39.6)
Bleeding	59 (39.6)
In people with a history of gestational hypertension or preeclampsia, what do you think is the likelihood of developing high blood pressure or heart disease later in life? (question from Jeiks et al., AJOG MFM 2023)	
1 in 100 (1%)	10 (6.5)
1 in 50 (2%)	21 (13.6)
1 in 20 (5%)	40 (26.0)
1 in 10 (10%)	43 (27.9)
1 in 5 (20%)	40 (26.0)
If you required treatment for high blood pressures in the first 6 weeks after delivery, which method of treatment would you prefer to start with?	
Starting daily exercise	45 (29.0)
Eating a healthier diet with limited salt intake	81 (52.3)
Starting blood pressure medication	29 (18.7)
If your preferred method of treatment was ineffective in lowering your blood pressure, would you be willing to start a blood pressure medication? (n = 126, if "Starting daily exercise" or "Eating a healthier diet with limited salt intake.")	
Yes	77 (61.1)
No	7 (5.6)
It depends.	42 (33.3)
Why would you *not* start a medication as treatment for high blood pressure after delivering your baby? (n = 7, if "No.")	
I do not want side effects.	3 (42.9)
I am afraid of being harmed by medication in the long term.	3 (42.9)
I do not want to be dependent on medication.	5 (71.4)
I usually forget to take medication.	1 (14.3)
I do not always take medication as prescribed.	1 (14.3)
I had normal blood pressure before pregnancy, and it should go back to normal after delivery.	6 (85.7)

What would affect your decision to start a blood pressure medication? (n = 41, if "It depends.")	
Less frequent dosing	15 (36.6)
Little to no effect on breastfeeding	27 (65.9)
Minimal side effects	23 (56.1)
Low cost of medication	7 (17.1)
Reduced risk of postpartum hospital readmission, emergency room visits, and/or additional clinic visits	13 (31.7)
Long-term health benefit	19 (46.3)
My doctor's recommendations	22 (53.7)
A professional society's recommendations	11 (26.8)
If I am going to get high blood pressure, there is not much I can do about it in my opinion.	
Strongly agree	3 (1.9)
Agree	25 (15.8)
Disagree	72 (45.6)
Strongly disagree	58 (36.7)
I think that my personal efforts will help control my risks of getting high blood pressure.	
Strongly agree	34 (21.5)
Agree	100 (63.3)
Disagree	19 (12.0)
Strongly disagree	5 (3.2)
I think that eating healthy and doing physical activity takes a lot of effort.	
Strongly agree	19 (12.2)
Agree	53 (34.0)
Disagree	60 (38.5)
Strongly disagree	24 (15.4)
I think that doing physical activity regularly and eating healthy may prevent high blood pressure from developing.	
Strongly agree	58 (36.9)
Agree	87 (55.4)
Disagree	11 (7.0)
Strongly disagree	1 (0.6)
I think that eating healthy and physical activity are easy for me to do after delivery.	
Strongly agree	30 (19.1)
Agree	86 (54.8)
Disagree	39 (24.8)
Strongly disagree	2 (1.3)
In the near future, are you planning to make changes in eating or physical activity to lower your chances of getting high blood pressure?	
Definitely not	1 (0.6)
Probably not	5 (3.2)
Probably	44 (27.8)

1124 | Risk Factors for Dual Demise in Monochorionic Pregnancies Undergoing Radiofrequency Ablation for Discordant Anomalies

Nahla Khalek[1]; Shelly Soni[1]; Juliana S. Gebb[2]; Christina Paidas Teefey[1]; Desiree Fiorentino[1]; Alekhya Jampa[1]; Violetta Bakunina[2]; Julie S. Moldenhauer[1]
[1]*Richard D. Wood Jr. Center for Fetal Diagnosis and Treatment at CHOP, Philadelphia, PA;* [2]*Richard D. Wood, Jr Center for Fetal Diagnosis and Treatment, Children's Hospital of Philadelphia, Philadelphia, PA*

4:00 PM - 6:00 PM
Objective: To determine the rate and risk factors for dual demise in monochorionic pregnancies with discordant malformation (DM) managed with selective cord occlusion (SCO) via radiofrequency ablation (RFA) of the affected fetus.
Study Design: Single center retrospective analysis of a prospective registry of complex monochorionic pregnancies managed with SCO via RFA for DM between 2010 and 2023. DM as indication for procedure was stratified by type of anomaly. Outcomes were analyzed based on the intended outcome of single survivor versus dual demise. Risk factors as defined by DM were compared between groups as well to the cohort of all MC pregnancies undergoing SCO via RFA during the same time period. Mann-Whitney U test was used for continuous variables and Fisher's exact test was used for categorical variables.
Results: A total of 213 pregnancies underwent RFA in the study period; 38 performed for the indication of DM. For the total registry cohort, the incidence of postprocedural dual demise regardless of indication was 23/213 (10.8%). The risk increased more than twofold when analyzed specifically for the indication of DM, 9/38 versus 14/175 when compared to other indications **(23.7% vs 8%; p = 0.009)**. Limb body wall complex (LBWC) yielded the highest risk for dual demise; 3 of 4 cases and 33.3% of all DM with dual demise. The remaining variables analyzed were not significant (Table)
Conclusion: Selective cord occlusion via RFA remains a safe and reasonable option in complex MC pregnancies. In the cohort where RFA was indicated for DM, the significantly increased

risk of dual demise in cases of LBWC should be reviewed when counseling patients.

Demographics and operative variables for pregnancies with dual demise vs single survivor in MCDA twins after undergoing RFA for DM

	Dual demise N=9	Single survivor N=29	P-value
Maternal age, years	32.5 [25.5-33.3]	30 [27-33]	0.81
BMI, kg/m^2	24.3 [24.0-30.1]	25.7 [22.2-29.3]	0.66
Number of fetuses Twins Triplet	 9 (100) -	 25 (86.2) 4 (13.8)	0.55
GA at procedure, weeks	18.3 [17.3-20.6]	19.2 [17.3-21.3]	0.93

1125 | Is the Etiology of Fetal Death Associated with Adverse Health Outcomes During Second-Trimester Medication Abortion?

Neha Reddy[1]; Vanya Manthena[2]; Jocelyn Wascher[1]; Eryn Wanyonyi[1]; Camille Johnson[1]; Lahari Vuppaladhadiam[3]; Julie Chor[1]; Beth Plunkett[4]; Isa Ryan[5]; Olivert Mbah[5]; Jungeun Lee[6]; Emily Barker[7]; Laura Laursen[8]; Leanne McCloskey[9]; Sloane York[8]; Ashish Premkumar[2]

[1]University of Chicago Medicine, Chicago, IL; [2]Pritzker School of Medicine, University of Chicago, Chicago, IL; [3]University of Chicago, Chicago, IL; [4]Northshore Endeavor Health, Chicago, IL; [5]NorthShore Health, Chicago, IL; [6]Endeavor Health, Evanston, IL; [7]Washington University in St Louis, St. Louis, MO; [8]Rush University, Chicago, IL; [9]Northwestern Medicine, Chicago, IL

4:00 PM - 6:00 PM

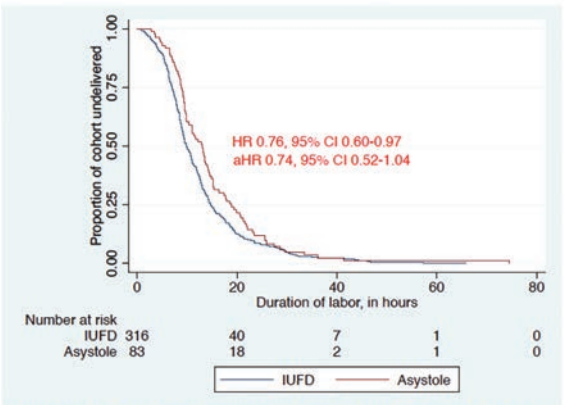
Objective: Induction of fetal asystole (IFA) is commonly used before second-trimester medication abortion (MAB). Data suggest a higher risk for adverse health outcomes when compared to MAB without IFA. Yet there is a poor understanding of whether the etiology of fetal death (IFA or intrauterine fetal demise [IUFD]) is associated with adverse health outcomes.

Study Design: We analyzed a retrospective cohort of people undergoing second-trimester MAB of a singleton at 4 centers from 2009-2019. Eligible individuals underwent IFA or had IUFD and did not have rupture of membranes, preterm labor, or cervical insufficiency. The primary exposure was etiology of fetal death. Fetal asystole was induced with potassium chloride. The primary outcome was duration of labor. The secondary outcomes were composite morbidity (i.e. uterine rupture, need for blood transfusion, clinical chorioamnionitis, intensive care unit admission, or need or readmission) and its components. Bivariate and multivariate analyses were performed. For the primary outcome, a survival curve was generated, censoring at the time of delivery, and a hazard ratio (HR) was computed. A sensitivity analysis was performed, matching participants based on gestational age and history of uterine scarring.

Results: 399 participants were analyzed. 83 (20.8%) underwent IFA and 316 (79.2%) had IUFD (Table). For the primary outcome, IFA was associated with a longer duration of labor, which was nonsignificant after adjusting for race/ethnicity and receipt of mifepristone (Figure). For the secondary outcomes, there was no difference in composite morbidity between the groups. However, IFA was associated with a higher frequency of uterine rupture and need for blood transfusion on bivariate analyses (Table). On sensitivity analysis, there was only a significant difference in frequency of blood transfusion.

Conclusion: The etiology of fetal death is not consistently associated with an increased length of labor or increased risk of most adverse health outcomes. IFA may be associated with the need for blood transfusion when compared to IUFD, which requires further investigation.

Figure: The relationship between etiology of fetal death and duration of labor, in hours



*Unadjusted and adjusted hazard ratios are depicted. Adjusted model accounts for receipt of mifepristone and participant self-reported race/ethnicity

1126 | Prescribing less than or greater than 150 MME after Cesarean Delivery: A Cost Effectiveness Analysis

Neha Mishra[1]; Megha Arora[2]; Aaron B. Caughey[2]
[1]Oregon Health and Science University, Portland, OR; [2]Oregon Health & Science University, Portland, OR

4:00 PM - 6:00 PM

Objective: Cesarean delivery is the most common major surgery performed in the United States, with an estimated 1,178,066 cesareans performed in 2022 alone. Current standards for postoperative pain management of cesarean deliveries include the use of nonsteroidal anti-inflammatory drugs (NSAIDs) combined with opioids for breakthrough pain. Despite increased caution around the over-prescription of opioids, more than 75% of post-cesarean patients fill an opioid prescription with wide variances in dosing. Previous studies indicate higher rates of adverse outcomes for opioid prescriptions exceeding 150 morphine milligram equivalents(MME). In this study, we evaluated cost-effectiveness of prescribing greater than or less than 150 MME(e.g. 20 oxycodone tablets, 5 mg each) on developing an opioid use disorder (OUD), overdose, and opioid-related death.

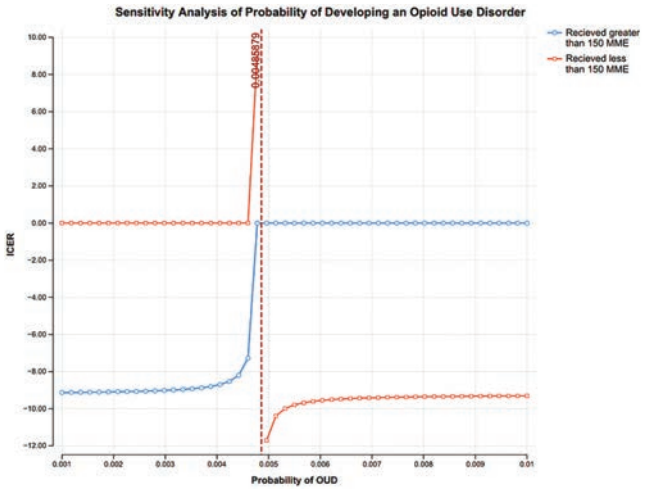
Study Design: We constructed a decision-analytic model to compare outcomes between receiving greater than 150 MME and less than 150 MME. Our theoretical cohort included 1,178,066 individuals, the number of cesareans performed in 2022. Outcomes were development of an OUD, overdose, opioid use-related death, costs, and quality adjusted life years (QALYs). We used a willingness-to-pay for the incremental cost-effectiveness ratio of $100,000/QALY. Model inputs were derived from the literature and assessed with sensitivity analyses.

Results: In our cohort, prescribing less than 150 MME was associated with 1587 fewer cases of developing an OUD. Prescribing less than 150 MME was cost-effective with an ICER of $8.94/QALY. In one way sensitivity analysis, receiving greater than 150 MME would only be cost effective if the probability of developing an OUD were below 0.005, above this probability, prescribing less than 150 MME is the only cost effective strategy.

Conclusion: In our study, prescribing less than 150 MME was a cost-effective strategy to improve outcomes and minimize the adverse events associated with opioid prescription. Adopting a standard of prescribing less than 150 MME post-cesarean delivery would be advantageous for recovery of patients and the health system.

Table 1. Outcomes in a theoretical cohort of 1,178,066 post-cesarean individuals.

	Greater than 150 MME	Less than 150 MME	Difference (>150 - <150)
Diagnosis of OUD	5,657	4,069	1,588
Overdose	3	4	-1
Opioid-related Death	0	0	0
Cost (USD)	$14,026,449,346	$14,026,340,908	$108,438
Effectiveness (QALYs)	31,003,979	31,016,110	-12,131
Incremental Cost Effectiveness Ratio (ICER)	$8.94/QALY		



1127 | Improved AI Prediction of Preterm Birth by Expanded Training and Retraining

Neil B. Patel[1]; John O'Brien[2]; Robert Bunn[3]; Brandon Schanbacher[2]; John A. Bauer[2]; Garrett K. Lam[2]
[1]Ascension Sacred Heart - Pensacola, Pensacola, FL; [2]University of Kentucky, Lexington, KY; [3]Ultrasound AI, Ultrasound AI, CO

4:00 PM - 6:00 PM

Objective: To assess improvements in Artificial Intelligence (AI) for predicting preterm birth (PTB) after the addition of 1,165,618 images to the training dataset and an 8-month retraining period.

Study Design: Proprietary AI software (V1) was initially trained on 877,141 de-identified ultrasound images from 19,940 unique ultrasound exams from a cohort of women who delivered at the University of Kentucky from 2017 to 2021. The AI trained on 79% of exams, and predictive performance was validated on a separate 21% of unique exams (n = 4306). Only de-identified ultrasound images were used to predict the days until delivery. Statistical analyses utilized R^2 values and mean absolute error (MAE).

An additional 1,165,618 ultrasound images with corresponding patient data from 2021 to 2023 were added to the training set (V2). The AI underwent 8 months of retraining (V3). The original validation set remained blinded and was utilized to evaluate the AI's performance using the original algorithm (V1) and dataset versus its performance in V2 (expanded images dataset) and V3 (expanded images dataset with retraining).

Results: After introduction of additional data and retraining, the AI's predictive performance improved across all outcomes (Table 1). The correlation coefficient for spontaneous PTB increased from 0.48 (V1) to 0.64 (V2) and 0.72 (V3). Correlation coefficients for prediction of Term+ all PTB increased from 0.85 (V1) to 0.88 (V2) to 0.92 (V3).

MAE was reduced (Table 2) in all categories from V2 and V3. For Term + all PTB, the MAE reduced from 14.30 days (V2) to 12.90 days (V3). Notable reductions were observed in the MAE for spontaneous PTB (22.08 days (V2) to 19.99 days (V3)), and for iatrogenic PTB (2.44 days (V2) to 19.33 days (V3)).

Conclusion: AI's ability to learn and improve its performance in PTB prediction is demonstrated. Expansion of the dataset and retraining sequentially improved its predictive ability and notably reduced the MAE.

Table 1. Correlation Coefficients for AI Predictions of Preterm Birth in the 4306 Exams of Validation Set between AI Versions

	Initial AI	Additional Images AI	Retrained AI
	V1	V2	V3
Term + all PTB	0.85	0.88	0.92
Term Births Alone	0.90	0.91	0.95
Term + Spontaneous PTB	0.88	0.90	0.94
Spontaneous PTB	0.48	0.64	0.72
Iatrogenic PTB	0.52	0.63	0.75

Table 2. Mean Absolute Error for Prediction of Time to Delivery Across All Categories in the Training Set: Expanded Training Dataset (V2) and Retrained AI (V3).

	Mean Absolute Error (days)	
	Additional Images AI	Retrained AI
	V2	V3
Term + all PTB	14.30	12.90
Term Births Alone	11.71	10.76
Term + Spontaneous PTB	12.67	11.62
Spontaneous PTB	22.08	19.99
Iatrogenic PTB	22.44	19.33

1128 | Mid-Trimester Concentrations of Total Cell-Free DNA in Amniotic Fluid–A Pilot Study

Dan Tirosh[1]; Amos Douvdevani[2]; Neta Benshalom-Tirosh[3]; Offer Erez[1]; Joel Baron[1]
[1]Department of Obstetrics and Gynecology, Soroka University Medical Center, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer Sheva, HaDarom; [2]Department of Clinical Biochemistry and Pharmacology, Faculty of Health Sciences, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, HaDarom; [3]Department of Obstetrics and Gynecology, Samson Assuta Ashdod University Hospital; Faculty of Health Sciences, Ben-Gurion University of the Negev, Ashdod, HaDarom

4:00 PM - 6:00 PM

Objective: 1) To test the feasibility of measuring total cell-free DNA (cfDNA) concentration in amniotic fluid, using a unique direct fluorometric assay; and 2) to determine the association between amniotic fluid total cfDNA concentration and gestational age at amniocentesis, establishing reference values for further studies.

Study Design: A prospective cohort pilot study was conducted, including women undergoing elective mid-trimester amniocentesis for genetic or other evaluation, between 16-23 weeks of gestation. Following written consent, an additional 1-2 ml of amniotic fluid were collected during amniocentesis. Total cfDNA was quantified by a validated rapid fluorometric assay, using the fluorochrome SYBR Gold without requiring prior DNA extraction and amplification.

Results: A total of 82 women were enrolled. Seventy-seven women were included in the analysis, as five were excluded due to preterm delivery (n = 4) or a genetic disorder (x-linked ichthyosis, n = 1). All samples had measurable total cfDNA concentrations. Maternal characteristics including indications for amniocentesis are presented in Table 1. Total cfDNA concentrations correlated significantly with gestational age at sample collection (rho = 0.41, p value< 0.001), as presented in Figure 1.

Conclusion: 1) Total cfDNA amniotic fluid concentrations in the mid-trimester, correlate with gestational age at sampling; 2) This simple assay enables rapid quantitative measurements, and thus should be further evaluated as an amniotic fluid biomarker for obstetric complications.

Table 1: Maternal characteristics (n=77)

Characteristic	
Maternal age (years); (mean ± SD)	34.69 (±4.04)
BMI (mean ± SD)	24.76 (±5.05)
Gestational age at amniocentesis (weeks); (mean ± SD)	19.4 (±1.61)
Gestational age at delivery (weeks); (mean ± SD)	39.21 (±1.17)
Birth weight (grams); (mean ± SD)	3319 (±431.1)
Indication for amniocentesis (n)	
Abnormal Down syndrome screening test	18
Maternal age	36
Maternal request	19
Other (CMV seroconversion, past fetal genetic abnormality)	4

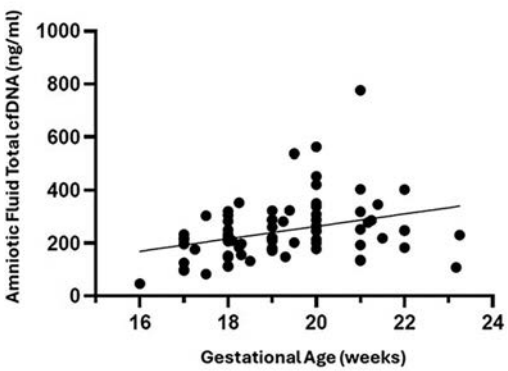
Figure 1: Amniotic Fluid Total cfDNA Concentrations (ng/ml) by gestational age (n=77)



1129 | Work-Related Musculoskeletal Disorders (WRMSD) among Ultrasound Sonographers

Nhu Q. Vu[1]; Ibrahim Tsolakian[2]; Hind N. Moussa[3]
[1]University of Toledo, Toledo, OH; [2]Susquehanna OB/GYN and Nurse Midwifery, Bel Air, MD; [3]ProMedica Toledo Hospital, University of Toledo, Toledo, OH

4:00 PM - 6:00 PM

Objective: Sonographers are at high risk for serious work-related musculoskeletal injuries. Despite ergonomic solutions, nearly 90% of sonographers experience chronic pain for more than half of their career, and one in five sustain a career-ending injury. Work-related musculoskeletal disorders (WRMSD) among sonographers have been an understudied topic. We aim to 1) assess the prevalence of WRMSD among sonographers in our local health system, 2) correlate workplace environment with the development of WRMSD, 3) assess the perception of WRMSD among sonographers, and 4) evaluate the impact of WRMSD on the career of affected sonographers.

Study Design: A cross-sectional study using a 40-question anonymous survey was electronically distributed to sonographers in our local health system. The survey was developed from previous research and had four main sections 1) demographic information, 2) work schedule and tasks, 3) pain and discomfort, 4) work environment.

Results: 91 surveys were distributed with a 45% response rate (n = 41). The majority were age < 29 (34.2%) with a BMI between 18.5-24.9 (39%). 60.9% scan patients with obesity most of the time. 17.1% gets no breaks during a typical shift and 31.6% disagreed that they can take scheduled breaks. 46.2% reports that pain is most pronounced during work hours, and 81.6% reports that scanning patients with obesity aggravates their pain the most. Of those who sought treatment for their injuries, only 17% reported that the interventions were successful and 59% continues to scan with pain. 100% of respondents are concerned about developing work-related injury. 84.6% know of other sonographers who have left the field due to their work-related injury or pain. Most respondents (29.3%) would modify the current equipment design and maneuverability to improve their workplace.

Conclusion: Our study shows that sonographers are at an increased risk for WRMSD. These injuries can potentially impact quality of life and can ultimately be career-ending. More research and advocacy are needed to improve ergonomics and working conditions to help reduce the rate of WRSMD among sonographers.

Table 1. Summary of Responses by Participants to Survey Questions

I. Demographics		n (%)	
Age			
	<29	14 (34.2%)	
	30-39	7 (17.1%)	
	40-50	9 (21.9%)	
	50+	11 (26.8%	
BMI (kg/m²)			
	<18.5	1 (2.4%)	
	18.5-24.9	16 (39%)	
	25-29.9	15 (36.6%)	
	30-39	9 (21.9%)	
	39+	0 (0%)	
II. Work Schedule & Tasks			
How many (at least 10 minute) breaks per shift do you get?			
	No breaks	7 (17.1%)	
	Once	18 (43.9%)	
	Twice	7 (17.1%)	
	Over twice	7 (17.1%)	
How often do you scan patients with obesity? (BMI >30)			
	Never	0 (0%)	
	Rarely	0 (0%)	
	About half of the time	8 (19.5%)	
	Most of the time	25 (60.9%)	
	Always	8 (19.5%)

1130 | Cesarean Delivery on Maternal Request Among Nulliparous Women: Rates, Timing and 10-Year Trends

Niall McGowan[1]; Clare Greaney[2]; John J. Morrison[3]

[1]University of Galway, Galway, Galway; [2]Galway University Hospital - Ireland, Galway University Hospital - Ireland, Galway; [3]Dept. of Obstetrics and Gynecology University of Galway - Ireland, University of Galway - Ireland, Galway

4:00 PM - 6:00 PM

Objective: Cesarean delivery on maternal request (CDMR) is defined as caesarean delivery (CD) performed without a clinical reason, i.e. no fetal or maternal indication. It is a controversial area of practice with huge variation in general CDMR rates globally (1,2). However it is difficult to ascertain nulliparous rates resulting in the primary CD. The aims of this study were to determine the following: 1. CDMR rate for nullipara in Irish obstetric practice; 2. Contribution of CMDR to overall CD rates; 3. Associated demographic features and models of obstetric care; 4. Trends in CDMR rates throughout 2014-2023.

Study Design: The data were obtained from EuroKing Obstetric Database at Galway University Hospital, a tertiary referral center in the West of Ireland. The information had been entered prospectively during 2014-2023. Descriptive statistics were calculated for each year, and compared using Chi2 for proportions and trend, using the program GraphPad Prism v10.2.3. Ethical Committee approval for the study was obtained.

Results: There were 28,264 deliveries of which 10,259(36.3%) were nullipara with singleton pregnancies ^{3} 36 weeks. There were n = 134 CDs performed solely for maternal request which represented 1.3% of all nullipara. CDMR contributed to 3.8% of all nulliparous CDs, and constituted 1.4% of all hospital CDs. The maternal age, BMI, and birthweight characteristics of these pregnancies are shown in Table 1. The prevalence of CDMR among nullipara attending a private obstetrician for care was 5.9% and was 0.7% ($P < 0.0001$) for women attending for public hospital care. The CDMR rate among nullipara increased significantly over the duration of the study from 0.9% in 2014 to 2.7% in 2023 ($P < 0.0001$), Figure 1.

Conclusion: These findings describe the prevalence of CDMR among nulliparous women and the subsequent contribution to overall CD rates. A significant increase in rates was observed in the last decade. The rates of CDMR were higher among women attending a private obstetric service.

1131 | Categorizing the cause of Maternal Instability with MEOWS

Nicholas W. Racchi[1]; Kourosh Kiyani[2]; William Schnettler[3]
[1]Trihealth, Cincinnati, OH; [2]TriHealth, Cincinnati, OH; [3]TriHealth, Cincinatti, OH

4:00 PM - 6:00 PM

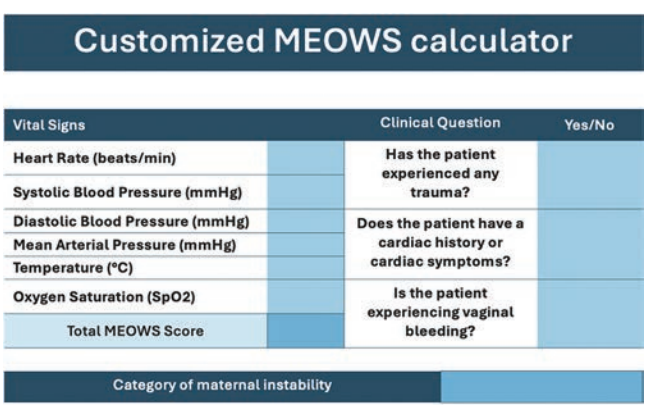
Objective: To investigate the ability of a customized MEOWS (Modified Early Obstetric Warning System) calculator to categorize the cause of maternal critical illness.

Study Design: This retrospective self-controlled cohort study evaluated all pregnant people admitted to an intensive care unit at two separate delivering hospitals in Cincinnati, Ohio, between January 1, 2018, and August 1, 2023. Inclusion required study participants to be at least 20 weeks' gestation through 6 weeks postpartum. Vital signs obtained within the 4 hours prior to the decision for ICU admission were compared to participants' prior vitals from earlier triage visits. These values were then put into a customized MEOWS calculator (Figure 1) that incorporated additional history-based questions to categorize the patient into a MEOWS subset (stable, hypertensive emergency, hemorrhage, cardiac/possible peripartum cardiomyopathy, sepsis, trauma, or not otherwise classified). The calculated MEOWS category was then compared to the final discharge diagnosis to determine accuracy using Exact Methods.

Results: Vital signs from 87 patients were obtained and used in the modified MEOWS calculator. Our modified MEOWS calculator could predict maternal instability with a sensitivity of 93.3% and a specificity of 83.3%. The calculator was able to correctly categorize the cause of maternal morbidity with a sensitivity of 89.8% and a specificity of 67.8%. The individual sensitivities and specificities for the individual categories of the cause of maternal morbidity can be seen in table 1.

Conclusion: The use of a modified MEOWS calculator can better help determine the cause of maternal instability. This type of modified MEOWS calculator could better help categorize the cause maternal instability and thus allow for the effective use of an appropriate clinical protocol.

Category of Maternal Instability	Specificity	Sensitivity
Stable	94.9%	87.5%
Stable Cardiac Patient	97.5%	50%
Trauma or Abruption	97.3%	63%
Sepsis	84.3%	95.6%
Hypertensive Emergency	94.5%	76.5%
Possible Peripartum Cardiomyopathy	95.7%	76.9%
Not otherwise classified	100%	12.5%



1132 | Validating the Use of Epigenetic Clocks in a Preconception Population

Nicola C. Perlman[1]; Jiaqi Zhang[1]; Andrea Cipriano[2]; Stephanie A. Leonard[1]; Xixi D. Plummer[1]; Samantha L. Kruger[1]; Arian Korshid[2]; Janet Hurtado[1]; Vittorio Sebastiano[2]; Danielle M. Panelli[1]; Ruth B. Lathi[1]; Katherine Bianco[1]
[1]Stanford University, Palo Alto, CA; [2]Stanford University, Stanford, CA

4:00 PM - 6:00 PM

Objective: Prior studies have attempted to use epigenetic clocks to correlate biologic age with pregnancy outcomes. Despite this, no epigenetic clock has been validated for use in pregnancy, and

biologic age outputs can vary in different tissues and populations. This study assessed the validity of 9 epigenetic clocks in a preconception cohort.

Study Design: This study utilized biobanked samples from preconception patients between 2020-2023. Peripheral blood mononuclear cell DNA was extracted from buffy coat, and DNA methylation was profiled using Illumina Infinium MethylationEPIC BeadChip array, allowing prediction of biologic age via 9 epigenetic clocks. Pearson correlation coefficients were calculated for biologic age and chronologic age (defined as age by birthdate) for each clock. An epigenetic clock was defined as valid if the correlation coefficient (r) was >0.800, in accordance with prior literature.

Results: 68 blood samples from people assigned female at birth were analyzed. The median chronologic age was 38.0 years [Q1-Q3 33.0-40.3]. No sample had the same biologic age in all 9 clocks. Of the epigenetic clocks evaluated, the correlation coefficient ranged from 0.673 to 0.916 (Table 1). Three clocks exceeded the preset validity threshold of r >0.800; the SkinBlood Clock (r = 0.916), the Zhang Clock (r = 0.915), and the Hannum Clock (r = 0.822). Each of the top 3 performing clocks had a different range of biologic age outputs (Figure 2). Although the Zhang and the SkinBlood Clock had similar correlation coefficients, the SkinBlood Clock produced biologic ages more akin to chronologic ages (median 35.8 years [32.6-39.2]) compared to the Zhang Clock (56.02 years [54.39-56.81]).

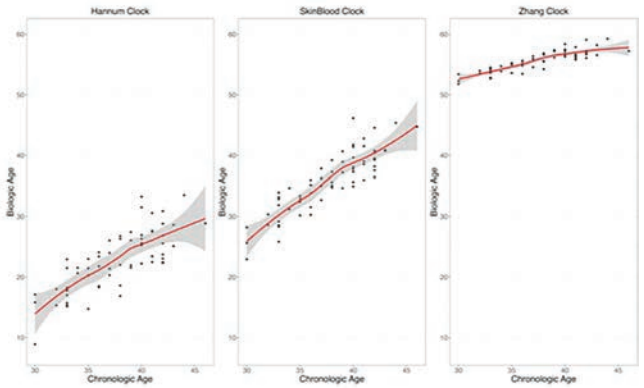
Conclusion: In this validation study we considered 9 different clocks for use in a preconception cohort. The SkinBlood Clock performed best with high correlation and chronologic age congruency. Epigenetic clocks are an exciting new technology for studying aging. Research using epigenetic clocks in pregnancy and fertility should assess validity prior to testing for association with perinatal outcomes.

Table 1: Correlation Between Biologic Age and Chronologic Age in a Preconception Population in 9 Frequently Cited Epigenetic Clocks.

DNA clock	Correlation coefficient (r)*	Clock Description
SkinBlood Clock	0.916	A widely used clock to predict lifespan and age related disease, for use with whole blood or buccal samples.
Zhang Clock	0.915	Based on specific sites of methylation changes related to mortality. For use with whole blood samples.
Hannum Clock	0.822	Based on specific sites of methylation changes related to mortality. For use with whole blood samples.
GrimAge Clock	0.796	Based On Predicted Age. Used in prior obstetric literature. For use with blood, sometimes saliva.
GrimAge2 Clock (Based on predicted HgbA1c, C-reactive protein)	0.793	Updated GrimAge Clock based on predicted HgbA1c, C-reactive protein. For use with blood samples.
DNAmAge Clock	0.781	The "Horvath" Clock. An early clock using pan-tissue samples.
GrimAge3 Clock	0.733	Updated GrimAge Clock based on predicted age, HgbA1c, c-reactive protein, and tuned for methylation variability.
GrimAge4 Clock	0.732	Updated GrimAge Clock based on predicted age, HgbA1c, c-reactive protein.
DNAmPhenoAge	0.673	Based on methylation loss and 10 measures of aging including chronologic age, albumin, and glucose. For use with blood.

*P-value <0.001 for all correlation coefficients.

Figure 1: Biologic versus Chronologic Age using Epigenetic Clocks with High Correlation Coefficients (>0.80).



1133 | The Association of Preconception Epigenetic Changes of Aging with Live Birth and Pregnancy Outcomes

Nicola C. Perlman[1]; Jiaqi Zhang[1]; Andrea Cipriano[2]; Stephanie A. Leonard[1]; Xixi D. Plummer[1]; Samantha L. Kruger[1]; Arian Korshid[2]; Janet Hurtado[1]; Vittorio Sebastiano[2]; Danielle M. Panelli[1]; Katherine Bianco[1]

[1]Stanford University, Palo Alto, CA; [2]Stanford University, Stanford, CA

4:00 PM - 6:00 PM

Objective: Biologic age from epigenetic clocks has been used to predict diseases of aging such as cardiac disease, however its association with fertility and pregnancy complications is not known. We examined the relationship between biologic age and both live birth and pregnancy complications.

Study Design: This study analyzed biobanked serum samples of people desiring pregnancy from 2020-2023. Pregnancy outcomes were followed for 1-4 years after sample collection. Peripheral blood mononuclear cell DNA was extracted and >850,000 CpG methylation loci were interrogated. This allowed prediction of biologic age (bio-age) using the SkinBlood Clock, which had the highest validity in the cohort. The difference between chronological age (chrono-age, measured from birthdate) and bio-age was calculated (chrono-bio age difference); decelerated aging was defined if bio-age was less than chrono-age. A multivariable logistic regression was performed to test the association between the chrono-bio age difference and (1) live birth in the entire cohort, and (2) a composite of pregnancy complications related to aging (miscarriage/fetal demise, preterm labor/delivery, hypertensive disorders, gestational diabetes, or placental insufficiency) in a sub-cohort which achieved pregnancy.

Results: Among 64 patients, the median chrono-age was 38.0 years (Q1-Q3 34.8-41.0), and bio-age was 35.8 (32.6-39.2). 46 patients achieved pregnancy; 38 (83%) had a live birth, and 23 (50%) had at least one pregnancy complication. Bio-ages differed between people with versus without a live birth (Table 1). When controlled for confounders, for every year that bio-age was less than chrono-age, there was a two-fold increased odds of live birth (aOR: 2.02; 1.20-4.11, Table2). There was no significant association between the chrono-bio age difference and the composite outcome of pregnancy complications.

Conclusion: In this study, decelerated biologic aging was associated with higher rate of live birth. Robust studies are needed to

understand ways to reverse biologic aging and use it to predict and optimize perinatal outcomes.

Table 1: Chronologic Age versus Biologic Age Overall and within Live Birth and No Live Birth Groups.

Age Instrument:	Overall Cohort n = 64	Live Birth n = 40	No Live Birth n = 24	p-value[i]

Chan School of Public Health, Harvard University, Boston, MA, USA Department of Biostatistics and Epidemiology, Rutgers School of Public Health, New Brunswick, NJ, USA, New Brunswick, NJ; [7]Fetal Surgeon Chief, Division of Fetal Medicine and Surgery Director of the Maternal Fetal Care Center Director of the Perinatal Surgery Fellowship Professor of Surgery, Boston Children's Hospital Harvard Medical School, Boston, MA

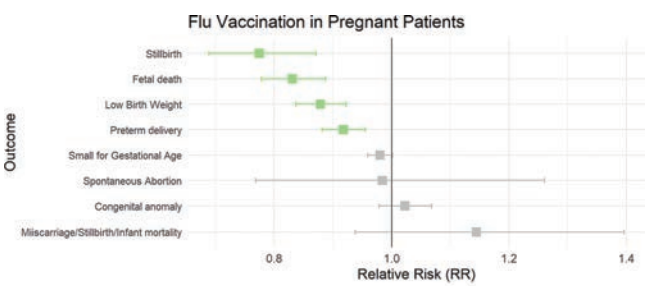
4:00 PM - 6:00 PM

Objective: Although influenza vaccination during pregnancy is known to prevent seasonal flu outbreaks, reliable and contemporary quantitation of benefits and safety has not been performed. The aim of the current umbrella review to synthesize evidence from multiple meta-analyses was to reliably and robustly provide quantitative measures of the effectiveness and safety of influenza vaccines among gravidae.

Study Design: We conducted a systematic search of PubMed, Scopus, Web of Science, and Embase from inception to 09/13/2023, including over 100 individual studies retaining 38 million pregnancies. Data were extracted from multiple meta-analyses, and included studies were filtered to ensure no duplication within outcomes. Risk ratios (RRs) and pooled proportions were calculated using R, with aggregate effect sizes and random-effects models applied. Egger's test was used to assess publication bias. PROSPERO registration: CRD42024519189.

Results: As shown in Figure & Table, influenza vaccination during pregnancy resulted in a significant risk reduction of fetal death or stillbirth (RR 0.83 & 0.77, 95% CI 0.78–0.89 and 0.69–0.87), PTB (RR 0.92, 95% CI 0.88–0.96), and LBW neonates (RR 0.88, 95% CI 0.84-0.93). Reflective of changes in co-morbidities and other respiratory illness pandemics over the study interval, there was heterogeneity in some outcomes, such as PTB (I^2: 63.06%), while other outcomes showed low to moderate heterogeneity. Egger's test for publication bias indicated no significant bias across the studies.

Conclusion: Influenza vaccination during pregnancy is associated with significant and quantifiable reductions in the risk ratio of multiple adverse perinatal outcomes. Providing these quantitative estimates may aid in public health messaging and shared decision-making with patients and their families.



Outcome	Pooled RR	Lower CI	Upper CI	I^2	Lower CI (I^2)	Upper CI (I^2)	Number Studies	p-value for Egger test

1135 | Risk of Hypertensive Disorders of Pregnancy in GLP-1 Agonist Exposed and Unexposed Patients

Nishita Pondugula[1]; Jennifer F. Culhane[1]; Lisbet S. Lundsberg[1]; Audrey A. Merriam[2]; Caitlin Partridge[1]
[1]Yale School of Medicine, New Haven, CT; [2]Yale New Haven Hospital, New Haven, CT

4:00 PM - 6:00 PM

Objective: To understand the effect of GLP-1 agonist use in the year prior to conception on risk of developing hypertensive disorders of pregnancy (HDP).

Study Design: All patients delivering between 2014-2024 with evidence of GLP-1 exposure in the year prior to conception were identified through electronic medical record (EMR) query with hand review to confirm exposure. GLP-1 exposed patients were classified according to GLP-1 indication for use: 1) pregestational diabetes mellitus (PGDM) or 2) weight management (WM) for increased body mass index (BMI). Control groups for each indication cohort were identified from 2021-2022 delivery EMR

data. PGDM controls were patients with pregestational DM1 or DM2 managed with medication other than GLP-1 agonist in the year prior to conception. WM controls were a stratified random sample of patients without PGDM not on antihyperglycemic medication in the year prior to conception with BMIs between 30 < 40 kg/m^2 (n = 100) and ≥ 40 kg/m^2 (n = 100). Demographic and clinical characteristics and obstetrical outcomes were compared. Logistic regression was employed to assess the crude (OR) and adjusted odds ratios (aOR) for HDP controlling for covariates significant in bivariate tests at < 0.05.

Results: 246 patients had GLP-1 exposure in the year prior to conception. Of these, 104 were exposed for PGDM and 142 for WM. For the PGDM cohort, 175 controls were identified from the two years of EMR data interrogated. For the WM cohort, random sampling yielded 200 controls.

Bivariate tests for race/ethnicity, pre-pregnancy BMI, and chronic hypertension identified significant differences between exposed and unexposed patients in the PGDM cohort. For the WM cohort, exposed and unexposed patients had significant differences in PCOS diagnosis, gestational weight gain, and HDP. For both the PGDM and WM cohort, exposed patients were half as likely to develop HDP compared to unexposed counterparts (PGDM aOR = 0.47 (0.27-0.83); WM aOR = 0.48 (0.29-0.80)).

Conclusion: GLP-1 use in the year prior to conception significantly reduced the likelihood of developing HDP for patients with PGDM and undergoing WM.

1136 | Early Pregnancy Cortisol Levels in Women with and without a History of Preterm Deliveries

Noam Tomasis Damri[1]; Eyal Sheiner[2]; Ifat Baram Goldberg[3]; Maayan Hagbi Bal[1]; Doron Bergman[1]; Ron Rosenbaum[1]; Ayal Haimov[4]; Tamar Wainstock[2]

[1]Ben Gurion University of the Negev, Beer Sheva, HaDarom; [2]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom; [3]Ben Gurion University Of The Negev, beer sheva, HaDarom; [4]Ben Gurion University of the Negev, Ramat Gan, HaMerkaz

4:00 PM - 6:00 PM

Objective: Elevated cortisol levels during pregnancy have been associated with an increased risk for preterm delivery (PTD). However, the precise nature of this relationship and its potential mechanisms remain poorly understood, particularly concerning cortisol levels in early pregnancy. The present prospective study was designed to investigate the association between early pregnancy cortisol levels and perceived stress, and adverse pregnancy outcomes in women with and without a history of PTD.

Study Design: In this prospective study, women with or without a history of PTD were recruited during 11-13 weeks of gestation at a tertiary medical center. All participants provided a saliva sample and answered a health and stress questionnaire. Pregnancy outcomes were compared between women with high and low salivary cortisol levels. Mean salivary cortisol levels were also compared between women with and without a history of PTD and between women with and without selected pregnancy complications.

Results: The study included 375 women, out of them 194 with, and 181 without previous PTD. The levels of cortisol were higher among women with vs. without PTD (0.1440 ug/dL $\pm$ 0.095 and 0.297 ug/dL $\pm$ 0.23, respectively, p-value$<$ 0.001) in total, and when comparing the groups at each gestational week (Figure 1). Women who had high cortisol levels were not at increased risk for adverse pregnancy outcomes including PTD (Table 1). No association was found between the perceived stress based on the questionnaire and the measured cortisol levels.

Conclusion: Although cortisol levels were higher among women with previous PTD, cortisol levels were not associated with the risk for PTD and other adverse pregnancy outcomes, possibly due to the early gestational age at which the cortisol was measured. Further study on early pregnancy markers for potential complications is needed to facilitate effective intervention and prevention.

4:00 PM - 6:00 PM

Objective: Headache is the most common neurologic symptom in pregnancy. There is a debate on the necessity and imaging indications for headache evaluation. We aimed to assess the effectiveness of brain imaging for persistent severe headaches in pregnant individuals.

Study Design: This retrospective study included pregnant individuals with headaches requiring brain imaging at a tertiary center from 2011 to 2024. Those with "red flags" (neurological signs, severe headaches, or lack of response to analgesics) were evaluated by a neurologist for imaging needs. Abnormal imaging was defined as new brain findings explaining the headache. The study details patient characteristics, etiologies, clinical features, immediate treatments, and impacts on pregnancy management.

Results: During the study period, 458 pregnant individuals had brain imaging due severe headache. Of them only 34 (7.4%) had positive imaging. Abnormal Imaging results included stroke (n = 10,29.4%), space-occupying lesion (n = 7,20.6%), Idiopathic Increased Intracranial Pressure (n = 6,6%.71), Cavernoma (n = 5, 14.7%), and other less frequent causes such as Multiple Sclerosis, Posterior Reversible Encephalopathy Syndrome (PRES) (n = 2, 5.9%) Acute Disseminated Encephalomyelitis (ADEM), Optic Neuritis, Subarachnoid Hemorrhage, Reversible cerebral vasoconstriction syndrome (RCVS), Internal carotid thrombus (n = 1, 2.9% each).

There were no differences in maternal and pregnancy baseline characteristics (Table 1).

Among individuals with abnormal imaging 19 (55.9%) needed medical or surgical treatment including 4 (11.7%) brain surgeries, 1 (2.9%) angiographic intervention, 16 individuals (47.0%) received medical treatment such as aspirin, low molecular weight heparin, nimodipine, steroids, and acetazolamide. Five (14.7%) patients underwent an early delivery between 29-36 weeks (Table 2).

Conclusion: At a tertiary care center, the yield of brain imaging to diagnose significant etiologies in pregnant individuals is 7.4% with CVA being the most common etiology. Medical or surgical treatment was required in 55.9% of the positive imaging group.

Table 1: Maternal and Obstetrical Characteristics

Variable	Overall, N = 458[1]	Normal, N = 424[1]	Abnormal, N = 34[1]	p-value[2]

1138 | Impact of Residence in a Food Desert on Prenatal Metabolic Health and Diet Indices

Noor K. Al-Shibli[1]; Anne L. L. Dunlop[2]; Suchitra Chandrasekaran[3]
[1]Emory University, School of Medicine, Atlanta, GA; [2]Emory University School of Medicine, Atlanta, GA; [3]Emory University, Atlanta, GA

4:00 PM - 6:00 PM

Objective: With increasing rates of metabolic syndrome and associated adverse pregnancy outcomes, there is a need to better understand risks for poor nutritional status. Little is known about the impact of the lived food environment on prenatal diet quality. We aimed to explore impact of living in a food desert (FD) on prenatal dietary scores & metabolic health indices.

Study Design: We performed a single-center prospective pregnancy cohort study from 2014-2024. Participants were a subset of those enrolled in the Atlanta African American Maternal-Child Cohort, which included pregnant people ages 18-40 with a singleton 8-14 weeks' gestation who identified as Black/African American. Block-Bodnar food frequency questionnaires (FFQ) were administered at 8-14 or 24-30 weeks' gestation. Dietary scores and indices were calculated from FFQ responses. FD status was assigned to participants residing in low-income/low-access census tracts according to U.S. Department of Agriculture (USDA) definitions. Descriptive and bivariate statistics were utilized.

Results: Of n = 543 pregnancies, n = 242 (45%) lived in a FD. Median cohort age was 25 and BMI 29.8 kg/m2. There were no significant differences in glycemic/lipid indices (Table 1) or diet quality scores (Table 2) by FD status. Notably, median Alternate Healthy Eating Index-Pregnancy (AHEI-P) scores showed low-moderate adherence to dietary guidelines for those residing in FD and non-FDs (41.5 & 40.2, respectively). Both groups demonstrated pro-inflammatory Dietary Inflammatory Index (DII) scores.

Conclusion: Prenatal glycemic/lipid intake and diet quality did not significantly differ by FD status. Rather, those residing in FD & non-FD demonstrated high intake of total sugar, mono/poly-unsaturated fat, low-moderate adherence to pregnancy dietary guidelines, and pro-inflammatory diets. This suggests that metabolic dietary risks in pregnancy are common, irrespective of FD status. Future directions should focus on nutrition education and behavioral approaches for all pregnant people regardless of their geographic food environment.

Table 1: Median Glycemic and Lipid Indices by Food Desert Status

	Non-Food desert	IQR [Q1-Q3]	Food Desert	IQR [Q1-Q3]	p-value
Glycemic Indices:					
Glycemic Index (glucose), average daily	0.916	4.18 [50.53-54.7]	1.598	4.83 [50.1-54.9]	0.720
Glycemic Load (glucose), average daily	52.72	106.1 [66.7-172.9]	52.6	105.1 [71.9-177.0]	0.562
Total Sugar, g	105.4	115.6 [59.3-174.9]	109.2	120.6 [60.8-181.4]	0.730

1139 | Hypertensive Disorders and Postpartum Follow up: Care in and Outside the Hospital

Oladunni Ogundipe[1]; Michelle Carfagno[2]; Adeola F. Adeyeye[3]; Cassandra Heiselman[3]; Kimberly Herrera[4]

[1]Stony Brook University, Stonybrook, NY; [2]Stony Brook University Hospital, Stonybrook, NY; [3]Stony Brook University Hospital, Stony Brook, NY; [4]Stony Brook University, Stony Brook, NY

4:00 PM - 6:00 PM

Objective: We sought to evaluate the role of social determinants of health (SDH) in postpartum care delivery and utilization among patients with hypertensive disorders of pregnancy (HDP) by examining rates of 6 week follow up and unscheduled healthcare utilization.

Study Design: This was a retrospective cohort study of patients who delivered at a single hospital between 12/2020 and 2/2023 including those diagnosed with preeclampsia with/without severe features during pregnancy or in the postpartum period. Exclusion criteria: < 18 years of age, delivered < 20 weeks GA, or delivered with community practices. SDH included age, self-identified race and ethnicity, marital status, number of living

children, health insurance, and area deprivation index (a mapping tool from 1 [most advantaged] to 10 [least advantaged] obtained from census data displaying relative socioeconomic conditions of regions). Statistical analysis included cross-tabulation, chi-square tests, independent samples t-tests, bivariate analyses, and multivariable logistic regression analyses. Statistical significance was determined using a threshold of $p < 0.05$.

Results: 257 patients were included (Table 1). Being single, having prior living children, and belonging to a racial or ethnic group other than White non-Hispanic was significantly associated with poor attendance at the six-week postpartum visit (Table 2). Unscheduled hospital admissions were also significantly associated with being black, higher ADI scores, and having living children ($p< 0.05$) (Table 3).

Conclusion: SDH were significantly associated with poor postpartum follow up and higher rates of unscheduled health care utilization.

1140 | Characterization of a 96-Cytokine Panel in Blood of Women with Healthy Pregnancies

Viktoriia Kolesnyk[1]; Colleen Sinnott[2]; Tobias Hartwich[2]; Yang Yang-Hartwich[1]; Olga Grechukhina[1]
[1]Yale School of Medicine, New Haven, CT; [2]Yale University, New Haven, CT

4:00 PM - 6:00 PM

Objective: Serological cytokines are potential biomarkers of pregnancy pathology. While this is a convenient non-invasive technique, establishing normal *versus* abnormal levels in pregnancy has been challenging, limiting its diagnostic value. Some cytokines vary between individuals or due to physiological factors. By evaluating a panel of 96 cytokines in serum from patients with normal pregnancies, our objective is to devise a comprehensive nomogram that integrates a complex cytokine profile and will allow determination of the normal versus abnormal cytokine levels.

Study Design: Serum samples collected at four timepoints (~12 weeks, 18-22 weeks, 26-30 weeks, 34-38 weeks) from 15 healthy pregnant subjects who had no pregnancy complications and delivered full-term were obtained from an institutional biobank. Human Cytokine 96-Plex Discovery Assay was performed. One-way ANOVA was used to analyze trends in each cytokine for each pregnancy. Cytokines with both low variability between timepoints and consistent trends across individuals were identified for further testing in clinical setting.

Results: Among the 96 cytokines (growth factors, chemokines, interleukins and others) that were assessed, levels of 54 significantly increased or decreased during pregnancy while 42 remained stable. Of those that showed change, 7 with low variability were manually picked: GROa, IL-27 and VEGF-A increased while BCA-1, IL-24, Lymphotactin, MCP-4 decreased during the course of pregnancy. Among those that showed no change during pregnancy IL-22, 6CKine (aka CCL21), Exotaxin 3, HMGB1, IL-11, IL-28A, MIP-3b were identified to have low variability.

Conclusion: Out of 96 tested cytokines, 54 change significantly during healthy pregnancy, which should be accounted for when studying maternal serum cytokines in various pregnancy pathologies. The remaining cytokines do not show level change over the course of pregnancy. Specific cytokines that are better suited for clinical setting were identified, setting up a foundation for studying cytokine levels and identifying cytokine footprint in specific pregnancy pathologies.

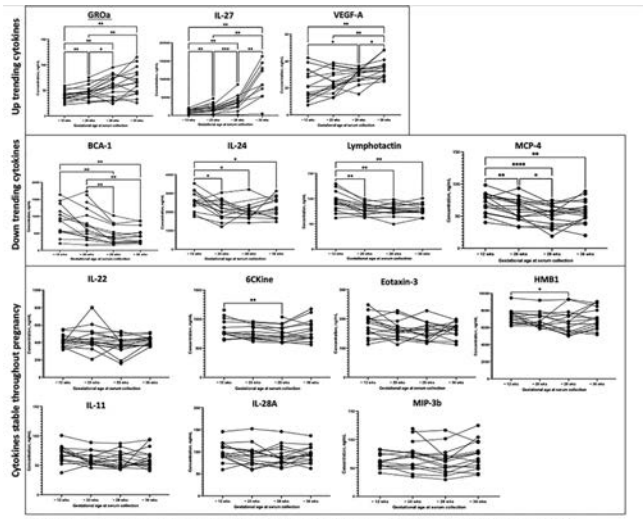

Figure 1. Cytokines with relatively narrow variability and consistent trends (up or down) or stable levels throughout the pregnancy.

1141 | Impact of Fetal Surgery Type and Complications on Maternal Perinatal Mental Health

Olivia Liseth[1]; Jessica Weng[1]; Mauro Schenone[2]; Katherine Moore[2]; Hannah Betcher[2]; Yan Li[2]; Megan E. Branda[2]; Enid Rivera-Chiauzzi[2]; Alyssa Larish[2]
[1]Mayo Clinic MSTP, Rochester, MN; [2]Mayo Clinic, Rochester, MN

4:00 PM - 6:00 PM

Objective: Previous work has identified high rates of depression and anxiety in fetal surgery patients, therefore, we sought to determine the effect of fetal surgery approach type and outcomes on perinatal mood and anxiety disorders (PMAD).

Study Design: A retrospective chart review was conducted of fetal surgery patients from 2017-2024 at a tertiary care center. Demographics, surgical, obstetric, and psychiatric diagnoses were recorded. Complications included surgical site infection, chorioamnionitis, NICU admission > 45 days, PPROM, preterm labor, or delivery < 34 weeks gestation. Severe complications included delivery < 30 weeks gestation, unplanned delivery at the time of the procedure, maternal ICU admission, and fetal or neonatal death. Minimally invasive surgery (MIS) included both fetoscopic and ultrasound guided.

Results: Our cohort had an average age of 30.5 yrs and a mean gravidity of 2.7 (n = 141). Of 141 surgeries, 32 (22.7%) were open and 109 (77.3%) were MIS. Pregnancy complications occurred in 115, with severe complications in 64 patients (Table 1). The rates of any or severe complications were 75.0%, 21.9%, respectively, for open procedures and 83.5%, 52.3%, respectively, for MIS. MIS patients did not have a lower rate of exacerbation or de novo PMAD (25/109, 22.9%) compared to open surgery (8/32, 25.0%, p = 0.8084; X^2 test). Patients with any complication did not have a higher risk of exacerbation or de novo PMAD (30/115, 26.1%), versus patients without any complications (3/26, 11.5%, p = 0.1315; Fisher's exact test). After adjusting for multiple testing, no individual complication was predictive of subsequent PMAD. Among patients with baseline mood disorders, complications did not result in increased exacerbation compared to no complications (2/5, 40% without vs 25/48, 52.1% with, p = 0.6687; Fisher's exact test).

Conclusion: Both complications and surgical approach are not predictive of PMAD; universal follow-up and screening are needed. Further research is necessary to determine the most effective timepoints and methods of screening in this population with a uniquely challenging life event.

Table 1. Pregnancy complications, stratified by fetal surgical approach.

Complications	Total (n = 141)	Open (n = 32)	Minimal Invasive (n = 109)	p-value
Maternal surgical site infection	7 (5.1%)[5]	3 (9.4%)	4 (3.8%)[5]	0.3548
Chorioamnionitis	11 (8.1%)[6]	2 (6.2%)	9 (8.7%)[6]	1.0000
Prolonged NICU admission >45 days; n (%)	33 (30.3%)[32]	6 (21.4%)[4]	27 (33.3%)[28]	0.2372
PPROM <34 weeks	33 (23.9%)[3]	7 (21.9%)	26 (24.5%)[3]	0.7578
Preterm labor <34 weeks	44 (31.9%)[3]	8 (25.0%)	36 (34.0%)[3]	0.3404
Gestational age at birth <34 weeks	71 (51.1%)[2]	11 (34.4)	60 (56.1)[2]	0.0312
Severe complications				
Gestational age at birth <30 weeks	40 (28.8%)[2]	5 (15.6%)	35 (32.7%)[2]	0.0757
Unplanned delivery at time of surgical procedure	7 (5.0%)	2 (6.3%)	5 (4.6%)	0.6571
Maternal ICU admission	2 (1.4%)[3]	1 (3.1%)	1 (0.9%)[3]	0.4113
Neonatal demise	25 (18.1%)[3]	4 (12.5%)	21 (19.8%)[3]	0.4389
Fetal demise	20 (14.8%)[6]	0 (0)	20 (19.4%)[6]	0.0037

Table 1. *Pregnancy and surgical outcomes for the general fetal surgery cohort. Data are represented as mean (standard deviation) when stated and count (percentage of total population subtract missing) otherwise. Superscripts indicate the counts of missing values, which are excluded from the percentage calculation. d, days; w, weeks; SD, standard deviation.*

1142 | Intrapartum Maternal Bacteremia: an Important Predictor of Puerperal Adverse Outcomes

Omer Nir[1]; Tal Israeli[2]; Michal Axelrod[2]; Sharon Amit[3]; Shali Mazaki-Tovi[2]; Michal Fishel Bartal[4]
[1]Department of Obstetrics and Gynecology, Sheba Medical Center, Tel Hashomer, Ramat Gan, HaMerkaz; [2]Department of Obstetrics and Gynecology, Sheba Medical Center, Tel HaShomer, Ramat Gan, HaMerkaz; [3]Clinical Microbiology, Sheba Medical Center, Tel HaShomer, Ramat Gan, HaMerkaz; [4]UTH Houston & Sheba Medical Center Israel, Houston, TX

4:00 PM - 6:00 PM

Objective: We aimed to assess the risk factors, pathogens, and outcomes in Individuals with intrapartum fever with and without proven bacteremia bacteremia.

Study Design: We conducted a retrospective study at a single tertiary center (October 2011 to February 2024). Included in the study were individuals with singleton pregnancies in labor beyond 24 weeks who experienced intrapartum fever (defined as > 38 degrees Celsius). We excluded those with unavailable blood cultures for review. Baseline demographic and delivery characteristics were compared between those with positive cultures and those with negative or non-pathogenic blood cultures (contaminants). The primary outcome was a composite adverse maternal outcome (CAMO), which included any of the following: length of stay > 4 days, ICU admission, CT-guided drainage, fever-related surgery, and death. A multivariable regression analysis was performed for the primary outcome, with adjusted odds ratios (aOR) and 95% confidence intervals (CI) reported.

Results: Out of 86,904 deliveries, 3,603 (4.1%) had intrapartum fever, and 3,047 (85%) met inclusion criteria. Among these, 117 (3.8%) had positive blood cultures, with the most common blood-borne pathogens being non-hemolytic Streptococci, Enterobacterales, and GBS (Figure). Those with bacteremia differed from those without in terms of age, rate of nulliparity, rate of spontaneous labor onset, preterm delivery, and neuraxial analgesia. Furthermore, patients with bacteremia had a higher maximal temperature and WBC count, had a higher rate of cesarean delivery, and required additional broad-spectrum second-line antibiotics. Following multi-variable regression, those with

bacteremia had a higher rate of CAMO (85.5% vs. 38.6%, aOR 16.0, CI 7.2-35.8, Table) compared to those without bacteremia.

Conclusion: Intrapartum fever accompanied by bacteremia is associated with an increased need for second-line antibiotic use and poorer maternal outcomes. This study underscores the importance of blood culture among individuals at risk in guiding treatment and identifying individuals at higher risk of adverse maternal complications.

Table: Baseline characteristics and outcomes

	Bacteremia N=117	No Bacteremia N=2930	p value

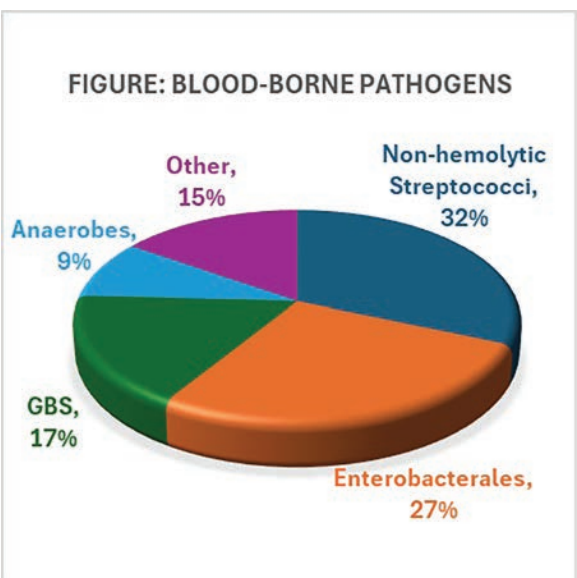
*Composite includes any of the following: length of stay ≥4 days, ICU transfer, CT-guided drainage, fever-related surgery, maternal death.
**Fever-related surgery includes laparoscopy, laparotomy, and hysterectomy.
#Adjusted for maternal age, nulliparity, induction of labor, preterm birth, and cesarean delivery.
Adjusted for maternal age, preterm birth, and cesarean delivery.



1143 | Maternal Lipidomics for the Accurate Prediction of Fetal Cyanotic Congenital Heart Defects

Onur Turkoglu[1]; Nadia Ashrafi[2]; Ali Yilmaz[2]; Romana Ashrafi[2]; Abdullah Khan[2]; Perry Friedman[3]; Ciara Talbot[4]; Stewart graham[2]; Ray Bahado-Singh[5]

[1]Baylor College of Medicine, Houston, TX; [2]William Beaumont University Hospital, Research Institute, Metabolomics Division, Royal Oak, William Beaumont University Hospital, Research Institute, Metabolomics Division, Royal Oak, MI; [3]Memorial Healthcare System, Memorial Healthcare System, FL; [4]Kaiser Permanente, Kaiser Permanente Brookwood at Peachtree Medical Office, GA; [5]Corewell Health William Beaumont University Hospital, Oakland University William Beaumont School of Medicine, Royal Oak, MI

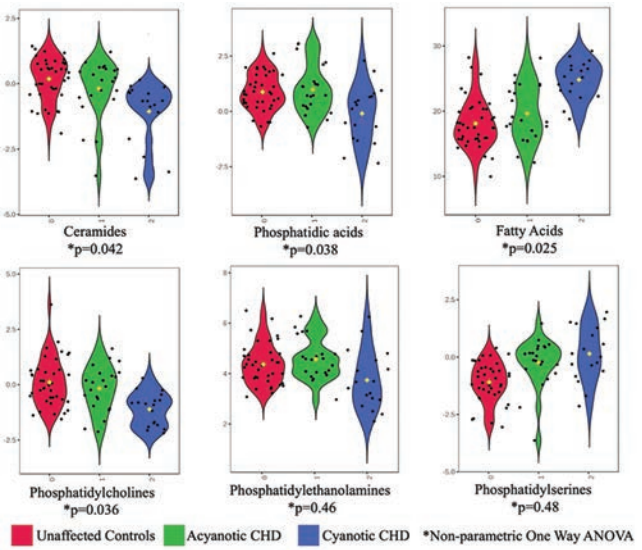
4:00 PM - 6:00 PM

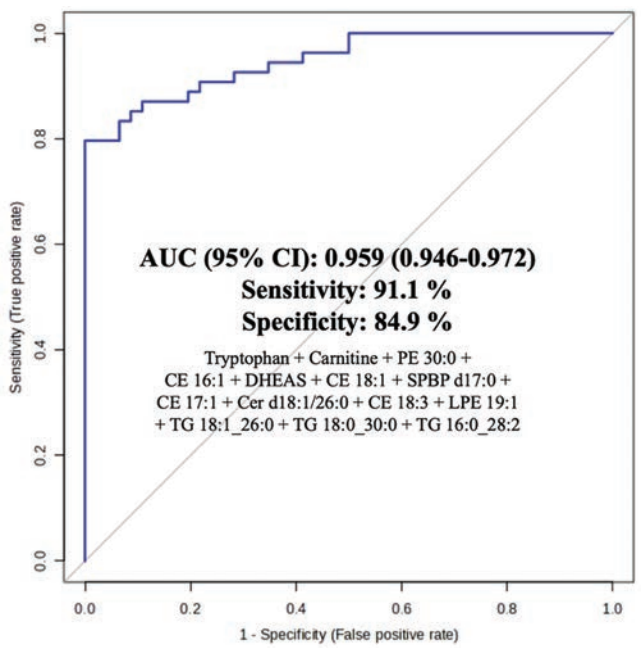
Objective: Late diagnosis of cyanotic congenital heart defects (CCHD) significantly increases newborn morbidity and mortality. However, a significant percentage of CCHD cases remain undetected prenatally. Our objectives were therefore to evaluate the accuracy of maternal serum lipidomic markers for the prenatal detection of CCHD and also to elucidate the pathogenesis of these disorders.

Study Design: This prospective case-control study included 40 cases of CHD (22 cyanotic, 18 acyanotic) and 39 unaffected controls. Maternal serum samples were profiled via a combination of Ultra-High-Performance Liquid Chromatography coupled with Mass Spectrometry and Nuclear Magnetic Resonance. The mean of each lipid specie was compared between CCHD vs all others. Logistic regression models were developed for the detection of CCHD. Areas under the receiving operating curve (AUC), sensitivity, and specificity values were calculated. Metabolite Set Enrichment Analysis (MSEA) was also performed to discover the top dysregulated biochemical pathways in CCHD.

Results: In total, 803 lipids and 97 metabolites were profiled in the maternal serum. In CCHD cases, concentrations of ceramides, phosphatidic acids, phosphatidylcholines, and phosphatidylethanolamines were decreased while fatty acids and phosphatidylserines were elevated ($p < 0.05$) (Fig1). The lipidomics model (Fig2) achieved outstanding predictive accuracy: AUC (95%) = 0.959 (0.946-0.972). This outperformed the accuracy of routinely used standard clinical risk predictors for CHD (diabetes + obesity + hypertension + in vitro fertilization + family history of CHD + alcohol or tobacco exposure). MSEA analysis revealed profound alterations of mitochondrial beta-oxidation of short and long-chain fatty acids involved in lipid metabolism, in CCHD.

Conclusion: Fetal CCHD was associated with significant disturbance of lipid metabolism. Maternal lipid biomarkers were highly accurate for the detection of fetal CCHD. This has the potential for the development of non-invasive pregnancy population screening which could help to reduce mortality and morbidity in CCHD.





1144 | Association Between Health Literacy and Cardiovascular Health in Early Pregnancy

Onyinye Ohamadike[1]; Xiaoning Huang[2]; Sadiya S. Khan[1]; William A. Grobman[3]; Philip Greenland[4]; David M. Haas[5]; Uma M. Reddy[6]; Lynn M. Yee[1]

[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Northwestern University, Chicago, IL; [3]The Ohio State University, Columbus, OH; [4]Northwestern, Northwestern/Chicago, IL; [5]Indiana University School of Medicine, Indianapolis, IN; [6]Columbia University, New York, NY

4:00 PM - 6:00 PM

Objective: Inadequate health literacy (HL) has been associated with adverse pregnancy outcomes, yet it is not well understood to what extent HL is associated with early pregnancy cardiovascular health (CVH). We aimed to understand the association between inadequate HL and CVH in early pregnancy.

Study Design: In this secondary analysis of cross-sectional data from a large, multi-site cohort of nulliparous people enrolled in a prospective observational study conducted at 8 US medical centers, we included participants who completed an assessment of HL at 6 to 13 weeks of gestation. HL, assessed using the Rapid Estimate of Adult Literacy in Medicine-Short Form (REALM-SF), was categorized as inadequate if the REALM-SF score was < 7 (8th grade level or lower) and adequate if score 7 or greater. The primary outcome was CVH at 6-13 weeks of gestation, quantified by a modified (i.e., non-fasting) version of the American Heart Association's Life's Essential 8 (LE8) score, a validated marker of CVH in which lower scores indicate worse CVH. Multivariable linear regression was performed to evaluate the association of inadequate HL with early pregnancy modified LE8 score.

Results: Of the 4,424 participants who completed the REALM-SF, 825 (18.6%) had REALM-SF scores representative of inadequate HL. People with adequate HL were older, less likely to identify as non-Hispanic Black or Hispanic, had higher incomes and education, and were less likely to have public insurance. Participants with adequate HL had higher early pregnancy LE8 scores [79.0 ± 13.3 vs. 73.0 ± 14.2, p< 0.001; mean difference 7.1 (95% CI 5.2-8.8)] compared to participants with inadequate HL. This association persisted after adjustment for age, insurance type, and family income (aβ 3.8, 95% CI 2.2-5.5). The overall association between adequate HL and better CVH was driven by the glucose, diet, physical activity, and sleep subcomponents of the LE8 (Table).

Conclusion: Adequate HL was associated with better CVH scores in early pregnancy. These findings highlight the importance of optimizing HL prior to pregnancy which might promote CVH in the peripartum period.

Table. Association of health literacy with cardiovascular health in early pregnancy

CVH[1]	Adequate HL[2] Mean difference (95% CI)	Adequate HL[3] Adjusted β (95% CI)
Overall LE8	**7.04 (5.23, 8.84)**	**3.83 (2.17, 5.50)**
Blood Pressure	0.19 (-1.87, 2.26)	0.080 (-0.62, 0.78)
Lipid	-1.53 (-3.90, 0.84)	0.79 (-1.48, 3.06)
Glucose	1.02 (-1.94, 3.98)	**2.48 (0.23, 4.73)**
Body mass index	**5.41 (2.30, 8.52)**	**3.49 (1.51, 5.47)**
Diet	**14.6 (8.42, 20.8)**	**5.36 (2.64, 8.08)**
Physical Activity	**16.1 (8.05, 24.2)**	**7.76 (2.76, 12.8)**
Nicotine Exposure	3.06 (-5.66, 11.8)	0.79 (-6.94, 8.52)
Sleep Health	**7.02 (5.91, 8.12)**	**3.12 (0.92, 5.32)**

1. Cardiovascular health (CVH) measured by American Heart Association Life's Essential 8 (LE8) score with subcomponents including blood pressure, lipids, glucose, BMI, diet, physical activity, nicotine exposure, and sleep health
2. Data presented as mean difference (95% confidence interval) in overall LE8 score and subcomponents of LE8 score between participants with inadequate health literacy (HL, reference point) and adequate HL in early pregnancy
3. Multivariable linear regression models were adjusted for maternal age, insurance type, and family income.

1145 | Association Between Health Literacy and Cardiovascular Health at 2-7 Years After First Birth

Onyinye Ohamadike[1]; Xiaoning Huang[2]; Sadiya S. Khan[1]; William A. Grobman[3]; Philip Greenland[4]; David M. Haas[5]; Uma M. Reddy[6]; Lynn M. Yee[1]
[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Northwestern University, Chicago, IL; [3]The Ohio State University, Columbus, OH; [4]Northwestern, Northwestern/Chicago, IL; [5]Indiana University School of Medicine, Indianapolis, IN; [6]Columbia University, New York, NY

4:00 PM - 6:00 PM

Objective: Inadequate health literacy (HL) is associated with worse cardiovascular health (CVH) in non-pregnant individuals and, among pregnant individuals, adverse pregnancy outcomes (APO). We aimed to study the association between HL in early pregnancy and CVH at 2-7 years after first birth.

Study Design: In this secondary analysis of longitudinal data from a large, multi-site cohort of nulliparous people enrolled in a prospective observational study at 8 US medical centers, we included participants who completed an assessment of HL. HL, assessed using the Rapid Estimate of Adult Literacy in Medicine-Short Form (REALM-SF), was categorized as inadequate if the REALM-SF score was < 7 and adequate if score 7 or greater. The primary outcome was CVH, quantified by the American Heart Association's Life's Essential 8 (LE8) score, a validated marker of CVH in which lower scores indicate worse CVH. Multivariable linear regression models were performed to evaluate the association of inadequate HL in early pregnancy (6-13 weeks of gestation) with LE8 score at 2-7 years after first birth.

Results: Of the 4,424 participants who completed the REALM-SF in early pregnancy and had 2-7 year follow-up data, 825 (18.6%) had REALM-SF scores representative of inadequate HL. People with adequate HL were older, less likely to identify as non-Hispanic Black or Hispanic, had higher incomes and education, and were less likely to have public insurance. Participants with adequate HL in early pregnancy had higher postpartum LE8 scores [80.5 ± 13.3 vs. 73.2 ± 13.8, p< 0.001; mean difference 7.3 (95% CI, 3.5-11.1)] compared to those with inadequate HL. When adjusted for age, insurance type, and family income, this relationship persisted (aβ 3.3, 95% CI 0.4-6.2). Findings were driven by higher scores for the body mass index, diet, physical activity, nicotine exposure, and sleep subcomponents of the LE8 (Table).

Conclusion: Adequate HL in early pregnancy is associated with better CVH scores at 2-7 years after first birth, suggesting interventions to optimize maternal HL should be evaluated as a strategy for long-term CVH promotion.

Table. Association of health literacy in early pregnancy with cardiovascular health at 2-7 years after first birth

CVH[1]	Adequate HL[2] Mean difference (95% CI)	Adequate HL[3] Adjusted β (95% CI)
Overall LE8	**7.28 (3.46, 11.1)**	**3.29 (0.44, 6.15)**
Blood Pressure	2.18 (-1.30, 5.67)	1.58 (-2.02, 5.18)

1146 | Association of Aspirin Use and Preeclampsia in Pregnancy after Kidney Transplant

Ophelia Yin[1]; Lisa Coscia[2]; Serban Constantinescu[3]; Michael Moritz[2]; Roxanna Irani[1]
[1]Division of Maternal Fetal Medicine and Reproductive Genetics, Department of Obstetrics, Gynecology, and Reproductive Sciences, University of California San Francisco, San Francisco, CA; [2]Transplant Pregnancy Registry International, Gift of Life Institute, Philadelphia, PA; [3]Section of Nephrology, Hypertension, and Kidney Transplantation, Department of Medicine, Lewis Katz School of Medicine, Temple University, Philadelphia, PA

4:00 PM - 6:00 PM

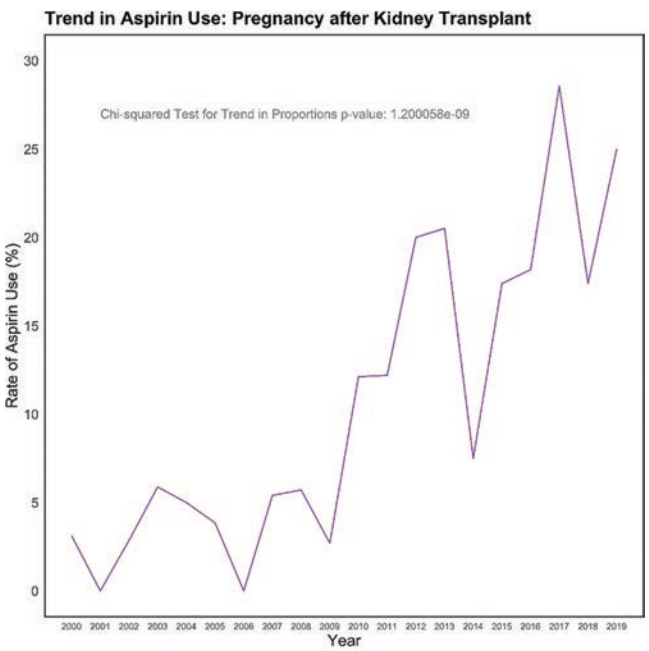
Objective: We aim to characterize trends in aspirin use in the kidney transplant population and the associations of aspirin use with preeclampsia, obstetric outcomes, and graft function.

Study Design: We conducted a retrospective cohort study using the Transplant Pregnancy Registry International of pregnancies after kidney transplant reaching 20 weeks gestation with year of conception from 2000 onwards. The primary outcome was preeclampsia with delivery at < 37 weeks. Univariate and multivariable logistic regression was performed in R.

Results: Our analysis included 708 pregnancies after kidney transplant resulting in 723 livebirths. Of the 708 pregnancies, 74 (10.5%) reported aspirin use and 634 (89.5%) reported no aspirin use in pregnancy. There was a significant increase in aspirin use over time, from 3.1% in 2000 to 25.0% in 2019, p< 0.001 (Figure 1). Aspirin use was associated with higher body mass index (BMI) (27 vs 25 kg/m^2), later year of conception (2014 vs 2009), and living unrelated kidney donor (32.4% vs 15.7%), all p< 0.01. After adjustment for chronic hypertension, year, diabetes,

pre-pregnancy creatinine, multiple gestation, donor type, and BMI, preeclampsia with delivery < 37 weeks occurred in 20 (27.0%) of aspirin use and 135 (21.3%) of no aspirin use pregnancies, (aOR 1.22, 95% CI 0.64 to 2.24, p = 0.5). Aspirin use was associated with postpartum hemorrhage (6.8% vs 2.2%, p = 0.04) but not blood transfusion (5.4% vs 1.7%, p = 0.06) and aspirin use was associated with reduced rates of small for gestational age neonates (9.1% vs 19.8%, p = 0.02). Aspirin use was not associated with any adverse graft outcomes including creatinine changes in pregnancy, acute graft rejection, or graft loss 2 years from time of delivery.

Conclusion: In kidney transplant recipients who reported aspirin use in pregnancy, there was no difference in rates of preeclampsia with preterm delivery. The lack of association could be due to variation in dosage, timing of use, and indication. The increased rates of postpartum hemorrhage and reduction in rates of small for gestational age babies warrants future prospective investigation.



Aspirin Use in Pregnancy after Kidney Transplant			
Maternal and Graft Variables	**No Aspirin (N=634)**	**Aspirin (N=74)**	**p value**
Age (years)	31.6	32.3	0.21

1147 | Transcriptional Meta-Analysis of Preeclampsia Compared to Placenta Accreta: Implications for Placentation

Ophelia Yin[1]; Laura Almonte[2]; Romina Appierdo[3]; Monica Yang[4]; Tomiko Oskotsky[5]; Yalda Afshar[6]; Marina Sirota[5]

[1]Division of Maternal Fetal Medicine and Reproductive Genetics, Department of Obstetrics, Gynecology, and Reproductive Sciences, University of California San Francisco, San Francisco, CA; [2]Bakar Computational Health Sciences Institute, University of California (UCSF), San Francisco, San Francisco, CA; [3]Program in Cellular and Molecular Biology, Department of Biology, University of Rome "Tor Vergata", San Francisco, CA; [4]Division of Rheumatology, Department of Medicine, University of California (UCSF), San Francisco, CA; [5]Bakar Computational Health Sciences Institute, University of California (UCSF), San Francisco, CA; [6]University of California, Los Angeles, Los Angeles, CA

4:00 PM - 6:00 PM

Objective: To compare the transcriptomic signature of early onset preeclampsia with placenta accreta to gain insight into genes and pathways relevant to placentation at the maternal-fetal interface.

Study Design: The Gene Expression Omnibus (GEO) was queried for preeclampsia and placenta accreta transcriptional datasets derived from human placental tissue from 2010 onwards. Microarray analysis was conducted in R and performed with *crossmeta* or *oligo* and batch corrected with *ComBat.* Differential gene expression using *Limma* was adjusted for cell type. Processing of single cell data was performed using *Seurat* with *MAST*. Gene hyper enrichment, correlation testing, and gene set enrichment analysis with *clusterprofiler* was performed for pathway analysis.

Results: We performed a gene expression meta-analysis of placental samples from 86 patients with early onset preeclampsia and 65 preterm controls from 4 publicly available microarray datasets. This preeclampsia gene signature was compared to 1 placenta accreta microarray with 6 accreta and 3 preterm controls and 1 placenta accreta single-cell dataset with 3 accreta and 3 controls. Comparing the 4,903 differentially expressed genes in the early onset preeclampsia meta-analysis to 416 differentially expressed genes in placenta accreta microarray, we found 120 overlapping genes with significant negative correlation in expression (r = -0.39, p = 8.06e-6). Key genes included *ANKRD37, AOX1, CP, GBP3, IFIT1, IGFBP6, NEK11, OPRK1,* and *SERPINA3* (Figure 1). Comparing to single-cell placenta accreta, we found that preeclampsia genes were enriched in all cell types and negatively correlated for decidua type, endothelial, and extravillous trophoblasts (Table 1). Shared pathways included hypoxia, glycolysis, oxidative phosphorylation, and early estrogen response.

Conclusion: We identified early onset preeclampsia genes that are oppositely regulated in placenta accreta, both in bulk tissue and in specific cell types at the maternal-fetal interface. We hypothesize that these candidate genes underly the biology of placental attachment and spiral artery remodeling for both disorders.

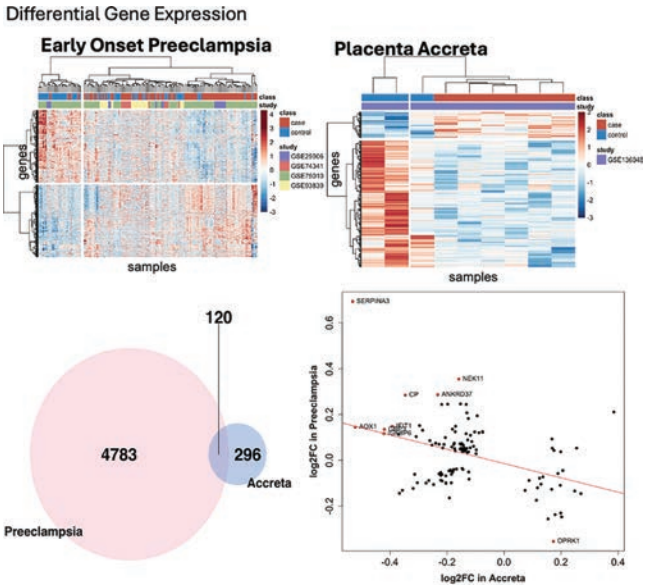

Table 1: Comparison of Early Onset Preeclampsia (Microarray) and Single-Cell Placenta Accreta

Placenta Cell Type	# Accreta Differentially Expressed Genes	# Overlap Genes with Early Onset Preeclampsia	Hyper enrichment p-value	Correlation coefficient *r*	Correlation p-value

1148 | Nomogram for Predicting Obstetric Anal Sphincter Injuries in Nulliparous Women

Or Bercovich[1]; Daniela Chen[2]; Ohad Houri[1]
[1]Rabin Medical Center, Petach Tikva, HaMerkaz; [2]Helen Schneider Hospital for Women, Rabin Medical Center, Petach-Tikva, Tel Aviv, HaMerkaz

4:00 PM - 6:00 PM

Objective: To develop a predictive model for obstetric anal sphincter injuries (OASIS) in nulliparous women.

Study Design: This retrospective observational study analyzed data from a tertiary care center. Inclusion criteria encompassed all singleton deliveries at ≥ 37 gestational weeks from January 2007 to December 2019, involving nulliparous women. The primary outcome was the occurrence of OASIS. The full multivariate logistic regression included variables such as age, body mass index (BMI), mode of delivery (MOD) (vaginal or vacuum-assisted), use of oxytocin, spontaneous or induced labor, birth weight, neuraxial analgesia, and episiotomy. The stepwise model, selected based on the Akaike Information Criterion, retained the variables BMI, MOD, induction, and birth weight. A nomogram was then developed using the best-fitting model to visually represent the predicted probability of OASIS. The nomogram was calibrated and validated internally to ensure accuracy and reliability.

Results: The study cohort comprised 22,738 deliveries: 17,518 vaginal deliveries (77%) and 5,220 vacuum-assisted deliveries (23%). Overall, 221 cases (1%) were diagnosed with OASIS. The variables significantly associated with the primary outcome in the multivariate model were BMI ($p = 0.034$), MOD ($p < 0.001$), induction of labor ($p = 0.010$), and birth weight ($p < 0.001$). Their respective predicted probabilities are represented in the nomogram (Figure 1).

Conclusion: The developed nomogram allows for the calculation of individual risk scores for OASIS, identifying patients with a very high risk for OASIS (above 10%) versus those with low risk (less than 1%).

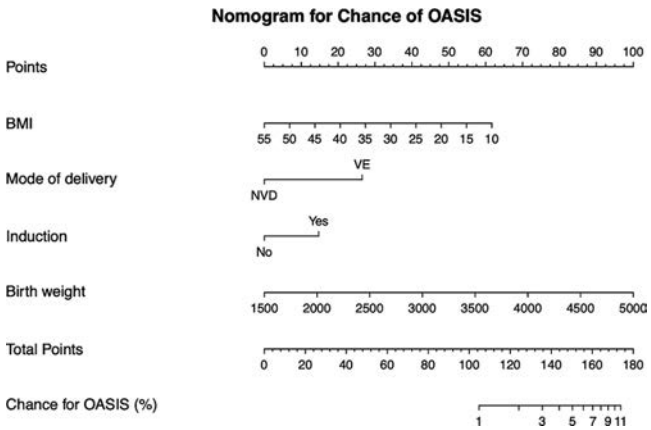

Table 1. Patient Characteristics

Variable	No OASIS, N = 22,517[1]	OASIS, N = 221[1]	p-value[2]

1149 | Intra-Operative Clinical 2019 FIGO Classification has High Correlation with Histologic PASD in a High-Risk Population

Oxana M. Zarudskaya[1]; Caitlin E. Martin[1]; Georgia A. McCann[1]; Kayla E. Ireland[1]; Alixandria F. Pfeiffer[2]; Patrick S. Ramsey[3]
[1]University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]University of Texas Health Science Center at San Antonio, San Antonio, TX; [3]University of Texas Health Science Center San Antonio, San Antonio, TX

4:00 PM - 6:00 PM

Objective: Accurate confirmation of intra-operative diagnosis of placenta accreta spectrum disorder (PASD) is essential for proper use of resources, use or withhold uterine artery embolization, transfusion strategy, anesthesia care and post operative management. To date there is limited data to suggest how clinical findings

correlate to microscopic or histologic diagnosis, when universal clinical FIGO staging is used intra-operatively.

Study Design: We conducted a retrospective review of all patients evaluated and delivered in our center with suspected PASD between January 2022 and July 2024. At our institution we implemented a universal reporting protocol for macroscopic PASD findings during cases with suspected PASD.

Results: During the study interval, 56 cases of PASD were delivered at our center. Of these cases, 50 had FIGO staging documentation of macroscopic PASD findings intra-operatively and were included in analysis. Clinical staging was done by the operative members of our PASD team. Histologic findings were uniformly documented by a designated pathologist. Coefficients of correlation were assessed between the clinical grade and the histologic grade. There was a very strong coefficient of correlation between clinical and histologic FIGO grading in cases with suspected PASD–0.96. This correlation was even stronger when analyzed grouped cased with accreta/increta/percreta 3A versus PASD cases with severe invasion (percreta 3B and 3C)–0.99.

Conclusion: Our data demonstrated a very strong correlation between clinical and histologic/microscopic FIGO grading when used in cases with suspected PASD.

	Clinical grading based on FIGO 2019	Histologic grading based on FIGO 2019	Correlation coefficient CC/ Determination Coefficient R^2/p-value
Grade 1 (accreta)	5 (10%)	4 (8%)	CC = 0.96
Grade 2 (increta)	6 (12%)	3 (6%)	R^2=0.92
Grade 3 A (percreta abounding serosa)	21 (42%)	30 (60%)	p<0.00001
Grade 3B (percreta with bladder involvement)	2 (4%)	2 (4%)	
Grade 3C (percreta with pelvic organs involvement)	3 (6%)	1 (2%)	
No PASD	13 (26%)	10 (20%)	

1150 | What type of Anesthesia Causes Worse Maternal Outcomes in Patients with Hypertensive Disorders of Pregnancy?

Patricia Rojas Mendez[1]; Rachael Sampson[1]; Jordan A. Gillenwater[1]; Marcia Des Jardin[2]; Nicholas Baranco[1]; Robert Silverman[1]

[1]SUNY Upstate Medical University, Syracuse, NY; [2]University of Alabama at Birmingham, Birmingham, AL

4:00 PM - 6:00 PM

Objective: Hypertensive disorders of pregnancy (HDP) are a leading cause of adverse obstetrical and neonatal outcomes. No optimal anesthesia strategy is established for pregnancies affected by HDP. The study objective is to compute the association between type of anesthesia and maternal and short-term neonatal adverse outcomes among patients with HDP undergoing cesarean delivery (CD).

Study Design: Secondary analysis was performed on a cohort of 736 patients who underwent CD at our institution from 2022-2023. HDP was stratified into five groups: chronic hypertension (HTN), gestational HTN, preeclampsia without severe features (SF), preeclampsia with SF (including HELLP and eclampsia), and superimposed preeclampsia. The primary outcome was a composite of maternal morbidity (CMM) (postoperative (PO) fever, PO antibiotics, blood transfusion, intensive care unit (ICU) admission, reoperation, readmission and death) in patients undergoing general vs. neuraxial anesthesia for CD. Secondary outcomes were Apgars < 7 and neonatal ICU admission. Multivariate logistic regression was performed. Adjusted odds ratios (aOR) with 95% confidence intervals (CI) for primary and secondary outcomes were calculated after controlling for potential confounders.

Results: In the cohort, 546 patients (74%) had HDP and were included in the analyses. Of these, 14% received general anesthesia and 86% received neuraxial anesthesia. Demographic characteristics and other preoperative risk factors were similar in both groups (Table 1). After adjusted analysis, general anesthesia was associated with higher rates of CMM when compared to neuraxial anesthesia among all groups (aOR 3.96, 95% CI 1.54, 10.22). The association was maintained after controlling for urgency, gestational age and delivery indication. We found no association between the type of anesthesia and 5-minute Apgar < 7 or neonatal ICU admission (Table 2).

Conclusion: Among patients with HDP undergoing CD, general anesthesia is associated with higher rates of adverse maternal outcomes even after controlling for urgency and delivery indication.

Table 1. Baseline Characteristics

	Neuraxial Anesthesia	General Anesthesia
Age (years)	31.3 (5.8)	30.3 (5.7)
BMI (kg/m^2)	37.9 (8.2)	39.2 (10.9)

1151 | Does an Early Isolated Increase in Fetal Abdominal Circumference Heighten the Risk of Macrosomia?

Patrick S. Kim[1]; David J. Rivera Vazquez[1]; Tiffany A. Lowtan[1]; Kelsey M. Pozerski[1]; Krista Howard[2]; Bradley H. Sipe[3]; Rachelle Schwartz[3]
[1]Orlando Health Bayfront Hospital, St. Petersburg, FL; [2]Texas State University, San Marcos, TX; [3]Johns Hopkins All Children's Hospital, St. Petersburg, FL

4:00 PM - 6:00 PM

Objective: To determine if an isolated second trimester fetal abdominal circumference (AC) >90th %tile is an independent risk factor for large for gestational age (LGA) neonates and macrosomia.

Study Design: This multi-center retrospective cohort study analyzed patients who delivered term singletons between 1/1/2019-1/1/2024. The exposed group involved normally grown fetuses with isolated AC's >90th %tile, measured between 18 and 24 weeks gestation. Control subjects were matched in a 1:1 ratio from the same period. Congenital anomalies were excluded. Statistical analyses included independent t-tests for continuous variables, chi-squared tests for categorical variables, and binary logistic regression models for LGA and macrosomia.

Results: Of the 1,188 patients screened, 752 met inclusion criteria (n = 376 per cohort). Mean AC in the AC >90 group was 94%tile compared to 51%tile in controls. Birthweights were higher in the AC >90 group (3,629g vs. 3,257g, p< 0.001). Rates of LGA (29.5% vs. 6.6%, p< 0.001) and macrosomia (15.2% vs. 2.9%, p< 0.001) were higher in the AC >90 group. AC >90%tile was an independent risk factor for both LGA (AOR 7.05 [3.43, 14.52]) and macrosomia (AOR 4.51 [2.78, 7.32]). Additional logistic regressions are shown in Table 1. Higher maternal BMI increased the risk of LGA and macrosomia. There were no differences in parity, pregestational or gestational diabetes, or mode of delivery between cohorts. Gestational hypertension was more prevalent in the AC >90 group (13.8% vs. 9.0%, p = 0.039), whereas chronic hypertension was more prevalent among controls (13.3% vs. 7.2%, p = 0.006). A sub-analysis of macrosomic infants is shown in Table 2. Macrosomic infants in the AC >90 group trended toward higher rates of lacerations (72.7% vs. 33.3%) and shoulder dystocia (9.1% vs. 0%), although overall incidence was low.

Conclusion: An isolated second trimester AC >90th %tile in an otherwise normally grown fetus is an independent risk factor for both LGA and macrosomia. An isolated increase in AC may also be a risk factor for lacerations and shoulder dystocia at birth, but further research is required.

1152 | Mode of Delivery and Neonatal Survival Among Periviable Vertex Singleton Pregnancies

Peeraya S. Sawangkum[1]; Jason L. Salemi[1]; Jean Paul P. Tanner[1]; Alexia Eiges[2]; Anjali J. Kaimal[3]
[1]Department of Obstetrics and Gynecology, University of South Florida, Tampa, FL; [2]Department of Obstetrics and Gynecology, University of South Florida, Nashville, TN; [3]University of South Florida, Tampa, FL

4:00 PM - 6:00 PM

Objective: To determine the association between mode of delivery and neonatal survival for periviable, vertex, singleton gestations.

Study Design: Retrospective cohort study using a maternal-infant linked database of live births in Florida from 2006 to 2019. Vertex, singleton deliveries of infants born at 22w0d to 25w6d with attempted neonatal resuscitation were included. We calculated risk ratios (RRs) for binary outcomes and hazard ratios (HRs) for time-to-event outcomes that were adjusted for confounders. Outcomes were examined overall and stratified by week of gestation. A planned sensitivity analysis was performed examining outcomes in neonates who survived beyond 24 hours of life.

Results: A total of 4,820 periviable deliveries were identified. Of those, 2,472 (51.3%) were cesarean deliveries. People who underwent cesarean delivery were more likely to have hypertension and diabetes. In the overall model, vaginal delivery was associated with a higher risk of mortality at 24 hours (aRR 1.20, 95% CI 1.01-1.44), lower risk of mortality at 7 days (aRR 0.88, 95% CI 0.79-0.99), but no difference in mortality at 28 days (aRR 0.94, 95% CI 0.86-1.02) or 1 year (aRR 0.95, 95% CI 0.89-1.03). After excluding neonates who died within the first 24 hours, vaginal delivery was associated with lower risk of mortality, with aRR of 0.70 (95% CI

0.59-0.83) at 7 days, aRR of 0.87 (95% CI 0.77-0.97) at 28 days, and aRR of 0.91 (95% CI 0.83-1.00) at 1 year. Stratified analyses by gestational age demonstrated increased mortality with vaginal delivery among 22w- and 23w-neonates (aHR 1.48, 95% CI 1.06-2.06 and aHR 1.19, 95% CI 1.01-1.43 respectively), but decreased mortality with vaginal delivery among 24w- and 25w-neonates (aHR 0.75, 95% CI 0.63-0.89 and aHR of 0.72, 95% CI 0.58-0.90 respectively).

Conclusion: Our study demonstrates the effect of mode of delivery on neonatal survival in the periviable period is dependent upon gestational age. Further study is needed to understand the clinical situations in which cesarean is most likely to improve neonatal outcome in order to balance this against potential maternal complications.

Table 2. Neonatal Outcomes Among Singleton Neonates Born 22w0d to 25w6d, by Method of Delivery

Neonatal Outcomes	Method of Delivery: Cesarean Delivery N = 2,472[1]	Vaginal Delivery N = 2,348[1]	Adjusted Risk Ratio (95% CI)[2]	Adjusted Risk Difference % (95% CI)[2]
Died within the 1st 24 hours	158 (6.4%)	287 (12.2%)	1.20 (1.01, 1.44)	1.7 (0.1, 3.3)

1153 | Fetal Fraction in Patients with Autoimmune Diseases of the Gastrointestinal Tract

Chi Nguyen[1]; Nicole Legro[1]; Sara N. Iqbal[1]; Taylor Martin[2]; Bailey Liter[2]; Allison Willett[2]; Victoria R. Greenberg[3]
[1]Medstar Washington Hospital Center / Georgetown, Washington, DC; [2]Georgetown School of Medicine, Washington, DC; [3]Medstar Washington Hospital Center /Georgetown, Washington, DC

4:00 PM - 6:00 PM

Objective: We sought to evaluate differences in fetal fraction (FF) in individuals with autoimmune diseases of the gastrointestinal (GI) tract compared to those without autoimmune disease. Additionally, we assessed whether use of immunomodulating medications (IM) at time of cell-free DNA (cfDNA) screening has any effect on FF for patients with autoimmune diseases of the GI tract

Study Design: We performed a retrospective cohort study of singleton pregnancies who had cfDNA testing 2017-2024. Patients without autoimmune disease served as controls and were matched to patients with GI autoimmune diseases (ulcerative colitis and Crohn's) during pregnancy in a 3:1 fashion, controlling for gestational age and BMI. Exclusion criteria included those on anticoagulants, history of organ transplant, and/or high-risk cfDNA results concerning for aneuploidy. IM therapy included mesalamine, infliximab, vedolizumab, and adalimumab. We used the student t-test for normally distributed variables, chi-square and Fisher's exact tests for categorical variables and ANOVA to compare three groups. Multivariate regression analysis was performed to evaluate the effect of immunomodulator use on fetal fraction, after adjusting for BMI and gestational age at the time of cfDNA draw.

Results: We included 300 patients in the study (75 with GI autoimmune disease and 225 without disease). Baseline demographics between the two groups were similar with respect to BMI, race, and smoking status (Table 1) with a statistically significant difference in age. Mean fetal fractions were similar in those with and without disease (Table 1). In the subset of individuals with GI autoimmune disease, use of IM medication did not result in higher fetal fraction compared to individuals with GI autoimmune disease not on IM medication, even after adjusting for gestational age and BMI (aβ .072, 95%CI -1.2, 2.3)

Conclusion: Contrary to other reports, this study found no effect of GI autoimmune disease on FF, even when adjusting for IM use. Further research is needed to assess the impact of various autoimmune diseases on FF.

1154 | Novel uEMG Technology Significantly Improves Preterm Birth Prediction: The Labor Status Monitor

Ponnila S. Marinescu[1]; Neil S. Seligman[1]; Jennifer B. Gilner[2]; Sarah Caveglia[1]; Win Phyo[1]; Hayden Rigsbee[2]; Roger C. Young[3]
[1]University of Rochester Medical Center, Rochester, NY; [2]Duke University Hospital, Durham, NC; [3]PreTeL, Inc., Portland, OR

4:00 PM - 6:00 PM

Objective: Using current methods, sensitivity for predicting preterm birth (PTB) in patients presenting with contractions before 37 weeks GA is < 50%. While not all contractions contribute towards labor, legacy toco cannot distinguish those who will deliver preterm. We developed a novel Labor Status Monitor that uses uterine bioelectrical synchronization and between-contraction, tissue-level stimulation to predict PTB < 7 days.

Study Design: Multicenter, prospective cohort study of pregnant individuals between 26-36 weeks GA, with a cervix £ 5 cm and self-reporting ³ 1 contraction in 10 minutes (min). 6-channel

uEMG recordings were obtained using PreTeL's directional uEMG sensors applied to the abdomen for up to 4 hours (hr). uEMG data were classified on a channel-by-channel basis as rest, contraction-associated signals (CAS), or fasciculation-like signals (FLS, tissue-level stimulation between contractions). Contraction Synchronization Index (CSI) was calculated as CAS in $\geq$ 5 channels observed over the previous 10-min, averaged over 60 min. FLS index (FLSi) was calculated as the fraction of time FLS occurred in each channel over the previous 10-min, averaged over all 6 channels, and then averaged over 1 hr. Primary outcome was delivery < 7 days of uEMG recording. Sensitivity and specificity were analyzed from receiver operator characteristic curves.

Results: 43 subjects were evaluated; 63% (27/43) delivered < 37 weeks GA, 34% (15/43) delivered < 7 days. AUC was 0.74 for CSI and 0.66 for FLSi for delivery < 7 days. Based on AUC, optimal sensitivities and specificities were 74% and 70% for CSI and 56% and 70% for FLSi. Assuming test independence, by applying CSI first, then applying FLSi to indeterminate results, sensitivity and specificity were 89% and 91% for delivery < 7 days.

Conclusion: Our analysis of the Labor Status Monitor suggests that uEMG significantly improves PTB prediction compared to current methods. Ability to predict PTB < 7 days has the potential to meaningfully impact management, particularly administration of antenatal corticosteroids. Further studies are needed to validate these findings.

1155 | Identifying Markers for Gestational Diabetes Using Continuous Glucose Monitoring

Pranaya Chilukuri; Lindsay Beechem; Aric Schadler; Abigail Leonhard; Josie Llanora; Kristina Naseman; Karen Playforth
University of Kentucky, Lexington, KY

4:00 PM - 6:00 PM

Objective: Per ACOG, all pregnant women should be screened for gestational diabetes (GDM) with an oral glucose tolerance test (OGTT). As continuous glucose monitor (CGM) use increases, CGM goals "target range" and "time in range" have been set for diabetes in pregnancy. This study aims to identify CGM metrics that may be linked to GDM diagnosis in patients considered at high risk.

Study Design: This single-institution pilot prospective observational study includes pregnant individuals at 24-28 weeks' with singleton gestation and 1-hour OGTT of 140-200mg/dl, without previous Type 1 or 2 Diabetes, PCOS, or recent metformin, insulin, or corticosteroid administration. Upon IRB approval, participants were screened through electronic medical records and recruited to wear Dexcom G6 CGM in blinded mode for 7-10 days. Patients completed a 3-hour OGTT, determining GDM diagnosis. Pearson's chi-square, independent samples t-test, and Mann-Whitney U tests were used as appropriate for analysis.

Results: CGM was worn by 22 participants, with 7 subsequently diagnosed with GDM. Metrics of CGM average glucose (124 vs. 111, p = 0.011), time in range (82% vs. 90%, p = 0.047), time above range (17% vs. 7%, p = 0.021), and glucose management indicator (GMI), analogous to HbA1c, (6.3 vs. 6.0, p = 0.009) significantly differed for those diagnosed with and without GDM, respectively (Table 1). Significant differences have not resulted in birth outcomes yet, with recruitment ongoing.

Conclusion: This study highlights CGM metrics that may be used as potential markers for patients at risk for GDM.

1156 | Interpregnancy Development of Chronic Hypertension after a Hypertensive Disorder of Pregnancy and Subsequent Pregnancy Outcomes

Praveen Ramesh[1]; Malamo Countouris[2]; Arun Jeyabalan[3]; Alisse Hauspurg[4]
[1]Magee-Women's Hospital of UPMC, Pittsburgh, PA; [2]University of Pittsburgh Medical Center, Pittsburgh, PA; [3]University of Pittsburgh School of Medicine, Pittsburgh, PA; [4]Alpert Medical School of Brown University, Providence, RI

4:00 PM - 6:00 PM

Objective: Hypertensive disorders of pregnancy (HDP) are associated with future cardiovascular (CV) risk, likely mediated through development of chronic hypertension (CHTN). We sought to assess if development of interpregnancy CHTN following a pregnancy complicated by an HDP was associated with adverse outcomes in the subsequent pregnancy.

Study Design: This is a cohort study of individuals with consecutive pregnancies with an index pregnancy complicated by an HDP. We compared demographics and outcomes in the subsequent pregnancy between those who developed interpregnancy CHTN with those who had blood pressure (BP) normalization. We included patients with a known diagnosis of CHTN and those who had 2 or more BPs $\geq$ 140/90 mmHg prior to 20 weeks. The primary outcome was preterm birth < 37 weeks (PTB). Secondary outcomes included a small-for-gestational age (SGA) newborn and recurrent pre-eclampsia. The association of all outcomes with interpregnancy CHTN was adjusted for age, BMI, and maternal self-identified race (as a social construct) via multivariable logistic regression.

Results: We included 4,437 individuals with an HDP during the index pregnancy. 523 (11.8%) developed interpregnancy CHTN. Individuals who developed interpregnancy CHTN were older, more likely to identify as Black race, had a higher index pregnancy BMI, and were more likely to have had preeclampsia with severe features in the index pregnancy compared to those with BP normalization (Table 1). Those who developed interpregnancy HTN were more likely to have a preterm birth, (19.5% vs.11%; aOR 2.25; 95% CI 1.66-3.04, p< 0.001), an SGA newborn (14.2% vs. 8.3%; aOR 2.48; 95% CI 1.76-3.48, p< 0.001) and develop recurrent pre-eclampsia (22.2% vs.12.6; aOR 2.27; 95% CI 1.70-3.04, p< 0.001) in the subsequent pregnancy compared to those with BP normalization.

Conclusion: Individuals with interpregnancy development of CHTN after an HDP have an increased odds of adverse pregnancy outcomes compared to those with BP normalization. Postpartum interventions to reduce the risk of interpregnancy CHTN may improve long-term CV health and future pregnancy outcomes.

Table 1. Characteristics of index and subsequent pregnancy by development of interpregnancy chronic hypertension (CHTN) after a hypertensive disorder of pregnancy

1157 | Prenatal Detection of Structural Heart Defects in Pre-Gestational Diabetes with Expanded Cardiac Screening

Rachel L. Wiley[1]; Maya Pai[2]; Tracy Anton[3]; Maryam Tarsa[4]
[1]University of California, San Diego, San Diego, CA; [2]UC San Diego School of Medicine, UC San Diego School of Medicine, CA; [3]UC San Diego, UC San Diego, CA; [4]University of California San Diego, San Diego, CA

4:00 PM - 6:00 PM

Objective: Pregnancies affected by pre-gestational diabetes mellitus (PDM) are recommended to have a fetal echocardiogram (ECHO). In an institution with expanded cardiac screening on level II ultrasounds, we aimed to examine detection of congenital heart disease (CHD) in pregnancies affected by PDM with selective referrals for fetal ECHOs.

Study Design: This was a retrospective cohort of pregnancies who received level II ultrasounds in a two-year period. Ultrasounds were performed by experienced MFM sonographers competent in image optimization techniques to visualize the fetal heart, including utilizing system settings that maximize frame rate and applying color Doppler. Standard and extended views of the heart were obtained and recorded using still frame and cine clips (Table 1). Patients were included if they had a diagnosis of prediabetes, type I, or type diabetes mellitus. Demographics were collected, and neonatal charts were reviewed for CHD. Groups were analyzed using one-way ANOVA, student's t-test, chi-squared or fisher exact test.

Results: 306 pregnancies complicated by PDM were included; 66% with type 2 diabetes mellitus, 19% with type I diabetes mellitus and 15% with prediabetes (Table 1). Of these, 64 (21%) had a fetal ECHO, with the indications of suboptimal cardiac views on level II ultrasound (n = 22, 34%), suspected anomaly (n = 20, 31%), other maternal indication (n = 13, 20%) and high initial A1C (n = 9, 14%). In total, 28 (7.8%) neonates had confirmed postnatal diagnosis of CHD, and 16 (57%) of the defects were diagnosed prenatally. CHD detected prenatally had higher A1C (8.1% vs 6.5%, P = 0.016), but no significant difference in maternal BMI (33.2 kg/m^2 vs 32.5 kg/m^2, p = 0.74). Of the 12 CHD that were diagnosed only postnatally, there were minor defects (small septal defects, bicuspid aortic valve), but no major cardiac defects.

Conclusion: In a tertiary center with expanded cardiac level II ultrasound protocols and selective ECHOs, all major CHD in PDM was detected prenatally. Protocols for selective fetal ECHOs in pregnancies affected by PDM may be considered in experienced tertiary centers.

Table 1. Characteristics of included pregnancies.

1158 | Methods of Estimating Blood Loss and Clinical Outcomes

Rachel L. Wiley[1]; Ipsita Ghose[2]; Hector M. Mendez-Figueroa[3]; Suneet P. Chauhan[4]
[1]University of California, San Diego, San Diego, CA; [2]Baylor College of Medicine, Houston, TX; [3]McGovern Medical School at UTHealth, Houston, TX; [4]Delaware Center of Maternal-Fetal Medicine at Christiana Care, Delaware, DE

4:00 PM - 6:00 PM

Objective: ACOG released a Committee Opinion stating quantitative blood loss (QBL) was more accurate than visually estimated blood loss (EBL), however the clinical impact of QBL remains uncertain.

Study Design: This was a secondary analysis of a retrospective cohort study of all singletons delivered at $\geq$ 20 weeks at a Level IV center during 24 months. This time period included an institutional transition from EBL to QBL, and patients with both methods of estimation recorded were included. Composite maternal adverse outcome included additional surgical techniques, transfusion of $\geq$ 4 units, balloon tamponade, intensive

care unit (ICU) admission, venous thromboembolism (VTE), hysterectomy or death. The diagnostic accuracy of CMAO for EBL and QBL were assessed by using the area under the curve (AUC) of receiver-operating characteristics (ROC) curves, and diagnostic test statistics were calculated and compared using overlapping confidence intervals.

Results: Of 8,623 deliveries, 1,530 (18%) had both EBL and QBL recorded; the demographics are included in Table 1. QBL identified more postpartum hemorrhages (PPH; blood loss ≥ 1000 mL) than EBL (9.0% vs. 6.0%; p< 0.01). CAMO occurred in 42 (3.0%) of patients, and Figure 1 shows the ROC curve for detecting CAMO with a nonsignificant difference in AUC of 0.91 for EBL and 0.86 for QBL (p = 0.07). Using the threshold for PPH of ≥ 1000 mL, EBL and QBL were equally sensitive, but EBL was more specific (95.8%; 95% CI 94.6% - 96.7% vs 92.6%; 95% CI 91.1% - 93.9%, Figure 1). While positive and negative predictive power and likelihood ratio did not differ significantly, negative predictive power and likelihood ratio performed better with EBL.

Conclusion: While QBL and EBL are both predictive for maternal morbidity, estimated blood loss is less likely to meet the threshold for PPH, EBL is more specific and may predict adverse outcomes better. The benefits of QBL over EBL and clinical outcomes need to be evaluated in prospective trials.

Table 1. Maternal Demographics with and without composite maternal adverse outcome.

	No CAMO		CAMO		P-value
	n = 1483	%	n=47	%	
Age (Years)					0.96

1159 | Concordance of Early Pregnancy Smoking Disclosure Rates with DNA Methylation among Pregnant Patients

Rachel S. Ruderman[1]; Lauren S. Keenan-Devlin[2]; Renee Odom-Konja[3]; Amy Inkster[4]; Lavisha Singh[5]; Mahitha Chaturvedula[3]; Linda M. Ernst[3]; Alexa A. Freedman[6]; Wendy P. Robinson[7]; Greg E. Miller[6]; Ann EB Borders[5]

[1]University of Chicago, CHICAGO, IL; [2]Endeavor Health/ University of Chicago Pritzker School of Medicine, Endeavor Health, IL; [3]Endeavor Health, Evanston, IL; [4]The University of British Columbia, The University of British Columbia, BC; [5]Endeavor Health, Evanston Hospital, Evanston, IL; [6]Northwestern University, Chicago, IL; [7]University of British Columbia, University of British Columbia, BC

4:00 PM - 6:00 PM

Objective: Prenatal substance use is an increasing cause of morbidity and mortality. Changes in gene function that do not affect nucleotide sequence, or epigenetics, has emerged as a screening mechanism for substance use. We evaluated the application of serum-validated epigenetic DNA methylation markers in human placental tissues to assess the correlation between reported smoking and placental epigenetic markers.

Study Design: This is a secondary analysis of the Stress, Pregnancy, and Health Study, a prospective study of 605 patients at an urban hospital from 2018-2022. Patients completed the Health Practices Survey (HPS) during mid-trimester and reported cigarette or marijuana use during pregnancy (current use) or in the 3 months prior to pregnancy (former use). We evaluated the degree of methylation in placental DNA using CPG sites previously associated with smoking. Differences in site cg05575921 have been reported from placental tissue, while sites cg23079012 and cg22112841 have been associated in serum. Methylation

percentages were determined using absolute values; p-values were calculated from log-transformed data.

Results: Among 488 patients who completed HPS, 440 (90.2%) reported never using cigarettes or marijuana, while 27 (6%) reported current smoking and 21 (5%) former smoking. Current smoking was not associated with placental DNA methylation of cg05575921 (51% vs 53% methylation in never users, p = 0.13). This finding was similar for the other sites (Table 1). A sensitivity analysis comparing current and former users to never users also yielded non-significant results.

Conclusion: In this novel exploration of placental DNA methylation using validated sites, we did not find significant DNA methylation changes with smoking status. However, methylation was lower in current than never smokers, which is similar to the change observed in serum. This study is amongst the first to explore the application of validated DNA methylation markers of smoking on placental tissues, and will inform larger explorations of the association between placental DNA methylation and reported substance use during pregnancy.

Table 1. DNA Methylation by Smoking Status

Methylation Site	Current Smoker	Never Smoker	p-value*

1160 | Psychopharmacotherapy Use in Pregnancies Conceived with IVF and Risk of Postpartum Hemorrhage

Rachel Solmonovich; Frank I. Jackson; Jamie Green; Brenda Lin; Randi Goldman; Matthew J. Blitz
Northwell, New Hyde Park, NY

4:00 PM - 6:00 PM

Objective: To determine differences in the frequency of psychopharmacotherapy (PPT) use during pregnancies conceived with and without in vitro fertilization (IVF). Secondary objectives were to evaluate rates of PPT drug classes among the cohorts and their associations with postpartum hemorrhage (PPH) requiring transfusion of packed red blood cells (pRBC) among IVF pregnancies.

Study Design: Retrospective cohort study of all deliveries that occurred at ≥ 23 weeks gestational age in a New York academic health system from January 2019 to December 2022. Adjusted odds ratios for non-Hispanic White ethnicity, public insurance, and obesity were calculated using a logistic regression in R version 4.3.1.

Results: A total of 3,383 IVF and 104,297 non-IVF pregnancies were included. Patients who conceived via IVF were more likely to self-identify as non-Hispanic white (54.9% vs. 43.1%), be nulliparous (59.0% vs. 48.7%), and have private insurance (92.3% vs. 64.4%), p< 0.001. Prenatal PPT exposure was more common in pregnancies conceived with IVF, 6.4% vs. 3.5%; aOR 1.62 (95% CI, 1.39 - 1.88; Table 1). IVF pregnancies exposed to PPT had nearly double the odds of experiencing a PPH requiring pRBC (aOR 1.90; 95% CI, 1.18-2.95). Selective Serotonin Reuptake Inhibitors (SSRIs) were associated with a two-fold increase in the odds of PPH requiring pRBC, aOR 2.11 (95% CI, 1.10 - 3.51), and benzodiazepines with three-fold increased odds, aOR 3.22 (95% CI, 1.56 - 6.12).

Conclusion: Prenatal PPT use is higher during IVF pregnancies, specifically SSRIs and benzodiazepines. Their use is associated with increased odds of clinically significant postpartum hemorrhage. While these findings suggest potential risks, they should not discourage mental health treatment, as untreated conditions are also associated with adverse outcomes. These results contribute to comprehensive counseling and informed decision-making when selecting PPT class during pregnancy.

Table 1: Rates of PPT use during IVF vs. Non-IVF pregnancies

1161 | Using Neighborhood-Level Indices to Discriminate Small for Gestational Age Birthweight Among Racial and Ethnic Groups

Raina Kishan[1]; Daniel L. Kuhr[2]; Nicola F. Tavella[1]; Zahava P. Michaelson[2]; Nicole Parkas[2]; Helen Feltovich[2]; Kimberly B. Glazer[3]
[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Division of Maternal-Fetal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [3]Department of Population Health Science and Policy; Department of Obstetrics, Gynecology and Reproductive Science, Blavatnik Family Women's Health Research Institute, Icahn School of Medicine at Mount Sinai, New York, NY

4:00 PM - 6:00 PM

Objective: To examine the performance of publicly available neighborhood-level indices of the built and social environment in the prediction of small for gestational age (SGA) in different racial/ethnic groups.

Study Design: This was an a priori secondary analysis of a retrospective cohort study examining risk of sPTB of 1000 patients who delivered at a tertiary, urban academic hospital between January 2013 and August 2023 with ≥ 1 transvaginal cervical length during pregnancy. The primary outcome was SGA, defined by birth weight ≤ 10th percentile for gestational age (GA), using Intergrowth-21st growth curves. Medical history, race, delivery GA, and birth weight were abstracted from electronic

medical records. The Childhood Opportunity Index (COI), Social Vulnerability Index (SVI) and Index of Concentrations at the Extremes (ICE) were determined through patients' listed 2020 census tracts. We used logistic regression models to predict the probability of SGA, incorporating neighborhood-level indices and clinically relevant individual-level covariates in the whole group and stratified by patient race. We compared model discrimination using the area under the receiver operating characteristics curve (AUC). All analyses were performed in R version 4.4 (24 April 2024).

Results: 1038 pregnancies among the 1000 patients met inclusion criteria, 105 of which resulted in SGA infants. 45% of patients were Hispanic, 25% were Black and 18% were White (Table 1). Models with all three neighborhood indices had an AUC of 0.49 in Black, 0.52 in Hispanic, and 0.68 in White patients (Table 2). The addition of socioeconomic and obstetric covariates improved discrimination in each model, particularly in the Black (AUC 0.74) and White (AUC 0.73) patients.

Conclusion: Individual neighborhood level indices were poorly predictive of SGA in each racial group. Including all indices improved model ability to discriminate SGA in White patients. The addition of sociodemographic and obstetric characteristics led to improved predictive ability in all racial groups, particularly among Black and White births.

1162 | Increased Adverse Perinatal Outcomes (APO) for Twin Pregnancies Complicated by Congenital Heart Disease (CHD)

Rainney Chiu[1]; Lihong Mo[2]; Herman L. Hedriana[2]; Shinjiro Hirose[3]; Sherzana Sunderji[4]; Amelia Mclennan[4]
[1]University Of California, Davis, University of California, Davis, CA; [2]UC Davis Health, Sacramento, CA; [3]UC Davis Health, UC Davis, CA; [4]UC Davis Health, UC Davis Health, CA

4:00 PM - 6:00 PM

Objective: APO, namely preterm birth (PTB), hypertensive disorders of pregnancy (HDP), and placental abruption have been associated with CHD in singleton pregnancies. This association has not been investigated in twin pregnancies. The aim of this study is to 1) evaluate the prevalence of APO in twin pregnancies affected by CHD using a large national database; 2) identify pregnancy characteristics associated with the APOs using a local database.

Study Design: A retrospective case-control study of twin pregnancies with CHD was conducted on Center of Disease Control and Prevention Natality Database from 1995-2000 (403,018 births) and 2016-2022 (842,878 births). Maternal demographics and perinatal outcomes were compared. Subsequently a local twin case series with CHD was reviewed for characteristics leading to APO.

Results: Demographically, there was no significant difference in twin pregnancies with or without CHD in both periods The CHD group showed significantly increased PTB: 1995-2000: < 37

weeks: Odds Ratio [OR], 2.37; (2.04-2.77 95% Confidence Interval [95%CI]); < 28 weeks: OR, 3.07; (2.54-3.71 95%CI); 2016-2022: < 37 weeks: OR, 1.91; (1.64-2.24 95%CI); < 28 weeks: OR, 2.18; (1.70-2.80 95%CI). Eclampsia was higher with CHD: 1995-2000: OR, 3.35; (2.30-4.89 95%CI); 2016-2022: OR, 5.32; (3.60-7.90 95%CI). Other HDP were not significantly increased in either cohort. Local center case series revealed that PTB was due to 6.7% spontaneous and 93.3% iatrogenic (18.2% for maternal indications, 81.8% for fetal indications).

Conclusion: CHD is associated with increased odds of PTB and eclampsia in twin pregnancies in CDC database collected in 1995-2000 and 2016-2022. Our single center study shed light on the common reasons for PTB in this CHD population. Further characterization with a larger sample size is needed to elucidate the incidence of APOs in twin pregnancies complicated by CHD.

Table 1. ECG Features Associated with Trimesters Compared to State Outside of Pregnancy or Postpartum

	1995-2000			2016-2022

1163 | Rate of Tethered Spinal Cord Release After Fetoscopic Repair of Open Spina Bifida

Ramen H. Chmait[1]; Jason K. Chu[2]; Alexander L. Van Speybroeck[3]; HaiThuy N. Nguyen[3]; Arlyn Llanes[1]; Grace Hamadeh[1]; Adam E. Masri[1]; Lisa M. Korst[4]; Eftichia V. Kontopoulos[5]; Ruben A. Quintero[5]; Denise A. Lapa[6]
[1]Keck School of Medicine, University of Southern California, Los Angeles, CA; [2]Riley Hospital for Children, Indianapolis, Indianapolis, IN; [3]Children's Hospital Los Angeles, Los Angeles, CA; [4]Childbirth Research Associates, North Hollywood, CA; [5]The Fetal Institute, USFETUS Research Consortium, Miami, FL; [6]Hospital Israelita Albert Einstein, Hospital Infantil Sabara, Sao Paulo, Sao Paulo

4:00 PM - 6:00 PM

Objective: A recent meta-analysis reported approximately 22% rate of symptomatic tethered spinal cord (TSC) at 4.1 years median age of follow-up after prenatal closure of open spina bifida (OSB). TSC was defined as either neurologic deterioration, urological deterioration, or need for a surgical TSC release. The aim of this study was to assess the rate of surgical TSC release in a cohort of patients who underwent fetoscopic repair of OSB, followed between 2.5 and 5 years of life.

Study Design: This was a prospective study of patients who underwent percutaneous or percutaneous mini-laparotomy fetoscopic OSB repair between 24 and 28 gestational weeks and who were followed for 2.5 to 5 years of life. The postnatal evaluation and treatment were at the discretion of the referring team and based on clinical findings and symptoms.

Results: Of 105 consecutive patients who received the fetoscopic OSB repair and achieved 30 months of age, 6 (5.7%) underwent a surgical TSC release procedure. Table 1 shows specific details of these 6 cases. Four of these 6 patients developed symptomatic hydrocephalus and were treated with a shunt or endoscopic third ventriculostomy, two at the same time of the TSC release. Because of the small number of affected patients, risk factors for receiving a detethering procedure could not be assessed.

Conclusion: Of patients who underwent fetoscopic OSB repair and were between 2.5 to 5 years of age, 5.7% underwent a surgical TSC release procedure. As TSC symptomology may not arise until the later childhood or adolescent period, further long term follow up is necessary. Understanding the risk factors for development of symptomatic TSC will be important to optimize the prenatal surgical approach.

Table 1. Characteristics of patients that underwent surgical tethered spinal cord (TSC) release.

Case Patient	Lesion type	Largest ventricle size (mm)	Two Layer vs Three Layer Closure	Anatomical level of the lesion	Hydro-cephalus treated by shunt or ETV	Symptoms of tethered spinal cord	Procedure	Age (mo) at release of TSC
1	Myelomeningocele	13.2	2	L4	No	Pain in legs and loss of function of bladder and bowel	Release of tethered spinal cord	26
2	Myeloschisis	10.1	2	L4	Yes	Development of site leakage	VPS insertion, detethering of spinal cord, and expansile duraplasty	16
3	Myelomeningocele	12.4	3	L3	Yes	Recurrent urinary tract infections	VPS insertion, Chiari decompression, detethering of spinal cord, and syrinx to peritoneal shunt	23
4	Myeloschisis	14.0	3	L5	No	Progressive scoliosis, shortened hamstrings, back pain	Release of tethered spinal cord	62
5	Myeloschisis	10.0	2	L5	Yes	Lower extremity spasticity	Release of tethered spinal cord	40
6	Myeloschisis	15.0	2	L4	Yes	Worsening neurogenic bowel symptoms	Release of tethered spinal cord	37

*VPS: ventriculo-peritoneal shunt

1164 | Maternal Outcomes of First- Versus Second-Line Intrapartum Antibiotic Prophylaxis for Group B Streptococcus: A Retrospective-Study

Raneen Abu Shqara[1]; Shany Or[2]; Lior Lowenstein[3]; Maya Frank Wolf[4]
[1]Galilee Medical Center, Nahariya, HaZafon; [2]Bar-Ilan univeristy, Bar-Ilan university, HaZafon; [3]Galilee Medical center, Nahariya, HaZafon; [4]Galilee Medical Center, Naharyia, HaZafon

4:00 PM - 6:00 PM

Objective: The incidence of maternal infectious morbidity according to the intrapartum antibiotic prophylaxis (IAP) regimen used for Group B streptococcus (GBS) prophylaxis is poorly described. We aimed to compare maternal peripartum infections and microbiological outcomes among GBS carriers according to IAP regimen.

Study Design: This retrospective study included women hospitalized in a tertiary university-affiliated hospital between March 2021 and March 2024, who were GBS positive at term and received first-line ampicillin (n = 1833), or second-line clindamycin (n = 78) due to penicillin allergy. The co-primary outcomes were clinical chorioamnionitis and neonatal intensive care admission rates. Univariate and multivariate analyses were performed. Chorioamniotic swabs were obtained after delivery, and microbiological outcomes were compared according to IAP regimen.

Results: Among GBS carriers who received clindamycin vs. ampicillin, the rates were higher of chorioamnionitis (p< 0.001), intrapartum fever (p< 0.001), postpartum fever (p = 0.001) and antibiotics use (p< 0.001) (Figure). The cesarean delivery rates were similar (p = 0.086). The rate of neonatal intensive care admission and other neonatal complications were similar. In multivariate analysis, the factors that were independently associated with clinical chorioamnionitis were: clindamycin-IAP, odds ratio (OR) 20.1, 95% confidence interval (CI) (6.6-61.4), p< 0.001; cervical ripening by catheter balloon, OR 4.1, 95%CI (1.2-13.6), p = 0.023; and prolonged rupture of membranes, OR 4.9, 95%CI (1.6-15.7), p = 0.006 (Table). In chorioamniotic swabs, among women who received clindamycin vs. ampicillin, rates were higher of positive GBS isolates, 28% vs. 11%, p< 0.001 and of overall positive cultures, 32.1% vs. 16.4%, p< 0.001.

Conclusion: Clindamycin compared with ampicillin was associated with a higher rate of maternal peripartum infectious morbidity.

This underscores the importance of minimizing clindamycin use for GBS prophylaxis. Further research is warranted to evaluate alternative second-line IAP options and their effectiveness in preventing GBS-related infections.

1165 | Contraceptive Counseling and use Among Pregnant Individuals who Underwent Spontaneous Versus Medically Indicated Preterm Birth

Rebecca Purvis[1]; Alicia Mastronardi[2]; Megan L. Young[3]; William S. Havron, IV[4]; Jill M. Maples[5]; Nikki B. Zite[4]

[1]University of Tennessee Medical Center Knoxville, Knoxville, TN; [2]University of Tennessee Graduate School of Medicine, Department of OB/Gyn, Knoxville, TN; [3]University of Tennessee Medical Center, Center for Women and Infants, Knoxville, TN; [4]University of Tennessee Graduate School of Medicine, Knoxville, TN; [5]University of Tennessee Health Science Center, College of Medicine, Knoxville, TN

4:00 PM - 6:00 PM

Objective: Preterm birth (PTB) contributes to maternal and neonatal morbidity. Adequate contraceptive uptake can help reduce rates of PTB, however, individuals who undergo PTB are less likely to obtain contraception than those who undergo term delivery. We sought to describe rates of contraceptive uptake and patient reported recollection of contraceptive counseling in our population who underwent PTB, as stratified by etiology.

Study Design: This retrospective cohort study examined all liveborn PTBs within a single regional academic medical center between January 2023-April 2024. Demographic and contraceptive data was collected via EMR and confirmed through billing data. Etiology of preterm birth was abstracted from the medical record and categorized by a single physician. Chi-square, t-test, and Mann-Whitney U were used to compare populations and outcomes, as appropriate.

Results: Of the 6,058 total births at our institution during the study, 934 (15.4%) delivered in the preterm period (< 37 weeks) and were analyzed. Of these, 426 (45.6%) were considered spontaneous (SPTB) and 508 (54.4%) were considered medically indicated (IPTB). Demographic information did not significantly differ between SPTB vs IPTB, other than median gestational age at delivery (34.6 weeks vs 35.3 weeks, p =˙.002) and limited/no prenatal care (11.3% vs 5%, p< .001). Those who underwent IPTB were more likely to recall contraceptive counseling (41.7% vs 30%, p< .001) and to identify their contraceptive desires at discharge (84.5% vs 77.9%, p = 0.24). Similar trends are present when stratifying each type of preterm birth by above and below 32 weeks at time of delivery (Table 2).

Conclusion: Pregnant individuals who undergo IPTB are more likely to recall contraceptive counseling and to identify their contraceptive desires at discharge than those who undergo SPTB. Future research will focus on identifying reasons why those who undergo IPTB vs SPTB recall differences in contraceptive counseling, given the importance of contraception in helping to reduce the risk of recurrent PTB.

1166 | First Trimester Machine Learning to Predict Preeclampsia in Normotensive Pregnancies by American Heart Association Guidelines

Rebecca Horgan[1]; Erkan Kalafat[2]; Elena Sinkovskaya[1]; Alfred Z. Abuhamad[1]; George R. Saade[1]
[1]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [2]Koc University Hospital, Istanbul, Istanbul

4:00 PM - 6:00 PM

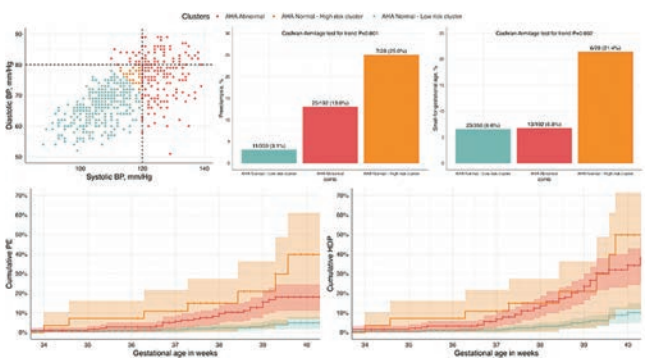
Objective: The threshold to define normal blood pressure (BP) outside pregnancy have been lowered. We assessed if machine learning can identify patients at high risk of hypertensive disorders of pregnancy (HDP) amongst normotensive first-trimester patients per American Heart Association (AHA) guidelines.

Study Design: This was a prospective cohort study which enrolled patients at ≤ 13+6 weeks' gestation without fetal,

umbilical cord or placental abnormalities. For this analysis, patients with chronic hypertension were excluded. Baseline maternal BP was classified according to the AHA guidelines (normal, elevated, stage I hypertension, stage II hypertension). The primary outcome was the incidence of HDP diagnosed per ACOG criteria. First trimester BP values were clustered using unsupervised machine learning models and patients were categorized as; AHA normal BP, low risk clustering; AHA normal BP, high risk clustering and AHA abnormal BP (elevated or above). Association with outcomes were assessed with regression analyses, which were adjusted for race, body-mass index, and risk factors for preeclampsia (PE).

Results: 570 patients were included in this analysis, with 43 developing PE and 73 any HDP. After clustering, 350 patients fell within the AHA normal BP low-risk cluster, 28 AHA normal BP high-risk cluster and 192 patients AHA abnormal BP (elevated or above). The PE rates in these categories were 3.1%, 25.0% and 13.0%, respectively (P< 0.001). The rate of small for gestational age (SGA) were 6.6%, 21.4% and 6.8% respectively (P = 0.032). The hazard of PE was higher in patients with AHA normal BP, high risk clustering (adjusted HR: 8.51, 95% CI: 3.30-22.0, P< 0.001) compared to AHA abnormal BP (adjusted HR: 4.33, 95% CI: 2.12-8.84, P< 0.001) (Figure). Similar findings were observed for any HDP (adjusted HR:4.15 vs 5.77, P< 0.001 both, Figure).

Conclusion: A cohort of patients with AHA normal BP, identified by unsupervised machine learning models, had significantly higher risk of preeclampsia and neonatal SGA than those with AHA abnormal BP or AHA normal BP clustered in the low-risk group.



1167 | Preeclampsia Associated Morbidity Requires a Double hit from First-Trimester Maternal Characteristics and Placental Dysfunction

Rebecca Horgan[1]; Erkan Kalafat[2]; Elena Sinkovskaya[1]; Alfred Z. Abuhamad[1]; George R. Saade[1]
[1]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [2]Koc University Hospital, Istanbul, Istanbul

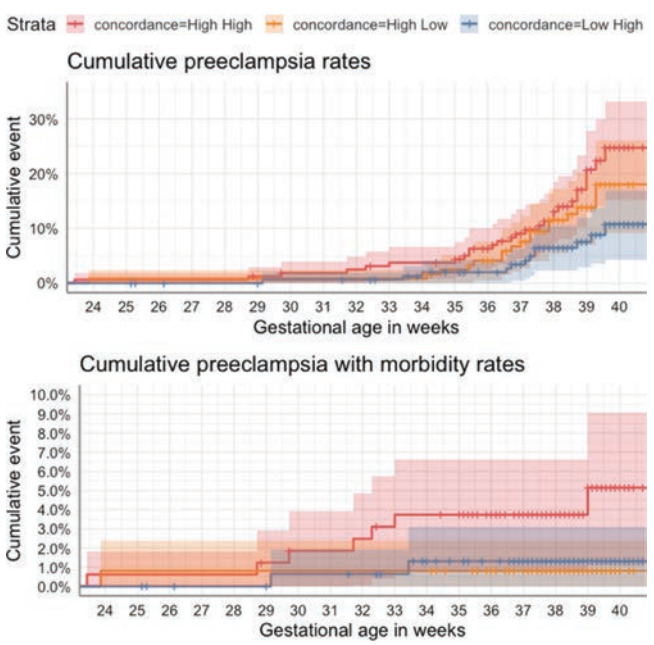
4:00 PM - 6:00 PM

Objective: To evaluate whether unsupervised machine learning clustering of first-trimester data can identify pregnancies at high risk for preeclampsia associated morbidity.

Study Design: This is a prospective cohort study which enrolled patients at ≤ 13+6 weeks' gestation without fetal, umbilical cord or placental abnormalities. Baseline maternal characteristics, blood pressure, and first trimester ultrasound including uterine and placental artery (spiral artery and intervillous arteriole) Dopplers were obtained. The primary outcome was the prevalence of preeclampsia with associated morbidity defined as delivery at < 34 weeks, eclampsia, HELLP syndrome or placental abruption. Patients were followed throughout pregnancy and outcomes collected by trained research coordinators. Maternal characteristics (BMI and blood pressure) and uterine & placental Dopplers (uterine, spiral, and intervillous artery pulsatility index) were used to create their distinct risk groups using unsupervised machine learning models. Outcomes of patients who were labeled as high risk in both (maternal characteristics and Doppler) or just one (Maternal characteristics or Doppler) were compared using cox-proportional hazard models.

Results: Analysis included 617 patients. Machine learning identified 164 patients as high risk of preeclampsia by both maternal characteristics and Dopplers, 126 by maternal characteristics alone, 161 by Dopplers alone, and 166 as low risk. Preeclampsia rates were highest in the dual high-risk group (17.1%), compared to maternal characteristics alone (13.5%) or Dopplers alone (7.5%) (HR: 1.80, 95% CI: 1.07-3.03, P = 0.026). The low-risk group had a 2.4% preeclampsia rate. 70% of preeclampsia cases with associated morbidity were in the dual high-risk group, significantly higher than those identified by only one criterion (HR: 4.15, 95% CI: 1.07-16.0, P = 0.039).

Conclusion: Preeclampsia with associated morbidity mostly occurs in patients with abnormalities in both first trimester blood pressure values and placental Doppler values.



1168 | Clinical Factors Associated with Survival of Periviable Rupture of Membranes

Rebecca Crowe[1]; Eliza R. McElwee[2]; Jessica Pittman[1]; Devin Hatchell[2]
[1]Medical University of South Carolina, Charleston, SC; [2]Medical University of South Carolina, Columbia, SC

4:00 PM - 6:00 PM

Objective: The aim of this study is to assess neonatal survival to discharge and factors that may influence survival in pregnancies affected by rupture of membranes (ROM) less than 25 weeks gestation (w).

Study Design: This is a retrospective cohort study of non-anomalous, singleton pregnancies with ROM prior to 25w delivered at a tertiary care center from 2005-2024. Patients included in the study elected for expectant management at the diagnosis of ROM and delivered a liveborn neonate that was a candidate for resuscitation. Patients who elected comfort care were excluded. Patients were stratified by neonatal survival to discharge. Maternal, obstetric, and neonatal variables were compared between survival groups. Chi-square and student's t-test were used to compare categorical and continuous variables.

Results: Of 90 patients with ROM less than 25 w, 54 (60%) neonates survived to discharge, and 36 (40%) had a neonatal demise. Gestational age (GA) at ROM (23.2w IQR 22.6-24 v 23.1w IQR 22.5 - 24, p = 0.318), GA at delivery (24.4w IQR 23.7-24.9 v 24.2w IQR 23.6-24.9, p = 0.197), and latency from ROM to delivery (4.6d (IQR 2-16) v 4 (IQR 2-16), p = 0.623) were not statistically different between survivors and non-survivors. Six percent of patients delivered prior to 23w0d. Residual amniotic fluid values were not statistically different between survivors and non-survivors (p = 0.42). Antenatal interventions, including antenatal corticosteroid (100% v 94.4%, p = 0.157) and antibiotic administration (90.7% v 83.3%, p = 0.337) were not different between groups. Mode and indication for delivery did not impact neonatal survival to discharge.

Conclusion: In our cohort, overall survival of expectantly managed pregnancies affected by ROM less than 25 weeks gestation is 60%. Survival to discharge is multi-factorial, and is challenging to predict in the periviable period.

	Survivors n=54	Non-survivors n=36	p-value
GA at ROM	23.2 (22.6-24)	23.1 (22.5-24)	0.318

1169 | Impact of Gestational Age on Outcomes in Periviable Rupture of Membranes

Rebecca Crowe[1]; Eliza R. McElwee[2]; Jessica Pittman[1]; Devin Hatchell[2]; Kelli M. McFarling[2]

[1]Medical University of South Carolina, Charleston, SC; [2]Medical University of South Carolina, Columbia, SC

4:00 PM - 6:00 PM

Objective: The aim of this study is to evaluate neonatal survival to discharge and neonatal outcomes based on gestational age of rupture of membranes (ROM) in pregnancies affected by ROM less than 25 weeks gestation (w).

Study Design: This is a retrospective cohort study of non-anomalous, singleton pregnancies with ROM prior to 25w delivered at a tertiary care center from 2005-2024. Patients included in the study elected for expectant management at the diagnosis of ROM and delivered a liveborn neonate that was a candidate for resuscitation. Patients who elected comfort care were excluded. Patients were stratified by gestational age at ROM (early ROM less than 22w, late ROM greater than 22w). The primary outcome was neonatal survival to discharge; secondary outcomes included neonatal variables amongst survivors. Chi-square and student's t-test were used to compare categorical and continuous variables.

Results: Of 90 patients with ROM less than 25w, 18 (20%) had early rupture and 72 (80%) had late ROM. Overall survival to discharge in the study group was 60% (n = 54). There was no statistical difference in survival to discharge when comparing early versus late ROM (44.4% v 63.9%, p = 0.132). Gestational age at delivery was not significantly different between early and late ROM groups (24w3d IQR 23w0d-27w5d v 24w2d IQR 23w5d-24w5d); however, the early ROM group did have greater latency to delivery (6.14 days v 0.4 days, p< 0.01). Six percent of patients delivered before 23 w. All neonates were affected by respiratory distress syndrome; remaining neonatal outcomes including bronchopulmonary dysplasia, intraventricular hemorrhage, retinopathy of prematurity, necrotizing enterocolitis, and sepsis were similar between groups.

Conclusion: In our cohort, gestational age at ROM did not affect neonatal survival to discharge. Patients with ROM less than 22w have greater latency to delivery, but no difference in gestational age at delivery or survival.

	Early ROM (<22w) n=18	Late ROM (≥22w) n=72	p-value
Survival to discharge	8 (44.4%)	46 (63.9%)	0.132
Gestational age at delivery (weeks)	24w3d (23w0d-27w5d)	24w2d (23w5d-24w5d)	0.62
Latency from ROM to delivery (days)	6.14 (2.60-8.46)	0.4 (0.15-1.10)	<0.01

1170 | Machine Learning Algorithm for the Point of Care Prediction of Preterm Labor

Reetam Ganguli[1]; Stephen Wagner[2]
[1]Elythea, San Jose, CA; [2]Beth Israel Deaconess Medical Center, Boston, MA

4:00 PM - 6:00 PM

Objective: Preterm birth is the leading cause of neonatal mortality and is 25-fold more expensive than term deliveries to payors. Relevant literature has demonstrated that clinical intervention indicated by early risk screening tests can reduce preterm birth occurrence by 20% and can save over $800 per patient. Current screening methods to detect patients at risk of preterm labor are limited with some studies suggesting established protocols such as cervical length screening have a sensitivity as low as 11%. Our goal was to develop a machine learning model to non-invasively predict risk of preterm birth at the point of care.

Study Design: We conducted a cohort study utilizing sociodemographic and clinical data obtainable in the 1st trimester from the CDC Vital Statistics System. Deliveries with missing preterm labor data and deliveries in hospitals not reporting preterm labor were excluded. The primary outcome was spontaneous preterm birth < 37 weeks.

Models were trained on years 2018-2020 of the CDC Vital Statistics System and were tested on a hold-out set of year 2021.

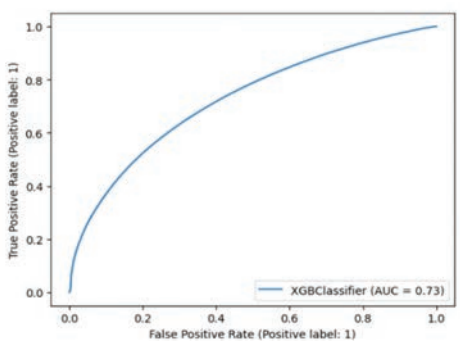
Results: 40 clinical variables for 12,476,992 obstetric patients were included in the training data. 2,685,095 (21.5%) patients had a preterm birth.

The model was tested on 3,666,801 patients, of which 450,318 (12.3%) patients went into preterm labor. The developed model had an area under the receiver operating characteristic curve of 0.73, sensitivity of 0.65, and F1 score of 0.68.

The highest weighted factors in the model were: number of prenatal visits, trimester that prenatal care was initiated in, and interval since last live birth.

Conclusion: Our developed ML model leveraging data available at early stages of pregnancy harbors the potential to identify women at increased risk for spontaneous preterm birth at nearly 6 times the sensitivity than existing cervical length measurement tests as soon as the point of care and may allow for targeted interventions to reduce spontaneous preterm labor incidence/lower healthcare expenditures related to preterm birth.

AUC Curve for Preterm Labor Machine Learning Model



1171 | Maternal Hypertension Care Bundle Implementation at an Academic Tertiary Hospital: System Redesign using Improvement Science

Isabella Toledo[1]; Joyce H. Xu[2]; Lori Fannin[2]; Mary Giles[2]; Heather N. Czarny[2]; Stephen Afflito[3]; Muhammad Zafar[2]; Robert M. Rossi[2]; On behalf of the Maternal Safety Quality Improvement Initiative of the Ohio Department of Health
[1]Indiana University School of Medicine, Indianapolis, IN; [2]University of Cincinnati College of Medicine, Cincinnati, OH; [3]Ohio Colleges of Medicine, Government Resource Center, Columbus, OH

4:00 PM - 6:00 PM

Objective: Uncontrolled hypertension in pregnancy is a major cause of maternal morbidity and mortality. Application of best-practice maternal hypertension care bundle reduces severe maternal morbidity. Our objective was to implement an in-patient, maternal hypertension bundle (HTN-bundle) with reliable adherence of >80% in an academic tertiary care hospital.

Study Design: University of Cincinnati Medical Center is a level IV maternal care academic center, safety net hospital. We participated in the AIM Hypertension Quality Improvement Project (AIM-QIP) by the Ohio Colleges of Medicine Government Resource Center.

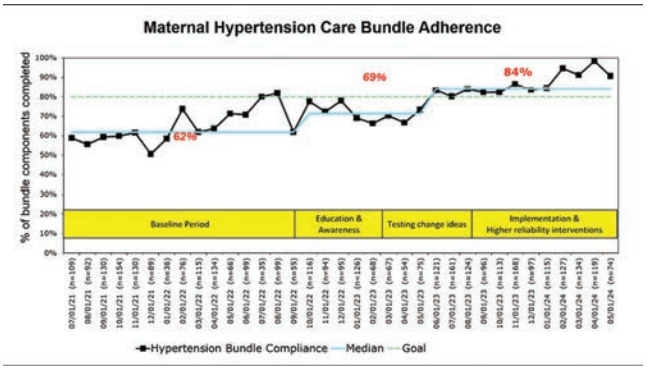
The HTN-bundle consisted of 1) treatment of systolic blood pressure (BP) or diastolic BP ≥ 160/110 in < 60 min, 2) appropriate medication use for acute HTN treatment, 3) patient education, 4) timely discharge follow-up, 5) blood pressure cuff provision. We aimed to improve the adherence to bundle components from 62% (baseline) to >80% within 6-months.

Staff education was led by the medical director and facilitated by AIM-QIP. We performed detailed process maps, Pareto analyses, empathy mapping, and Go-see activities to identify improvement opportunities. Interventions for redesign were testing using iterative Plan-Do-Study-Act (PDSA) cycles (Fig 1). Bundle adherence was tracked by chart reviews and plotted on run-chart.

Results: The baseline HTN-bundle adherence was 62%. We performed 33 PDSA cycles, testing 16 interventions. By 6-months, HTN-Bundle adherence reached 84% with a sustainable system shift on the run-chart (Fig 2). The highest increases were noted in provision of BP cuffs and 3-day follow-up BP check appointments. The HTN-bundle delivery now relies on different team members performing inter-dependent task, making it a system property rather than an individual's responsibility.

Conclusion: Using improvement science methods, adherence to HTN-bundle can be made a part of reliable, standard-of-care for all affected patients. Key success factors were setting a clear aim, team engagement, QI expertise, data-guided change efforts, and availability of resources.

Key Drivers	Interventions with Level 1 Reliability	Interventions with Level 2-3 Reliability
Standard notification Process	1. Case review and follow-up feedback loops 2. Visual aids for staff on unit 3. MEWS education	1. HTN coordination added to discharge huddle discussion 2. Charge RN notified of severe range BP 3. Best practice advisory notification for severe HTN
Early recognition and Timely response	1. Case review and follow-up feedback loops 2. Visual aids for staff on unit 3. MEWS education for all staff	1. New HTN order set in Epic 2. Charge RN notified of severe range BP 3. Best practice advisory notification for severe HTN
Ease of access to medications	1. Visual aids for staff on unit	1. New HTN order set in Epic
Standard protocol for communications	1. MEWS education for all staff 2. Unit visual aids for communication	1. HTN coordination added to discharge huddle 2. Charge RN notified of severe range BP 3. Creation of BP smartphrases in Epic for documentation for nurses and providers
Timely access to follow up appointment	1. Case review and follow-up feedback loops	1. Prioritization of BP check appts in outpatient obstetric clinic (Mon-Fri) 2. Weekend telehealth BP visits
Reliable provision of BP cuff	1. Case review and follow-up feedback loops	1. Hospital discharge pharmacy providing BP cuff (meds to bed) 2. HTN coordination added to discharge huddle 3. Discharge flowsheet with BP cuff selection
Access to remote BP monitoring	1. Case review and follow-up feedback loops	1. Utilization of BabyScripts App for remote BP monitoring



1172 | Xenobiotic Transfer of Tranexamic Acid Through an ex vivo Placental Perfusion Model

Roshini Zachariah[1]; Helen Zhao[2]; Andrea D. Shields[3]; Richard Wagner[1]

[1]University of Connecticut Health Center, Farmington, CT; [2]University of Connecticut, West Hartford, CT; [3]University of Connecticut Health, Avon, CT

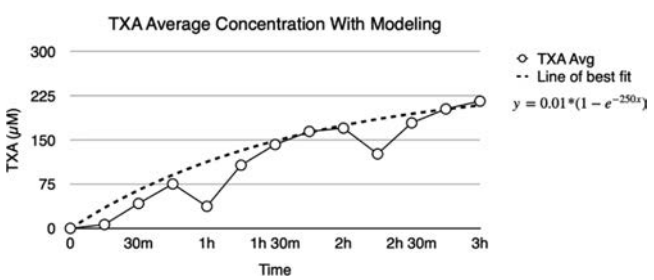
4:00 PM - 6:00 PM

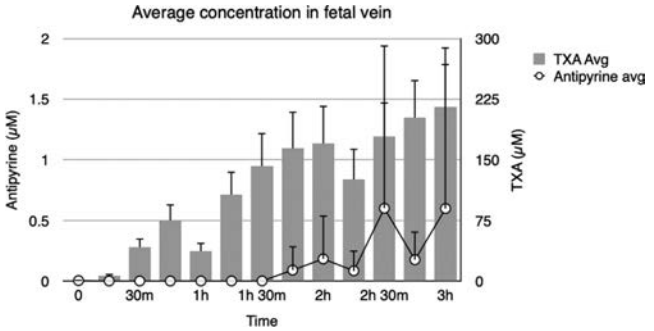
Objective: In obstetrics, intravenous tranexamic acid (TXA) is used to treat postpartum hemorrhage via inhibition of fibrinolysis and is effective in reducing mortality from postpartum hemorrhage. TXA is not currently approved for prophylactic use of postpartum blood loss but existing meta-analyses suggest it may reduce the incidence of postpartum hemorrhage and overall blood loss. However, data on use of TXA for antepartum bleeding is limited.

Study Design: We used an *ex vivo* placental perfusate model to study the rate of transfer of TXA across the placental interface. Placentas from term uncomplicated singleton pregnancies were obtained immediately after scheduled cesarean deliveries. A fetal vein-artery pair supplying a cotyledon was isolated, cannulated and perfused. Maternal circulation was also established through placental storm. After addition of TXA and antipyrine (positive control) to the system, fetal samples were collected every 15 minutes for 3 hours with two parallel closed circulations (maternal and fetal). Fetal artery pressure and pH of the maternal and fetal reservoir were monitored every 15 minutes to continuously assess the integrity of the model. Fetal vein samples were analyzed via HPLC to quantify TXA and antipyrine concentrations.

Results: TXA rapidly crosses the placental interface within 15 minutes of administration. TXA levels in the fetal vein rose over 3 hours and was modeled with a logarithmic curve. The predicted final fetal vein concentration was 250 μM. The *in vivo* fetal concentration would likely be lower due to increased maternal circulating volume and renal clearance. Based on transfer seen in this *ex vivo* model, we would predict an *in vivo* fetal vein concentration of 7 μg/mL (clinical effects are seen at 10-15 mg/mL).

Conclusion: Tranexamic acid rapidly crosses the placental interface in an ex vivo model. However, the fetal vein concentration is reduced compared to maternal concentration. This suggests that in vivo use may be ethically safe to test as expected fetal concentrations would be below the clinically effective threshold.





1173 | Amlodipine Versus Nifedipine ER for Managing Postpartum Hypertension: Medication Continuation Beyond 6 weeks Postpartum

Ross F. Lordo[1]; Alondra DeSantiago[2]; Zachary C. Travis[2]; Himashreya Katti[2]; Stella Self[3]; Laura Carlson[4]; Katelyn Pratt[4]
[1]Prisma Health Upstate, Greenville, SC; [2]University of South Carolina School of Medicine Greenville, Greenville, SC; [3]University of South Carolina Arnold School of Public Health, Columbia, SC; [4]Prisma Health Upstate/University of South Carolina School of Medicine Greenville, Greenville, SC

4:00 PM - 6:00 PM

Objective: Despite being a leading cause of maternal morbidity, data on optimal management of postpartum (PP) hypertension (HTN) is limited. Our parent study demonstrated noninferiority of amlodipine for treatment of PP HTN in the immediate PP period when compared to nifedipine ER. In this secondary analysis, we sought to assess use of antihypertensives beyond 6 weeks PP. We hypothesized that the majority of patients using either medication would discontinue treatment prior to 6 weeks PP and that of those who continued treatment, participants assigned to amlodipine would be more likely to continue the assigned study drug than those assigned to nifedipine ER, as use of amlodipine is more common in the non-obstetric setting.

Study Design: This was a secondary analysis of a randomized controlled noninferiority trial. 175 patients were enrolled in the parent study, with 120 patients started on either amlodipine or nifedipine ER in the per protocol cohort (n = 51 amlodipine, 69 nifedipine ER). Charts of the per protocol cohort were abstracted to assess continuation of the initially assigned antihypertensive at 6 weeks, 12 weeks, and 12 months PP. Data was analyzed utilizing chi-squared and Fishers exact test.

Results: Overall, forty percent of patients remained on antihypertensives at 6 weeks PP. No significant differences were found in rates of continuation of any antihypertensive at 6 weeks, 12 weeks, or 12 months PP. Those assigned to amlodipine were significantly more likely to be continued on their assigned study medication at 6 weeks and 12 weeks, but not 12 months, PP (Table 1).

Conclusion: While the majority of patients discontinue antihypertensives by 6 weeks PP, some patients with hypertensive disorders of pregnancy will require prolonged treatment. In patients requiring prolonged treatment, patients assigned to amlodipine were significantly less likely to be changed to an alternative antihypertensive. Although this was not statistically significant at 12 months PP, this may be due to sample size. Our findings support that amlodipine should be considered for treatment of postpartum hypertension.

	Amlodipine (N = 51)	Nifedipine ER (N = 69)	p-value
Any antihypertensive at 6 weeks*	20 (39.2)	28 (40.6)	1
Any antihypertensive at 12 weeks*	10 (19.6)	11 (15.9)	0.779

Changed antihypertensive at 6 weeks†	0 (0)	6 (21.4)	< 0.033
Changed antihypertensive at 12 weeks†	0 (0)	5 (45.5)	0.035
Changed antihypertensive at 12 months†	1 (14.3)	5 (62.5)	0.119

Reported as N (%). *Reported as percentage of overall per protocol cohort. † Reported as percentage of patients remaining on medication.

1174 | Impact of Chorioamnionitis on Maternal and Neonatal Outcomes Categorized by Presence or Absence of Fever

Rula Atwani; George R. Saade; Tetsuya Kawakita
Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA

4:00 PM - 6:00 PM

Objective: To examine the impact of a chorioamnionitis diagnosis on maternal and neonatal outcomes categorized by the presence or absence of documented fever.

Study Design: We conducted a secondary analysis using data from the Nulliparous Pregnancy Outcomes Study: Monitoring Mothers-to-Be. We excluded individuals who delivered before 20 weeks' gestation and those with missing chorioamnionitis data, then categorized participants based on the diagnosis of chorioamnionitis with versus without fever. Data was obtained prospectively by trained research coordinators. Our primary outcome was the neonatal composite outcome including suspected or confirmed neonatal sepsis, necrotizing enterocolitis, respiratory distress/transient tachypnea of the newborn (RDS/TTN), seizure, hypoglycemia, and hyperbilirubinemia. We also examined maternal outcomes (cesarean delivery, endometritis, and postpartum hemorrhage). We calculated adjusted relative risks (aRRs) with 95% confidence intervals (95% CIs) using modified Poisson regression.

Results: Of 9,432 individuals, 574 (6.1%) had chorioamnionitis with fever and 46 (0.5%) had chorioamnionitis without fever. Proportions and relative risks of outcomes are present in Tables 1 and 2. Compared to individuals with no chorioamnionitis, chorioamnionitis without fever was associated with higher risks of neonatal composite outcomes, neonatal sepsis, RDS/TTN cesarean delivery and postpartum hemorrhage. Compared to individuals with no chorioamnionitis, chorioamnionitis with fever was associated with higher risks of neonatal composite outcomes, neonatal sepsis, RDS/TTN, hypoglycemia, cesarean delivery, endometritis; and lower risk of hyperbilirubinemia.

Conclusion: Chorioamnionitis is associated with adverse maternal and neonatal outcomes regardless of fever, supporting ACOG's recommendations for diagnosing intraamniotic infections without maternal fever.

Table 1. Proportions of primary and secondary outcomes.

	No chorio	Chorio without fever	Chorio with fever	P-value

1175 | Predicting Gestational Latency Using Serial Monitoring Among Nulliparous, Singleton Pregnancies with low-Normal Mid-Trimester Cervical Lengths

Sandhya Chandrasekaran[1]; Vanya Manthena[2]; Andrew Rausch[2]; Ryan E. Longman[2]; Ashish Premkumar[2]
[1]University of Chicago School of Medicine, Chicago, IL; [2]Pritzker School of Medicine, University of Chicago, Chicago, IL

4:00 PM - 6:00 PM

Objective: Preterm births account for approximately 70% of neonatal deaths and 36% of infant deaths. In this setting, cervical length screening is of utmost importance as a predictor of preterm birth. Nulliparous patients pose a particularly difficult challenge with respect to counseling reading cervical insufficiency given their lack of pregnancy history. We sought to explore predictive trends in serial CLs associated with preterm birth in this otherwise low-risk population.

Study Design: We performed a retrospective case control analysis of all nulliparous, singleton pregnancies from 2021 to 2023 who underwent an anatomy scan with an initial low-normal cervical length (CL) >25mm and < 30mm followed by at least one serial CL with available gestational age at the time of delivery. The primary outcome was gestational latency (GL), defined as time of diagnosis of low-normal cervical length to delivery. Trajectory analysis was performed to gauge CL changes as a function of time from delivery between the two groups, using linear regression models. Bivariate analyses were performed.

Results: 30 nulliparous, singleton pregnancies with initial low-normal CL were evaluated, with 23 resulting in term deliveries ("tb", > = 37 weeks) and 7 resulting in preterm deliveries ("ptb", < 37 weeks, Table). When plotting serial CLs as a function of time, CL in the "tb" controls generally increased with GL (slope: 0.05), while CLs in the "ptb" controls demonstrated a modest decrease with GL (slope: -0.12). Importantly, there was a high degree of individual variability in CL trajectories among those whose pregnancies resulted in preterm deliveries (Figure).

Conclusion: 23% of individuals with a low-normal cervix will deliver preterm. However, high individual variability exists across groups. These data point to the use of serial monitoring in the setting of low-normal cervix and the need for further work into deciphering individuals factors contributing to these differences to drive novel interventions aimed at stabilizing the cervix with the goal of minimizing risk of preterm birth.

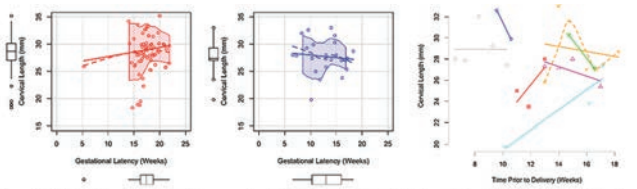

Figure. Serial CL trends in nulliparous, singleton pregnancies with initial low-normal CL resulting in term ("tb", n=23; left) and preterm ("ptb", n=7; middle) births, depicted as time to prior to delivery (ie, gestational latency) vs. CL (mm). Right: Individual trajectories of serial CL trends in the "ptb" group. Different colors/lines depict distinct individuals.

Table. Sociodemographic and biomedical characteristics.

	Preterm Birth (n=7)	Term Birth (n=23)	p value
Maternal Age	28 (8.5)	28 (7)	0.84

1176 | COVID-19 Vaccine Uptake Amongst Adult Women of Reproductive Age in the United States

Sandra O. Anazor[1]; Samuel Tundealao[2]; Valentine C. Nriagu[3]; Ezinne J. Ugwoke[4]; Hezborn Magacha[5]; Chisom Nwaneki[6]; Nnamdi J. Omenuko[7]; Francis T. Okeke[8]
[1]Corewell Health West/Michigan State University, Grand Rapids, Michigan., Grand Rapids, MI; [2]Rutgers University, New Jersey, Rutgers University, NJ; [3]Maimonides Medical Center, Brooklyn,

NY; [4]Montefiore St. Luke's Cornwall, Newburgh, NY; [5]East Tennessee State University, Johnson City, TN; [6]Saint Peter's Healthcare System, New Jersey., Jersey City, NJ; [7]University of Chicago, Chicago, IL; [8]Oklahoma University Health Science Center, Tulsa, OK

4:00 PM - 6:00 PM

Objective: To evaluate COVID-19 vaccine uptake rate and the association between COVID-19 vaccine uptake and race/ethnicity and, education in women of reproductive age in the United States.

Study Design: A secondary data analysis was conducted using United States COVID-19 Vaccine Hesitancy Survey dataset from the OpenICPSR database. The final sample size was 681 for females aged 18 to 49 years. Descriptive statistics (unweighted and weighted) frequencies and percentages, multivariable and adjusted bivariate logistic regression analyses were obtained for COVID-19 vaccine uptake, race/ethnicity, age, educational achievement, urbanicity, and chronic disease status.

Results: The COVID-19 vaccine uptake rate was found to be 32.2%. The population consisted of individuals from different racial backgrounds, with the majority identifying as non-Hispanic White (49.7 %), followed by Hispanic (25.4%), non-Hispanic Black (14.4%), non-Hispanic Asian (7.8%), and others (2.9%). The education level varied similarly: Bachelor's degree (36%), associate's or trade school (33%) and high school or less (32%). After adjusting for all predictor variables, only educational achievement of bachelor's degree or higher (AOR: 3.60, C.I: (2.20,5.91), p-value: < .0001) and urbanicity-not living in rural area (AOR: 0.55, C.I: (0.37,0.82), p-value: 0.0031) retained statistical significance in predicting uptake of any COVID-19 vaccine. Those who had a bachelor's degree or higher were 3.6 times more likely to have received any COVID-19 vaccine compared to those who had high school education or less (AOR: 3.60, C.I: (2.20,5.91), p-value: < .0001). There was no statistically significant association between COVID-19 vaccine uptake and race/ethnicity and age (table 2).

Conclusion: This study found statistically significant association between COVID-19 vaccine uptake and having a bachelor's degree or higher amongst adult women of reproductive age in the United States. Interventions to increase bachelor education can increase COVID-19 vaccine uptake and other vaccine uptake amongst women of reproductive age in the United States.

1177 | Collaborative Care Model Reduces Perinatal Mood and Anxiety Symptoms

Sarah J. Weingarten[1]; Semra Etyemez[2]; Spencer Darveau[2]; Xiaoyue Ma[2]; Lorena Rincones Rojas[2]; Emily Tutino[2]; Kristin M. Voegtline[2]; Steven Yen[2]; Lauren M. Osborne[2]
[1]*Weill Cornell Medicine at New York Presbyterian, New York, NY;* [2]*Weill Cornell Medicine, New York, NY*

4:00 PM - 6:00 PM

Objective: Collaborative care (CC) models, which embed mental health care into the outpatient setting, have been shown to improve mental health outcomes in primary care settings, but evidence is still scarce for effectiveness in perinatal settings. We aimed to determine if our CC intervention model would decrease depressive and anxiety symptoms in our perinatal population.

Study Design: Patients from three prenatal clinics at Weill Cornell Medicine were systematically screened and those with an Edinburgh Postnatal Depression Scale (EPDS) ≥9 were eligible for referral. EPDS, Perinatal Anxiety Screening Scale (PASS), Generalized Anxiety Disorder Screen (GAD-7), Adverse Childhood Experiences Questionnaire (ACE) and Client Satisfaction Questionnaire (CSQ-8) were measured at the intake and discharge visits. Treatment plans included psychotherapy, medication management, or referral to psychiatry for long-term management. Differences in depression and anxiety scales were compared between the intake and discharge visits.

Results: During 1/23/23-07/24/24, 219 patients completed the CC program. Demographics and patient treatment plans are shown in Table 1. 158 (72.5%) of enrolled patients had a past mental health history. Most patients had current anxiety or obsessive-compulsive disorder, adjustment disorder, or a depressive disorder at the intake visit. 42 (19.4%) patients were taking psychiatric medications at the intake visit and 33 of those patients (78.6%) were on an SSRI. 72 (33%) were on a medication at time of discharge, with 83.3% being an SSRI. There were significant changes in EPDS, PASS and GAD-7 scores from intake to discharge visit ($p < 0.001$) (Table 2). Patients showed high scores on the CSQ-8, indicating high satisfaction with the CC.

Conclusion: A CC program within the OB setting is an effective intervention to reduce perinatal symptoms of anxiety and depression.

1178 | Low-Fetal Fraction on NIPT: The Role of the 11-14 week Ultrasound

Sarah J. Weingarten[1]; Alex Raghunandan[2]; Stephen T. Chasen[3]
[1]*Weill Cornell Medicine at New York Presbyterian, New York, NY;* [2]*Weill Cornell Medical College, New York, NY;* [3]*Weill-Cornell Medical College, New York, NY*

4:00 PM - 6:00 PM

Objective: Low fetal fraction (LFF) on non-invasive prenatal testing (NIPT) is associated with a higher risk of chromosomal abnormalities. Our goal was to determine the negative predictive value (NPV) of a normal 11-14 week ultrasound (US) in the setting of LFF on NIPT.

Study Design: This was a retrospective review of patients with LFF on first-trimester NIPT who had an 11-14 week US from 2021-2024. Patients with multiple gestations were excluded. Body mass index (BMI), age and estimated gestational age (EGA) at time of NIPT were assessed. Normal genetic outcomes were defined as normal repeat NIPT, normal invasive testing or normal postnatal evaluation. The primary outcome was the negative predictive value of the 11-14 week US in those with LFF. Fisher's exact test was used for statistical comparison.

Results: 179 patients with LFF were included. Five (2.8%) had chromosomal abnormalities including Trisomy 18 (n = 3), Trisomy 21 (n = 1) and Monosomy X (n = 1). Eight patients (4.5%) had an abnormal US: all eight had abnormal nuchal translucency, and two had additional structural abnormalities. 167 patients (93.3%) had a normal repeat NIPT or underwent invasive testing. Of those who underwent repeat NIPT, LFF was found again in 18.3%. Of these patients, one patient had an abnormal genetic result of Monosomy X. There was a strong correlation between abnormal US and chromosomal abnormalities (50% vs. 0.6%; $p < 0.001$), with four of five affected pregnancies having an abnormal US. The NPV of normal US after LFF result was 99.4% and the sensitivity of the 11-14 week US was 80%. There was no significant difference in BMI or gestational age at NIPT between those with normal and abnormal outcomes, and rates of obesity were similar in those with normal vs abnormal outcomes (36.1% vs 40%; p = 1.0).

Conclusion: In patients with LFF choosing between repeat NIPT vs invasive testing, the 11-14 week US has high sensitivity and NPV in screening for chromosomal abnormalities. As with all screening tests, patients must be counseled about the potential for false-negative results.

Table 1: Patient Characteristics

Characteristic	Patients N = 179
Age	35.0 (32.0, 38.0)
BMI at time of NIPT	27 (23, 33)
EGA at NIPT	10.00 (10.00, 10.00)
Repeat NIPT done?	159 (89%)
Timing of repeat NIPT	12.00 (12.00, 13.00)
Repeat NIPT result	
Normal	127 (80%)
Trisomy 18	2 (1.3%)
Trisomy 21	1 (0.6%)
Low fetal fraction	29 (18%)
Abnormal 11-14 week US	8 (4.5%)
Invasive testing done?	58 (32%)
Normal pregnancy outcome[1]	174 (97%)

1179 | Utero-Cervical Angle in Standing Position Improves Prediction of Spontaneous Preterm Birth: A Multicenter Cohort Study

Jean-Charles Pasquier[1]; Isabelle Boucoiran[2]; Marie-Ève Roy-Lacroix[3]; Begona Martinez de Tejada Weber[4]; Mi-Suk Kang Dufour[5]; Sarah Bilodeau[6]; Emmanuel Bujold[7]
[1]Research Centre of Centre hospitalier de l'Université de Montréal, Montreal, PQ; [2]University of Montreal, Montreal, PQ; [3]Université de Sherbrooke, Sherbrooke, PQ; [4]Hopitaux Universitaires Genève (HUG), Geneve, Geneve; [5]Ste-Justine Hospital, Montreal, PQ; [6]Research Center Of Centre Hospitalier De L'Université De Montréal, Montreal, PQ; [7]Université Laval, PQ

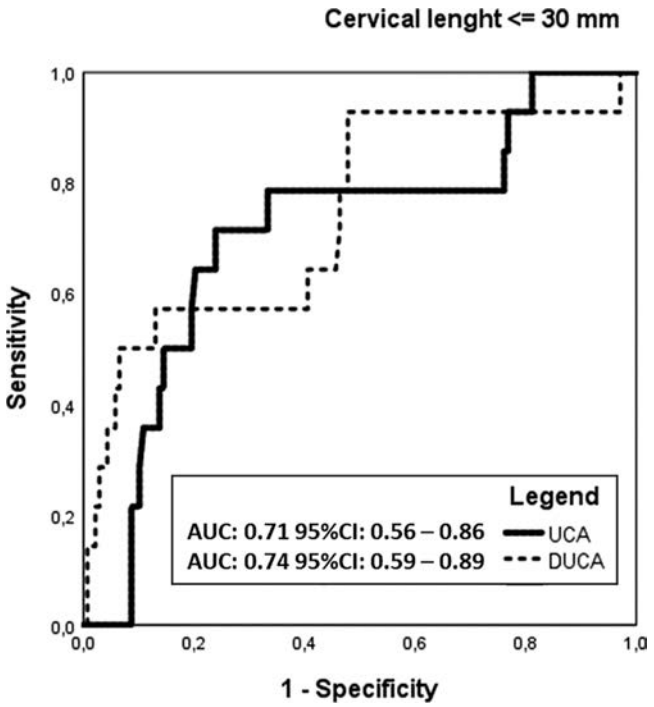
4:00 PM - 6:00 PM

Objective: Measuring cervical length (CL) is a standard practice of stratifying the likelihood of preterm birth (PTB). Dynamic changes in the cervix can also be explored by placing the patient in the upright position, i.e. in the usual position of activity and measuring the shortening of the cervix and changes in the utero-cervical angle (UCA). The aim of this study is to determine whether dynamic measurement of CL and UCA improves prediction of PTB compared additionally to the CL measurement performed in a gynecological position.

Study Design: This is a prospective cohort study of women who had vaginal ultrasound exam for CL measurement at 4 institutions in Canada and Switzerland. The ultrasound exam was performed endovaginally in the supine position, then in the standing position with measurements taken at 1 minute, 3 minutes and during standing Valsalva (SV). UCA were measured after the exam on the images according to a standardized measurement procedure and the differences in UCA (DUCA) between the supine and standing positions were calculated.

Results: 253 participants were included, with a mean age at ultrasound of 27.4 weeks of gestation (WG), a median CL of 26 mm, and a funneling present in 29% of cases in the gynecological position. Among those women, 68 (26.8%) experienced PTB. LC mean was 28.5mm (standard deviation (SD) 10) at rest and 27.3mm (11.5) in SV in the term group, compared with 23.5mm (10.2) and 21.4mm (10) in the PB group respectively. The UCA mean was 113° (25) at rest and 115° (28) in SV in the term group compared with 88.6° (25) and 99° (27) in the PTB group respectively. From the ROC curves, we chose a threshold for UCA of 104° and 5° for DUCA (figure 1). Among participants with LC<31mm, the use of UCA and DUCA significantly improved the prediction of PB but not the LC.

Conclusion: Using endovaginal screening to select a population at risk of PB (LC<31mm), the use of UCA measurement and its variation between the supine and upright positions (DUCA) improves prediction of PB.



1180 | McDonald versus Shirodkar Cervical Cerclage for the Prevention of Preterm Birth in Patients with Obesity

Sarah H. Abelman; Frank I. Jackson; Nathan A. Keller; Julie Chen; Luis A. Bracero; Matthew J. Blitz
Northwell, New Hyde Park, NY

4:00 PM - 6:00 PM

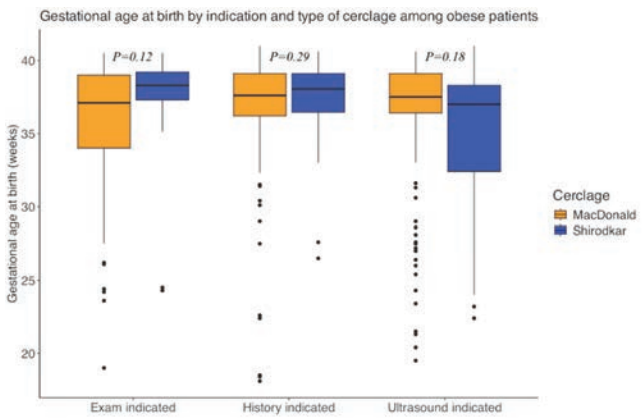
Objective: Differences in outcomes after Shirodkar versus McDonald cerclage techniques remain unclear. Some evidence suggests a potential benefit of Shirodkar cerclage in obese patients. This study aims to compare gestational age at delivery of patients with obesity who received either McDonald or Shirodkar cerclages.

Study Design: This was a retrospective cohort study of all patients with obesity (BMI $\geq$ 30 kg/m^2) who received cerclage during pregnancy between January 2018 and December 2023 within a large health system in New York. The primary exposure was cerclage type. The primary outcome evaluated was gestational age at delivery. Outcomes were compared using a linear mixed model regression analysis, and were then adjusted for maternal age, BMI, nulliparity, history of prior preterm birth, cerclage indication, and gestational age at cerclage placement. A

subgroup analysis was performed based on cerclage indication, additionally adjusting for very short cervix less than 1 cm in the ultrasound-indicated cerclage subgroup.

Results: 517 pregnant patients with obesity who received cerclages were included in this study. 238 (46%) were ultrasound-indicated, 118 (23%) were exam-indicated, and 158 (31%) were history-indicated cerclages. 385 (74%) received a McDonald cerclage and 132 (26%) received a Shirodkar cerclage. The mean gestational age at placement was 17.0 weeks (SD 3.5) for the McDonald group and was 17.3 (SD 3.4) for the Shirodkar group. Unadjusted and adjusted analyses showed no significant difference in pregnancy duration between the two groups, with the mean gestational age at delivery being 36.2 weeks (SD 4.4) for the McDonald group and 35.8 (SD 4.5) for the Shirodkar group (P = 0.48). Subgroup analyses by cerclage indication also showed no difference in gestational age at delivery based on Shirodkar versus McDonald technique (figure 1).

Conclusion: In this large cohort of patients with obesity undergoing cerclage placement during pregnancy, there was no difference in delivery timing based on cerclage technique. Both techniques appear equally effective in prolonging pregnancy.



1181 | Screening and Diagnosis of Gestational Diabetes, and Perinatal Outcomes in Patients with Bariatric Surgery History

Silpa Annavarapu[1]; Charlette Williams[2]; Rodney A. McLaren, Jr., Jr.[3]; Sarah Boudova[4]

[1]Thomas Jefferson University Sidney Kimmel Medical College, Philadelphia, PA; [2]Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA; [3]Thomas Jefferson University Hospital, Philadelphia, PA; [4]Thomas Jefferson University, Philadelphia, PA

4:00 PM - 6:00 PM

Objective: History of bariatric surgery is increasingly common in pregnancy. The glucose tolerance test (GTT) is the gold standard for diagnosing gestational diabetes (GDM), however individuals with a history of bariatric surgery may not tolerate the sugar load and there is concern that the test may be inaccurate in this population. There are no current ACOG guidelines regarding screening for GDM in patients with a history of bariatric surgery. We aimed to characterize how individuals with a history of bariatric surgery were screened and diagnosed with GDM and describe pregnancy outcomes by screening method.

Study Design: This was a retrospective cohort study of pregnancies with a history of bariatric surgery delivered at a major urban referral hospital from 1/17-12/23. Demographics, bariatric surgery history, GDM screening method, pregnancy outcomes and neonatal outcomes were abstracted. The protocol was IRB approved. Data were analyzed with descriptive statistics.

Results: Of the 192 identified pregnancies with a history of bariatric surgery, 17 (8.9%) had pregestational diabetes and 11(5.7%) had no data on screening and were excluded from analysis. Among the remaining 164 pregnancies, 29 (17.7%) were diagnosed with GDM, and 59 (36.0%) did not complete screening. The most common screening method was exclusive GTT (47, 28.7%), followed by glucose fingersticks (34, 20.7%), followed by mixed screening methods (18, 11.0%) (Table 1). GTT was most commonly used for those with sleeve gastrectomy, while fingersticks were most commonly used for Roux-en-Y. Cesarean delivery occurred in 68, 41.5% pregnancies. Hypertensive disorder of pregnancy occurred in 28, 17.1% pregnancies. The composite adverse neonatal outcome occurred in 40 (24.4%) deliveries and was more common among those diagnosed with GDM (Table 2).

Conclusion: Among pregnancies with a history of bariatric surgery, GDM was common, however, there was a low rate of completed GDM screening. GTT was the most common screening method. Further research is needed to determine the reason for low rates of GDM screening.

Table 1: Demographics of patients by screening method

1182 | The Effect of Gestational Weight Gain on Successful Operative Vaginal Delivery

Shannon R.O Moran; James A. Shelton; Dawei David Wang
University at Buffalo, Buffalo, NY

4:00 PM - 6:00 PM

Objective: Successful operative vaginal delivery (OVD) has been associated with reduced maternal and neonatal morbidity. However, appropriate patient selection is necessary to reduce the risks of failed OVD. Previous studies have shown mixed results regarding the effect of body mass index (BMI) on rates of OVD success. However, no studies have examined the effect of gestational weight gain (GWG) on OVD success. Therefore, we sought to investigate the effect of excessive GWG on OVD success.
Study Design: This was an IRB-approved retrospective cohort study of birth certificate data from our institution from 2014 to 2023. We included singleton, term, vertex livebirths with no major fetal anomalies who attempted OVD. Those with excessive GWG based on the Institute of Medicine guidelines were compared to those with adequate GWG. The primary outcome was successful OVD. Secondary outcomes included composite maternal and neonatal morbidity among those who achieved successful OVD. Logistical regression models estimated the odds ratios (OR) of successful OVD by GWG adjusted for maternal age and race, infant birthweight, gestational diabetes, gestational hypertension, previous cesarean section, prolonged labor, prior vaginal delivery, and BMI.
Results: 2,433 patients were included. 1,055 had adequate GWG (43%). 1,378 had excessive GWG (57%). 2,271 had a successful OVD (93%) and 162 had a failed OVD (7%). OVD was not affected by GWG (aOR 0.99, CI 0.64-1.55). Subgroup analyses based on pre-pregnancy BMI revealed no effect of weight gain on the success rate of OVD across all BMI groups. Finally, there was no difference in both maternal and neonatal outcomes in those with excessive GWG who had a successful OVD (14%, p-value 0.6 versus 14% for those with adequate GWG and 14%, p-value 0.095 versus 11% for those with adequate GWG, respectively).
Conclusion: Excessive GWG is not associated with a reduction in the rate of successful OVD or with adverse maternal or neonatal outcomes in those who do achieve successful OVD. Excessive GWG should not be considered a relative contraindication to OVD.

1183 | Monogeneic Disorder (MD) Screening using Cell-Free DNA (cfDNA) In Routine Practice

Xiteng Yan[1]; Samantha R. Ratner[2]; Andrei Rebarber[3]; Tamar H. Goldwaser[4]; Shari Gelber[5]
[1]Mount Sinai West, New York, NY; [2]Perelman School of Medicine, Philadelphia, PA; [3]Icahn School of Medicine at Mount Sinai Hospital, New York, NY; [4]Maternal Fetal Medicine Associates, New York, NY; [5]Icahn School of Medicine at Mount Sinai, New York, NY

4:00 PM - 6:00 PM

Objective: More pregnancies are affected by MDs than by trisomy 21. MDs are often not identified on ultrasound, standard invasive testing, or microarray. Clinical studies of cfDNA detection of MD report >99% sensitivity and specificity, with a 1:600 incidence of positive results in a high-risk population. We sought to determine (1) the feasibility of offering routine cfDNA for MD, (2) false positive rate of MD diagnosed at the time of cfDNA for

aneuploidy, (3) accuracy of cfDNA for MD when routinely offered to low-risk patients.

Study Design: From 10/11/2021-7/15/2024 all patients in a single obstetrical practice were offered MD screening (25 conditions in 47 genes) at the time of cfDNA screening for aneuploidy. Patients with egg donors, multiple gestation, and vanishing twins were excluded, as were those who had testing for ultrasound findings or other risk factors. Genetic counseling, diagnostic CVS/amniocentesis, and parental testing were recommended for patients with positive results. Repeat testing was recommended for patients who did not receive a result.

Results: 1831 pregnancies in 1746 women were included. Results were positive in 5 pregnancies (0.28%) (**Table**), negative in 1730 (94%), and 96 (5.2%) received no initial result. 75/96 patients repeated testing: 63 were negative and 12 did not result (0.66% final no-call rate). Of the positive tests, 4 were true positive on confirmatory testing with CVS or amniocentesis and one was negative for both fetus and parents. MD testing was positive in 1:366 patients; incidence of the disorders was 1:458. False positive results occurred in < 1% of tests.

Conclusion: MDs affected >1:500 pregnancies. Screening for MDs is not recommended by professional societies or offered as part of routine care. Screening for MD in low-risk pregnancies is feasible. MD screening in the general population should be considered, as it is unlikely to significantly increase unnecessary invasive testing and may prenatally diagnose conditions and afford women reproductive choice in the current pregnancy and the future.

Table: Summary of positive cfDNA results

1184 | Tighter Blood Pressure Control Targets to Reduce Adverse Pregnancy Outcomes for Patients with Chronic Hypertension

Sharon W. Shu; Meena Mishra; Frank B. Williams
Ochsner Clinic Foundation, New Orleans, LA

4:00 PM - 6:00 PM

Objective: The Chronic Hypertension and Pregnancy (CHAP) Trial demonstrated improved outcomes for pregnant women with mild chronic hypertension (HTN) assigned strict blood pressure (BP) target of ≤ 140/90 compared to controls with target of ≤ 160/110. CHAP-based treatment guidelines were implemented at our health system in 2022. We hypothesize that implementation of CHAP guidelines in a large, socio-demographically diverse population reduced HTN-related morbidity.

Study Design: This is a retrospective cohort study of singleton pregnancies with a known or new diagnosis of mild HTN receiving prenatal and delivery care at a large regional health system in 2021 and 2023. In April 2022, BP targets of ≤ 140/90 were implemented. We compared 2021 with 2023 deliveries, with 2022 a washout period. Multiple gestations, major fetal anomalies, > 1 baseline antihypertensive, phospholipid syndrome or HTN-related cardiac or kidney disease were excluded. Primary outcome per CHAP was a composite of medically indicated preterm birth before 35 weeks, superimposed preeclampsia with severe features, placental abruption & perinatal death. Secondary outcomes included small-for-gestational-age and preterm birth before 37. Outcome adjusted odds ratios were generated via regression analyses controlling for maternal age, body mass index, public insurance, history of preeclampsia, and pre-existing diabetes.

Results: Of 1626 pregnant women with HTN, 134 were excluded for twins, congenital anomalies, >1 baseline antihypertensive or HTN-related comorbidities. Of the 1492 remaining, 710 were pre-, while 782 were post-implementation. The post-intervention group had higher BMI and higher public payor insurance status (Table 1). The primary composite outcome occurred in 30.9% of pre-implementation pregnancies compared to 29.2% of post-implementation pregnancies (aOR 0.84, 95% CI 0.66-1.09). Medically indicated delivery before 35 weeks was lower in the post-intervention group (10.4% vs 12.1%, aOR 0.7, 95% CI 0.47-0.99, Table 2).

Conclusion: Tighter BP control targets did not reduce the CHAP-defined outcome.

	Pre-Implementation (n=710)	Post-Implementation (n=782)	P
Median Age at Delivery	31.0 [27.0, 35.0]	32.0 [27.0, 35.0]	0.391

1185 | Intertwin EFW Discordance and Perinatal Loss in Monochorionic Diamniotic Twins with Selective Fetal Growth Restriction

Shelly Soni[1]; Juliana S. Gebb[2]; Christina Paidas Teefey[1]; Beverly G. Coleman[3]; Julie S. Moldenhauer[1]; Nahla Khalek[1]
[1]Richard D. Wood Jr. Center for Fetal Diagnosis and Treatment at CHOP, Philadelphia, PA; [2]Richard D. Wood, Jr Center for Fetal

Diagnosis and Treatment, Children's Hospital of Philadelphia, Philadelphia, PA; [3]Richard D. Wood, Jr Center for Fetal Diagnosis and Treatment, The Children's Hospital of Philadelphia, Philadelphia, PA

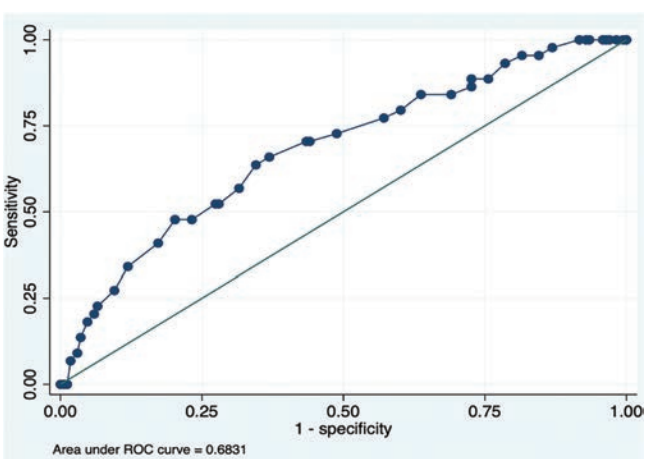
4:00 PM - 6:00 PM

Objective: To identify the association between the degree of intertwin estimated fetal weight (EFW) discordance and perinatal loss in monochorionic diamniotic (MCDA) twin pregnancies complicated by selective fetal growth restriction (sFGR).

Study Design: Single center retrospective review of MCDA twins diagnosed with sFGR that opted for expectant management between 2010-2021. The relationship between intertwin EFW discordance and perinatal loss was evaluated using receiver–operating characteristics (ROC) and survival analysis to identify the optimal cut-off for EFW discordance. The 2 groups of different intertwin discordance were compared to evaluate and identify other risk factors.

Results: A total of 212 MCDA twin pregnancies with sFGR underwent expectant management in the study period. 18 pregnancies (8.5%) were dual demise and 11 (5.2%) had demise of one fetus. Of those born alive, dual neonatal demise was seen in 5 (2.4%) pregnancies whereas neonatal demise of one twin was seen in 11 pregnancies (5.2%). Further, of the 11 pregnancies with one fetal demise, 5 (2.4%) had neonatal demise. Total perinatal loss rate was 73 fetuses/neonates (17.2%) of 424 (212 twins). The area under curve (AUC) ROC curve for intertwin EFW discordance and perinatal loss was 0.68 [95% CI 0.59-0.78] with a p-value of 0.0001 (Graph 1). A discordance of ≥ 33% was 56.82% sensitive and 68.45% specific in predicting perinatal loss. The gestational age at delivery and two survivors to discharge were significantly lower in pregnancies with a discordance of ≥ 33% (Table). Kaplan–Meier analysis showed that pregnancies with a discordance of ≥ 33% had a significantly lower survival trend with a p-value of 0.0001 and hazards ratio for risk of perinatal loss of 3.83 [95% CI 1.85-7.95] (Graph 2).

Conclusion: Intertwin EFW discordance of ≥ 33% can be used as the optimal cut-off for prediction of perinatal loss in cases of MCDA twin with sFGR.



AUC for intertwin EFW discordance and perinatal loss

	Intertwin EFW discordance < 33% (N=134)	Intertwin EFW discordance ≥ 33% (N=78)	P value

1186 | A Scoring System for Estimating Risk of Perinatal Loss in Monochorionic Diamniotic Twins with sFGR

Shelly Soni[1]; Juliana S. Gebb[2]; Christina Paidas Teefey[1]; Edward R. Oliver[2]; Julie S. Moldenhauer[1]; Nahla Khalek[1]

[1]Richard D. Wood Jr. Center for Fetal Diagnosis and Treatment at CHOP, Philadelphia, PA; [2]Richard D. Wood, Jr Center for Fetal Diagnosis and Treatment, Children's Hospital of Philadelphia, Philadelphia, PA

4:00 PM - 6:00 PM

Objective: To evaluate a novel scoring system based on markers of placental insufficiency and fetal physiology that can assist in predicting perinatal loss in monochorionic diamniotic (MCDA) twins complicated by selective fetal growth restriction (sFGR).

Study Design: Single center retrospective review of MCDA twins diagnosed with sFGR that opted for expectant management between 2010-2021. Various demographic and outcome variables were compared in pregnancies with and without perinatal loss. Significant variables were analyzed in a multiple logistic regression model with backward elimination method to identify factors predictive of perinatal loss. The identified significant factors were re-run in multiple logistic regression to assess individual effect on outcomes. A score was then assigned based on the strength of the effect. The relationship between the assigned score and perinatal loss was evaluated using receiver–operating characteristics (ROC) and survival analysis to identify optimal cut-off.

Results: A total of 212 MCDA twin pregnancies with sFGR underwent expectant management in the study period. Perinatal loss occurred in 44 pregnancies (20.8%). Of the significant variables from univariate analysis (Table 1); intertwin EFW discordance, and abnormal findings in growth restricted twin including low amniotic fluid, abnormal UA Dopplers and abnormal MCA Dopplers were identified as significant in the stepwise multiple logistic regression. These variables were re-entered into a logistic regression model and a score was assigned according to the relative contribution of each variable in this model (Table 2). The area under ROC curve(AUC) for the score and perinatal loss was 0.78 [95% CI 0.7-0.85] with a p-value of 0.0001 (Graph 1). A score of ≥ 3 was 70.5% sensitive and 76.2% specific in predicting perinatal

loss. Kaplan–Meier analysis showed that pregnancies with a high score (≥ 3) had a significantly lower survival trend with a p-value of < 0.0001 (Graph 2).

Conclusion: This novel scoring system in MCDA twins with sFGR can be used to assess risk of perinatal loss that can be used to assist in counseling.

Table 1: Univariate analysis of various variables in pregnancies with and without perinatal loss

1187 | Association Between Being Born Small for Gestational Age and the Risk for Childhood Celiac Disease

Shir Luvaton[1]; Tamar Wainstock[2]; Eyal Sheiner[2]; Gali Pariente[2]
[1]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Be'er Sheva, HaDarom; [2]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom

4:00 PM - 6:00 PM

Objective: Celiac disease is a common immune disorder, frequently associated with other autoimmune conditions. Autoimmunity is recognized as a potential factor contributing to placental insufficiency, by affecting placental development and structure, which may lead to fetal growth restriction. Based on the possible correlation between autoimmunity, celiac disease and placental insufficiency, we sought to investigate whether small for gestational age (SGA) newborns are at an increased risk of developing celiac disease during childhood.

Study Design: A population-based cohort study was conducted to evaluate the risk of celiac disease during childhood (up to the age of 18 years) among individuals who were born SGA between the years 1991-2021, in a single tertiary medical center. Data for the diagnosis of celiac disease was extracted from community-based clinics and hospitalization records. Kaplan-Meier survival curve was used to compare the cumulative incidence of celiac disease between the study groups (SGA vs. no SGA). A cox proportional hazards model was used to control for confounders.

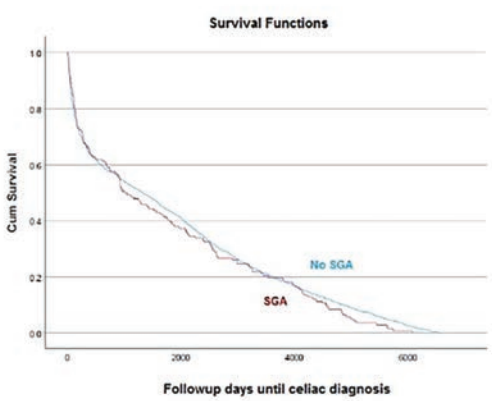
Results: During the study period, 356,356 newborns were included in the analysis; of which 16,210 (4.5%) were born SGA. Being born SGA was associated with higher risk for celiac disease as compared to children who were not born SGA (0.9% vs 0.5%, P< 0.001, Table). However, the Kaplan-Meier survival curve did not demonstrate higher cumulative incidence rates of celiac disease in infants born SGA (Log Rank p = 0.287, Figure). Likewise, using a Cox proportional hazards model, adjusted for maternal celiac disease, maternal age and gestational age at birth, the finding was no longer statistically significant (adjusted HR 1.10, 95% CI 0.92-1.30, p = 0.274, Table).

Conclusion: According to our results, being born SGA is not an independent risk factor for long-term childhood celiac disease.

The association between being born SGA and celiac disease; univariable analysis, Kaplan-Meier survival curve and a Cox proportional hazards model

	SGA (n=16,210) n (%)	No SGA (n=340,146) n (%)	OR (95% CI)	P value	Adjusted HR* (95% CI)	P* value
Celiac disease	142 (0.9%)	1819 (0.5%)	1.6 (1.38-1.95)	<0.001	1.1 (0.92-1.30)	0.274

*Adjusted for gestational age, maternal age at birth and maternal celiac disease



1188 | Risk of Severe Maternal Morbidity in Pregnant People with Malignant Neoplasm Using a Population Database

Shriddha Nayak[1]; Kristin C. Darwin[2]; Arthur Jason Vaught[2]; Marika Toscano[1]
[1]*Johns Hopkins University, School of Medicine, Baltimore, MD;*
[2]*Johns Hopkins University, Baltimore, MD*

4:00 PM - 6:00 PM

Objective: The objective of this study was to determine the difference in odds of severe maternal morbidity (SMM) in people with and without malignant neoplasm in pregnancy using a real-world sample derived from TriNetX, a research network containing de-identified electronic health record data from 93 health care organizations and > 131 million patients.

Study Design: This population-based, retrospective cohort study queried TriNetX from inception to 8/2024 for subjects 12-55 years with a diagnosis of pregnancy. Two cohorts were derived: subjects with and without active diagnosis of any malignant neoplasm within one year prior to, or up to one month after, first instance of pregnancy. Cohorts were propensity score matched 1:1 based on demographic characteristics (age, race, and ethnicity) and comorbidities (diabetes, hypertension, obesity, cardiovascular disease, asthma, and tobacco use) by TriNetX analysis tools. SMM was defined as CDC's 21 indicators and corresponding ICD-10 codes. The primary outcome was difference in odds ratio (OR) between cohorts of composite SMM occurring up to one year after first instance of pregnancy. Secondary outcomes were differences in odds of individual indicators of SMM. All statistical analyses were conducted 8/2024 using the TriNetX platform.

Results: Of 5567972 pregnant subjects, 5373233 had no malignancy history. After propensity score matching, subjects with and without (n = 51484 for both) malignant neoplasm in pregnancy were analyzed (Table). Subjects with malignant neoplasm in pregnancy had significantly higher odds of composite SMM (OR 3.43 (95% CI 3.24-3.64), p< 0.001) compared to those without malignant neoplasm in pregnancy. Cases of malignant neoplasm in pregnancy had significantly higher odds of all individual indicators of SMM compared to controls, except for eclampsia (Table).

Conclusion: Subjects with malignant neoplasm in pregnancy had over threefold increased odds of composite SMM, as well as significantly increased odds of 16 of the 21 individual indicators of SMM, compared to those without malignancy in pregnancy.

TABLE. Severe maternal morbidity (SMM) in patients with malignant neoplasm in pregnancy

SMM Indicator	Rate of SMM		Odds Ratio	95% Confidence Interval (lower limit, upper limit)	p value
	Malignant Neoplasm in Pregnancy (n=51484)	Pregnancy, No Cancer History (n=51484)			
Composite	12.9%	4.1%	3.43	(3.24, 3.64)	<0.001
Acute myocardial infarction	1.7%	0.6%	2.79	(2.44, 3.18)	<0.001
Aneurysm and dissection	0.5%	0.2%	2.80	(2.22, 3.53)	<0.001
Acute renal failure	1.4%	0.6%	2.40	(2.09, 2.75)	<0.001
Acute respiratory distress syndrome	7.7%	2.2%	3.76	(3.50, 4.05)	<0.001
Amniotic fluid embolism	0%	0%	~	~	N/A
Cardiac arrest/ventricular fibrillation	0.5%	0.2%	2.70	(2.12, 3.43)	<0.001
Conversion of cardiac rhythm	0.1%	0.1%	1.84	(1.20, 2.84)	0.005
Disseminated intravascular coagulation	4.3%	1.3%	3.30	(3.02, 3.61)	<0.001
Blood transfusion	1.2%	0.7%	1.90	(1.66, 2.17)	<0.001
Eclampsia	0.2%	0.2%	1.02	(0.77, 1.35)	0.910
Heart failure/arrest during surgery or procedure	0.0%	0.0%	~	~	N/A
Puerperal cerebrovascular disorders	4.5%	1.2%	3.69	(3.37, 4.05)	<0.001
Pulmonary edema/acute heart failure	1.9%	0.8%	2.58	(2.29, 2.90)	<0.001
Severe anesthesia complications	0%	0%	~	~	N/A
Sepsis	2.1%	0.7%	3.17	(2.80, 3.58)	<0.001
Shock	1.0%	0.4%	2.71	(2.30, 3.20)	<0.001
Sickle cell disease with crisis	0.0%	0.0%	~	~	N/A
Air and thrombotic embolism	1.7%	0.6%	2.97	(2.60, 3.39)	<0.001
Hysterectomy	0.6%	0.2%	3.54	(2.78, 4.50)	<0.001
Temporary tracheostomy	0.1%	0.1%	2.21	(1.42, 3.43)	<0.001
Ventilation	0.5%	0.2%	2.08	(1.66, 2.59)	<0.001

1189 | Prevalence of Severe Maternal Morbidity Associated with Different Cancer Types in Pregnancy

Shriddha Nayak[1]; Kristin C. Darwin[2]; Arthur Jason Vaught[2]; Marika Toscano[1]
[1]*Johns Hopkins University, School of Medicine, Baltimore, MD;*
[2]*Johns Hopkins University, Baltimore, MD*

4:00 PM - 6:00 PM

Objective: To describe prevalence of composite severe maternal morbidity (SMM) in the top ten most common types of female cancers in the United States using a real-world sample derived from TriNetX, a research network containing de-identified electronic health record data from 93 health care organizations and > 131 million patients.

Study Design: This descriptive cohort study queried TriNetX from inception to 8/2024 for subjects 12-55 years with a diagnosis of malignant neoplasm within one year prior to, or up to one month after, first instance of pregnancy. A cohort of all malignant neoplasm types, further subdivided by individual types, were analyzed. Included malignant neoplasm types were identified from CDC's most recently reported female cancer types associated with new cancer diagnoses, or cancer deaths, in the United States. SMM was defined as CDC's 21 indicators and corresponding ICD-10 codes. The primary outcome was prevalence of composite SMM occurring up to one year after first instance of pregnancy. Secondary outcomes included prevalence of individual indicators of SMM. All descriptive analyses were conducted 8/2024 using the TriNetX platform.

Results: There were 51484 individuals with malignant neoplasm in pregnancy. Mean age was 32.4 years and comorbid conditions included hypertension (12.3%), diabetes mellitus (11.1%), obesity (13.6%), asthma (11.3%) and tobacco use (13.0%). Breast cancer and skin cancer/melanoma were the most common malignancies co-occurring with pregnancy (Table). The prevalence of composite SMM for all cancer type in pregnancy was 12.9% with morbidity most often acute respiratory distress syndrome (7.7%) (Table). Composite SMM prevalence was highest for liver/bile duct cancer (17.4%). Thyroid cancer in pregnancy had the lowest composite SMM rate of 6.5%.

Conclusion: Close to one in eight patients with a malignant neoplasm in pregnancy will experience SMM, with prevalence of composite SMM differing by malignancy type. Further research is needed to evaluate the short- and long-term outcomes of patients with cancers during pregnancy.

Table. Prevalence of severe maternal morbidity associated with different cancer types in pregnancy

Population	Composite SMM Rate (%)	Most Prevalent Individual Indicators of SMM		
		First	Second	Third
All Cancer in Pregnancy (n=51484)	12.9	ARDS (7.7%)	PCD (4.5%)	DIC (4.3%)
Cancer Type in Pregnancy				
Liver and Bile Duct (n=1274)	17.4	ARDS (11.6%)	PCD (4.6%), Sepsis (4.6%)	DIC (4.4%)
Colorectal (n=7570)	17.2	ARDS (11.6%)	DIC (5.5%)	PCD (5.0%)
Uterus (n=2395)	16.4	ARDS (8.9%)	PCD (5.1%)	DIC (4.6%)
Lung (n=2143)	15.8	ARDS (10.8%)	PCD (6.2%)	DIC (5.7%)
Ovary (n=1700)	15.2	ARDS (5.7%)	PCD (5.0%)	DIC (3.5%)
Pancreas (n=533)	14.9	ARDS (9.3%)	PCD (5.7%)	DIC (4.8%)
Leukemia (n=2333)	14.8	ARDS (8.5%)	Sepsis (5.8%)	DIC (5.1%)
Kidney and Renal Pelvis (n=754)	14.7	ARDS (7.9%)	PCD (7.4%)	DIC (4.8%)
Breast (n=9937)	14.4	ARDS (8.5%)	PCD (5.2%)	DIC (4.3%)
Non Hodgkin's Lymphoma (n=2487)	13.2	ARDS (8.9%)	DIC (5.8%)	PCD (5.7%)
Brain (n=719)	12.6	PCD (6.6%)	ARDS (4.4%)	Sepsis (4.1%)
Skin and Melanoma (n=9342)	10.7	ARDS (7.6%)	DIC (4.1%)	PCD (4.0%)
Thyroid (n=2708)	6.5	ARDS (3.8%)	PCD (2.8%)	DIC (2.6%)

Abbreviations: ARDS= acute respiratory distress syndrome, DIC = disseminated intravascular coagulation, PCD = puerperal cerebrovascular disorder, SMM = severe maternal morbidity

1190 | Risk of Severe Maternal Morbidity Among Pregnant People with Breast Cancer Using a Population Database

Shriddha Nayak[1]; Kristin C. Darwin[2]; Arthur Jason Vaught[2]; Marika Toscano[1]
[1]Johns Hopkins University, School of Medicine, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD

4:00 PM - 6:00 PM

Objective: A new breast cancer diagnosis is more common than all other cancer types in females 15-39 years in the United States and is the second leading cause of female cancer deaths. Our objective was to determine the odds of severe maternal morbidity (SMM) in breast cancer in pregnancy using TriNetX, a research network containing real-world data from 93 health care organizations and > 131 million patients.

Study Design: This retrospective cohort study queried TriNetX from inception to 8/2024 for subjects 12-55 years with a pregnancy diagnosis. Two cohorts were derived: (1) individuals with an active diagnosis of breast cancer 1 year prior to, or up to 1 month after, first instance of pregnancy and (2) those without a history of any cancer type in pregnancy. Cohorts were propensity score matched 1:1 by demographics and comorbidities by TriNetX built-in analysis tools. SMM was defined as CDC's 21 indicators and corresponding ICD-10 codes. The primary outcome was odds ratio (OR) between cohorts of composite SMM occurring up to 1 year after first instance of pregnancy. Secondary outcomes were odds of individual indicators of SMM. All statistical analyses were conducted in the TriNetX platform.

Results: Propensity score matching yielded 9937 cases of breast cancer in pregnancy and 9937 cases of pregnancy without cancer history (Table). Subjects with breast cancer in pregnancy had significantly higher odds of composite SMM (OR 3.61 (95% confidence interval (CI) 3.17-4.12), p< 0.001) compared to those without malignancy in pregnancy. The odds of acute respiratory distress syndrome (ARDS) were highest (OR 3.89 (95% CI 3.31-4.56), p< 0.001), followed by cerebrovascular disorders (OR 3.30 (95% CI 2.73-3.98), p< 0.001) and disseminated intravascular coagulation (DIC) (OR 3.01 (95% CI 2.47-3.67), p< 0.001).

Conclusion: Individuals with breast cancer in pregnancy have more than three-fold increased odds of composite SMM compared to those without cancer history, with considerably higher risk of ARDS, cerebrovascular disorders, and DIC.

TABLE. Severe maternal morbidity (SMM) in pregnant people with breast cancer

SMM Indicator	Rate of SMM		Odds Ratio	95% Confidence Interval (lower limit, upper limit)	p value
	Breast Cancer in Pregnancy (n=9937)	Pregnancy without Cancer (n=9937)			
Composite	14.5%	4.5%	3.61	(3.17, 4.12)	<0.001
Acute myocardial infarction	1.6%	0.6%	2.51	(1.86, 3.39)	<0.001
Aneurysm and dissection	0.5%	0.3%	1.90	(1.18, 3.06)	0.007
Acute renal failure	1.2%	0.6%	1.95	(1.42, 2.68)	<0.001
Acute respiratory distress syndrome	8.5%	2.3%	3.89	(3.31, 4.56)	<0.001
Amniotic fluid embolism	0%	0%	~	~	N/A
Cardiac arrest/ventricular fibrillation	0.5%	0.3%	1.68	(1.05, 2.68)	0.029
Conversion of cardiac rhythm	0.1%	0.1%	1.00	(0.42, 2.40)	0.998
Disseminated intravascular coagulation	4.3%	1.5%	3.01	(2.47, 3.67)	<0.001

Temporary tracheostomy	0.1%	0.1%	1.00	(0.42, 2.40)	0.999
Ventilation	0.2%	0.2%	0.83	(0.46, 1.50)	0.536

1191 | Timing of Alpha-Feto Protein (AFP) Screening: Unveiling the Best Predictor for Adverse Pregnancy Outcomes

Siddharth Hariharan[1]; Hameeda A. Naimi[2]; Eric K. BRONI[3]; Shifa Turan[4]; Ozhan M. Turan[5]
[1]University of Rochester, Rochester, NY; [2]Virginia Women's Center, Inc., Richmond, VA; [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [4]University of Maryland Medical System, Baltimore, MD; [5]University of Maryland Medical Center, Baltimore, MD

4:00 PM - 6:00 PM

Objective: AFP at second trimester is used for prediction of neural tube defects and adverse pregnancy outcomes (APO). We hypothesized that first trimester is a better time for screening APOs than second trimester.

Study Design: This secondary analysis of a prospective cohort study included 2,245 patients. Pregnancies with known structural or chromosomal abnormalities, multifetal gestation, or incomplete data were excluded. Primary outcomes were preterm premature rupture of membranes (PPROM), preterm delivery (PD), and composite outcomes (CO: any occurrence of PPROM, PD, placental abruption, or preeclampsia). Alpha-fetoprotein (AFP) levels were measured in the first and second trimesters. A cutoff of 1.33 multiples of the median (MoM) for first trimester AFP, determined via receiver operating curve analysis, was used to predict adverse pregnancy outcomes (APOs) in the 1,713 first-trimester cases. The routine 2.5 MoM threshold was applied for second trimester AFP. A statistical model, adjusted for common risk factors (maternal age, sepsis, chronic hypertension, and preeclampsia), was used to assess associations with APOs, and

the predictive values of first and second trimester AFP levels were compared in the statistical model.

Results: In the final analysis, 1,224 patients were included (Figure 1). Those with elevated first trimester AFP were more likely to be nulliparous (53.4% vs. 36.0%, p< 0.001) and have elevated second trimester AFP (5.54% vs. 0.65%, p< 0.001). Adjusted odds ratios for elevated first trimester AFP were 2.28 (p = 0.004) for PPROM, 3.42 (p< 0.001) for PD, and 1.66 (p = 0.009) for CO. A high negative predictive value (92.4-96.6%) was observed (Table 1). More patients with APOs were detected using first trimester AFP compared to second trimester AFP (p< 0.001 for all, Table 2).

Conclusion: First trimester AFP is a reliable biomarker with a high negative predictive value for excluding pregnancies at risk for APOs. In our study, it effectively replaced second trimester AFP, potentially eliminating the need for second trimester blood draws in care centers with advanced ultrasound capabilities.

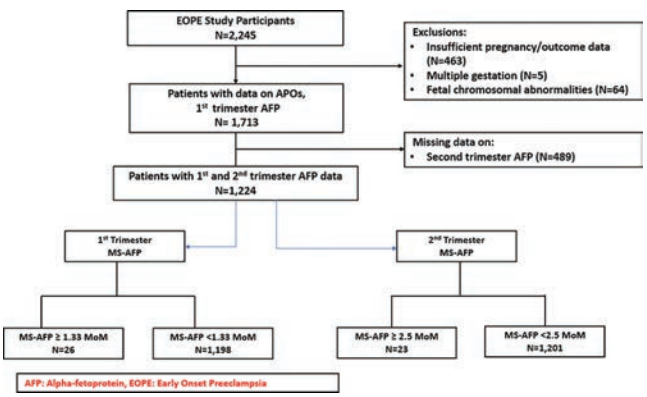

Table 1: Test Characteristics for Adverse Pregnancy Outcomes by 1st Trimester MS-AFP ≥ 1.33 MoM

	PPROM	PTD	CO
Sensitivity	42.5	51.3	32.08
Specificity	75.7	75.1	75.96
PPV	7.49	20.68	16.61
NPV	96.62	92.46	88.22

Table 2: Comparisons of number of APOs detected by 1st and 2nd trimester AFP

	1st trimester MS-AFP ≥ 1.33	2nd trimester MS-AFP ≥ 2.5	P value
PPROM	23/56 (41%)	3/56 (5%)	<0.0001
PTD	19/40 (48%)	3/40 (8%)	<0.0001
CO	67/205 (33%)	10/205 (5%)	<0.0001

PPROM: preterm premature rupture of membranes, PTD: Preterm delivery, CO: Composite outcome, PPV: Positive predictive value, NPV: Negative predictive value, AFP: Alpha feto protein

1192 | The Diagnostic Accuracy of the sFlt-1/PlGF Ratio vs. PlGF alone for Preeclampsia

Siobhan Wilson[1]; Elaine Carson[2]; Lei Fu[3]; Nir Melamed[4]
[1]University of Toronto, Toronto, ON; [2]Department of Maternal Fetal Medicine, Leeds Hospital Trust, Leeds, England; [3]Sunnybrook Health Sciences Centre, Toronto, ON; [4]Division of Maternal Fetal Medicine, Department of Obstetrics and Gynecology, Sunnybrook Health Sciences Centre, Toronto, ON

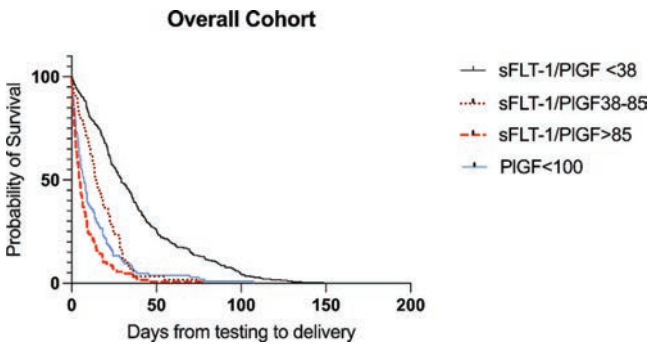
4:00 PM - 6:00 PM

Objective: Preeclampsia is a leading cause of maternal and fetal morbidity and mortality. Abnormal levels of the angiogenic proteins soluble fms-like tyrosine kinase (sFLT-1) and placental growth factor (PlGF) have been shown to be predictive of preeclampsia. However, it remains unclear whether the combination of these proteins in the form of the sFlt1/PlGF ratio performs better than PlGF alone. The objective of the current study was to compare the diagnostic accuracy of the sFlt1/PlGF ratio for preeclampsia with that achieved with PlGF alone under real-life settings.

Study Design: A retrospective cohort study of patients with a singleton pregnancy evaluated in a single center for suspected preeclampsia using the Roche Elecsys sFlt1/PlGF Ratio Assay between 2020-2023. The sFlt1/PlGF ratio was interpreted as low-risk (≤ 38), moderate-risk (38-85), or high-risk (> 85), while PlGF was defined as low-risk (≥ 100 pg/mL) or high-risk (< 100 pg/mL).

Results: Of the 509 patients who met the study criteria, 206 (40.5%) had a final diagnosis of preeclampsia. When compared to PlGF< 100 ng/pL, a sFLT-1/PlGF ratio > 85 was associated with a greater risk of delivery within < 14 (RR = 2.0 [1.8-2.4] vs 1.4 [1.3-1.6]), < 7 (RR = 2.7 [2.1-3.5] vs 1.5 [1.3-1.8]), and < 3 days (RR = 2.7 [2.0-3.8] vs 1.4 [1.2-1.8]). In addition, the area under the ROC curve was higher for the sFLT-1/PlGF ratio to PlGF for delivery within < 7 days (0.86 [0.83-0.89] vs. 0.64 [0.58-0.71]) and preeclampsia diagnosis within < 7 days (0.91 [0.91-0.95] vs. 0.72 [0.65-0.78]). Finally, in a time-to-event analysis, the cumulative risk of delivery was significantly higher among patients with sFLT-1/PlGF ratio > 85 compared to those with PlGF < 100 ng/pL (p< .001) (Figure 1).

Conclusion: The diagnostic accuracy and prognostic value of the sFLT-1/PlGF ratio appears to be greater than that achieved with PlGF alone.



1193 | Small-For-Gestational-Age Predictors in Gestational Diabetes Mellitus: The Impact of Metformin use in GDMA2 Pregnancies

Sivan Farladansky Gershnabel; Dina Lidsky-Sachs; Nur Abd El Qadir; Ronny Ram Biton; Tal biron shental; Michal Kovo; Dorit Ravid
Meir Medical Center, Kfar Saba, HaMerkaz

4:00 PM - 6:00 PM

Objective: Gestational diabetes mellitus (GDM) affects 3% - 25% of pregnancies worldwide, posing risks to maternal, fetal, and neonatal health. GDM is often associated with macrosomia and large-for-gestational-age (LGA) infants. However, the relationship between GDM and small-for-gestational-age (SGA) infants is less understood. This study aims to identify predictors of SGA in women with GDM.

Study Design: This retrospective study included GDM patients (GDM A1 and A2) admitted to the high-risk unit between 2014 and 2023. The study population was divided into those who delivered an appropriate for gestational age (AGA) neonate (AGA group) and those who delivered an SGA neonate (SGA group), defined as birthweight < 10th percentile. Women with pregestational diabetes mellitus were excluded. Obstetric and neonatal outcomes were compared between the groups. A subgroup analysis focused on GDMA2 patients, comparing maternal and neonatal outcomes and treatment regimens (insulin and metformin use).

Results: The study included 894 GDM patients. Compared to the AGA group (n = 712), the SGA group (n = 182) had lower maternal BMI (p = 0.02). Maternal age (p = 0.04), rates of GDMA2 (30.2% vs. 23.45%, p = 0.07), and hypertensive disorders (7.2% vs. 5.1%, p = 0.21) did not differ significantly between the groups. The SGA group had lower neonatal birthweight (2375 ± 432 g vs. 3021 ± 165 g, p = 0.005) and a higher rate of CD due to NRFHR (51% vs. 27.2%, p< 0.01). Among GDMA2 patients (n = 222), more women in the SGA group (n = 55) were treated with metformin compared to the AGA group (n = 167) (72.7% vs. 28.7%, p< 0.001). Multivariate regression analysis revealed that metformin treatment was independently associated with the risk of SGA among GDMA2 patients (OR 1.7, CI 1.18-1.35, p< 0.01).

Conclusion: Metformin use in GDMA2 pregnancies may be linked to SGA neonates. The impact of metformin on fetal growth highlights the need for careful monitoring and individualized treatment strategies in managing GDMA2.

Maternal characteristics and Obstetrics outcomes of GDMA2 patients

	SGA group - n=55	AGA group- n=167	p-value
Maternal age (years)	32.6±5.26	32.3±5.3	0.29
BMI (kg/m^2, SD)	27.3±3.4	28.2±2.2	0.02

Meconial amniotic fluid	12%	81%	0.02
Gender- Male	42.9%	47.2%	0.3
Days of hospitalization mean(SD)	3.23 (1.97)	2.91 (0.89)	0.7

Data are presented as % or mean ± SD. BMI stands for Body Mass Index (kg/m²). CD refers to Cesarean Delivery. Hypertensive disorders include gestational and chronic hypertension, as well as preeclampsia. NICU stands for Neonatal Intensive Care Unit. Composite adverse neonatal outcome includes the presence of at least one of the following outcomes: NICU hospitalization, neonatal hypoglycemia, neonatal jaundice, phototherapy, or neonatal respiratory support. SGA refers to Small for Gestational Age, while AGA stands for Appropriate for Gestational Age. GDMA2 indicates Gestational Diabetes Mellitus requiring medication. CS refers to Cesarean Section, NRFHR stands for Non-Reassuring Fetal Heart Rate, VE refers to Vacuum Extraction, and NVD stands for Normal Vaginal Delivery.

1194 | MRI-Based Prediction of the Need for Surgical Intervention in Fetuses with Micrognathia

Stephanie Marie Cruz; Oluseyi Ogunleye; Jason Xia; Mitchell Rees; Mai-Lan Ho; Jonathan Grischkan; Meredith Lind; Adolfo Etchegaray; Oluyinka Olutoye
Nationwide Children's Hospital, Columbus, OH

4:00 PM - 6:00 PM

Objective: Diagnosis of fetal micrognathia, characterized by a small fetal mandible causing upper airway obstruction and immediate postnatal respiratory distress, has historically relied on subjective ultrasound assessments. More recent objective measurements including the inferior facial angle (IFA), jaw index (JI), mandibular width/maxillary ratio (MD/MX ratio), and oropharyngeal area (OP) aim to enhance diagnostic accuracy. This study aimed to evaluate the ability of fetal MRI measurements to predict the need for immediate postnatal surgical intervention.

Study Design: We conducted a retrospective query of our Radiology database for 'micrognathia' cases from 2007 to 2022. Radiologists, blinded to clinical details, independently assessed JI, IFA, MD/MX ratio, and OP area. Baseline demographics, comorbidities and clinical outcome metrics including the need for any Otolaryngologic surgical intervention were collected. Logistic regression models were fitted to examine the association

between each parameter and the need for surgery, using median radiologist-assessed values.

Results: Forty fetal MRI scans of 37 patients were analyzed at a median gestational age of 27 weeks. Median values of JI, IFA, MD/MX ratio, and OP area were lower in cases requiring surgical intervention compared to those not needing surgery, but these differences were not statistically significant ($p > 0.05$). Receiver operating characteristic (ROC) analysis revealed optimal cutoffs for predicting surgery. The more reliable predictors demonstrated modest performance: JI (sensitivity 65.4%, specificity 63%) and IFA (sensitivity 52.5%, specificity 52.8).

Conclusion: While not statistically significant, both JI and IFA showed modest performance as predictors of the need for the need for surgical intervention compared to MD/MX ratios and OP area when assessed via ROC curves. This suggests their potential utility in delivery planning and selection of surgical management strategies.

1195 | Effect of Intrapartum Antibiotic Prophylaxis on Systemic Maternal Inflammation During Labor Induction

Stephanie L. Pierce[1]; Jennifer Peck[1]; Erin Schone[1]; Dean Myers[1]; Rodney Edwards[2]

[1]University of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]University of Florida College of Medicine, Gainesville, FL

4:00 PM - 6:00 PM

Objective: Labor is an inflammatory process, but excessive inflammation may contribute to abnormal labor by causing myometrial dysfunction, leading to cesarean delivery. We explore whether serum pro-inflammatory cytokines during labor differ in women who receive intrapartum antibiotic prophylaxis (IAP) for group B streptococcus compared with those who do not.

Study Design: This prospective cohort study enrolled women age 18-45 years, term, and undergoing labor induction (IOL) with cervical Foley and oxytocin. Exclusion criteria were known fetal demise and multiple gestation. We drew blood samples prior to IOL and 6-12 and 18-24 hours (h) after IOL start and compared pro-inflammatory cytokine levels (IL-1α, IL-1β, IL-6, IL-8, GM-CSF, IFN-g, MCP-1, and TNF-α) in those who received IAP versus those who did not. We used linear mixed models to evaluate differences in labor cytokines between IAP groups over time, controlling for obesity, parity, race/ethnicity, chronic hypertension, preeclampsia and diabetes.

Results: 113 women (n = 59 did not receive IAP and n = 54 received IAP) were recruited. Cytokine concentrations significantly increased between pre-labor and 12-24h post-IOL measures with the exception of IFN-g, IL-1α and TNF-α (Figure). Overall, patients who received IAP had higher mean concentrations of IFN-g (unadjusted geometric mean ratio [GMR] 1.27 [95% CI 1.05, 1.55]) and lower levels of TNF- α (unadjusted GMR 0.87 [95% CI 0.76, 0.99]; Table). IL-1α levels did not differ by IAP status pre-labor but were 80% greater for those with IAP at 6-12h post-IOL. TNF-α concentrations at 6-12h were significantly lower in those who received IAP compared with those who did not (GMR 0.84 [95% CI 0.71, 0.99]).

Conclusion: Intrapartum TNF-α concentration was lower in those who received IAP for GBS compared with those who did not, while IFN-g, IL-1α concentrations were higher. Given the known effects of these cytokines on uterine contractility and labor, this could suggest a mechanism by which prophylactic antibiotics during labor induction may influence uterine activity and the risk of abnormal labor.

Figure 1a-h. Distribution of pro-inflammatory cytokine concentrations at three time points during labor.

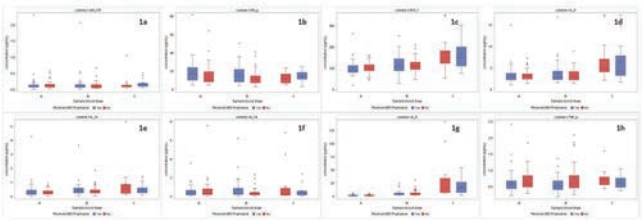

Table. Geometric mean ratios (GMR) and 95% confidence intervals to examine mean differences in cytokine concentrations among those who received IAP for GBS and those who did not across 3 time points during labor induction

1196 | No Association Between Biological Therapeutics and Infections in Pregnant Patients with Autoimmune Disease

Beverley Cruz Alfonso; Mindy Pike; Christine Nolde; Manya Puri; Trent Bronnenberg; Alisa B. Kachikis; Stephen A. McCartney

University of Washington, Seattle, WA

4:00 PM - 6:00 PM

Objective: The incidence of autoimmune disease (AID) peaks during reproductive years. Active AID increases pregnancy risks, making disease control during pregnancy crucial for improving maternal and fetal outcomes. Biologic therapeutics (biologics) targeting the immune system have significantly improved AID management. Current clinical guidelines generally recommend continuation of biologics during pregnancy to maintain clinical remission, however, there is conflicting evidence regarding risk of infections. This study evaluates the association between the use of biologics during pregnancy and peripartum infections.

Study Design: We performed a retrospective cohort study including pregnant patients with autoimmune disease from a single institution during 2013-2023. Data on demographics, medical conditions, pregnancy, and therapeutics was abstracted from the medical record. The primary outcomes were rates of antepartum and postpartum infections between patients exposed to biologics during pregnancy versus unexposed. We hypothesized that the rate of antepartum and postpartum infections is higher in patients exposed to biologics during pregnancy compared to unexposed.

Results: We identified a total of 202 pregnancies in 131 individuals. 94 pregnancies (46.5%) were exposed to biologics, while 108 (53.5%) pregnancies were unexposed. Logistic regression adjusted for non-independent data was used to assess the association between biologic exposure and antepartum and postpartum infections. There was no significant difference in the rates of overall antepartum ($p = 0.66$) or postpartum ($p = 0.39$) infections between the biologics exposed and unexposed pregnancies as well as no difference in the rates of individual infections.

Conclusion: There was no significant association between the use of biologics during pregnancy and the incidence of peripartum infections. Studies in larger populations are needed to confirm safety of biologics during pregnancy as they may be useful for treatment of pregnancy complications related to inflammation.

Table 1. Characteristics

	Overall	Biologics	No Biologics

1197 | Vasa Previa: Factors Associated with Inpatient vs. Outpatient Antepartum Management

Sarah Heaps[1]; Stephen T. Chasen[2]
[1]Weill Cornell Medicine, New York, NY; [2]Weill-Cornell Medical College, New York, NY

4:00 PM - 6:00 PM

Objective: When vasa previa is diagnosed, guidelines support recommendations about timing and route of delivery, as well as steroid administration. While elective admission to ensure proximity to care is common, evidence does not support a clear recommendation. Our objective was to compare patients with vasa previa managed as inpatients vs outpatients.

Study Design: This is a single institution cohort study of patients with a prenatal diagnosis of vasa previa from 2013-2023. Cases resolved in the third trimester were excluded. Decisions about inpatient vs. outpatient management and timing of planned delivery were made by physicians and patients. Demographic factors and outcomes were obtained through chart review. Cohorts managed with elective admission for the indication of vasa previa were compared with those managed as outpatients. Mann-Whitney U and Fisher's Exact test were used for statistical comparison.

Results: 89 patients were included, including 72 (80.9%) electively admitted vs. 17 (19.1%) managed as outpatients. The cohorts are compared in Table 1. The groups were of similar age and parity. A higher proportion of patients managed as outpatients had public insurance. There were no differences in the rate of a short cervical length or antepartum vaginal bleeding between the cohorts, and the rates of non-scheduled Cesarean Delivery were similar. Betamethasone was administered at a median gestational age of 32-33 weeks in both groups. Elective admission was associated with earlier gestational age at delivery overall, as well as earlier scheduled delivery. There were no stillbirths or neonatal deaths, and the rates of NICU admission were not significantly different between the groups.

Conclusion: Patients electively admitted for vasa previa do not appear to have been at higher risk for emergent delivery, though admission was associated with earlier delivery, including scheduled deliveries. The lower rate of admission in those with Medicaid could indicate a disparity in management, though

further study is necessary. While our data do not rule out a benefit to routine admission, the benefits remain unproven.

Table 1. Prenatal diagnosis of Vasa Previa with Inpatient vs Outpatient Management.

	Inpatient (N = 72)	Outpatient (N = 17)	p-Value
Maternal Age (years)	36 [33-40]	36 [32-40]	.89
Nulliparous	68.1%	58.8%	.57
Medicaid	5.6%	23.5%	.04
Vaginal Bleeding Episodes	28.1%	23.5%	1.0
Short Cervix	7.4%	5.9%	1.0
Gestational age at Betamethasone (Weeks)	32 2/7 [31 3/7-33 3/7]	32 6/7 [32.0-35.4]	.054
Unscheduled Delivery	46.5%	35.3%	.43
Gestational age at Delivery (Weeks)	35 1/7 [34 1/7-35 5/7]	36 0/7 [35 4/7-36 2/7]	<.001
Gestational age at Planned Delivery (Weeks)	35 3/7 [35 0/7–35 5/7]	36 1/7 [35 6/7–36 2/7]	.002
NICU Admission	67.8%	50.0%	.23

1198 | A Comparison Between Provider Density and Severe Maternal Morbidity Rates: A Georgia State Review

Suchitra Chandrasekaran; Ran Zhang; Jane Ellis; Sheree L. Boulet
Emory University, Atlanta, GA

4:00 PM - 6:00 PM

Objective: Georgia's (GA) maternal morbidity & mortality rate is among the highest in the country. GA also has one of the highest rates of maternity deserts, defined as counties without obstetric care providers. Increasing the rates of non-physician providers, including certified nurse midwives (CNM), nurse practitioners (NP), advanced practice nurses (APRN), & physician assistants (PA) has been proposed to address the physician provider shortage. We analyzed the change in non-physician & physician provider density in relation to severe maternal morbidity (SMM) rates in GA from 2011 to 2020.

Study Design: We conducted a population-based cohort study utilizing GA Birth Certificate Data from 2011-2020 (n = 1,278,299). SMM included admission to intensive care, unplanned hysterectomy, eclampsia, & maternal blood transfusion. Changes in provider density for non-physician & physician providers were calculated & compared with changes in SMM rates overall & stratified by rural residence.

Results: Between 2011-2020, non-physician provider density increased significantly *[CNM (60.3%), NP (164.4%), APRN (151.1%), & PA (62.3%)] (Table 1)*. This increase of >50% in non-physician providers was seen in both rural and non-rural settings. While overall physician density increased by 12.8%, physician density in rural settings declined by 5% (Table 1). The SMM rate per 10,000 births increased from 42.2 in 2011 to 65.2 in 2020, indicating a 54.5% increase. There was no significant difference between changes in non-physician provider density & SMM rate *($p = 0.91$)* or changes in physician provider density & SMM rate *($p = 0.61$)*.

Conclusion: Our data demonstrate significant increases in CNM, NP, APRN, & PA rates across GA, including rural settings. While physician density in rural settings decreased, further efforts to provide directive education regarding maternal health in pregnancy to existing non-physician providers could help optimize care quality and access. Leveraging the opportunity to train non-physician providers in rural settings could help stratify care needs & facilitate transfer to higher level facilities when necessary.

1199 | Second Trimester Placental Proteins are Associated with Maternal Vascular Malperfusion Among Patients with Adverse Outcomes

Sunitha Suresh[1]; Alexa A. Freedman[2]; Beth Plunkett[3]; Linda M. Ernst[1]
[1]Endeavor Health, Evanston, IL; [2]Northwestern University, Chicago, IL; [3]Northshore Endeavor Health, Chicago, IL

4:00 PM - 6:00 PM

Objective: Adverse pregnancy outcomes (APO) are known to be heterogenous in etiology; many are linked to maternal vascular malperfusion (MVM) of the placenta. Second trimester placental proteins have poor prediction of APO. Placental proteins may have a greater association with APO related to a specific underlying mechanism such as MVM. The objective of this study is to evaluate levels of second trimester placental proteins and placental MVM among patients with an APO.

Study Design: This is a secondary analysis of a prospective cohort study of 9,289 low risk nulliparous patients with singleton gestation (nuMom2b). For this analysis, participants who met the following criteria were included: 1. APO defined as preterm birth (< 37 weeks), preeclampsia/eclampsia, small for gestational age infant, or stillbirth; 2. Maternal serum placental proteins (sFlt-1, Adam-1, VEGF, endoglin, bHcg, AFP, PlGF, Inhibin A, Papp-A, sFlt/PlGF) collected between 16 and 21 weeks gestational age; 3. Placental pathology data. A single perinatal pathologist (LE) manually reviewed all placental data (lesions and additional comments included in the publicly available data set) to categorize participants as MVM absent or present. Placental protein levels were compared by MVM category using Wilcoxon rank sum.

Results: Of the 9,289 participants in the parent study, 2,091 (24%) had APO. Of these, 510 patients were eligible for inclusion, of which 216 (42%) had any presence of MVM. There was a significantly higher level of inhibin-A and sFlt-1/PlGF ratio and lower levels of VEGF and PlGF among those with MVM compared to those without (Table). A trend towards increase in sFlt-1, ADAM-12, and endoglin was additionally seen in MVM related APO.

Conclusion: Among individuals with APO, MVM is associated with significant differences in second trimester maternal serum placental proteins, especially those related to angiogenesis. Over half of APO were unrelated to MVM in this cohort. Classifying APO by placental pathology may lead to improvement in use and development of predictive biomarkers, given the underlying heterogeneity of APO.

Table: Second trimester maternal serum placental proteins by presence/ absence of maternal vascular malperfusion (MVM) among patients with adverse pregnancy outcomes

Second-trimester maternal serum placental proteins	Maternal Vascular Malperfusion Absent (N=294)	Maternal Vascular Malperfusion Present (N=216)	*p- value*
sFlt-1 (pg/mL)	871 (572, 1189)	899 (655, 1229)	0.06
Adam-12 (ng/mL)	10.0 (7.5, 12.4)	10.4 (8.2, 12.9)	0.09
Endoglin (ng/mL)	5.4 (4.7, 6.3)	5.5 (4.9, 6.8)	0.09
VEGF (pg/mL)	1.2 (0.8, 1.7)	0.9 (0.7, 1.7)	0.007
BHcg (ng/mL)	3.9 (2.6, 6.1)	4.1 (2.6, 6.6)	0.62
AFP (IU/mL)	48.3 (37.2, 62.7)	48.5 (39.0, 69.1)	0.20
PlGF (pg/mL)	183 (117, 284)	169 (102, 256)	0.04

Silver[10]; Samuel Parry[11]; George R. Saade[12]; Judith H. Chung[13]; William A. Grobman[3]; Kartik K. Venkatesh[3]

[1]The Ohio State University, College of Medicine, Columbus, OH; [2]The Ohio State University College of Medicine, Columbus, OH; [3]The Ohio State University, Columbus, OH; [4]Northwestern University Feinberg School of Medicine, Chicago, IL; [5]Indiana University School of Medicine, Indianapolis, IN; [6]Research Triangle International, Durham, NC; [7]Case Western Reserve University, Cleveland, OH; [8]University of Pittsburgh Medical Center, Pittsburgh, PA; [9]Columbia University, New York, NY; [10]University of Utah, Salt Lake City, UT; [11]University of Pennsylvania, Philadelphia, PA; [12]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [13]University of California- Irvine, Irvine, CA

4:00 PM - 6:00 PM

Objective: To evaluate whether neighborhood-level socioeconomic disadvantage is associated with an increased risk of antenatal depressive symptoms.

Study Design: We conducted a secondary analysis of data from the Nulliparous Pregnancy Outcomes Study: Monitoring Mothers-To-Be, a prospective cohort of nulliparous pregnant individuals. Data were obtained throughout pregnancy by patient interviews and health record abstraction. Participant home addresses in the first trimester were geocoded at the census-tract level. The exposure was socioeconomic disadvantage (categorized by tertile, with the least deprived [T1] as the reference) by the Area Deprivation Index (ADI). The outcome was depressive symptoms in the early third trimester (median gestational age: 26.9 weeks) by the Edinburgh Postnatal Depression Scale (EPDS), assessed as a score $\geq$ 10, a cutoff which is commonly used for screening, and secondarily, $\geq$ 13, a higher more specific cutoff. Modified Poisson regression was used and adjusted for maternal age, individual-level social determinants (insurance, household income), and EPDS score in the first trimester.

Results: Of 8,678 assessed nulliparous individuals, the mean ADI was 44.4 (SD: 30.2), 16.1% had an EPDS score $\geq$ 10, and 6.5% had an EPDS score $\geq$ 13. In adjusted analyses, individuals who lived in a community with the highest tertile of ADI were nearly 40% more likely to screen positive for depressive symptoms in the third trimester compared with those in the lowest tertile (21.6% vs. 11.7%; aRR: 1.38; 95% CI: 1.16, 1.63). The association was similar at the higher EPDS screening threshold $\geq$ 13 (9.9% vs. 3.8%; aRR: 1.75; 95% CI: 1.29, 2.38).

Conclusion: Neighborhood-level socioeconomic disadvantage early in pregnancy was associated with an increased risk of screening positive for depressive symptoms in the third trimester, even after accounting for depressive symptoms in early pregnancy. These findings highlight the need for multilevel and structural interventions to address perinatal mental health.

TABLE. Association between first trimester area deprivation index (ADI) and antepartum depressive symptoms in the third trimester in nulliparous individuals

	EPDS n, % (Row Percentage)		Unadjusted and adjusted analysis	
			Unadjusted risk ratio (95% CI)	Adjusted risk ratio (95% CI)[1]
	≥10	<10		
ADI				
Tertile 1 (low)	337 (11.7)	2,550 (88.3)	Ref	Ref
Tertile 2	452 (15.3)	2,506 (84.7)	**1.31 (1.15, 1.49)**	1.15 (0.98, 1.35)
Tertile 3 (high)	611 (21.6)	2,222 (78.4)	**1.85 (1.63, 2.09)**	**1.38 (1.16, 1.63)**
	≥13	<13		
ADI				
Tertile 1 (low)	109 (3.8)	2,778 (96.2)	Ref	Ref
Tertile 2	171 (5.8)	2,787 (94.2)	**1.53 (1.21, 1.94)**	1.24 (0.92, 1.67)
Tertile 3 (high)	281 (9.9)	2,552 (90.1)	**2.63 (2.12, 3.26)**	**1.75 (1.29, 2.38)**

1201 | The Impact of Denying Abortion Access to Patients with Heart Failure: A Cost-Effectiveness Analysis

Sydney McCarthy[1]; Emily Modlin[1]; Stacia C. Hickey[1]; Ava D. Mandelbaum[2]; Aaron B. Caughey[2]

[1]Oregon Health and Science University, Portland, OR; [2]Oregon Health & Science University, Portland, OR

4:00 PM - 6:00 PM

Objective: In June 2022, the *Dobbs v. Jackson Women's Health* Supreme Court decision eliminated constitutional protections for abortion access. This ruling has far-reaching impacts on long-term morbidity, mortality, and health-related expenses for individuals capable of pregnancy. This study investigates the influence of abortion access on outcomes for pregnant individuals with stage 1 or 2 heart failure (HF) seeking abortion care based on the presence of a statewide abortion ban.

Study Design: A decision-analytic model was developed to evaluate the outcomes and cost-effectiveness associated with providing in-state abortion services versus those incurred under a statewide abortion ban for individuals with HF seeking an abortion. Clinical outcomes included preeclampsia, preterm birth, pregnancy-related major adverse cardiac events (MACE), disease progression, and mortality. The likelihood and financial burden of traveling out of state for abortion care was considered. The cost-effectiveness threshold was set at $100,000/QALY. Model inputs were derived from the literature.

Results: In our theoretical cohort of 1,515 pregnant people with HF, access to abortion services led to 348 fewer cases of preeclampsia, 315 fewer preterm births, 218 fewer cases of pregnancy-related MACE, 233 fewer cases of HF stage progression, and 112 fewer deaths annually relative to no access to

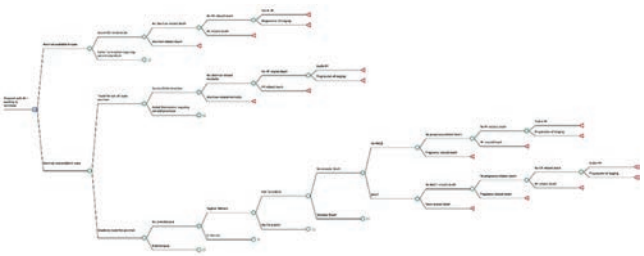
abortion services (Table 1). In-state abortion access was the dominant strategy, resulting in a $57,229,928 reduction in the costs and an increase in 3,182 QALYs.

Conclusion: Protecting in-state abortion access for pregnant individuals with HF is a cost-effective strategy, reducing adverse perinatal outcomes, enhancing resource allocation, and improving quality of life. These findings may inform policies to improves individual and societal outcomes for this vulnerable population in the context of restrictive abortion laws.

Table 1. Outcomes in a cohort of 1,515 pregnant people with heart failure

Outcome	In-State Abortion Access	No in-State Abortion Access	Difference (No IS access – IS access)*
Preeclampsia (cases)	0	348	+348
Preterm Birth (cases)	0	315	+315
Cesarean Delivery (cases)	0	870	+870
Neonatal Death (cases)	0	12	+12
Pregnancy-related MACE (cases)	0	218	+218
HF Progression (cases)	72	305	+233
Mortality (cases)	76	188	+112
Cost ($)	60,773,664	118,003,592	+57,229,928
Effectiveness (QALY)	16,180	12,999	-3,182

*IS = In-state



1202 | Assessing the Reliability of ChatGPT for Evaluation of Risk-of-Bias in Randomized Clinical Trials

Takeshi Nagao[1]; George R. Saade[2]; Tetsuya Kawakita[2]
[1]*The Jikei University School of Medicine, Minatoku, Tokyo;*
[2]*Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA*

4:00 PM - 6:00 PM

Objective: To examine whether ChatGPT can be useful in the assessment of the risk-of-bias in Randomized Clinical Trials (RCTs) traditionally performed by reviewers performing systematic reviews.

Study Design: The study analyzed systematic reviews and meta-analyses published in the American Journal of Obstetrics and Gynecology from 2021 to 2023, focusing on the risk-of-bias assessments in RCTs using Version 2 of the Cochrane risk-of-bias tool for randomized trials (RoB 2). ChatGPT-4 was trained on RoB 2 guidelines and then tasked with evaluating each RCT across five domains: Randomization process, Deviations from intended interventions, Missing outcome data, Measurement of the outcome, and Selection of the reported result. Each domain, along with the overall bias, was rated as Low risk of bias, Some concerns, or High risk of bias. ChatGPT's evaluations were compared to those of human reviewers, as described in published papers, using Cohen's Kappa to determine agreement. Additionally, for each RCT, ChatGPT conducted three separate evaluations to calculate the intra-ChatGPT agreement rate using Fleiss' Kappa.

Results: The study included 161 RCTs. The Cohen's Kappa scores for agreement between ChatGPT's evaluations and those of the reviewers were as follows: Domain 1 (Randomization) 0.485, Domain 2 (Deviations) 0.489, Domain 3 (Missing) 0.596, Domain 4 (Measurement) 0.446, Domain 5 (Selection) 0.484, and Overall bias 0.262. For the three separate evaluations conducted by ChatGPT on the same RCTs, the Fleiss' Kappa scores were Domain 1 (Randomization) 0.245, Domain 2 (Deviations) 0.359, Domain 3 (Missing) 0.555, Domain 4 (Measurement) 0.493, Domain 5 (Selection) 0.351, and Overall bias 0.760.

Conclusion: ChatGPT's risk-of-bias assessments moderately agreed with human reviewers across five domains but showed only fair agreement in overall bias assessment. Intra-ChatGPT evaluations were inconsistent for certain domains (Randomization, Deviations, Selection), though the overall bias assessment showed substantial agreement.

	Cohen's Kappa (GPT vs reviewer)	Fleiss' Kappa (Three evaluations by Chat GPT)
Domain 1 (Randomization)	0.485	0.245
Domain 2 (Deviations)	0.489	0.359
Domain 3 (Missing)	0.596	0.555
Domain 4 (Measurement)	0.446	0.493
Domain 5 (Selection)	0.484	0.351
Overall bias	0.262	0.760

TABLE 1. Agreement between ChatGPT and human reviewers in risk-of-bias assessments and consistency of ChatGPT's own evaluations. Kappa categories for agreement: none for 0, slight for 0.10-0.20, fair for 0.21-0.40, moderate for 0.41-0.60, substantial for 0.61- 0.80, near perfect for 0.81-0.99, and perfect for 1.

1203 | The effect of One-Abnormal Glucose-Value of the 100-gram Oral-Glucose Tolerance-Test According to Carpenter-and-Coustan on Obstetrical-Outcomes

Tal zilberman kimhi[1]; Yuri Perlitz[2]; Zohar Nachum[3]; Enav Yefet[2]

[1]Tzafon Medical Center, tzafon medical center, HaZafon; [2]Tzafon Medical Center, Poriya, HaZafon; [3]Emak Medical Center, Afula, HaZafon

4:00 PM - 6:00 PM

Objective: To examine the effect of one abnormal glucose value only according to C&C criteria in 100 g OGTT on pregnancy outcomes.

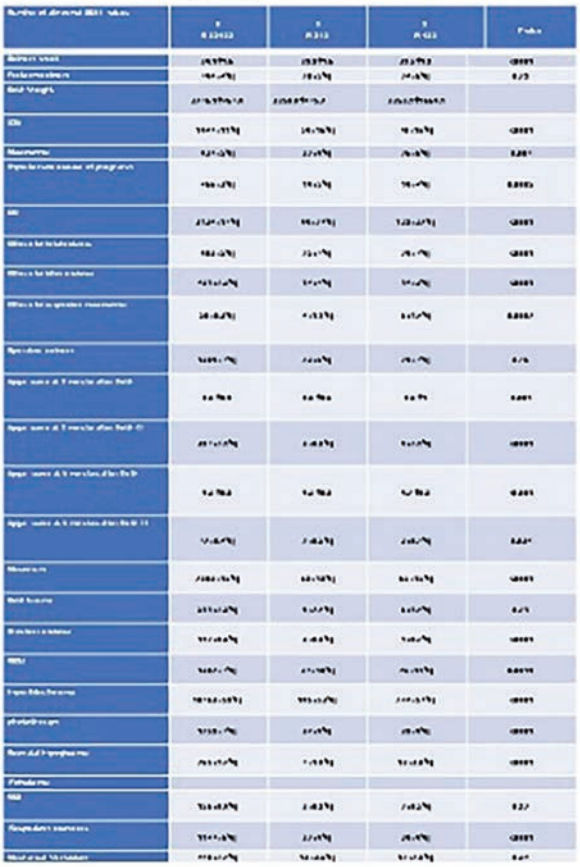
Study Design: A population-based retrospective cohort study was conducted involving women who delivered at Tzafon Medical Center in Israel between March 2012 and December 2022. The women were categorized into three groups: (1) those without GDM (either normal GCT or OGTT; N = 18,422), (2) those with one abnormal OGTT value according to C&C criteria (fasting glucose 95-104, one hour 180-189, two hours 155-164, and three hours 140-144 mg/dL; N = 371), and (3) those with GDM, defined as at least two abnormal OGTT values according to C&C (N = 431). Only the last group was officially diagnosed with GDM. The primary outcome measured was the rate of large for gestational age (LGA) neonates.

Results: Univariable and multivariable analyses are detailed in Tables 1 and 2. After adjusting for background characteristics, having one abnormal glucose value significantly increased the risk, compared to the control group, and similar to the values in the two pathologic values group, for the following outcomes: large for gestational age (LGA) neonates (adjusted OR 1.5, 95% CI [1.2-2.0]), macrosomia (2.0, 95% CI [1.3-2.8]), cesarean delivery (1.5, 95% CI [1.2-1.9]), and hypertensive disease of pregnancy (2.0, 95% CI [1.3-3.3]).

Univariable and multivariable analyses are detailed in Tables 1 and 2. After adjusting for background characteristics, having one abnormal glucose value significantly increased the risk, compared to the control group, and similar to the values in the two pathologic values group, for the following outcomes: large for gestational age (LGA) neonates (adjusted OR 1.5, 95% CI [1.2-2.0]), macrosomia (2.0, 95% CI [1.3-2.8]), cesarean delivery (1.5, 95% CI [1.2-1.9]), and hypertensive disease of pregnancy (2.0, 95% CI [1.3-3.3]).

Conclusion: Women with one abnormal OGTT value, according to the C&C criteria, had worse outcomes compared to normoglycemic women, and similar to those with GDM. Therefore, these women should be considered as having GDM.

Table 1. Pregnancy and neonatal outcomes



Values are presented as number (percent) or mean±SD.
Missing values: Birth number- 5218 missing values, Age- 3 missing values.
CD, cesarean delivery; LGA, large foe gestational age; NICU, neonatal intensive care unit; OGTT, oral glucose tolerance test; RDS, respiratory distress syndrome;

Table 2. Multivariable analysis

	Adjusted OR 95% CI*		
Number of abnormal OGTT values	1 vs 0	1 vs 2	2 vs 0
LGA	1.5 [1.2-2.0]	0.97 [0.7-1.4]	1.6 [1.2-2.1]
Macrosomia	2.0[1.3-2.8]	1.3[0.7-2.9]	1.5[1.0-2.3]
Cesarean delivery	1.5[1.2-1.9]	0.8[0.6-1.1]	1.8[1.5-2.3]
Cesarean Delivery for suspected macrosomia	4.2[1.5-11.9]	0.7[0.2-2.6]	5.8[2.4-13.8]

1204 | Risk of HDP in Nulliparas with Treated Versus Untreated Mood and Anxiety Disorders

Taylor M. Lewis[1]; Alyssa M. Hernandez[2]; Nadine Sunji[2]; Liyun Zhang[2]; Amy Y. Pan[2]; Anna Palatnik[2]
[1]Medical College of Wisconsin, Oconomowoc, WI; [2]Medical College of Wisconsin, Milwaukee, WI

4:00 PM - 6:00 PM

Objective: The impact of mood and anxiety disorders (MAD) on the risk of developing hypertensive disorders of pregnancy (HDP) remains unclear. This study aimed to explore the risk of HDP in nulliparas with either treated or untreated MAD.

Study Design: This was a secondary analysis of the Nulliparous Pregnancy Outcomes Study: Monitoring Mothers-to-Be (nuMoM2b). Nulliparas with singleton gestations ≥20 weeks without chronic hypertension were grouped as follows: no MAD, untreated MAD, and treated MAD. The diagnoses included in the MAD groups were depression, bipolar disorder, other mood disorders (dysthymia, seasonal affective disorder), and anxiety disorders (generalized anxiety disorder, panic disorder, obsessive-compulsive disorder). Treatment was defined as the use of a psychotropic medication for a psychiatric indication. The risk of HDP was compared between groups using univariate and multivariate analyses.

Results: Of the 8,492 patients included in the analysis, 6,877 (81.0%) had no MAD diagnosis, 1,014 (11.9%) had an untreated MAD, and 601 (7.1%) had a treated MAD. Patients with a treated MAD were more likely to be older (p< 0.001), white (p< 0.001), non-Hispanic (p< 0.001), college-educated (p = 0.01), privately insured (p< 0.001), have a higher pre-pregnancy BMI (p = 0.001), and score higher on the Edinburgh Postnatal Depression Scale (EPDS) in early pregnancy (p< 0.001). Compared to patients with no MAD, the risk of any HDP was similar across groups in both unadjusted and adjusted models (untreated MAD, aRR 0.96 [CI 0.85-1.08]; treated MAD, aRR 0.92 [CI 0.79-1.08]) (Table 1). The risk of preeclampsia was also not significantly different by MAD diagnosis or treatment exposure. To account for patients who may have undiagnosed or undertreated MAD, a multivariate model was created to examine the risk of any HDP or preeclampsia alone by EPDS score, which also showed no significant difference in risk (aRR 0.93 [CI 0.80-1.07]).

Conclusion: This large cohort analysis found no significant statistical difference in the risk of HDP by MAD diagnosis, psychotropic treatment, or worst mood symptoms during pregnancy.

Table. Relative risk of hypertensive disorder of pregnancy by mental health disorder and treatment status

	Cohort (N)	Any HDP n (%)	Unadjusted RR (95% CI)	Adjusted[a] RR (95% CI)	Preeclampsia n (%)	Unadjusted RR (95% CI)	Adjusted[b] RR (95% CI)
No mood and anxiety disorder[c]	6877	1604 (23.3)	Ref	Ref	580 (8.4)	Ref	Ref
Untreated mood and anxiety disorders	1014	241 (23.8)	1.02 (0.91-1.15)	0.96 (0.85-1.08)	89 (8.7)	1.00 (0.72-1.37)	0.93 (0.75-1.16)
Treated mood and anxiety disorders	601	138 (23.0)	0.98 (0.85-1.15)	0.92 (0.79-1.08)	53 (8.8)	0.96 (0.78-1.19)	0.92 (0.69-1.21)
EPDS Score < 13[d]	7636	1793 (23.5)	Ref	Ref	640 (8.4)	Ref	Ref
EPDS Score ≥ 13	615	145 (23.6)	1.00 (0.87-1.16)	0.93 (0.80-1.07)	67 (10.9)	1.26 (1.00-1.60)	1.07 (0.84-1.35)

Abbreviations: HDP, hypertensive disorder of pregnancy (defined as gestational hypertension or preeclampsia); RR, relative risk; CI, confidence interval; Ref, reference; EPDS, Edinburgh Postnatal Depression Scale.
[a]Adjusted for known risk factors for HDP, including race, pre-pregnancy BMI, diabetes, renal disease, autoimmune disease, family history of preeclampsia, and aspirin use.
[b]Adjusted for significantly different variables from univariate analysis, including age, race, ethnicity, education, insurance, BMI, diabetes, autoimmune disease, aspirin, EPDS score, and gestational age at delivery.
[c]Mood and anxiety disorders included depression, bipolar disorder, other mood disorders (dysthymia, seasonal affective disorder), and anxiety disorders (generalized anxiety disorder, panic disorder, obsessive compulsive disorder).
[d]EPDS score of ≥13 suggests diagnosis of depression.

1205 | More Frequent Emergency care Utilization, Prior to 20w0d, is Associated with Higher Preterm Birth Rates

Tenisha D. Wilson[1]; Lauren Kucirka[2]; Catherine Vladutiu[3]; M. Kathryn Menard[2]
[1]University of North Carolina Chapel Hill, Chapel Hill, NC; [2]University of North Carolina, Chapel Hill, Chapel Hill, NC; [3]University of North Carolina, Chapel HIll, Chapel Hill, NC

4:00 PM - 6:00 PM

Objective: Frequent emergency care (EC) utilization throughout pregnancy has been associated with adverse pregnancy outcomes, including preterm birth (PTB). Given that it has previously been shown that care coordination of at-risk populations in North Carolina (NC) is associated with a reduced PTB rate, identifying early EC utilization as a risk factor for PTB affords an opportunity for intervention with the potential for introduction of a care coordination program in EC settings. To that end, the objective of this study was to assess whether the frequency of early EC utilization, prior to 20w0d, is associated with higher rates of PTB.

Study Design: Retrospective cohort study of pregnant Medicaid recipients who had a live birth in NC between 01/01/2014–12/31/2019, using linked birth records and NC Medicaid hospital claims. Early pregnancy EC use was defined as an encounter in OB triage or the emergency department prior to 20w0d. We categorized frequency of EC visits before 20w0d as follows: 0, 1, 2, or 3 visits. We built a multivariable modified Poisson regression model to analyze the association between early EC visits and PTB, adjusted for potential confounders.

Results: With increasing EC utilization prior to 20w0d (Table 1), the % of patients with PTB increased. Among those with zero EC visits prior to 20w0d, 0.53% delivered < 28w0d, compared to 0.86%, 1.02%, and 1.43%, in those with 1, 2, and 3 ED visits, respectively. A similar trend was observed among those who delivered between 28w0d-33w6d and between 34w0d-36w6d. In a multivariable model adjusted for confounders, a higher number of early ED visit was associated with an increased risk of PTB < 28 weeks (adjusted relative risk (aRR) = 1.35, 95% CI: 1.28-1.42), 28w-33w6d (aRR = 1.18, 95% CI: 1.15-1.20), and >34 weeks (aRR = 1.13, 95% CI: 1.11-1.15).

Conclusion: More frequent, early EC utilization is associated with a higher rate of PTB in every gestational age category assessed. Clinically, the study reveals an area of opportunity to initiate a prenatal care coordination plan as an intervention in the EC setting, which may potentially reduce the rate of PTB.

Table 1: Gestational age at delivery, by frequency of early EC utilization

EC utilization visits <20 weeks	<28 weeks N=1,161 (0.76)	28-33w6d weeks N=5417 (3.57)	34-36w6d N=7937 (5.23)	≥37 weeks N=137,289 (90.44)

1206 | Is First Trimester Hemorrhage with Concurrent Anemia Associated with Placenta Accreta Spectrum?

Tess E.K Cersonsky[1]; Henri M. Rosenberg[2]; Eugenia Alleva[1]; Isabelle C. Band[1]; Calvin E. Lambert, Jr.[1]; Angela T. Bianco[1]

[1]*Icahn School of Medicine at Mount Sinai, New York, NY;* [2]*Icahn School of Medicine at Mount Sinai, Division of Maternal-Fetal Medicine, Icahn School of Medicine at Mount Sinai, NY*

4:00 PM - 6:00 PM

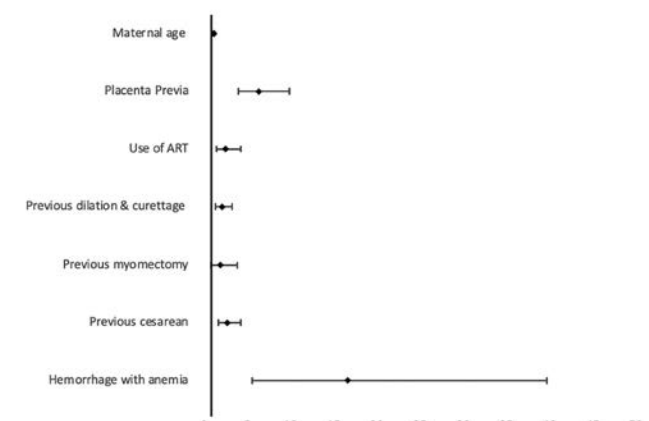
Objective: First trimester hemorrhage may contribute to abnormal placentation. These abnormalities can have devastating consequences in the form of placenta accreta spectrum (PAS), which is associated with significant maternal morbidity and mortality. Subchorionic hematoma, a leading cause of first trimester hemorrhage, and anemia may contribute to placental hypoxia and aberrant placentation. We sought to establish if an association exists between anemia, hemorrhage, and PAS.

Study Design: his is a secondary analysis of a retrospective case-control study using patient data from 2007 to 2022 at a large tertiary care center. Demographics and clinical characteristics of patients with and without PAS (diagnosed by histopathology or high index of clinical suspicion) were collected as well as complete blood count in early pregnancy. Bivariate analyses compared baseline case and control characteristics. Logistic regression was performed to assess risk of PAS according to the presence of first trimester hemorrhage with concurrent anemia (hemoglobin < 11 g/dL) while adjusting for relevant covariates.

Results: The final cohort included 88 patients with confirmed PAS and 27,126 controls. Rates of first trimester hemorrhage alone were not significantly different between groups (12.3% of those without PAS versus 17.0% of those with PAS, $p = 0.2$); however, those with PAS were more likely to have first trimester hemorrhage and concurrent anemia (0.4% of those without PAS versus 5.7% of those with PAS, $p < 0.001$). In multivariate logistic regression, first trimester hemorrhage and concurrent anemia was associated with higher odds of PAS than any other covariate, including prior cesarean or placenta previa (adjusted odds ratio = 16.6, 95% confidence interval 5.58 - 39.7).

Conclusion: Patients with a first trimester hemorrhage and concurrent anemia have 16-fold higher odds of PAS. This suggests that early pregnancy placental disruptions may significantly increase the risk for PAS. Further research into the pathophysiology of this process is warranted to fully understand this phenomenon.

Figure 1: Multivariate regression for placenta accreta spectrum



Adjusted odds ratio (OR) and 95% confidence interval for each covariate according to multivariate logistic regression. ART = assisted reproductive technologies. Dark vertical line represents OR = 1.

1207 | Use of Mean Arterial Blood Pressure to Predict Superimposed Preeclampsia with Severe Features

Tetsuya Kawakita[1]; Justin Leach[2]; On behalf of the CHAP Consortium

[1]*Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA;* [2]*University of Alabama at Birmingham, Birmingham, AL*

4:00 PM - 6:00 PM

Objective: To examine whether longitudinal assessment of mean arterial pressure (MAP) could predict the development of superimposed preeclampsia (SIPE) with severe features.

Study Design: This was a secondary analysis of the Chronic Hypertension and Pregnancy (CHAP) trial. We excluded individuals with missing or invalid information regarding SIPE diagnosis. Our primary outcome was SIPE with severe features. We fitted Bayesian joint longitudinal and time-to-event models (linear and non-linear natural spline-based) using MAP from baseline and throughout pregnancy prior to the diagnosis of SIPE or censoring as repeated measures. A hazard ratio (HR) with a 95% credible interval was estimated. The fitted models were evaluated using the area under the receiver-operating curves (AUC) and Brier scores, estimated by 5-fold cross-validation 5 times.

Results: Of 2316 individuals with chronic hypertension, 600 (25.9%) developed SIPE with severe features. Compared to individuals without SIPE with severe features, those with SIPE with severe features had higher MAP, were more likely to be Black or smokers, and were more likely to have government insurance and diabetes (Table 1). Higher MAP was associated with an increased risk of SIPE with severe features (HR 1.15; 95% CI 1.12-1.19), indicating that each mmHg increase in MAP was associated with a 15% increase in the risk of SIPE with severe features. AUCs (Table 2) were low-to-moderate, with better performance for intervals later in pregnancy and shorter in duration (e.g., 0.60 at 20-40 weeks to 0.71 at 34-37 weeks). Similarly, Brier scores were low-to-moderate indicating poor performance. Estimated HRs and prediction performance were nearly indistinguishable between linear and spline-based models.

Conclusion: While repeated measures of MAP are associated with developing SIPE with severe features, the predictive ability of longitudinal MAP alone was fair to moderate. Future studies should consider longitudinal MAP in modeling the risk of SIPE with severe features, but additional predictors are necessary to improve predictive performances.

1208 | Association between Levels of Perceived Stress and Severity of Nausea and Vomiting in Pregnancy

Ummayhany F. Bharmal[1]; George R. Saade[2]; Tetsuya Kawakita[2]
[1]Medical College Baroda, Medical College Baroda, Gujarat; [2]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA

4:00 PM - 6:00 PM

Objective: The role of psychosocial factors such as perceived stress in the severity of Nausea and Vomiting of Pregnancy (NVP) is unclear. Our objective was to determine the association between perceived stress levels and NVP severity.

Study Design: This was a secondary analysis of data from the Nulliparous Outcomes Study: Mothers to be (nuMoM2b). Perceived stress was assessed in the first trimester using the Perceived Stress Scale, categorized into mild (0-14), moderate (15-27), and severe (28-40). NVP severity over the past 24 hours was assessed at 6-13 (visit 1), 16-21 (visit 2), and 22-29 weeks (visit 3) using the Pregnancy Unique Quantification of Emesis and Nausea tool, categorizing symptoms as no symptoms (0-3), mild (4-6), moderate (7-12), and severe (13-15). The primary outcome was the moderate or severe NVP in each trimester. Modified Poisson regression with robust variance was used to calculate adjusted relative risks (aRR) and 95% confidence intervals (CI), controlling for potential confounders (mild stress as the referent).

Results: Of 8,867 participants, 5,279 (59.5%) had mild stress, 3,298 (37.2%) had moderate stress, and 290 (3.3%) had severe stress. Maternal characteristics and socioeconomic factors varied across the groups (Table 1). The risk of moderate or severe NVP is presented in Table 2. Individuals with severe stress had a significantly increased risk of having moderate or severe NVP in visit 1 (aRR 1.65, 95% CI 1.25-2.13) and visit 2 (aRR 2.08, 95% CI 1.15-3.77) when compared to those with mild stress. Individuals with moderate stress had a significantly increased risk of having moderate or severe NVP in all visits when compared to those with mild stress (visit 1 aRR 1.24, 95% CI 1.09-1.40; visit 2 aRR 1.49, 95% CI 1.10-2.02: visit 3 aRR 1.59, 95% CI 1.06-2.41).

Conclusion: Elevated perceived stress levels show a significant association with increased severity of NVP throughout all trimesters, warranting the need for specific interventions in the management of NVP in high-stress pregnancies.

TABLE 1: Maternal characteristics and socioeconomic factors

aRRs were adjusted for age, BMI, insurance type, employment status, marital status, depression, and anxiety.

1209 | Hypertensive Control and Delivery Outcomes with Use of Oral Antihypertensives in Pregnancy for Non-severe Hypertension

Tiffany Yang[1]; Hannah K. Agoglia[2]; David Garry[1]; Cassandra Heiselman[1]
[1]Stony Brook University Hospital, Stony Brook, NY; [2]Renaissance School of Medicine at Stony Brook University, Stonybrook, NY

4:00 PM - 6:00 PM

Objective: This study aims to determine if there are differences in pregnancy outcomes and hypertension control for patients on single versus multiple antihypertensive maintenance drug regimens.

Study Design: Retrospective chart review of adult pregnant patients who received prenatal care and delivered at a single academic institution with a diagnosed hypertensive disorder requiring antenatal antihypertensive maintenance medications started by 34 weeks GA or for a minimum of 2 weeks. Exclusion criteria were pregnancies of known anomalous fetus and multifetal gestations. Patients were then stratified by type and number of medications prescribed. Chi-squared, Fischer's exact, and student's t-test analysis were performed.

Results: 112 patients met inclusion criteria. 96 (85.7%) were prescribed a single drug regimen: labetalol 71(63.4%), metoprolol 2(1.8%), nifedipine 11 (9.8%), other 12 (10.7%); 16 (14.3%) were taking a combination of medications. There were no differences in age, obesity, race/ethnicity, insurance status, hypertensive diagnosis, maternal co-morbidities, aspirin or tobacco use. More women requiring polytherapy had more history of preeclampsia versus those on monotherapy (89% vs 28%, p< 0.001), along with higher diastolic BP and MAP at first prenatal visit. Patients on multidrug regimens had higher rates of change in hypertensive diagnosis (i.e. chronic to preeclampsia) (p = 0.01), inpatient admission for blood pressure control (p = 0.002), higher BP and MAP at delivery (p< 0.001), earlier gestational age at delivery (p< 0.001), rates of medically indicated PTD (p< 0.001), cesarean delivery (p< 0.001), and longer maternal hospitalization (p = 0.02), as compared to the monotherapy group (Table 1).

Conclusion: Requiring multidrug antihypertensive regimens may be a proxy for pregnancies with poor hypertensive control, and furthermore a marker for poor maternal outcomes. Close supervision and attention to these patient populations may be warranted to optimize their pregnancy outcomes.

Table 1: Hypertension Control and Pregnancy Outcomes for Patient Requiring Antepartum Antihypertensive Maintenance Medications

	Single drug regimen (n=96)	Multiple drug regimen (n=16)	p
Antepartum

1210 | Maternal Delivery Outcomes at 35-37 Versus 34 weeks after PPROM <34 weeks in the US

Timothy Wen[1]; Brittany Arditi[2]; Nasim C. Sobhani[3]; Cynthia Gyamfi-Bannerman[4]; Adina R. Kern-Goldberger[5]; Teresa C. Logue[6]; Maria Andrikopoulou[2]; Lanbo Yang[7]; Milli Desai[8]; Alexander M. Friedman[2]; Kartik K. Venkatesh[9]
[1]University of California, San Diego, Irvine, CA; [2]Columbia University Irving Medical Center, New York, NY; [3]UCSF, San Francisco, CA; [4]University of California, San Diego, San Diego, CA; [5]Cleveland Clinic Lerner College of Medicine, Cleveland, OH; [6]Christiana Care Health System, Newark, DE; [7]Tulane University School of Medicine, Tulane University School of Medicine, LA; [8]University of California, San Francisco, University of California, San Diego, CA; [9]The Ohio State University, Columbus, OH

4:00 PM - 6:00 PM

Objective: International data suggest that expectant management of preterm premature rupture of membranes (PPROM) up to 37 weeks is safe compared with 34-week delivery. U.S. data on this evolving practice is lacking. We examined maternal outcomes and healthcare utilization between delivery at 35-37 versus 34 weeks after a PPROM diagnosis < 34 weeks.

Study Design: This study included livebirth delivery hospitalizations in the Nationwide Inpatient Sample from 2016-2021 that had a diagnosis of PPROM < 34 weeks with consequent delivery between 34-37 weeks. The exposure was timing of delivery defined as 34+0 to 34+6 versus 35+0 to 37+6 weeks per best obstetrical estimate of gestational age in completed weeks at delivery per National Center for Health Statistics recommendations. Outcomes at delivery included a composite of maternal infection (chorioamnionitis, endometritis, sepsis, shock), severe maternal morbidity (SMM) with and without transfusion, and cesarean delivery. Secondary outcomes included postpartum length of stay (ppLOS) and total hospitalization costs. Logistic regression models adjusted for payer type, self-reported race as a social construct, obstetric comorbidity index, hospital characteristics, and birth year.

Results: Among 73,365 deliveries between 34-37 weeks with a PPROM diagnosis < 34 weeks, 920 (1.3%) delivered between 35-37 weeks. Delivery between 35-37 weeks was associated with a higher risk of maternal infection (3.3% vs. 12.5%, aOR: 3.74, 95% CI: 2.37, 5.91) and cesarean delivery (28.4% vs. 44.7%, aOR 1.69, 95% CI: 1.22, 2.34) versus delivery at 34 weeks. There were no differences in SMM by timing of delivery (Figure 1). Hospitalization costs were three-fold higher with delivery between 35-37 weeks ($22,487 vs. $6,669), but median ppLOS were similar between the two groups (Figure 2).

Conclusion: Later delivery between 35+0 to 37+6 weeks following PPROM < 34 weeks was associated with higher likelihood of infectious morbidity and cesarean delivery compared with delivery between 34+0 to 34+6 weeks. These national U.S. observational data contrast with recent international trials.

1211 | Firearm-Related Injuries and Severe Maternal Morbidity in the United States, 2017-2021

Timothy Wen[1]; Brittany Arditi[2]; Cynthia Gyamfi-Bannerman[3]; Adina R. Kern-Goldberger[4]; Nasim C. Sobhani[5]; Teresa C. Logue[6]; Maria Andrikopoulou[2]; Chia-Ling Nhan-Chang[3]; Alexander M. Friedman[2]; Kartik K. Venkatesh[7]

[1]University of California, San Diego, Irvine, CA; [2]Columbia University Irving Medical Center, New York, NY; [3]University of California, San Diego, San Diego, CA; [4]Cleveland Clinic Lerner College of Medicine, Cleveland, OH; [5]UCSF, San Francisco, CA; [6]Christiana Care Health System, Newark, DE; [7]The Ohio State University, Columbus, OH

4:00 PM - 6:00 PM

Objective: Firearm violence is a preventable public health crisis in the United States and a primary cause of maternal mortality, but its national impact on perinatal outcomes remains to be fully examined. We examined trends in firearm-related injuries (FRI) during pregnancy, and their association with severe maternal morbidity (SMM) and adverse pregnancy outcomes (APOs).

Study Design: We utilized all delivery hospitalizations in the Nationwide Inpatient Sample from 2017-2021. The exposure was any firearm-related injuries at delivery hospitalization. We analyzed trends of FRI overall. The primary outcome was non-transfusion severe maternal morbidity (ntSMM) and secondarily SMM with transfusion, inpatient mortality, stillbirth, critical care procedures, and preterm birth < 37 weeks. We evaluated the association between FRI and perinatal outcomes using survey-adjusted logistic regression models, adjusting for demographic factors, hospital factors, delivery year, and obstetric comorbidity score.

Results: Among 17.5 million deliveries, 6,365 were complicated by FRI at a rate of 3.6 per 10,000 delivery hospitalizations. Deliveries with FRI significantly increased from 2.7 to 3.6 per 10,000 delivery hospitalizations from 2017 to 2021 (p< 0.01), with a peak of 5.0 per 10,000 delivery hospitalizations in 2020 [Figure 1]. In adjusted analyses, FRI was associated with over a five-fold increased likelihood of ntSMM (5.1% vs 0.8%; aOR 5.21, 95% CI: 3.91, 6.95). In addition, FRI was associated with higher likelihood of adverse of all APOs, with the highest likelihood of needing critical care procedures (aOR 8.47, 95% CI: 4.64, 15.44) and inpatient mortality (aOR 19.19, 95% CI: 4.66, 79.07) [Figure 2].

Conclusion: Firearm-related injury at delivery hospitalization has increased across the US from 2017 to 2021 and is associated with an increased risk of SMM as well as APOs. Preventing gun violence has the potential reduce perinatal morbidity and mortality and should be an urgent public health priority.

Figure 1: Trends of firearm-related injuries complicating delivery hospitalizations, 2017-2021

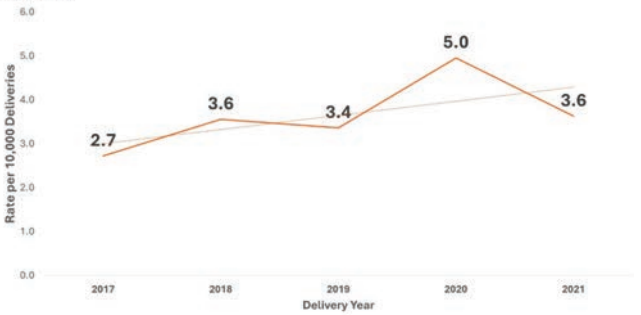

Figure 2: Prevalence and association of maternal outcomes with firearm related injuries (FRI), 2017-2021

	ntSMM	SMM	Transfusion	Stillbirth	Mortality	Critical care procedure	PTB<37w
No FRI	0.8% 131,975	1.8% 311,730	1.2% 205,150	0.5% 86,255	0.0% 935	0.1% 12,075	9.9% 112,620
FRI	5.1% 325	7.5% 475	3.2% 205	1.0% 65	0% DS	0.9% 60	15.7% 90
aOR 95% CI	5.21 (3.91-6.95)	3.49 (2.73-4.44)	2.21 (1.59-3.08)	1.80 (1.03-3.12)	19.19 (4.66-79.07)	8.47 (4.64-15.44)	1.70 (1.06-2.74)

aOR: adjusted odds ratio. *CI*: confidence interval, *ntSMM*: non-transfusion severe maternal morbidity. *PTB*: preterm birth
Analysis reference group was no firearm-related injury
Adjusted analysis accounted for: payer, maternal race, median income quartile by ZIP code, social vulnerability, obstetric comorbidity index score, hospital region, hospital teaching status, and year of delivery

1212 | Determining time Course of Complex Gastroschisis Development in Fetal Lambs with Standardized Abdominal Wall Defect

Tomohiro Arai[1]; Jan A. Deprest[1]; Marianna Scuglia[2]; David Basurto[2]; Wasinee Tianthong[1]; Watananirum Kanokwaroon[2]; Emma Van Den Eede[1]; Simen Vergote[2]; Tom Bleeser[2]; Francesca M. Russo[2]; Keswani Sundeep[3]; Michael A. Belfort[4]; Luc Joyeux[3]

[1]My FetUZ Fetal Research Center, Universitary Hospital Leuven, Leuven, Vlaams-Brabant; [2]My FetUZ Fetal Research Center, Department of Development and Regeneration, Cluster Woman and Child, Biomedical Sciences, KU Leuven, Leuven, Belgium, Leuven, Vlaams-Brabant; [3]Department of Surgery, Division of Pediatric Surgery, Baylor College of Medicine and Texas Children's Hospital, Houston, TX; [4]Texas Children's Hospital and Baylor College of Medicine, Houston, TX

4:00 PM - 6:00 PM

Objective: Complex gastroschisis is the severe type of gastroschisis, characterized by intestinal atresia, stenosis, volvulus, perforation, or necrosis. A systematic review (Arai, *Prenatal Diagnosis* 2024) demonstrated complex gastroschisis can be reliably surgically induced in fetal lambs using a 1.5 cm left lateral abdominal wall defect stabilized by a 1.5 cm silicone ring. It results in a 60% complex gastroschisis and a 40% fetal death rate *by term*. We aimed to identify from what time point after induction gastroschisis becomes complex.

Study Design: Gastroschisis was induced in 75-day (term = 145d) fetal lambs, which were harvested between 13 and 21d post-induction. Primary outcome was the occurrence of *complex* gastroschisis; secondary outcomes included *in-vivo* ultrasound characteristics of the bowel, *ex-vivo* bowel contractility, and

histology (Fig. 1). We first assessed 6 animals at 13-16d and 6 at 17-21d post-induction to sufficiently power the study.
Results: In the first 12 lambs, 0/6 developed *complex* gastroschisis at 13-16d, whereas this was present in 4/6 at 17-21d. Hypothesizing a complex gastroschisis rate of 10% at 13-16d and 65% at 17-21d, we added 6 lambs (total:18). Finally, 17-21d post-induction, *complex* gastroschisis was present in the vast (5/8 = 63%) majority, whereas it was simple at 13-16d (9/10 = 90%, p = 0.0265, 2-sided Fisher exact). Bowels from lambs with complex gastroschisis display inappropriate bowel relaxation on contractility testing and a thicker muscular layer on histology. Remarkably, lambs with complex gastroschisis presented with intra-abdominal bowel dilation on prenatal ultrasound at obduction; a 2.58mm cut-off could identify complex with 100% sensitivity and 60% specificity.
Conclusion: Gastroschisis can be reliably induced in fetal lambs. This leads to simple gastroschisis early on (13-16d), whereafter (17-21d) complex gastroschisis becomes very common. Complex gastroschisis coincided with intra-abdominal bowel dilation on ultrasound, which may be used as a non-invasive biomarker. This defines a time window of opportunity and signs to guide experiments for prenatal intervention.

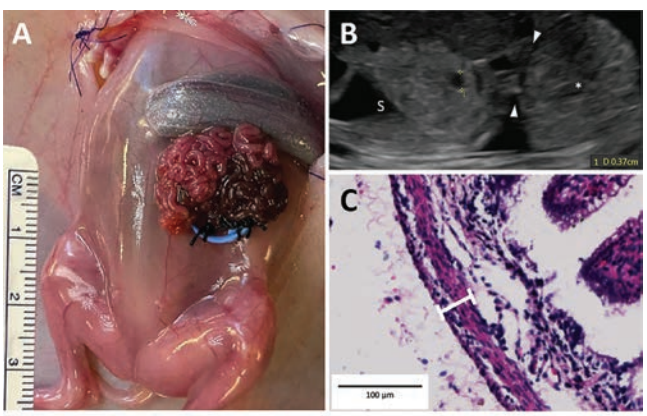

Fig 1: Gastroschisis induced at 75 d through creation of a 1.0 cm defect in the left lower abdominal quadrant, stabilized with a 1.0 cm ring (A). Ultrasound image of intra-abdominal bowel dilatation, measured at the most dilated part near the stalk (arrowhead) of the exteriorized bowel (*); S: stomach (B). Muscular layer thickness measured on hematoxylin-eosin staining of the bowel (C).

4:00 PM - 6:00 PM
Objective: To determine whether neighborhood socioeconomic disadvantage in early pregnancy was associated with severe maternal morbidity (SMM) at delivery hospitalization.
Study Design: This was a secondary analysis from the prospective cohort Nulliparous Pregnancy Outcomes Study: Monitoring Mothers-To-Be study. Participant residential addresses in the first trimester were geocoded at the census-tract level. The exposure was neighborhood socioeconomic disadvantage, measured by the Area Deprivation Index (ADI) and modeled in quartiles from the least (quartile 1, Q1, reference) to most (Q4) disadvantage. The outcome was SMM, based on the Centers for Disease Control and Prevention definition. Secondarily, SMM without transfusion was assessed. Modified Poisson regression with robust error variance was used and adjusted for individual-level covariates: age, pre-pregnancy body mass index, chronic hypertension, and diabetes in pregnancy. We also evaluated whether any observed associations between ADI and SMM differed by race/ethnicity, understood as a social construct (effect modification).
Results: Among 9,588 nulliparous individuals, 2.3% (n = 221) experienced any SMM and 0.5% (n = 48) experienced non-transfusion SMM. Individuals who self-identified as non-Hispanic Black were more likely to experience SMM than non-Hispanic White individuals (3.9% vs. 2.1% p < 0.001). Individuals living in the most disadvantaged neighborhoods (Q4) were more likely to experience SMM compared with those in the least disadvantaged neighborhoods (Q1) (3.4% vs 2.1%; aRR 1.73; 95% CI 1.17, 2.58) (Table). In secondary analyses, the association was also significant for non-transfusion SMM (1.0% vs 0.3%; aRR 2.82; 95% CI 1.15, 6.93). There was no evidence of effect modification by self-reported race and ethnicity (interaction p >0.05).
Conclusion: Nulliparous individuals living in the most disadvantaged US neighborhoods were at increased risk of experiencing SMM. Known racial and ethnic disparities in SMM may be related to differential neighborhood-level social determinants.

Table. Association of neighborhood-level socioeconomic disadvantage in early pregnancy and severe maternal morbidity (SMM) at delivery hospitalization

4:00 PM - 6:00 PM

Objective: The relationship between maternal mental health during pregnancy and consequent severe maternal morbidity (SMM) remains to be investigated. Therefore, we examined whether antepartum depressive symptoms in early pregnancy were associated with SMM at delivery hospitalization.

Study Design: This was a secondary analysis from the prospective cohort Nulliparous Pregnancy Outcomes Study: Monitoring Mothers-To-Be study. Nulliparous pregnant individuals were followed from the first trimester through delivery at 8 centers in the United States. The Edinburgh Postnatal Depression Scales (EPDS) was administered at 11-13 weeks' gestation. The EPDS was assessed categorically at ≥10 and ≥13, which are thresholds commonly used in clinical practice. The outcomes were SMM (including transfusion) and SMM (without transfusion) at delivery hospitalization. SMM was identified based on the Centers for Disease Control and Prevention definition. Modified Poisson regression with robust error variance was used and adjusted for age, insurance status, tobacco use, and Area Deprivation Index.

Results: Among 8,784 nulliparous individuals, 2.3% experienced any SMM and 0.5% had non-transfusion SMM. In early pregnancy (median gestational age: 12.0 weeks; IQR: 11.0,13.0), 17.2% of individuals had EPDS scores ≥10 and 7.1% ≥13. In univariable analysis, having an EPDS ≥10 was associated with a greater frequency of SMM (3.0% vs 2.1%; RR: 1.42; 95% CI: 1.02, 1.96), although this did not remain statistically significant after adjustment (Table). Individuals who met the higher EPDS threshold of ≥13 had a statistically significant increase in risk of SMM without transfusion in both univariable (1.1% vs. 0.4%, RR 2.53, 95% CI: 1.13, 5.67) and multivariable analyses (aRR: 3.12; 95% CI: 1.11, 8.81).

Conclusion: In a prospective cohort of nulliparous individuals from across the US, depressive symptoms in early pregnancy, defined by an EPDS score ≥13 was associated with an increased risk of SMM without transfusion.

4:00 PM - 6:00 PM

Objective: Low dose aspirin (LDA) mitigates antenatal preeclampsia risk. Data is scarce regarding LDA effectiveness in preventing de novo postpartum hypertension (dnPPHTN), a growing contributor to maternal morbidity and mortality. We investigated the association between antenatal LDA prescription and dnPPHTN in a diverse multicenter cohort.

Study Design: We conducted a retrospective cohort study of patient data extracted from a multicenter electronic medical record system, including patients delivering from 2017 to 2024 from 90 locations and ~320 providers. Patients who met ACOG criteria for LDA 81 mg once daily throughout pregnancy for preeclampsia risk reduction were included in the analysis. Exclusion criteria were: preexisting HTN, congenital heart disease, or pregnancy-related HTN in the index pregnancy. Patients were grouped by LDA exposure (based on provider completion of prescription/recommendation). The primary outcome was dnPPHTN incidence, defined as "postpartum HTN" recorded at the postpartum encounter or on the delivery outcome form. We fit logistic regression models for dnPPHTN with unadjusted and adjusted odds ratios (OR, aOR) presented as measures of association.

Results: A total of 15,899 patients met criteria for LDA for preeclampsia risk reduction and did not develop hypertension antenatally; of those 10209 (64%) had been appropriately prescribed LDA. The overall incidence of dnPPHTN was 2.9% (n = 466). (Table 1) LDA-exposed patients had an increased odds of dnPPHTN compared to LDA-unexposed patients (OR 1.4, 95% CI 1.2,1.7). After controlling for baseline differences in clinically-relevant risk factors and other clinical characteristics (Table 2), this association persisted (aOR 1.4, 95% CI 1.1,1.8).

Conclusion: Patients at increased risk of preeclampsia by ACOG criteria who are prescribed LDA remain at elevated risk for

HTN in the postpartum period. Given limitations in assessing adherence and unmeasured confounders, prospective trials may help elucidate whether aspirin serves any preventative role beyond delivery.

1216 | Comparing Perinatal Outcomes between Women with Subcapsular Liver Hematoma versus Preeclampsia - A Population-Based Study

Uri Amikam[1]; Ahmad badeghiesh[2]; Haitham Baghlaf[3]; Michael H. Dahan[4]; Richard Brown[4]
[1]Lis Maternity & Women's Hospital, Tel-Aviv, Tel Aviv; [2]Department of Obstetrics and Gynecology, King Abdulaziz University, Rabigh Branch, Rabigh, Makkah; [3]Department of Obstetrics and Gynecology, University of Tabuk, Tabuk, Saudi Arabia, Tabuk; [4]McGill University, Montreal, PQ

4:00 PM - 6:00 PM

Objective: Subcapsular Liver Hematoma (SLH) is a rare life-threatening complication of preeclampsia and the data regarding it is scarce. We aimed to compare pregnancy and perinatal outcomes in women with preeclampsia with and without an SLH.
Study Design: We conducted a retrospective cohort study using the Healthcare Cost and Utilization Project, Nationwide Inpatient Sample (HCUP-NIS). Included in the study were all pregnant women who delivered or had a maternal death in the US between 2004-2014 with an ICD-9 diagnosis of preeclampsia. We divided the cohort into women with a diagnosis of SLH (study group) and women without an SLH (control group). Pregnancy and perinatal outcomes were compared between the two groups using multivariate logistic regression models adjusting for potential confounders.
Results: Overall, 327,485 women met the inclusion criteria. Amongst them, 119 women had a diagnosis of SLH. Women with an SLH, compared to those without, were more likely to be older ($p = 0.002$); had a higher BMI (BMI >30kg/m^2) ($p = 0.004$); and suffered from chronic hypertension ($p = 0.007$). Patients in the SLH group, compared to those without, had a higher rate of eclampsia (aOR 15.23, 95% CI 4.82-48.16, p< 0.001); and placental abruption (aOR 8.87, 95% CI 5.62-14.01, p< 0.001). Additionally, they had a higher rate of cesarean delivery (aOR 3.02, 95% CI 1.95-4.68, p< 0.001), postpartum hemorrhage (aOR 3.5, 95% CI 2.24-5.48, p< 0.001), packed red blood cell transfusion (aOR 23.58, 95% CI 16.41-33.89), disseminated intravascular coagulation (DIC) (aOR 23.11, 95% CI 14.67-36.41, p< 0.001), and maternal death (aOR 98.48, 95% CI 36.4-266.45, p< 0.001). Regarding neonatal outcomes, patients with an SLH, compared to those without, had a higher rate of intrauterine fetal demise (IUFD) (aOR 30.69, 95% CI 19.36-48.67, p< 0.001).
Conclusion: Women diagnosed with an SLH had a higher incidence of myriad pregnancy and perinatal complications, including DIC, maternal death, and IUFD, as compared to women with preeclampsia alone, highlighting the severity of this condition.

Table – Pregnancy and perinatal outcomes

a- Pregnancy Outcomes: adjusted for age, obesity, and chronic hypertension.
Abbreviations and definitions: SLH – subcapsular liver hematoma GDM – gestational diabetes mellitus; PPH – post-partum hemorrhage; DIC – disseminated intravascular coagulation; SGA – small for gestational age; IUFD – intrauterine fetal death; N/A – not available.
Per convention of the HCUP database when N<11, absolute cell number of subjects was not provided to protect patient anonymity (zero subjects could be reported because it would not affect anonymity).
OR and CI cannot be calculated if zero cases occur in one group

1217 | Rare Inflammatory Arthritis and Obstetric and Neonatal Outcomes - A Population-Based Study

Uri Amikam[1]; Ahmad badeghiesh[2]; Haitham Baghlaf[3]; Richard Brown[4]; Michael H. Dahan[4]
[1]Lis Maternity & Women's Hospital, Tel-Aviv, Tel Aviv; [2]Department of Obstetrics and Gynecology, King Abdulaziz University, Rabigh Branch, Rabigh, Makkah; [3]Department of

Obstetrics and Gynecology, University of Tabuk, Tabuk, Saudi Arabia, Tabuk; [4]McGill University, Montreal, PQ

4:00 PM - 6:00 PM

Objective: Inflammatory Arthritis (IA) is a common pathology among reproductive-aged women. While abundant data exists regarding pregnancy outcomes in the more common IA subtypes, data is scarce regarding these outcomes in rare IA subtypes. We aimed to compare pregnancy and perinatal outcomes between women who suffered from rare types of IA and those who did not.

Study Design: A retrospective cohort study using the Healthcare Cost and Utilization Project, Nationwide Inpatient Sample (HCUP-NIS). Included in the study were all pregnant women who delivered or had a maternal death in the US (2004-2014) with an ICD-9 diagnosis of any of the following rare IA subtypes: Arthritis Nodosa, Acute Febrile Mucocutaneous Lymph node, Hypersensitivity Angiitis, Wegner Granulomatosis, Giant Cell Arteritis, and Takayasu Arteritis. We divided the cohort into women with rare IA (study group) and women without (control group). Obstetric and perinatal outcomes were compared between the two groups using multivariate logistic regression adjusting for potential confounders.

Results: A total of 9,096,788 women met the inclusion criteria. Amongst them, 335 women (3.7/100,000) had a diagnosis of rare IA. Women with rare IA, compared to those without, were more likely to be older; Caucasian; in the highest income quartile; be insured by private insurance; and suffer from obesity, pregestational diabetes mellitus, thyroid disorders, and chronic hypertension ($p< 0.05$, all). Patients in the rare IA group, compared to those without, had a higher rate of hypertensive disorders of pregnancy (HDP) (aOR 1.89, 95% CI 1.4-2.56, $p< 0.001$); preterm delivery (aOR 1.76, 95% CI 1.28-2.42, $p< 0.001$); and blood products transfusion (aOR 3.68, 95% CI 2.14-6.34, $p< 0.001$); with lower rates of spontaneous vaginal delivery (SVD) (aOR 0.76, 95% CI 0.61-0.94, $p = 0.012$); and a higher rate of congenital anomalies (aOR 4.1, 95% CI 2.03-8.31, $p< 0.001$).

Conclusion: Women with rare IA had a higher incidence of maternal complications, including HDP and preterm delivery, as well as an increased risk of congenital anomalies.

1218 | The social Vulnerability (SV) Index is Related to Toxicology Testing During Pregnancy

Virginia Lijewski[1]; Jeanelle Sheeder[2]; Heather Straub[2]
[1]University of Colorado, School of Medicine, Aurora, CO; [2]University of Colorado School of Medicine, Aurora, CO

4:00 PM - 6:00 PM

Objective: To compare the demographic profiles and SV of pregnant patients who did and did not receive urine toxicology (uTox) testing. We also wished to determine if the declaration of the opioid epidemic as a National Public Health Emergency (PHE) on 10/27/17 led to increased testing rates. We hypothesized that patients receiving uTox testing were more likely to be SV than those who did not and that testing rates would increase post-PHE declaration.

Study Design: Patients receiving prenatal care and delivered within a multihospital academic healthcare system with urban, suburban, and rural hospitals from 8/23/2016-12/31/2018 were included. Patient addresses were matched to the CDC Social Vulnerability Index to obtain overall and domain-specific (Household Composition, Socioeconomic Status, Racial/Ethnic Minority Status, and Housing/Transportation) SV scores. Scores ≥ 0.75 indicate high SV. Chi-squared or Fisher's exact tests were used to compare categorical variables, and Mann-Whitney U tests were used to compare continuous variables.

Results: 3,938 were included; 3,405 (86%) did not receive uTox testing, and 533 (14%) did. Testing rates did not differ pre- and post-PHE (14% vs 13%; $p = 0.25$). Patients with uTox testing were

more likely to be non-Hispanic Black or Hispanic, older, unmarried, without private insurance (Table 1). Overall elevated SV scores were significantly higher among those who received uTox testing and individually in all domains except for racial/ethnic minority status (Table 1). Those who received testing were more likely to have inadequate prenatal care, fetal or neonatal demise, abruption, PPROM and poor pregnancy outcomes (Table 2).

Conclusion: The PHE declaration did not impact testing rates. Demographic and other clinical differences in uTox testing may highlight provider biases. A high SV score may be a helpful tool for investigating other ways to make substance use testing in pregnancy more reliable.

1219 | Factors Associated with Subsequent Diagnosis of T2DM Following an Initial Pregnancy with GDM

Wendy Tian; Bharti Garg; Alyssa R. Hersh; Aaron B. Caughey
Oregon Health & Science University, Portland, OR

4:00 PM - 6:00 PM

Objective: Gestational diabetes (GDM) affects more than 200,000 people annually in the US, with prevalence continuing to rise. GDM is associated with development of type 2 diabetes mellitus (T2DM) in the future, which can affect subsequent pregnancies. The purpose of this study was to identify factors that are associated with the development of T2DM in a subsequent pregnancy in patients who had GDM in their initial pregnancy.

Study Design: This was a retrospective cohort study of pregnant persons in California between 2008-2020 with two births that were both singleton, non-anomalous, gestational ages 23-42 weeks. Included persons had GDM in their index pregnancy. We assessed factors associated with development of T2DM in a subsequent pregnancy compared to those who did not develop T2DM. Statistical analyses were performed utilizing chi squared and multivariable logistic regression with a p-value of 0.05.

Results: There were 65,160 (6.9%) of patients who had GDM in their initial pregnancy, of which 3,904 (6.0%) developed T2DM in their second pregnancy. Factors associated with development of T2DM at second delivery included non-Hispanic black race (aOR 1.98, CI 95% 1.67-2.35), Hispanic ethnicity (aOR1.88, CI 95% 1.70-2.08), overweight or obese body mass index (BMI) (aOR 1.81, CI 95% 1.62-2.02; aOR 3.61, CI 95% 3.27-3.99), public insurance (aOR 1.26, CI 95% 1.17-1.36), and diagnosis of chronic hypertension (CHTN) (aOR 1.93, CI 95% 1.66-2.25). Patients that were less than 20 years of age were less likely to develop T2DM in their subsequent pregnancy (aOR 0.82, CI 95% 0.68-0.98).

Conclusion: We found that a new diagnosis of T2DM in a subsequent pregnancy after an initial pregnancy with GDM is associated with several factors, including non-Hispanic black race, Hispanic ethnicity, overweight or obese BMI, public insurance and diagnosis of CHTN during initial pregnancy. These findings can be used when counseling patients with a history of GDM to discuss the risk of development of T2DM in subsequent pregnancies. Future studies should assess structural and sociocultural factors that may contribute to these findings.

1220 | Association of Active Antenatal Management before Periviable Birth and Birthing Parent race in the US

Niurka L. Monteserin[1]; Whitney Bender[2]
[1]Virginia Women's Center, Richmond, VA; [2]Thomas Jefferson University Hospital, Philadelphia, PA

4:00 PM - 6:00 PM

Objective: sMFM provides guidance on the use of antenatal corticosteroids, antibiotics, and cesarean delivery in the periviable period. Although differences exist in postnatal active management of periviable neonates by parent race, less is known about the receipt of antenatal interventions. The objective of this study is to describe differences in antenatal interventions before a periviable delivery by birthing parent race.

Study Design: This is a population-based cohort study of the National Center for Health Statistics database of periviable deliveries (20w0d-25w6d) from 2016-2021. Subjects were included if they delivered a non-anomalous live singleton gestation in a hospital. To minimize inaccurate dating, subjects were excluded for birthweight >97% for gestational age. The exposure was self-reported race; those of Black race were compared to those of non-Black race. Outcomes included receipt of antenatal steroids or antibiotics, and cesarean delivery. The relationship of race to antenatal interventions was assessed using multivariable logistic regression.

Results: Of 45339472 live births during the study period, 93686 met inclusion criteria for this study. 37626 (40.2%) periviable births occurred in Black subjects. Black subjects differed from non-Black subjects in baseline characteristics (Table 1). As seen in Table 2, Black subjects were less likely to receive antenatal steroids (33.5% v. 34.3%, aOR 0.93, 95% CI 0.90-0.96), receive antibiotics (36.8% v. 38.1%, aOR 0.96, 95% 0.93-0.99), or receive antibiotics in the presence of intraamniotic infection(64.7% v. 67.4%, aOR 0.87, 95% CI 0.78-0.97). There were no differences in mode of delivery in adjusted analyses.

Conclusion: Black birthing parents are less likely to receive antenatal steroids or antibiotics prior to a periviable delivery. Given the complexity of counseling and clinical-decision making required in those at risk of periviable birth, additional research is warranted to understand the root of these disparities with the goal of equitable, patient-centered care in the periviable period.

[5]*University of Tennessee, Knoxville, TN;* [6]*High Risk Obstetrical Consultants of Knoxville, Knoxville, TN*

4:00 PM - 6:00 PM

Objective: To investigate maternal and neonatal risk factors and outcomes among pregnant individuals with positive hepatitis C virus (HCV) screening results stratified by undetectable or detectable HCV RNA or viral load (VL).

Study Design: This retrospective cohort study included all deliveries between January 2022 and June 2023 at our institution with positive HCV antibody screening results and quantitative HCV RNA testing. Data on demographics and maternal and neonatal outcomes were collected. Comparisons were performed on factors and outcomes stratified by undetectable or detectable VL. Pearson chi-square tests were used to compare populations and outcomes as appropriate and can be found in the table.

Results: Of the 6,337 births with HCV screening results, the prevalence of positive HCV screening serology was 3.6% (n = 228). HCV VL results were available for 206 patients. When stratified by undetectable or detectable VL, there were no statistically significant differences in preterm delivery, hypertensive disorders of pregnancy, late or limited prenatal care, delivery route, NICU admission, or neonatal abstinence syndrome diagnosis. There were no differences in the rate of self-reported current substance misuse or a history of IV substance misuse. A history of substance misuse was significantly higher in patients with a detectable viral load (92.4% vs. 83.2%, p = .043). Full outcome data is shown in the table.

Conclusion: Although obstetric complications have been reported among women with HCV, the frequency of these outcomes remained unchanged when stratified by detectable VL. The only factor associated with detectable VL was a self-reported history of substance misuse. HCV genotyping remains an important factor in determining treatment type and duration. Future research will focus on understanding factors related to HCV infection that drive delivery and neonatal outcomes, including the temporal association of last substance use, IV misuse, and VL in pregnancy.

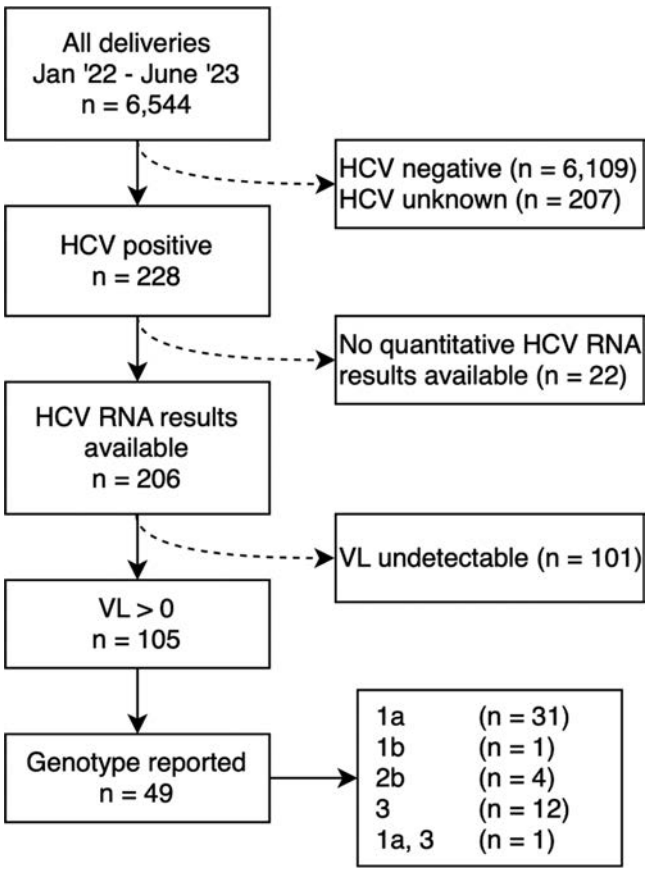

Table. Demographics and outcomes by VL

	Total	Undetectable VL n=101 (49.0%)	Detectable VL n = 105 (51.0%)	p-value
Age	30.6 +/- 4.9	30.4 +/- 4.7	30.8 +/- 5.2	0.532

1222 | Collagen's Critical Role in Uterine Structure and Function and Implications in Placenta Accreta Spectrum

Sohum Shah[1]; Lior Kashani Ligumsky[1]; Alex Kot[1]; Liwen Xu[1]; Anhyo Jeong[1]; Guadalupe Martinez[1]; Scott A. Shainker[2]; Deborah Krakow[1]; Yalda Afshar[1]

[1]*University of California, Los Angeles, Los Angeles, CA;* [2]*Maternal Fetal Care Center Associate Professor of Surgery Associate Professor of Obstetrics, Gynecology and Reproductive Biology Harvard Medical School, Boston, MA*

4:00 PM - 6:00 PM

Objective: Properly synthesized and cross-linked collagen fibrils are the principal source of tensile strength in tissues and altered during pregnancy. We previously described changes in collagen at the decidual-stromal interface in placenta accreta spectrum (PAS). We aim to describe histoarchitectural variables of collagen organization in the uterus of wild type and mutant type I collagen mice to understand the role of collagen in pregnancy and repair as it related to PAS.

Study Design: We utilized two mutant type I collagen mice: *Col1a1*$^{Aga2/+}$ (*Aga2/+*) mice which express modified *Col1a1,* C-terminal frameshift mutation, and *Col1a1*$^{+/-}$ which express reduced levels of type I collagen. These mice, historically used in the study of skeletal dysplasias, allow us to interrogate the role of type I collagen. Uteri and placenta from wildtype (WT), *Col1a1*$^{+/-}$, and *Aga2/+* mice were harvested. Additionally, we utilized a surgical mouse model of PAS. We employed quantitative histomorphometry with standard histochemistry as well as label-free 3D spectroscopy to understand collagen fibril orientation and distribution.

Results: Type I (Col1a1) collagen was expressed in WT non-pregnant mice and at postpartum day (PP). In the WT, collagens were organized around smooth muscle and in the basement membranes of luminal and glandular epithelium (Fig 1). PP type I collagen staining was prominent within the endometrial stroma. *Aga2/+* mice demonstrated decreased type I collagen with a compensatory increase in type III collagen but no difference in type I and III collagen PP. *Aga2/+* stromal thickness was decreased. Utilizing the surgical PAS mouse, RNA and protein expression of COL1A1 was altered and there was an increase deposition of type III collagen at the decidual-placental interface in PAS (Fig 2).

Conclusion: Collagens are a main component of the dynamic architecture of the uterus. Type I collagen remodeling is a physiological component of pregnancy and birth and altered in PAS. The increased abundance and disorganization of collagen fibers at the site of adherence in PAS provide spatiotemporal clues to the mechanisms of PAS.

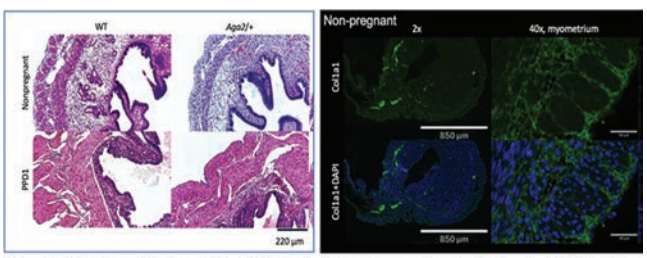

Figure 1. H&E staining of uteri from WT and Col1A1 mutant mice (non-pregnant and postpartum day 1 [PPD1]) without significant gross differences. Immunofluorescence demonstrates visualization of endometrial and myometrial Col1a1 protein (green) relative to nuclear staining (DAPI; blue) in non-pregnant WT mice.

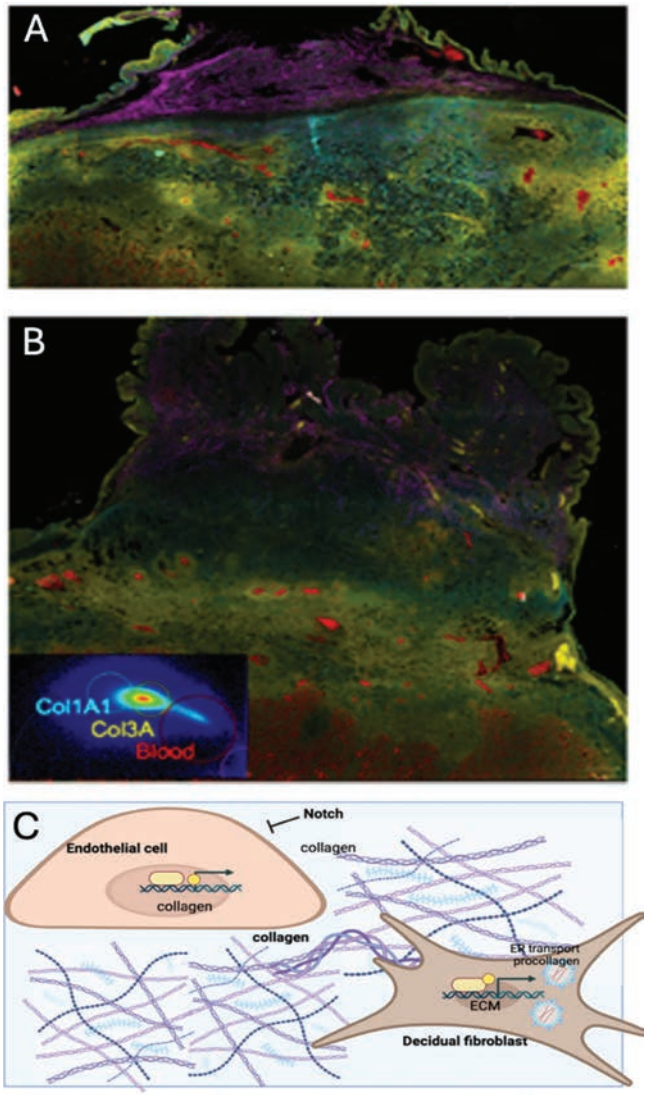

Figure 2. (A) Fluorescence lifetime imaging microscopy of uterine tissues from mouse pregnancies without PAS and without scarring compared to (B) PAS mice. (C) Collagen remodeling is a requirement for endothelial cell migration at the maternal-fetal interface and modulated by decidual fibroblast driven ECM production.

1223 | Cervicovaginal Microbiome in Pre vs Post Cerclage Placement

Yasaman C. Yaghoubian[1]; Dzhamala Gilmandyar[2]; Burton Rochelson[3]; Jane Cerise[4]; Anette Lee[4]
[1]Zucker School of Medicine at Hofstra/ Northwell, Queens, NY; [2]Zucker School of Medicine, Queens, NY; [3]Northwell, New Hyde Park, NY; [4]Feinstein Institute for Research, Manhasset, NY

4:00 PM - 6:00 PM

Objective: Though an association between changes in the cervicovaginal microbiome (CVM) and preterm birth has previously been demonstrated, the impact of cerclage placement on the CVM is poorly understood. Our objective was to assess significant changes in CVM due to cerclage placement, and association of CVM makeup with preterm delivery in patients with cervical insufficiency requiring cerclage placement.

Study Design: This was a prospective cohort study of singleton, non-anomalous pregnancies from 2022-2023 at two tertiary care centers. We enrolled 22 subjects receiving ultrasound or physical exam indicated cerclage, and 20 subjects with no prior preterm delivery and a normal cervical length as controls. Cervicovaginal fluid samples were collected prior to, and 1-2 wks post cerclage placement for the study group, and during routine anatomical surveys for the control group. Samples were analyzed using 16S rRNA gene sequencing.

Results: We detected no significant difference in Shannon diversity between study and control groups. However, a significant difference in distribution was observed in Shannon diversity between preterm and term deliveries (p = 0.01, Graph1). There were significant differences in differential abundance of 14 taxa in study vs control groups, and 4 taxa in preterm vs term deliveries (Table 1).

When comparing samples pre vs post cerclage placement, no significant difference was observed in Shannon diversity. However, a significant difference in distributions was observed in beta diversity between these samples (p =˙.04). There were no differences in specific taxon abundance between pre and post cerclage samples.

Conclusion: In a diverse patient population, differences in CVM distribution are associated with preterm delivery. The abundance of certain taxa may be associated with cervical insufficiency and preterm birth. Though cerclage placement did not implicate a difference in specific taxa present, it does appear to alter the distribution of the CMV.

1224 | Do Maternal Fetal Medicine Fellowship Websites Adequately Depict Training Opportunities?

Zenobia Gonsalves[1]; Rachel Lee[2]; Lama R. Noureddine[3]; Kimberly Herrera[4]; Cassandra Heiselman[1]

[1]Stony Brook University Hospital, Stony Brook, NY; [2]Stony Brook University Hospital, Lake Grove, NY; [3]Rutgers New Jersey Medical School, Newark, NJ; [4]Stony Brook University, Stony Brook, NY

4:00 PM - 6:00 PM

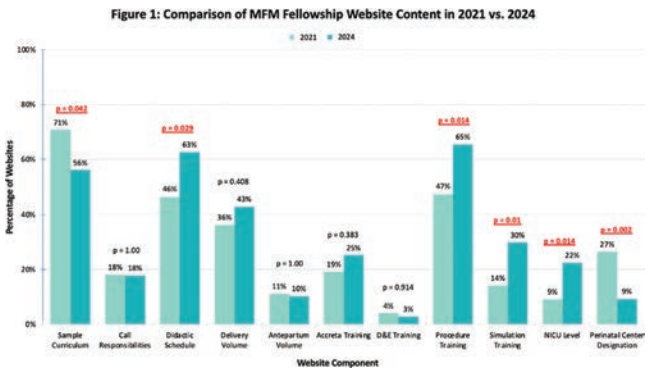
Objective: After the COVID-19 pandemic and with current virtual fellowship interviews, applicants rely heavily on programs' websites early in the application process to assess a program's unique training attributes and fit with their professional goals. We aimed to evaluate and compare the availability of information on education and training on MFM fellowship program websites between 2021 and 2024.

Study Design: This was a cross-sectional analysis of MFM fellowship websites for the 109 ACGME-accredited programs. Fellowship program websites had previously been reviewed in July 2021 and then again in July/August 2024 for the following information: delivery and antepartum volumes; level of neonatal intensive care units (NICU); regional perinatal center designation; sample curriculum with didactic schedule, simulation sessions, and call responsibilities; and training in placenta accreta spectrum (PAS) disorders, prenatal diagnostic procedures, and dilatation and evacuation (D&E). The percentage of websites that included each of these components was calculated and compared

across time points. Chi-square and Fisher's exact analyses were performed with a p-value < 0.05.

Results: 107 (98%) of the 109 ACGME-accredited MFM fellowship programs had an official website as of August 2024. Less websites were "up to date" for the current academic year in July 2024 (50%) compared to July 2021 (65%) [p = 0.04]. A larger proportion of programs in 2024 included information about the didactic schedule (p = 0.029), procedure training (p = 0.014), simulation training (p = 0.01), NICU level (p = 0.014), and perinatal center designation (p = 0.002) [Figure 1]. However, a smaller percentage of websites in 2024 included the rotation schedule as compared to 2021 (56% vs 71%, p = 0.03).

Conclusion: This study demonstrates continued gaps in the availability of desired information about education and training on MFM fellowship program websites. Programs should continue to improve information availability to enhance the application process, particularly as fellowship programs look to adopt signaling as AGCME residency applications have implemented.



1225 | Uterine Electrical Activity in Labor: EMMI Insights on Contraction "Pacemakers"

Zichao Wen[1]; Hui Wang[2]; Hansong Gao[2]; Yuelin Li[2]; Yuan Nan[2]; Josephine Lau[2]; Yong Wang[2]

[1]Washington University School of medicine in St. Louis, St. Louis, MO; [2]Washington University School of Medicine in St. Louis, St. Louis, MO

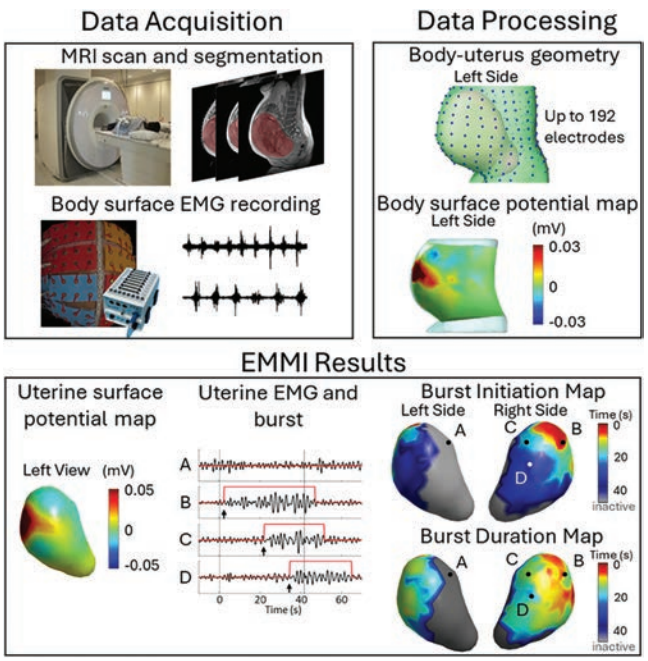
4:00 PM - 6:00 PM

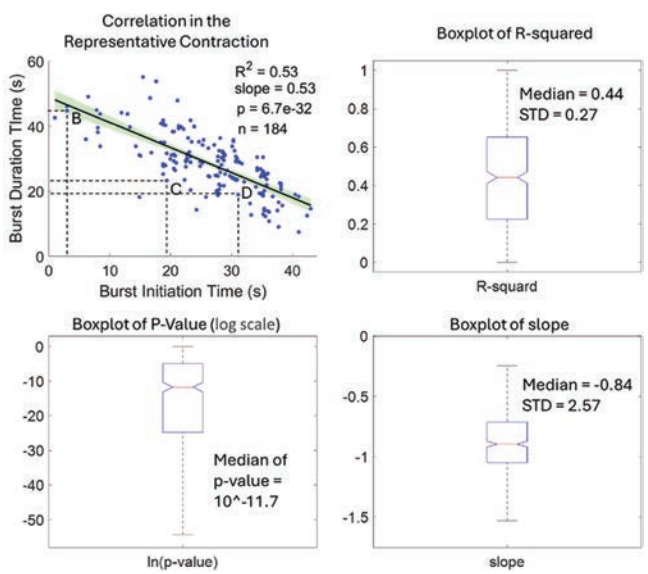
Objective: This study aims to analyze the correlation between initiation and duration of Electromyometrial Imaging (EMMI)-reconstructed electrical activity across the whole 3D uterine surface, which could provide new insights into electrophysiological "pacemakers" in human labor contractions.

Study Design: The Washington Institutional Review Board approved this prospective cohort study. Following informed consent, 38 subjects underwent MRI at ~37 weeks of gestation to capture subject-specific body-uterus geometry. Upon admission to Labor & Delivery Unit and during active labor (≥4 cm dilation with regular contractions), ≤192 electrodes were applied to the abdomen and back. Electrical potentials on the body were recorded for ~1 hour. EMMI generated uterine potential maps, electrogram bursts, and isochrone maps of burst initiation and duration (Fig. 1). Four representative uterine EMG (A-D) are shown.

Results: A strong negative correlation (Fig. 2) was observed between burst initiation time and duration, suggesting uterine regions with earlier activation had longer burst durations. Uterine locations B-D in Fig. 1 are depicted in the scatter plot. Statistics of R2, P-values, and slopes for 482 contractions from 38 subjects are also shown in Fig. 2. This finding aligns with the concept that the uterus does not have a single, dedicated, anatomical pacemaker, but instead shows variable initiation sites for each contraction, supporting the idea of multiple, widely dispersed, functional "pacemakers".

Conclusion: The inverse relationship between burst initiation time and duration highlights the importance of early-activating regions in maintaining normal uterine contractions. These findings challenge the traditional notion of an anatomically fixed uterine pacemaker like the heart's sinoatrial node. Instead, the data support the hypothesis that the uterus operates with multiple functional "pacemakers," likely coordinated through intrauterine pressure. Future studies should address potential bias from varying detected contractions per subject to refine these findings and explore uterine contraction coordination mechanisms.





1226 | Determining Potentially Avoidable Blood Transfusion after Cesarean Delivery: A Retrospective Cohort

Zoya Pervaiz Butt; Rebecca F. Hamm
University of Pennsylvania Perelman School of Medicine, Philadelphia, PA

4:00 PM - 6:00 PM

Objective: Prior work shows that actual blood loss is similar between vaginal (VD) and cesarean deliveries (CD). Yet, 12-hour complete blood counts (12hCBCs) are only routinely performed after CD, possibly contributing to a higher blood transfusion rate after CD as compared to VD. We sought to determine the proportion of blood transfusions after CD performed secondary to the routine post-CD 12hCBC alone, thus potentially avoidable.

Study Design: This retrospective cohort evaluated indications for packed red blood cell (pRBC) transfusion after CD in the postpartum (PP) period at a single institution from 2017-2022. Patients were evaluated for: pRBC transfusion before or after 12hCBC, high risk clinical criteria for PP anemia warranting a CBC (defined as ≥1 of the following: EBL≥1L, ≥3 CD, placental abnormalities, severe preeclampsia, multiple gestation, bleeding/clotting disorder, antepartum pRBC transfusion, admission Hb< 9.5g/dL, and surgical injury), and documented symptomatology (lightheadedness and/or fatigue) or abnormal vital signs (VS, defined as ≥1 of the following HR≥100; BP< 90/50; O2 sat < 95%) prior to transfusion. Those transfusions that occurred post-12hCBC, without high-risk clinical criteria, symptoms, or abnormal VS, were deemed potentially avoidable without a routine 12hCBC. Descriptive statistics were utilized.

Results: 421 patients were included; demographics are shown in the Table. Of those 421, 244 (58.0%) of post-CD transfusions occurred after the 12hCBC. Among those 244, 216 had at least one of the high-risk clinical criteria. Of the remaining 28 (6.6% of the initial cohort), 17 had either documented symptoms or abnormal VS. Thus, of 421 patients receiving pRBC transfusions post-CD after the 12hCBC, only 11 (2.6%), encompassing 19 pRBC units out of 984 transfused in the cohort (1.9%), were deemed potentially avoidable (Figure).

Conclusion: This study highlights that the majority (>97%) of patients who received pRBCs post CD would not have avoided the transfusion even in the absence of a routine 12hCBC. Alternative interventions to reduce unnecessary post-CD transfusion should be pursued.

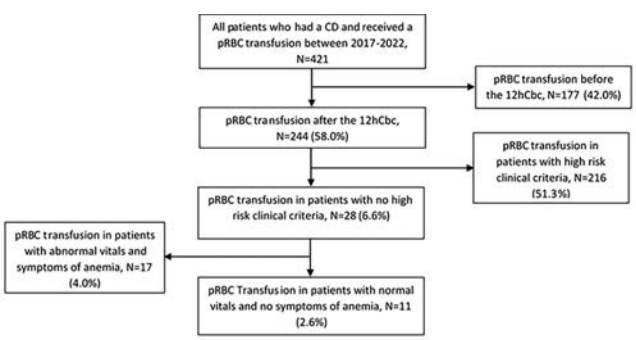


Figure: All percentages are out of the total patients transfused after CD

1227 | Severe Early Post-Partum Hemorrhage: An Individualized Risk Assessment by Machine Learning Models

Ido Bachar[1]; Zvi Ehrlich[2]; Ari Weiss[3]; Rivka Farkash[4]; Tzuria Peled[3]; Sorina Grisaru Granovsky[5]
[1]Bnei Zion, Bnei Zion, Yerushalayim; [2]Shaare Zedek Medical Center, Jerusalem, Yerushalayim; [3]Shaare Zedek Medical Center, Shaare Zedek Medical Center, Yerushalayim; [4]SZMC, SZMC, Yerushalayim; [5]Hebrew University, Jerusalem, Yerushalayim

4:00 PM - 6:00 PM

Objective: Severe early post-partum hemorrhage (SEPPH) is a common, life-threatening obstetric challenge. The risk factors of early postpartum hemorrhage had been researched, however, early, upon admission for labor, recognition of high-risk parturients by machine learning models (ML) has not been attempted.

Study Design: Analysis of a multi-parameter dataset of 227,424 births at a tertiary medical center. SEPPH was defined as - Hemoglobin loss more than 4 g/dl or post-partum hemoglobin level less the 8 g/dl or treatment of 2 or more pRBC post-partum. For the ML analyses, the data set was divided into two groups: SEPPH and no SEPPH; analysis was conducted using a gradient boosting model (CatBoost) algorithm, to create a model predicting the risk score of SEPPH. Furthermore, this type of analysis categorized the study population high-risk and low-risk groups for SEPPH by using the Youden's Index.

Results: Study population is depicted in Figure 1. Using traditional statistical methods dissected into the individual risk factors for SEPPH. Notably, we revealed that the primiparity is a major risk factor for extreme postpartum hemorrhage (OR 4.5 [4.0-5.0] CI, p< 0.001). In addition, Multiple gestation (OR 2.5 [2.0-3.1]

CI p< 0.001), previous caesarean section (OR 3.0 [2.6-3.5] CI, p< 0.001), placentation anomaly (OR 4.0 [3.424-4.814] CI, p< 0.001), were significant risk factors.

The high-risk group identified by the ML model showed a significant higher risk for adverse maternal and neonatal outcomes including among the low and high risk for SEPPH: uterine rupture (OR-3.5), re-admission 42 and 90 days after delivery (OR -2.2, 2.2 respectively) and perinatal fever (OR-2.2), uterine scar dehiscence (OR-1.9). Newborn infection (OR-2.5), postnatal intensive care unit (NICU) stay >3 days (OR 2.4, 2.37 respectively) and low Apgar (1-7) at 1st and 5th min (OR 2.0, 1.26 respectively). Figure -2.

Conclusion: We built a machine learning model with defined measurable predictable factors to identify high risk for SEPPH. Prediction models for early PPH may allow appropriate risk reducing preventive care during and after delivery.

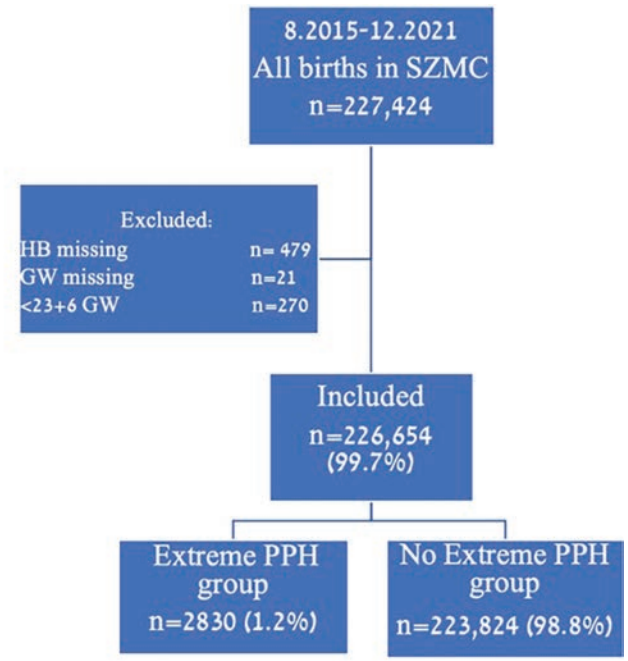

Figure 1 - study population

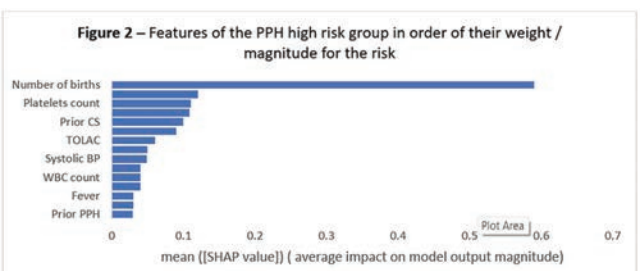

Figure 2 - Risk ranking using a gradient boosting model to identify the most important influencing features in order of relative importance. The top most influential features according to the GBM, by order of importance. As seen, the number of parity was the most influential feature. Values are measured by relative importance based on shapely additive explanation (SHAP). CS- cesarean section, TOLAC- trial of labor after cesarean, BP – blood pressure. RBC- red blood cell, WBC- white blood cell.

10:00 AM - 10:15 AM

Objective: Routine assessments in near-term pregnancies often fail to accurately detect fetal compromise due to placental insufficiency, especially in non-small for gestational age fetuses. The cerebroplacental ratio (CPR) serves as a potential indicator of placental insufficiency and adverse outcomes. This study aims to evaluate whether expedited birth in women with reduced fetal movements, potentially a sign of placental insufficiency, and low CPR improves neonatal outcomes.

Study Design: In this international, multicenter, cluster-randomized controlled trial, we randomly assigned 22 Dutch and 1 Australian hospitals to CPR-based management (i.e. expedited birth in case of CPR < 1.1) and concealed CPR measurement with routine clinical care in case of reduced fetal movements at term (37+0 to 40+6 weeks' gestation). Women were eligible to participate in the trial if the fetus was estimated to be above the 10th percentile, if cardiotocography was normal, and if there were no other reasons necessitating expedited birth within 4 days. Primary outcome was a composite of severe adverse perinatal outcomes: stillbirth, neonatal mortality, 5-minute Apgar score < 7, umbilical artery pH < 7.10, emergency birth for fetal distress and/or severe neonatal morbidity.

Results: From July 2020 to September 2024, 1816 women participated in the trial. 1676 Women with complete data were included in the intention to treat analysis. In preliminary data, the composite of severe adverse perinatal outcomes occurred in 99 (11.7%) of 849 participants who received CPR-based management versus in 127 (15.4%) of 827 participants in the concealed CPR group (relative risk 0.76; 95% confidence interval 0.58 to 0.99, Figure 1, Table 1). This was mainly driven by a reduction in severe neonatal morbidity, Apgar score < 7, umbilical artery pH < 7.10 and/or emergency birth for fetal distress.

Conclusion: In women presenting with perceived reduced fetal movements at term in non-small for gestational age fetuses, CPR-based management, i.e. expedited delivery if CPR < 1.1 and expectant management if CPR > 1.1, reduced severe adverse perinatal outcomes.

10:15 AM - 10:30 AM

Objective: Sildenafil citrate (SC) has been proposed as a drug to reduce fetal distress during labour. We assessed its effectiveness in a large placebo controlled clinical trial.
Study Design: This was a double-blind multicentre randomised controlled trial (Trial Registration Number ACTRN12621000231842) funded by the Australian Medical Research Future Fund. We randomised women attempting vaginal birth at term to 50mg SC every 8 hours during labour (maximum of 3 doses) or placebo. Primary outcome was a composite of 10 adverse neonatal outcomes (intrapartum stillbirth, neonatal death, Apgar score < 4 at 5 minutes, cord artery pH < 7.0, neonatal encephalopathy, neonatal seizures, neonatal respiratory support >4 hours, neonatal unit admission > 48hours, persistent pulmonary hypertension of the newborn and meconium aspiration syndrome). Secondary outcomes were caesarean section (CS) or instrumental vaginal birth (IVB) for fetal distress. The sample size of 3200 women was predicated on a 35% reduction in the RR of the composite perinatal outcome by 35% (7% to 4.55%).
Results: Between 7 September 2021 and 30 June 2024 we randomized 3257 women (including 18 sets of twins) to SC (1626) and placebo (1631). Induction of labour occurred in 83.5% of the SC cohort and 82.9% of the placebo group. Electronic fetal heart rate monitoring rates were similar (97.4%) in both arms. The primary outcome occurred in 5.1% of women taking SC and 5.2% of those taking placebo [RR 1.02 (0.75-1.37)] with no differences in any of the components of the composite outcome. There was also no difference in rates of CS or IVB for fetal distress [21.1% vs. 18.8%, RR 1.12 (0.98-1.29)]. Blood loss >1000ml occurred in 10.1% in the SC group vs. 7.9% [RR1.29, (1.03-1.60)].
Conclusion: Maternal oral SC in women undergoing term labour did not result in a reduction of adverse neonatal outcomes potentially related to intrapartum hypoxia.

10:00 AM - 10:15 AM

Objective: Maternal iron deficiency anaemia (IDA) is a persistent global health challenge with increased risk of adverse perinatal outcomes. Obstetric guidelines recommend first line treatment with oral iron, however rates of maternal IDA remain above global targets. We aimed to determine whether single dose intravenous (IV) iron for maternal IDA in the 2nd trimester was superior to oral iron in reducing incidence of low birth weight (LBW) infants and maternal anemia at delivery.
Study Design: This is a parallel, three-arm superiority randomized controlled multi-center trial in India of pregnant singletons at 14-17 weeks with moderate IDA randomized to: (1) 60mg oral ferrous sulphate twice daily; or single dose infusion of (2) intravenous (IV) ferric derisomaltose (FDM) or (3) IV ferric carboxymaltose (FCM). The dual primary outcomes were: (1) LBW (< 2500 grams [g]) and (2) maternal non-anemic state (NAS) (Hb >11·0 g/dL at 30-34 weeks or delivery). Participants received rescue treatment per local clinical care guidelines (Hb< 7g/dL or < 1g/dL improvement in Hb). Sensitivity analysis performed defining NAS as Hb≥11.0 without additional non-study iron or blood transfusion.
Results: The oral iron, FDM, and FCM arms included 1450, 1456, and 1462 participants respectively. There was a reduced rate of LBW with IV FCM (25·2%, Relative Risk [RR] 0·87 [97·55% CI 0·75,0·99]), but not IV FDM (29·1%, RR 0·98 [97·55% CI 0·86,1·12]) vs oral iron (Fig1). Achievement of NAS was not improved: IV FCM (RR 1·05 [99·95% CI 0·97-1·15]) and IV FDM (RR 1·06 [99·95% CI 0·98, 1·16]) vs oral (Fig 1, 2A). In sensitivity analysis, there was increased rate of NAS in both IV FDM (RR 1.25 (1.13-1.396), p< 0.0001) and IV FCM (RR 1.24 (1.12-1.38), p< 0.0001) vs oral (Fig 2C).
Conclusion: First-line treatment of maternal IDA with single dose infusion of IV iron results in a reduced incidence of LBW infants (IV FCM) and higher incidence of maternal NAS without additional iron or blood transfusion (IV FCM and FDM).
Clinical guidelines should address the potential benefit of single dose IV iron as the primary treatment of IDA in pregnancy.

10:15 AM - 10:30 AM

Objective: Obstetric advances have had limited impact on preterm birth (PTB) rates and neonatal outcomes. We assessed outcomes in a cohort of average risk singleton pregnancies using biomarker-based PTB risk stratification, followed by interventions for those identified at higher risk.

Study Design: This randomized controlled trial enrolled 5,018 singleton pregnancies at 19 U.S. centers from 2020-2023. Individuals with prior PTB, short cervix, severe maternal conditions, or known genetic/fetal anomalies were excluded. We measured the ratio of maternal circulating insulin-like growth factor-binding protein 4 to sex hormone-binding globulin between 18w0d and 20w6d, with participants randomized 1:1. The control arm, blinded to test results, received usual care, while the prevention arm received test results. Prevention arm participants identified as high-risk were offered a regimen of daily vaginal progesterone, low-dose aspirin, and weekly nursing calls. Lower-risk participants in the prevention arm received usual care. Follow-up continued through delivery and neonatal discharge. The prespecified modified intent-to-treat (mITT) analysis included the control group, prevention arm low-risk participants, and high-risk participants who consented to intervention by 24 weeks, while excluding those hospitalized with COVID-19. Primary outcomes included neonatal length of stay (NNLOS) and a composite morbidity index (NMI). A planned intent-to-treat (ITT) analysis assessed multiple neonatal outcomes.

Results: Baseline characteristics did not differ between arms. mITT analysis of co-primary outcomes (Table 1) showed significantly decreased NMI and NNLOS in the prevention arm. The ITT analysis displayed significant reductions in NMI (20%), NNLOS (8%), neonatal intensive care unit (NICU) length of stay (6%), and NICU admission (20%) (Table 2).

Conclusion: In an average risk singleton population, a mid-trimester blood test identified pregnancies at higher PTB risk, and implementing the treatment bundle significantly reduced neonatal morbidity and hospital stay compared to usual care.

Table 1. Modified intent-to-treat analysis of co-primary endpoints

Variable	Measure	N	Adjusted Rate*	95% CI	P†
NMI‡	Odds Ratio	4468	0.75	0.62 - 0.91	0.003
NNLOS¶	Hazard Ratio	437	0.82	0.68 - 0.99	0.044

NMI, neonatal morbidity index; NNLOS, neonatal hospital length of stay.

*Controlled for parity, pre-enrollment aspirin use, and COVID-19 positivity.

†Prespecified alpha reserved for final analysis was 0.0482 post-interim analysis.

‡Ordinal logistic regression analysis in entire mITT population; prevention versus control arm. An odds ratio <1 reflects lower NMI scores in the prevention arm.

¶Cox regression analysis in a prespecified quantile (~10%) of longest stays; control versus prevention arm. A hazard ratio <1 reflects shorter length of hospital stay in the prevention arm.

Table 2. Neonatal outcomes in the intent-to-treat population.

Full Analysis Set of the Intent-to-Treat Population*

10:15 AM - 10:30 AM

Objective: To evaluate whether postpartum (PP) patient navigation (PN) improves PP health care quality among birthing people with low income.

Study Design: In this single-center RCT, English- or Spanish-speaking pregnant people aged 16 or older with Medicaid were randomly assigned between 30 weeks of gestation and PP discharge to one year of PN versus usual care. Participants assigned to PN were partnered with a trained lay navigator who provided individualized, intensive PN services designed around PP-specific barrier ascertainment and reduction. PN services included social needs assessments and support, healthcare appointment and insurance assistance, health education, and support for engagement in shared decision making. Data were collected via patient report and medical record abstraction at enrollment, 4-12 weeks PP, and 11-13 months PP. The primary outcome was achievement of a six-component composite measure representing receipt of optimal PP care by 12 weeks PP (Table 1). Secondary outcomes included a PP care score (% of components achieved), each component of optimal PP care, and 11-13 month health services outcomes.

Results: From January 2020 to June 2023, 405 people were randomized (203 PN, 202 usual care) of whom 50% identified as non-Hispanic Black and 41% as Hispanic. The primary outcome of optimal PP care was similar between groups (9.4% PN vs. 7.9% usual care, p = 0.6); however, the mean PP care score was significantly higher among PN recipients (72% ±17% vs. 64% ±23%, p = 0.001). Three components drove this difference: PP visit completion (96% vs. 80%, p< 0.001), receipt of all indicated anticipatory guidance (65% vs. 51%, p = 0.008), and PP depression screening/care (86% vs. 72%, p< 0.001). At 11-13 months, PN recipients were significantly more likely to be using their desired family planning method and have attended a primary care appointment (Table 2).

Conclusion: The primary outcome, a composite measure of optimal PP care, was not different between groups but was achieved infrequently. However, PN improved several aspects of PP care quality and increases frequency of transition to primary care.

Table 1. Postpartum care outcomes at 4-12 weeks in participants receiving patient navigation versus usual care

	Usual care N=202	Navigated N=203	p-value
Primary Composite Outcome			
Optimal postpartum care[1]	7.9%	9.4%	0.6
Postpartum Care Score			
Mean (± standard deviation) percent of total number of postpartum care components achieved	64% ± 23%	72% ± 17%	0.001
Components of Primary Outcome			
Completed comprehensive postpartum visit[2]	80%	96%	<0.001
Received all indicated anticipatory guidance[3]	51%	65%	0.008
Received desired family planning method[4]	89%	94%	0.08
Screening for postpartum depression and linkage to care, if indicated[5]	72%	86%	<0.001
Initiated and maintained breast/chestfeeding[6]	60%	63%	0.5
Received all indicated vaccinations (influenza, Tdap, measles-mumps-rubella, human papillomavirus)[7]	32%	27%	0.3

1. Optimal postpartum care was defined as all six components of the primary outcome achieved. A sample size of 400 (90% power, assuming 30% attrition) was needed to detect a 20% difference in the primary outcome.
2. Defined as a present when a visit with an obstetric clinician occurred that addressed physical health, mental health, and other postpartum needs within 4-12 weeks postpartum. Visits solely for wound care, blood pressure checks, or other single-issue topics were not considered comprehensive postpartum visits.
3. Domains included: 1) Mental health (mood, smoking cessation, substance use, mental health disorders); 2) Infant feeding; 3) Social needs (family/child material needs, social services resources); 4) Sexuality (resumption of sexual activity); 5) Reproductive life planning (pregnancy spacing, reproductive life planning); 6) Prevention of future pregnancy complications; 7) Family planning (family planning preferences, options); 8) Sleep management (sleep, fatigue, social support); 9) Physical recovery (physical activity, recovery from birth); 10) Chronic disease management (management of chronic diseases, prevention of morbidity); and 11) Health maintenance (health maintenance, vaccinations).
4. Participants were considered to have received their desired family planning method if they had been given a prescription for a method, had a device inserted/implanted, had received male or female permanent contraception, chose a barrier method, or declined a method by 12 weeks postpartum. Participants were ineligible for this outcome if they had undergone a hysterectomy or had a monogamous same-sex partnership (N=2).
5. Participants were considered to have been screened if they completed a Patient Health Questionnaire-9 (PHQ-9) by 12 weeks postpartum; among those with PHQ-9 score >9, linkage was considered to have occurred if they received further mental health care.
6. Breast/chestfeeding: participants who were exclusively or partially feeding their own milk within the 4-12 week postpartum period were considered to be breast/chestfeeding. Participants who did not have custody of their infant or whose infant was deceased were ineligible for this outcome (N=2).
7. All participants were considered eligible for Tdap or influenza. Participants were considered eligible for MMR if they were measles or rubella non-immune. Participants were considered eligible for HPV vaccination if they had never initiated or completed the series. Vaccinations were considered received if they occurred during pregnancy or until 12 weeks postpartum.

Table 2. Outcomes at 11-13 months postpartum in participants receiving patient navigation versus usual care

	Usual care N=202	Navigated N=203	p-value
Received or continued use of desired family planning method	43%	65%	<0.001
Maintained breast/chestfeeding[1]	26%	26%	>0.9
Attended primary care visit	30%	57%	<0.001
Diabetes testing among patients with history of GDM (N=31)			
OGTT completion at 4-12 weeks postpartum	43%	75%	0.2
Any other diabetes testing after 12 weeks postpartum	20%	38%	0.4

GDM, gestational diabetes mellitus; OGTT, oral glucose tolerance test
1. Included participants who self-reported or medical record review indicated sustained breastfeeding during the 11-13 month postpartum period.

LB06 | Comparing 162mg vs. 81mg Aspirin for Prevention of Preeclampsia (ASAPP): A Randomized Control Trial

Amrin Khander[1]; Kathy Matthews[2]; Charlene Thomas[3]; Paul Christos[4]; Stephen T. Chasen[5]; Daniel W. Skupski[3]; Laura E. Riley[3]; Phyllis August[6]; Line Malha[3]

10:15 AM - 10:30 AM

Objective: Low dose aspirin (ASA) < 100 mg vs placebo reduces the incidence of preterm preeclampsia (PE) by 20-30% for those at high risk. Doses 100-150mg may further reduce the incidence by 60% compared to placebo. We compared 162mg to 81mg of ASA per day in the prevention of PE in high-risk pregnancies.

Study Design: We conducted a pragmatic prospective randomized open label blinded-endpoint (PROBE) clinical trial. Pregnant persons at high risk for PE (as defined by ACOG) with one or more of the following criteria: chronic hypertension, history of PE, diabetes mellitus, autoimmune disease, multifetal gestation or kidney disease were randomized (< 16weeks) to either 81mg or 162mg ASA daily and monitored throughout pregnancy (20±2 weeks, 26±2 weeks, and 36±2 weeks) until 6 weeks postpartum. The primary outcome was a composite of developing preterm PE (< 37 weeks) or PE with severe features. Outcomes were adjudicated by independent investigators blinded to treatment group and clinical diagnosis. Secondary outcomes were adherence to therapy (determined by a validated Simplified Medication Adherence Questionnaire), maternal and fetal complications. Based on a prespecified interim analysis of the first 100 participants, we estimated that 400 participants would be required to detect a 7.1% difference in the primary outcome between the groups.

Results: Of 400 participants randomized, 369 had delivery data and were included in the intention to treat analysis (17 lost to follow up/withdrew, 14 elective terminations) with 186 participants in the 162mg and 183 in the 81mg group. Baseline characteristics were similar. The incidence of preterm PE or PE with severe features was 25/183 (13%) in the 162mg group vs. 28/180 (14%) in the 81mg group (p = 0.7). Adherence rates ranged from 88%-91% vs 89%-92% for the 162mg vs 81mg groups respectively across study visits. Infant birthweight was slightly lower in the 162 mg group (2.9 kg vs 3.2 kg; p = 0.002).

Conclusion: Our data show that the rates of preterm PE or PE with severe features were similar in pregnant people at high risk for PE taking either 81mg or 162mg ASA.

Table 1. Demographics

Characteristic	162mg (Arm 2) N = 186	81mg (Arm 1) N = 183
Age (years)	35 [32, 37]	35 [32, 38]
Race		
American Indian/Alaska Native	0 (0%)	2 (1%)
Asian	30 (16%)	40 (22%)
Black or African American	37 (20%)	42 (23%)
More Than One Race	37 (20%)	25 (14%)
Unknown / Not Reported	7 (4.1%)	15 (8.5%)
White	74 (40%)	58 (32%)
Ethnicity		
Hispanic or Latino	46 (25%)	31 (17%)
NOT Hispanic or Latino or Unknown	140 (75%)	152 (83%)
Insurance Payor		
Commercial	125 (70%)	116 (63%)
Medicaid	54 (28%)	56 (30%)
Unknown	7	11
Parity	1 [1, 1]	1 [1, 1]
Pre-Gravid BMI (kg/m^2)	29 [24, 34]	26 [23, 33]
Gestational Age at Randomization	13.00 [12.14, 14.29]	13.14 [12.43, 14.43]
Eligibility Criteria		
Chronic Hypertension	76 (38%)	60 (30%)
History of preeclampsia	69 (35%)	62 (31%)
Type 1 or Type 2 Diabetes	37 (19%)	37 (19%)
Autoimmune Disease	33 (17%)	17 (8.5%)
Multifetal Gestation	25 (13%)	38 (19%)
Kidney Disease	9 (4.5%)	9 (4.5%)
Number of prior pregnancies with PE	1 [1, 1]	1 [1, 1]

All data presented as median [IQR] or n (%).

Table 2. Outcomes by Treatment Group

Outcome	162mg (Arm 2) N = 186	81mg (Arm 1) N = 183	p-value
Primary Composite Outcome: Preterm PE or PE with Severe Features	25 (13%)	28 (14%)	0.7
Primary Outcome by Subgroup^			
Chronic Hypertension	13/76 (17%)	10/60 (17%)	>0.9
Type 1 or Type 2 Diabetes	6/37 (16%)	7/37 (19%)	0.8
Autoimmune Disease	1/33 (3.0%)	1/17 (5.9%)	>0.9
Multifetal Gestation	1/25 (4.0%)	8/38 (21%)	0.08
History of Preeclampsia	13/69 (19%)	4/62 (6.5%)	0.04
Kidney Disease	3/9 (33%)	3/9 (33%)	>0.9
Adherence*			
At 18-22 weeks GA†	127/144 (88%)	109/123 (89%)	
At 24-28 weeks GA	128/142 (90%)	126/140 (90%)	
At 34-38 weeks GA	102/112 (91%)	108/117 (92%)	
Spontaneous Pregnancy Loss			
<20 weeks GA	5 (2.7%)	4 (2.2%)	>0.9
≥20 weeks GA	3 (1.6%)	2 (1.1%)	>0.9
Quantitative Blood Loss at Delivery (mL)	705 [350, 872]	552 [300, 1,000]	0.5
GA (weeks) at Delivery (singleton)	37.57 [36.71, 38.71]	38.00 [37.00, 39.00]	0.04
Birthweight (grams) (singleton)	2,943 [2,525, 3,290]	3,210 [2,776, 3,511]	0.002
NICU Admission (singleton)	27 (16%)	14 (9.3%)	0.06

† GA = gestational age
All data presented as median [IQR] or n (%).
^ Presented as number of respondents with composite outcome over total participants with criterion (percentage).
* Adherence defined on SMAQ score. Presented as number of respondents who qualified as 'adherent' over total respondents (percentage).
