Conference Schedule

SMFM 2025 Pregnancy Meeting

SMFM2025 PREGNANCY MEETING™

Postgraduate Courses and Scientific and Clinical Meeting

Society for Maternal-Fetal Medicine

January 27–February 1, 2025
Gaylord Rockies Resort and Convention Center
Aurora, Colorado

All abstract presentations take place at the Gaylord Rockies Resort and Convention Center.

SCHEDULE OF ORAL PRESENTATIONS

THURSDAY, January 30

7:15 AM–8:00 AM — **Opening Addresses and Awards**

8:00 AM–10:00 AM — **Oral Plenary Session 1**
Abstracts 1-8 | *Aurora Ballroom*

10:00 AM–10:30 AM — **Late-Breaking Research Presentations Session 1**
Abstracts LB01-02 | *Aurora Ballroom*

10:30 AM–12:30 PM — **Poster Session 1**
Abstracts 105-384 | *Exhibit Hall*

1:30 PM–3:30 PM — **Oral Concurrent Sessions**

Session 1 — **Equity, Public Health, and Policy**
Abstracts 9-18 | *Aurora Ballroom A*

Session 2 — **Clinical Obstetrics and Quality**
Abstracts 19-28 | *Aurora Ballroom B*

Session 3 — **Ultrasound and Genetics**
Abstracts 29-38 | *Aurora Ballroom CD*

4:00 PM–6:00 PM — **Poster Session 2**
Abstracts 385-665 | *Exhibit Hall*

FRIDAY, January 31

7:45 AM–8:00 AM — **Foundation for SMFM Chair Address**

8:00 AM–10:00 AM — **Oral Plenary Session 2 – Fellows Plenary**
Abstracts 39-46 | *Aurora Ballroom*

10:00 AM–10:30 AM — **Late-Breaking Research Presentations Session 2**
Abstracts LB03-04 | *Aurora Ballroom*

10:30 AM–12:30 PM — **Poster Session 3**
Abstracts 666-947 | *Exhibit Hall*

1:30 PM–3:30 PM — **Oral Concurrent Sessions**

Session 4 **Basic and Translational Science**
Abstracts 47-56 | *Aurora Ballroom A*

Session 5 **Hypertension**
Abstracts 57-66 | *Aurora Ballroom B*

Session 6 **Prematurity and Newborn**
Abstracts 67-76 | *Aurora Ballroom CD*

4:30 PM–6:00 PM — **Poster Session 4**
Abstracts 948-1227 | *Exhibit Hall*

SATURDAY, February 1

8:00 AM–10:15 AM — **Oral Concurrent Sessions**

Session 7 **Diabetes**
Abstracts 77-85 | *Aurora Ballroom A*

Session 8 **Fetus and Fetal Intervention**
Abstracts 86-94 | *Aurora Ballroom B*

Session 9 **Medical Complications**
Abstracts 95-104 | *Aurora Ballroom CD*

10:15 AM–10:30 AM — **Late-Breaking Research Presentations Session 3**
Abstract LB05 | *Aurora Ballroom A*

10:15 AM–10:30 AM — **Late-Breaking Research Presentations Session 4**
Abstract LB06 | *Aurora Ballroom B*

Future Pregnancy Meeting Dates

SMFM 2026 Pregnancy Meeting™
February 8–13, 2026
Caesars Forum
Las Vegas, NV

SMFM 2027 Pregnancy Meeting™
March 21–26, 2027
Gaylord National Resort and Convention Center
National Harbor, MD

SMFM 2028 Pregnancy Meeting™
April 23–28, 2028
Caesars Forum
Las Vegas, NV

Congratulations to Our Abstract Awards Winners

Bruce A. Work Award for Best Research by a Practicing or Training Maternal-Fetal Medicine Physician Outside of the US

5: Atosiban versus placebo in threatened preterm birth (APOSTEL 8-study): an international randomized controlled trial

Larissa I. van der Windt, MD

Disparities Award for Best Research on Diversity/Disparity in Health Outcomes

11: Black Maternal Morbidity and its Association with Systemic Racism

Sebastian Z. Ramos, MD

Dru Carlson Memorial Award for Best Research in Ultrasound and Genetics

3: Fetal fraction amplification enables accurate prenatal cell-free DNA screening at 8 weeks gestation

Lorraine Dugoff, MD

Norman F. Gant Award for Best Research in Maternal Medicine

58: Nifedipine versus Labetalol for Treatment of Postpartum Hypertension: A Randomized Controlled Trial

Todd R. Lovgren, MD

The SMFM Outstanding Early Career Investigator Travel Award *Supported by Dr. Laxmi Baxi*

69: Fully Quantitative Cervical Remodeling: Race Group Differences Responsibilities and Cautions

LeAnn A. Louis, MD, MPH

PREGNANCY

ABSTRACTS OPEN ACCESS

2025 SMFM Oral Schedule

Thursday, January 30, 2025 • 8:00 AM – 10:00 AM		
Time	**Abstract**	**Oral Plenary Session 1**
8:00 AM	1	**Antenatal corticosteroid in twin pregnancy at risk of late preterm birth: A randomized controlled trial** **Seung Mi Lee[1]**; Hyun Soo Park[2]; Soo Ran Choi[3]; Jeesun Lee[1]; Hyun Ji Kim[4]; Jee Yoon Park[4]; Kyung Joon Oh[4]; Geum Joon Cho[5]; Min-Jeong Oh[5]; Jin Hoon Chung[6]; Sun Min Kim[7]; Byoung Jae Kim[8]; Suk Young Kim[9]; Subeen Hong[10]; Young Mi Jung[5]; Se Jin Lee[11]; Ji Su Seong[12]; Haemin Kim[13]; Sohee Oh[8]; Joongyub Lee[1]; Ji Hoi Kim[1]; Hee Young Cho[14]; Chan-Wook Park[1]; Joong Shin Park[1]; Jong Kwan Jun[15] [1]Seoul National University College of Medicine, Seoul, Seoul-t'ukpyolsi; [2]Dongguk University Ilsan Hospital, Goyang, Kyonggi-do; [3]Inha University Hospital, Inha University College of Medicine, Incheon, Inch'on-jikhalsi; [4]Seoul National University Bundang Hospital, Seoul National University College of Medicine, Bundang, Kyonggi-do; [5]Korea University College of Medicine, Seoul, Seoul-t'ukpyolsi; [6]University of Ulsan College of Medicine, Asan Medical Center, Seoul, Seoul-t'ukpyolsi; [7]101 Daehak-ro, Jongno-gu, Seoul, Seoul-t'ukpyolsi; [8]Seoul Metropolitan Government Seoul National University Boramae Medical Center, Seoul, Seoul-t'ukpyolsi; [9]College of Medicine, Gachon University, Incheon, Inch'on-jikhalsi; [10]Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Seoul-t'ukpyolsi; [11]Kangwon National University Hospital, School of Medicine, Kangwon National University, Chuncheon, Kangwon-do; [12]Chung-Ang University Gwang-Myeong Hospital, Chung-Ang University College of Medicine, Gwang-Myeong, Kyonggi-do; [13]Kyungpook National University Chilgok Hospital, Kyungpook National University, School of Medicine, Daegu, Ch'ungch'ong-bukto; [14]Seoul National University, Seoul, Seoul-t'ukpyolsi; [15]Ewha Womans University College of Medicine, Seoul, Seoul-t'ukpyolsi
8:15 AM	2	**The Frequency and Severity of Complications after Previable PROM in Texas following SB8** Danna Ghafir[1]; **Emily Fahl[1]**; Nancy Ukoh[1]; Han-Yang M. Chen[1]; Sean C. Blackwell[1]; Julie Gutierrez[2]; Irene A. Stafford[1] [1]McGovern Medical School at UTHealth Houston, Houston, TX; [2]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX
8:30 AM	3	**Fetal fraction amplification enables accurate prenatal cell-free DNA screening at 8 weeks gestation** **Lorraine Dugoff[1]**; Summer Pierson[2]; Jhett Bordwell[3]; Brent Mabey[2]; Arielle B. Dorch[3]; Alexander Gutin[2]; Dmitry Pruss[2]; Diana Iliev[2]; Dale Muzzey[2]; Katie Johansen Taber[4] [1]University of Pennsylvania, Philadelphia, PA; [2]Myriad Genetics, Inc., Salt Lake City, UT; [3]Myriad Genetics, Inc., South San Francisco, CA; [4]Myriad Genetics, Inc., South San Fransisco, CA

Time	Abstract	Oral Plenary Session 1, continued
8:45 AM	4	**AI Significantly Improves Detection of Prenatal Ultrasounds Suspicious for Major Congenital Heart Defects by OBGYN/MFMs** **Jennifer Lam-Rachlin[1]**; Rajesh Punn[2]; Sarina K. Behera[3]; Miwa Geiger[1]; Matthias Lachaud[4]; Nadine David[5]; Sara Garmel[6]; Matthew K. Janssen[7]; Kendra Sylvester[8]; John Kennedy[9]; Jessica Spiegelman[1]; Mia A. Heiligenstein[10]; Nathan S. Fox[1]; Andrei Rebarber[1]; Greggory R. DeVore[11]; Carolyn M. Zelop[12]; Roger Bessis[13]; Marilyne Levy[14]; Bertrand Stos[14]; Malo De Boisredon[15]; Eric Askinazi[15]; Valentin Thorey[15]; Christophe Gardella[15]; Alisa Arunamata[2] [1]Icahn School of Medicine at Mount Sinai Hospital, New York, NY; [2]Pediatrics - Cardiology, Stanford University School of Medicine, Stanford, CA; [3]Palo Alto Medical Foundation, Sutter Health, Palo Alto, CA; [4]University of Grenoble Alpes, Grenoble, Rhone-Alpes; [5]Medical Training Center, Rouen, Haute-Normandie; [6]Michigan Perinatal Associates and Corewell Health, Dearborn, MI; [7]University of Pennsylvania, Pittsburgh, PA; [8]Perinatal Specialists of the Palm Beaches, West Palm Beach, FL; [9]Wayne State University School of Medicine, Detroit, MI; [10]Mount Sinai West, Astoria, NY; [11]The Fetal Diagnostic Center of Pasadena, Pasadena, CA; [12]Valley Health System, Paramus, NJ; [13]Centre d'Echographie de l'Odéon, Paris, Ile-de-France; [14]UE3C - Unité d'explorations cardiologiques - Cardiopathies Congénitales, Paris, Ile-de-France; [15]BrightHeart, Paris, Ile-de-France
9:00 AM	5	**Atosiban versus placebo in threatened preterm birth (APOSTEL 8-study): an international randomized controlled trial** **Larissa I. van der Windt[1]**; Job Klumper[1]; Ruben G. Duijnhoven[1]; Marjolein Kok[1]; Ben W. Mol[2]; Kate F. Walker[3]; Fionnuala M. M. McAuliffe[4]; Joris A. M. van der Post[5]; Carolien Roos[1]; Martijn A. Oudijk[1] [1]Amsterdam UMC, location University of Amsterdam, Amsterdam, Noord-Holland; [2]Monash University, Clayton, Victoria; [3]Centre of Perinatal Research University of Nottingham, Queen's Medical Centre, Dublin, England; [4]UCD Perinatal Research Centre, University College Dublin, Dublin 2, Dublin; [5]Amsterdam UMC, location University of Amsterdam, Amsterdam, Noord-Brabant
9:15 AM	6	**Prediction of severely small-for-gestational-age infants using a novel cell-free RNA model** Morten Rasmussen[1]; **Kara M. Rood[2]**; Aram Saravani[1]; Michal A. Elovitz[3]; Carrie Haverty[4]; Alison Moe[1]; Alison Cowan[1]; Arkady Khodursky[1]; Maneesh Jain[1]; Manfred Lee[1]; Thomas F. McElrath[5]; Elizabeth F. Sutton[6]; Arun Jeyabalan[7]; George R. Saade[8]; Antonio F. Saad[9]; Luis D. Pacheco[10]; Joseph R. Biggio, Jr[11]; Ebony B. Carter[12]; Antonina I. Frolova[13]; Esther Park-Hwang[14]; Cynthia Gyamfi-Bannerman[15]; Ai-ris Y. Collier[16]; William A. Grobman[2]; Vincenzo Berghella[17] [1]Mirvie Inc., South San Francisco, CA; [2]The Ohio State University, Columbus, OH; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Mirvie Inc., South San Fransisco, CA; [5]Brigham Women's Hospital, Boston, MA; [6]Woman's Hospital, Baton Rouge, LA; [7]University of Pittsburgh School of Medicine, Pittsburgh, PA; [8]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [9]Inova Health, Falls Church, VA; [10]University of Texas Medical Branch, Galveston, TX; [11]Ochsner Health, New Orleans, LA; [12]University of North Carolina, Chapel Hill, NC; [13]Washington University School of Medicine, St. Louis, MO; [14]Multicare, Orlando, FL; [15]University of California, San Diego, San Diego, CA; [16]Beth Israel Deaconess Medical Center, Boston, MA; [17]Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA
9:30 AM	7	**Metformin paradoxically increases insulin resistance during pregnancy in a Rhesus macaque model** **Enrico R. Barrozo[1]**; Tyler Dean[2]; Claire E. Jensen[3]; Melissa A. Suter[1]; Maxim D. Seferovic[1]; Kristin Sauter[2]; Jacob E. Friedman[4]; Maureen Gannon[5]; Stephanie R. Wesoloski[6]; Carrie E. McCurdy[7]; Paul Kievit[2]; Kjersti M. Aagaard[8] [1]Baylor College of Medicine and Texas Children's Hospital, Houston, TX; [2]Oregon National Primate Research Center, Beaverton, OR; [3]University of North Carolina, Chapel Hill, NC; [4]Harold Hamm Diabetes Center, University of Oklahoma Health Sciences Center, Oklahoma City, OK; [5]Vanderbilt University Medical Center, Nashville, TN; [6]University of Colorado, Anschutz Medical Campus, Aurora, CO; [7]University of Oregon, Eugene, OR; [8]Boston Children's Hospital, Division of Fetal Medicine and Surgery, Boston, MA; HCA Healthcare and HCA Healthcare Research Institute, Nashville, TN; HCA Texas Maternal Fetal Medicine, Houston, TX; Baylor College of Medicine and Texas Children's Hospital, Houston, TX, Boston, MA
9:45 AM	8	**INTER-ACT interpregnancy and pregnancy lifestyle intervention for a healthy future: a randomized controlled trial** Yael Winter Shafran[1]; Hanne Van Uytsel[2]; Annick Bogaerts[2]; Lieveke Ameye[2]; **Roland Devlieger[3]** [1]Kaplan Medical Center and REALIFE Research Group, Rehovot, HaMerkaz; [2]REALIFE Research Group, KU Leuven, Leuven, Vlaams-Brabant; [3]University Hospital Leuven, Leuven, Vlaams-Brabant

Thursday, January 30, 2025 • 10:00 AM – 10:30 AM

Time	Abstract	Late-Breaking Abstract Presentations Session 1
10:00 AM	LB01	**CErebro Placental RAtio based management in reduced fetal movements; an international cluster-randomized clinical trial (CEPRA)** **Laura A. Lens[1]**; Selina Posthuma[2]; Stefanie E. Damhuis[3]; Renée J. Burger, N/A[1]; Henk Groen[4]; Ruben G. Duijnhoven[5]; Sailesh Kumar[6]; Alexander E.P Heazell[7]; Asma Khalil[8]; Wessel Ganzevoort[9]; Sanne J. Gordijn[10] [1]Amsterdam UMC, Amsterdam, Noord-Holland; [2]Uiversity Medical Center Groningen, University Medical Center Groningen, Groningen; [3]Amsterdam University Medical Centers, Amsterdam University Medical Centers, Noord-Holland; [4]University Medical Center of Groningen, University Medical Center of Groningen, Groningen; [5]Amsterdam UMC, location University of Amsterdam, Amsterdam, Noord-Holland; [6]The University of Queensland, Brisbane, Queensland; [7]The University of Manchester, Manchester, England; [8]Fetal Medicine Unit, St George's Hospital, St George's University of London, Fetal Medicine Unit, St George's Hospital, S George's University of London, England; [9]Amsterdam University Medical Centers, Amsterdam, Groningen; [10]University Medical Center Groningen, Groningen, Groningen
10:15 AM	LB02	**iSEARCH RCT: Evaluating the effectiveness of maternal sildenafil to reduce complications related to intrapartum hypoxia** **Sailesh Kumar[1]**; Ben W. Mol[2]; William Tarnow-Mordi[3]; Jon Hyett[4]; Nadia Badawi[4]; Annalene Seidler[5]; Helen Liley[6]; Emily Callander[7]; Vicky Flenady[6]; Sue Walker[8]; Rachel O'Connell[4] [1]The University of Queensland, Brisbane, Queensland; [2]Monash University, Clayton, Victoria; [3]The University of Sydney, Sydney, New South Wales; [4]University of Sydney, Sydney, New South Wales; [5]Medical Uni Rostock, Rostock, Mecklenburg-Vorpommern; [6]Mater Research Institute-University of Queensland, Brisbane, Queensland; [7]University Technology Sydney, Sydney, New South Wales; [8]Department of Obstetrics, Gynaecology and Newborn Health, University of Melbourne, Melbourne, Victoria

Thursday, January 30, 2025 • 1:30 PM - 4:00 PM

Time	Abstract	Oral Concurrent Session 1 - Equity, Public Health, and Policy
1:30 PM	9	**Dysregulated gene expression in placentas with exposure to persistent maternal socioeconomic disadvantage** Greg E. Miller[1]; Lauren Keenan-Devlin[2]; Alexa A. Freedman[1]; Renee Odom-Konja[3]; Linda M. Ernst[3]; Steve Cole[4]; **Ann EB Borders[2]** [1]Northwestern University, Chicago, IL; [2]Endeavor Health, Evanston Hospital, Evanston, IL; [3]Endeavor Health, Evanston, IL; [4]University of California, Los Angeles, Los Angeles, CA
1:45 PM	10	**Association Between Maternal-Fetal Medicine Physician Density and Adverse Pregnancy Outcomes** Tetsuya Kawakita; **Rula Atwani**; Lindsay S. Robbins; George R. Saade Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA
2:00 PM	11	**Black Maternal Morbidity and its Association with Systemic Racism** **Sebastian Z. Ramos**; Meghan I. Short; Erika F. Werner; Chloe E. Bird; Ndidiamaka Amutah-Onukagha; Michael B. Siegel Tufts University School of Medicine, Boston, MA
2:15 PM	12	**Low-income Birthing Individuals' Need for and Satisfaction with Services in a One-Year Postpartum Navigation Program** **Maya J. Daiter[1]**; Laura Diaz[1]; Hannah M. Green[1]; Ying Cheung[1]; Viridiana Carmona-Barrera[1]; Brittney R. Williams[1]; Charlotte M. Niznik[1]; Joe M. Feinglass[1]; William A. Grobman[2]; Lynn M. Yee[1] [1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]The Ohio State University, Columbus, OH
2:30 PM	13	**Impact of WIC Enrollment on Adverse Maternal and Neonatal Adverse Outcomes in Medicaid Populations** **Reetam Ganguli[1]**; Stephen Wagner[2] [1]Elythea, San Jose, CA; [2]Beth Israel Deaconess Medical Center, Boston, MA

Thursday, January 30, 2025 • 1:30 PM - 4:00 PM		
Time	**Abstract**	**Oral Concurrent Session 1 - Equity, Public Health, and Policy, continued**
2:45 PM	14	**Homicide and Suicide: The Leading Cause of Maternal Death, and How Firearm Legislation Affects It** **Hooman A. Azad[1]**; Dana Goin[2]; Lisa Nathan[3]; Dena Goffman[1]; Uma M. Reddy[4]; Danielle Laraque-Arena[2]; Mary E. D'Alton[1] [1]Columbia University Medical Center, New York, NY; [2]Columbia University Mailman School of Public Health, New York, NY; [3]Columbia University Irving Medical Center, New York, NY; [4]Columbia University, New York, NY
3:00 PM	15	**Elimination of a threefold racial disparity in aspirin recommendation using integrated clinical decision support** **Melissa S. Wong[1]**; Rommy Coutelin Johnson[2]; Karla Gonzalez[1]; Ojiugo Onwumere[3]; Kristin Parrinella[4]; Camelita Thrift[3]; Samira Torna[1]; Matthew Wells[1]; Kimberly D. Gregory[3] [1]Cedars-Sinai Medical Center, Los Angeles, CA; [2]Cedars-Sinai, Los Angeles, CA; [3]Cedars Sinai Medical Center, Los Angeles, CA; [4]Kaiser-Permanente, Los Angeles, CA
3:15 PM	16	**Severe maternal morbidity differences by state Medicaid expansion and abortion coverage: national database analysis, 2014-2022** **Ishana Shetty**; Mark C. Valentine; Mark Hoofnagle; Jennifer Reeves; David L. Eisenberg Washington University, St. Louis, MO
3:30 PM	17	**Elevated micro- and nanoplastics detected in preterm human placentae** **Enrico R. Barrozo[1]**; Marcus A. Garcia[2]; Michael D. Jochum, Jr.[1]; Rui Liu[2]; Alex Nihart[2]; Eliseo Castillo[2]; Eliane El Hayek[2]; Jorge Gonzalez-Estrella[3]; Lori Showalter[1]; Cynthia Shope[1]; Melissa A. Suter[1]; Matthew J. Campen[2]; Kjersti M. Aagaard[4] [1]Baylor College of Medicine and Texas Children's Hospital, Houston, TX; [2]University of New Mexico, Albuquerque, NM; [3]Oklahoma State University, Stillwater, OK; [4]Boston Children's Hospital, Division of Fetal Medicine and Surgery, Boston, MA; HCA Healthcare and HCA Healthcare Research Institute, Nashville, TN; HCA Texas Maternal Fetal Medicine, Houston, TX; Baylor College of Medicine and Texas Children's Hospital, Houston, TX, Boston, MA
3:45 PM	18	**Severe Maternal Morbidity among Asian and Pacific Islander Parturients in a Contemporary Northern California Cohort** **Shalila A. de Bourmont[1]**; Janet Alexander[2]; Baiyang Sun[2]; Erica P. Gunderson[2]; Mara Greenberg[1] [1]Kaiser-Permanente Northern California, Oakland, CA; [2]Kaiser-Permanente Northern California, Pleasanton, CA

Thursday, January 30, 2025 1:30 PM - 4:00 PM		
Time	**Abstract**	**Oral Concurrent Session 2 - Clinical Obstetrics and Quality**
1:30 PM	19	**Aberrant Fetal Growth in ARRIVE Trial** **Bonnie L. Hermann[1]**; Cassidy A. O'Sullivan[2]; Fabrizio Zullo[3]; Suneet Chauhan[4]; Hector M. Mendez-Figueroa[5] On behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units (MFMU) Network [1]UTHealth Houston, Houston, TX; [2]Christiana Care Health System, Newark, DE; [3]University of Rome La Sapienza, Rome, Lazio; [4]Christiana Care, Newark, DE; [5]McGovern Medical School at UTHealth, Houston, TX

Thursday, January 30, 2025 • 1:30 PM - 4:00 PM

Time	Abstract	Oral Concurrent Session 2 - Clinical Obstetrics and Quality, continued
1:45 PM	20	**Decreased Neuraxial Morphine Dose to Reduce Opioid Side Effects and use After Cesarean Delivery RCT** **Ayodeji Sanusi[1]**; Yumo Xue[2]; Kevin S. Shrestha[2]; Ayamo Oben[3]; Hanna Hussey[2]; Annalese Neuenschwander[2]; Michelle Tubinis[2]; Mark Powell[2]; Alan T. Tita[2]; Casey Brian[4] [1]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL; [2]University of Alabama at Birmingham, Birmingham, AL; [3]Maternal Fetal Consultants of Houston, Houston, TX; [4]West Virginia University, Morgantown, WV
2:00 PM	21	**Proportion of Time Spent in Category II Fetal Heart Tracing During Labor: Associated Adverse Outcomes** **Kristen A. Cagino[1]**; Rachel L. Wiley[2]; Aaron W. Roberts[3]; Claudia J. Ibarra[4]; Natalie L. Neff[5]; Kimen S. Balhotra[4]; Khalil M. Chahine[4]; Christina Cortes[4]; Shareen Patel[4]; Tala Ghorayeb[4]; Holly Flores[6]; Fabrizio Zullo[7]; Hector M. Mendez-Figueroa[4]; Suneet Chauhan[8] [1]UT Houston, Houston, TX; [2]University of California, San Diego, San Diego, CA; [3]McGovern Medical School at UTHealth Houston, Houston, TX; [4]McGovern Medical School at UTHealth, Houston, TX; [5]McGovern Medical School at UT Health, Houston, TX; [6]University of Texas Health Science Center, Houston, TX; [7]University of Rome La Sapienza, Rome, Lazio; [8]Christiana Care, Newark, DE
2:15 PM	22	**Tranexamic acid prophylaxis during cesarean delivery among patients with and without hypertension** **Adam K. Lewkowitz[1]**; Mariam Ayyash[2] On behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units (MFMU) Network [1]Women & Infants Hospital of Rhode Island and Alpert Medical School of Brown University, Providence, RI; [2]Columbia University Irving Medical Center, New York, NY
2:30 PM	23	**Preclinical Development of a Continuous Fetal Lactate Biosensor to Detect Acidosis** **Jonathan M. Morris[1]**; Arjun Kaushik[2]; Michael Challenor[2]; Lee J. Hubble[2]; Chaitya Shah[2]; Maureen Ross[2]; Ranjusha Rajagopalan[2]; Hassan Mahmood[2]; Allana Gurney[3]; Hayley Powell[3]; Jane Choi[3]; Helen Kershaw[3]; Gabrielle Musk[3]; Jane Pillow[3] [1]University of Sydney, New South Wales; [2]VitalTrace Pty Ltd, Western Australia; [3]University of Western Australia, Crawley, Western Australia
2:45 PM	24	**After Cesarean Time Interval to Exercise (ACTIVE) Trial: A Randomized Controlled Trial** **Brittany J. Roser[1]**; James Kinderknecht[2]; Brett Toresdahl[3]; Patricia Ladis[4]; Sonali Iyer[5]; Megan Savage[6]; Timothy Dekker[7]; Paul Christos[5]; Robin B. Kalish[8] [1]Stony Brook University Hospital, NY; [2]Hospital for Special Surgery, New York, NY; [3]University of Utah Health, Salt Lake City, UT; [4]WiseBody Physical Therapists, New York, NY; [5]Weill Cornell Medical College, New York, NY; [6]Northwell Health at Lenox Hill, New York, NY; [7]Ascension Medical Group, Rochester, MN; [8]New York Presbyterian- Weill Cornell, New York, NY
3:00 PM	25	**Intrauterine Resuscitative Maneuvers for Management of Abnormal Fetal Heart Tracings: A Systematic Review and Meta-Analysis** **Amanda J. Jones[1]**; Fabrizio Zullo[2]; Luis Sanchez-Ramos[3]; Lauren C. Roby[1]; Stephanie Roth[4]; Suneet Chauhan[5]; Matthew K. Hoffman[1]; Anthony C. Sciscione[1] [1]Christiana Care Health System, Newark, DE; [2]University of Rome La Sapienza, Rome, Lazio; [3]University of Florida College of Medicine, Jacksonville, FL; [4]Christiana Care Health Services, Newark, DE; [5]Christiana Care, Newark, DE

Thursday, January 30, 2025 • 1:30 PM - 4:00 PM

Time	Abstract	Oral Concurrent Session 2 - Clinical Obstetrics and Quality, continued
3:15 PM	26	**Reducing Postpartum Hemorrhage: The Impact of a Standardized High-Dose Oxytocin Protocol** **Evan J. Keil[1]**; Elizabeth J. Campbell[2]; Joanne M. Bailey[2]; David E. Arnolds[2]; Diana Peacor[2]; Molly J. Stout[2]; Jourdan E. Triebwasser[1] [1]University of Michigan, Ann Arbor, MI; [2]University of Michigan Medical Center, Ann Arbor, MI
3:30 PM	27	**Hysterotomy using Barbed vs. Vicryl Suture for Scheduled Cesarean Delivery: A Randomized Controlled Trial** **Ayisha B. Buckley[1]**; Nicola F. Tavella[2]; Camila Cabrera[2]; Keisha S. Paul[2]; Mariah McKevitt[2]; Monica J. Patel[2]; Lauren A. Ferrara[2]; Jenny Tang[2]; Joanne Stone[3]; Calvin E. Lambert, Jr.[2]; Luciana A. Vieira[4]; Angela T. Bianco[2] [1]Weill Cornell Medical Center, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Mt. Sinai Medical Center, New York, NY; [4]Stamford Hospital, Stamford, CT
3:45 PM	28	**Investigating selection bias in research using placental pathology samples** **Linda M. Ernst[1]**; Alexa A. Freedman[2]; Renee Odom-Konja[1]; Lauren Keenan-Devlin[3]; Greg E. Miller[2]; Ann EB Borders[3] [1]Endeavor Health, Evanston, IL; [2]Northwestern University, Chicago, IL; [3]Endeavor Health, Evanston Hospital, Evanston, IL

Thursday, January 30, 2025 • 1:30 PM - 4:00 PM

Time	Abstract	Oral Concurrent Session 3 - Ultrasound and Genetics
1:30 PM	29	**Beyond the Fetus: Unveiling Maternal Health Risks Through Prenatal Genome Sequencing** **Brittany Arditi[1]**; Caitlin D. Baptiste[2]; Jessica L. Giordano[1]; Rachel Herz-Roiphe[2]; Vaidehi Jobanputra[3]; Ronald J. Wapner[4] [1]Columbia University Irving Medical Center, New York, NY; [2]Columbia University Medical Center, New York, NY; [3]New York Genome Center, New York, NY; [4]Columbia University, New York, NY
1:45 PM	30	**Artificial Intelligence System Accurately Detects Fetal Ultrasound Findings Suspicious For Major Congenital Heart Defects** **Carolyn M. Zelop[1]**; Jennifer Lam-Rachlin[2]; Alisa Arunamata[3]; Rajesh Punn[3]; Sarina K. Behera[4]; Matthias Lachaud[5]; Nadine David[6]; Greggory R. DeVore[7]; Andrei Rebarber[2]; Nathan S. Fox[2]; Marjorie Gayanilo[2]; Sara Garmel[8]; Philippe Boukobza[9]; Pierre Uzan[10]; Hervé Joly[11]; Romain Girardot[12]; Laurence Cohen[13]; Marilyne Levy[14]; Bertrand Stos[14]; Malo De Boisredon[15]; Eric Askinazi[15]; Valentin Thorey[15]; Christophe Gardella[15]; Miwa Geiger[2] [1]Valley Health System, Paramus, NJ; [2]Icahn School of Medicine at Mount Sinai Hospital, New York, NY; [3]Pediatrics - Cardiology, Stanford University School of Medicine, Stanford, CA; [4]Palo Alto Medical Foundation, Sutter Health, Palo Alto, CA; [5]University of Grenoble Alpes, Grenoble, Rhone-Alpes; [6]Medical Training Center, Rouen, Haute-Normandie; [7]The Fetal Diagnostic Center of Pasadena, Pasadena, CA; [8]Michigan Perinatal Associates and Corewell Health, Dearborn, MI; [9]CEDEF - Centre Européen de Diagnostic et d'Exploration de la Femme, Le Chesnay, Ile-de-France; [10]Groupe IMEF - Imagerie Médicale de l'Est Francilien, Rosny-sous-Bois, Ile-de-France; [11]CARPEDIOL - Cardiologie Pédiatrique, fœtale et congénitale adulte de L'Ouest Lyonnais, Ecully, Rhone-Alpes; [12]Unité de Dépistage de Cardiopathies Foetales et Néonatales, Bordeaux, Aquitaine; [13]ETCC - Exploration et Traitement des Cardiopathies Congénitales, Massy, Ile-de-France; [14]UE3C - Unité d'explorations cardiologiques - Cardiopathies Congénitales, Paris, Ile-de-France; [15]BrightHeart, Paris, Ile-de-France
2:00 PM	31	**Effect of Home Ultrasound in Patients with Previous Late Pregnancy Loss- A Randomized Control Trial** **Liat Mor[1]**; Hagit Eisenberg[2]; Liliya Tamayev[3]; Daniel Tairy[1]; Ben Oren[3]; Yael Ganor Paz[1]; Michal Levy[3]; Eran Weiner[2]; Giulia Barda[2] [1]Edith Wolfson Medical Center, Holon, HaMerkaz; [2]Wolfson Medical Center, Wolfson Medical Center, Tel Aviv; [3]Edith Wolfson Medical center, Holon, HaMerkaz

Thursday, January 30, 2025 • 1:30 PM - 4:00 PM		
Time	**Abstract**	**Oral Concurrent Session 3 - Ultrasound and Genetics, continued**
2:15 PM	32	**Genetic diagnoses in a national cohort with non-immune hydrops and other fetal effusions** **Natalie B. Gulrajani[1]**; Billie R. Lianoglou[2]; Katie Tick[3]; Nuriye Sahin-Hodoglugil[3]; Ugur Hodoglugil[4]; Patrick Devine[4]; Jessica Van Ziffle[4]; Mary E. Norton[2]; Teresa N. Sparks[3] [1]University of California, San Francisco, School of Medicine, San Francisco, CA; [2]Center for Maternal-Fetal Precision Medicine, University of California San Francisco, San Francisco, CA; [3]University of California, San Francisco, San Francisco, CA; [4]Genomic Medicine Laboratory, University of California, San Francisco, San Francisco, CA
2:30 PM	33	**Genomewide monogenic Non Invasive Prenatal Genetic Screening based on maternal cfDNA** Dolev Rahat[1]; Ravit Mesika[1]; Lilach Schneor[1]; **Noa Liscovitch-Brauer[2]**; Tom Rabinowitz[1]; Noam Shomron[1]; Reut Tomashov Matar[3]; Lina Basel-Salmon[3] [1]Identifai Genetics, Tel Aviv, Israel; [2]Identifai Genetics, Tel Aviv; [3]Raphael Recanati Genetic Institute, Rabin Medical Center, Beilinson Hospital, Tel Aviv
2:45 PM	34	**AI Assistance Enhances Physician Performance in Identifying Congenital Malformations** Clémentine Morisset[1]; Frédéric Logé-Munerel[1]; **Celia Amabile[1]**; Louis Chouinard[1]; Vianney Debavelaere[1]; Remi Besson[1]; Nikola Matevski[1]; Guillaume Corda[1]; Julien Stirnemann[2]; Yves Ville[3]; Yinka Oyelese[4]; Andrew Combs[5] [1]Sonio, Paris, Ile-de-France; [2]Hôpital Necker Enfants Malades, Paris, Ile-de-France; [3]University and Necker-Enfants Malades Hospital, Paris, Ile-de-France; [4]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA; [5]Pediatrix Medical Group, Sunrise, FL
3:00 PM	35	**Exploring Gastroschisis Patterns and Pesticide Use in California's Central Valley: A population-based cohort Study** **Alejandro Perez[1]**; Bharti Garg[2]; Hope Delgado[3]; Joshua F. Robinson[4]; Aaron B. Caughey[2]; Stephanie L. Gaw[4] [1]University of California, San Francisco, Kerman, CA; [2]Oregon Health & Science University, Portland, OR; [3]University of California, Berkeley, Berkeley, CA; [4]University of California, San Francisco, San Francisco, CA
3:15 PM	36	**AI software demonstrates strong performance for screening of Tetralogy of Fallot and Truncus Arteriosus Communis** **Remi Besson[1]**; Nicolas Fries[2]; Julien Stirnemann[3]; Yves Ville[4]; Guy Vaksmann[5] [1]Sonio, Paris, Ile-de-France; [2]Imagyn'Echo, Imagyn'echo Montpellier, Languedoc-Roussillon; [3]Hôpital Necker Enfants Malades, Paris, Ile-de-France; [4]University and Necker-Enfants Malades Hospital, Paris, Ile-de-France; [5]Cabinet Vendôme, Lille, Nord-Pas-de-Calais
3:30 PM	37	**Genetic Etiologies of Bilateral Renal Agenesis** **Bobby Brar[1]**; Robert Weatherford[2]; Carol Nowlen[1]; Katelynn Sagaser[3]; Ahmet A. Baschat[1]; Karin Blakemore[1]; Jena L. Miller[1]; Angie C. Jelin[1] [1]Johns Hopkins Medicine, Baltimore, MD; [2]Massachusetts General Hospital, Boston, MA; [3]23andMe, South San Fransisco, CA
3:45 PM	38	**Fully Quantitative Cervical Remodeling: Inter-pregnancy interval shows differences in biomechanical characteristics of the cervix** **Sarah M. Dwyer[1]**; LeAnn A. Louis[1]; Methodius G. Tuuli[2]; Adam K. Lewkowitz[2]; Julie Tumbarello[1]; Emily Dively, BSN[3]; Madeline Felske[1]; Wendy Sparks[1]; Giselle Kolenic[4]; Peinan Zhao[5]; Molly J. Stout[6] [1]University of Michigan Hospital, Ann Arbor, MI; [2]Women & Infants Hospital of Rhode Island and Alpert Medical School of Brown University, Providence, RI; [3]Washington University School of Medicine, St. Louis, MO; [4]University of Michigan, Ann Arbor, MI; [5]Washington University, St. Louis, MO; [6]University of Michigan Medical Center, Ann Arbor, MI

Friday, January 31, 2025 • 8:00 AM - 10:00 AM

Time	Abstract	Oral Plenary Session 2 (Fellows Plenary)
8:00 AM	39	**Methylergonovine to Decrease Blood Loss During Cesarean Delivery in Twins: A Triple-Blinded Placebo-Controlled Randomized Trial** **Helen B. Gomez Slagle[1]**; Shai Bejerano[2]; Russell S. Miller[2]; Dena Goffman[2]; Mary E. D'Alton[2]; Mirella Mourad[2] [1]Columbia University Irving Medical Center, New York, NY; [2]Columbia University Medical Center, New York, NY
8:15 AM	40	**Management of postpartum preeclampsia and hypertensive disorders (MOPP): Postpartum tight versus standard blood pressure control** **Emily B. Rosenfeld[1]**; Deepika Sagaram[1]; Rachel Lee[1]; Ernani Sadural[2]; Richard C. Miller[2]; Ruby Lin[1]; Deshae Jenkins[1]; Kristin Blackledge[3]; Ivana Nikodijevic[4]; Alex Rizzo[2]; Vanessa Martinez[1]; Emily E. Daggett[5]; Olivia McGeough[1]; Cande V. Ananth[1]; Todd J. Rosen[1] [1]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; [2]Cooperman Barnabas Medical Center, RWJBarnabas Health, Livingston, NJ; [3]Rutgers New Jersey Medical School and Cooperman Barnabas Medical Center, Livingston, NJ; [4]New Jersey Medical School, Newark, NJ; [5]Rutgers Robert Wood Johnson Medical School, Edison, NJ
8:30 AM	41	**Impact of living in a food desert on prenatal macro- and micronutrient intake** **Noor K. Al-Shibli[1]**; Anne L. Dunlop[2]; Suchitra Chandrasekaran[3] [1]Emory University, School of Medicine, Atlanta, GA; [2]Emory University School of Medicine, Atlanta, GA; [3]Emory University, Atlanta, GA
8:45 AM	42	**Small for gestational age prediction using unsupervised machine learning of first trimester fetal cardiac parameters** **Rebecca Horgan[1]**; Elena Sinkovskaya[1]; Erkan Kalafat[2]; George R. Saade[1]; Alfred Abuhamad[3] [1]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [2]Koc University Hospital, Istanbul, Istanbul; [3]Eastern Virginia Medical School, Norfolk, VA
9:00 AM	43	**Pravastatin dose-range and pharmacokinetic study in a pregnant rat model** **Xiao-Yu Wang[1]**; Sydney Lammers[2]; Jennifer Reno-Graber[3]; Frederick Reno[3]; Alan Hoberman[4]; George R. Saade[5]; Monica Longo[6]; Victoria L. Pemberton[7]; Ronald J. Wapner[8]; Nicole Abbott[1]; Zhiliang Xie[1]; Joo Young Na[1]; Mitch A. Phelps[1]; Maged M. Costantine[1] [1]The Ohio State University, Columbus, OH; [2]The Ohio State University, College of Medicine, Columbus, OH; [3]Reno & Associates, FL; [4]Charles River Laboratories, PA; [5]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [6]National Institute of Child Health and Human Development, Bethesda, MD; [7]National Heart, Lung, and Blood Institute, Bethesda, MD; [8]Columbia University, New York, NY
9:15 AM	44	**Patterns of perceived and everyday stress, resilience, and adverse placentally mediated outcomes** **Maura Jones Pullins**; Sarah Heerboth; Joy McNeal; Ashlyn Tolbert; Annie Dude; Johanna Quist-Nelson; Rebecca Fry; Tracy A. Manuck University of North Carolina, Chapel Hill, NC
9:30 AM	45	**Microfluidic Device Successfully Replaces Traditional Models of Pregnancy Associated Drug Pharmacokinetic Studies** **Ana Collins-Smith**; Ananth Kammala; Lauren Richardson; Xiao-ming Wang; Ramkumar Menon University of Texas Medical Branch, Galveston, TX
9:45 AM	46	**Continuous Glucose Monitoring for Gestational Diabetes Diagnosis: A Comparative Effectiveness Randomized Control Trial (PRECISE)** **Sarah A. Nazeer[1]**; Joycelyn A. Corntwaithe, RD, CDE[1]; Rafael Bravo Santos[1]; Claudia Pedroza[1]; Sean C. Blackwell[2]; Suneet Chauhan[3]; Farah H. Amro[2]; Ghamar Bitar[2]; Jon Tyson[1]; Baha M. Sibai[2]; Michal Fishel Bartal[4] [1]The University of Texas Health Science Center at Houston (UTHealth), Houston, TX; [2]McGovern Medical School at UTHealth Houston, Houston, TX; [3]Christiana Care, Newark, DE; [4]UTH Houston & Sheba Medical Center Israel, Houston, TX

Friday, January 31, 2025 • 10:00 AM – 10:30 AM

Time	Abstract	Late-Breaking Abstract Presentations Session 2
10:00 AM	LB03	**Single-dose intravenous iron versus oral iron for maternal iron deficiency anemia: a randomized controlled trial** Richard Derman[1]; Mrutyunjaya Bellad[2]; Manjunath Somannavar[2]; Sudhir Bhandari[3]; Sudhir Mehta[3]; Seema Mehta[3]; Dharmesh Sharma[3]; Yogesh Kumar[4]; Umesh Charantimath[4]; Amaresh Patil[5]; Ashalata Mallapur[6]; Umesh Ramdurg[6]; Radha Sangavi[7]; Praveen Patil[7]; Subarana Roy[8]; Phaniraj Vastrad[9]; Chander Shekhar[10]; Benjamin Leiby[10]; Rebecca Hartman[10]; Michael Georgieff[11]; Stephen Mennemeyer[10]; Zubair H. Aghai[12]; Simal Thind[10]; **Rupsa C. Boelig[13]** [1]Jefferson Health, Philadelphia, PA; [2]KLE Academy of Higher Education and Research's J N Medical College„ Belagavi, Karnataka; [3]Sawai Man Singh Medical College, Jaipur, Rajasthan; [4]KLE Academy of Higher Education and Research's J N Medical College„ KLE Academy of Higher Education and Research's J N Medical College„ Karnataka; [5]KLE Academy of Higher Education and Research's J N Medical College, Belagavi, Karnataka; [6]S Nijalingappa Medical and HSK Hospital and Research Center, Bagalkote, Karnataka; [7]Raichur Institute of Medical Sciences, Raichur, Karnataka; [8]ICMR – National Institute of Traditional Medicine, Belagavi, Karnataka; [9]Model Rural Health Research Unit, Sirwar, Karnataka; [10]Thomas Jefferson University, Philadelphia, PA; [11]University of Minnesota, Minneapolis, MN; [12]Sidney Kimmel Medical College at Thomas Jefferson University, Philadelphia, PA; [13]Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA
10:15 AM	LB04	**Neonatal impact of prematurity risk biomarker screening with targeted interventions: A multicenter randomized controlled trial** Brian K. Iriye[1]; John O'Brien[2]; Christopher S. Ennen[3]; Perry Barrilleaux[4]; Jill Berkin[5]; Anna Palatnik[6]; Moeun Son[7]; Cynthia Gyamfi-Bannerman[8]; Mollie McDonald[9]; Glenn Markenson[10]; Anthony C. Sciscione[11]; Joseph R. Biggio, Jr[12]; Samuel Wolf[13]; Scott Sullivan[14]; Michael Walker[15]; Babak Shahbaba[16]; Stephen P. Pound[17] [1]Hera Womens Health, Las Vegas, NV; [2]University of Kentucky, Lexington, KY; [3]University of Virginia School of Medicine, Charlottesville, VA; [4]Ochsner Louisiana State University Health Shreveport, Shreveport, LA; [5]Icahn School of Medicine at Mount Sinai, New York, NY; [6]Medical College of Wisconsin, Milwaukee, WI; [7]Weill Cornell Medicine, New York, NY; [8]University of California, San Diego, San Diego, CA; [9]Austin Maternal-Fetal Medicine, Austin, TX; [10]Boston Medical Center, Boston, MA; [11]Christiana Care Health System, Newark, DE; [12]Ochsner Health, New Orleans, LA; [13]Emerald Coast OBGYN Clinical Research, Panama City, FL; [14]Inova Fairfax Medical Campus, Fairfax, VA; [15]Walker Bioscience, Carlsbad, CA; [16]University of California, Irvine, Irvine, CA; [17]Virginia Physicians for Women, North Chesterfield, VA

Friday, January 31, 2025 • 1:30 PM - 4:00 PM

Time	Abstract	Oral Concurrent Session 4 - Basic and Translational Science
1:30 PM	47	**Novel Neural Extracellular Vesicle miRNA Biomarkers Identify Suboptimal Response to Cooling in Neonatal Encephalopathy** **Sarah T. Mehl[1]**; Baharan Fekry[1]; Lierni Ugartemendia[1]; Dhanashree Rajderkar[2]; Nikolay Bliznyuk[2]; Shaveka Gaskins[2]; Michael D. Weiss[3]; Laura Goetzl[1] [1]McGovern Medical School at UTHealth Houston, Houston, TX; [2]University of Florida, Gainesville, FL; [3]University of Florida College of Medicine, Gainesville, FL
1:45 PM	48	**3D-printed humanized feto-maternal interface tests exosomal delivery of anti-inflammatory Interleukin-10 (IL-10) to reduce infection-associated inflammation** Leah Saylor[1]; Rahul Cherukuri[2]; Ananth Kammala[1]; Marc Ferrer[3]; Cristina Antich Acedo[3]; Arum Han[2]; Lauren Richardson[1]; **Ramkumar Menon[1]** [1]University of Texas Medical Branch, Galveston, TX; [2]Texas A&M University, College Station, TX; [3]National Center for Advancing Translational Sciences, National Institute of Sciences, Bethesda, MD
2:00 PM	49	**Decoy peptide to (pro)renin receptor as a potential therapeutic target for preeclampsia: a translational study** **Michelle Harris[1]**; Ahmed F. Pantho[2]; Kelsey R. Kelso[1]; Jessica C. Ehrig[3]; Ram R. Kalagiri[1]; Niraj Vora[1]; Thomas J. Kuehl[2]; Steven R. Lindheim[1]; Mohammad N. Uddin[4] [1]Baylor Scott & White Health Temple Medical Center, Temple, TX; [2]Artemis Biotechnologies LLC, Temple, TX; [3]Baylor Scott and White Health, Temple, TX; [4]Baylor Scott & White Medical Center and Texas A&M School of Medicine, Temple, TX

Friday, January 31, 2025 • 1:30 PM - 4:00 PM		
Time	**Abstract**	**Oral Concurrent Session 4 - Basic and Translational Science, continued**
2:15 PM	50	**Longitudinal changes in epigenetic aging in pregnant versus non-pregnant people: a prospective cohort study** **Danielle M. Panelli**; Nicole Gladish; Nicola C. Perlman; Andres Cardenas; Katherine Bianco Stanford University, Palo Alto, CA
2:30 PM	51	**Lactobacillus crispatus mitigates Group B Streptococcus-induced inflammation in the cervicovaginal epithelium** Briana Ferguson; Aaron Loder; Lauren Anton; **Kristin D. Gerson** University of Pennsylvania Perelman School of Medicine, Philadelphia, PA
2:45 PM	52	**Expression of CD300E in human myometrium and its impact on parturition** **Meera M. Thakkar[1]**; William E. Ackerman, IV[1]; Guomao Zhao[1]; Zoe B. Strong[1]; Elizabeth Feoktistov[2]; Ekaterina Snegovskikh[2]; Catalin S. Buhimschi[1]; Irina A. Buhimschi[1] [1]University of Illinois at Chicago, College of Medicine, Chicago, IL; [2]University of Illinois at Chicago, Chicago, IL
3:00 PM	53	**Personalized models of fetal brain development as biomarkers of offspring neurodevelopmental outcomes after maternal SARS-CoV-2** Lydia L. Shook; Liam T. McCrea; Olyvia Jasset; Steven D. Sheridan; Roy H. Perlis; **Andrea G. Edlow** Massachusetts General Hospital, Boston, MA
3:15 PM	54	**The Placental Vascular Transcriptome in Pregnancies Resulting in Low vs. Normal Birth Weight Neonates** **Samantha Carson[1]**; Morgan E. Wasickanin[1]; Emily Sheikh[1]; Hillary Kinsman[1]; Lydia Bettridge[1]; Katherine E. Free[1]; Jennifer Damicis[1]; Robert Walton[1]; Peter Napolitano[2]; Nicholas Ieronimakis[1] [1]Madigan Army Medical Center, Tacoma, WA; [2]University of Washington, Seattle, WA
3:30 PM	55	**Commonly Used Non-Steroidal Anti-Inflammatory Drug (NSAIDs) in Obstetrics & Associated Placental Cytotoxicity** **Ana Collins-Smith** University of Texas Medical Branch, Galveston, TX
3:45 PM	56	**Evaluating Semaglutide in Human Fetal Neural Stem Cells: Could Early Exposure Impact Neurodevelopment?** **Morgan E. Wasickanin[1]**; Samantha Carson[1]; Hillary Kinsman[1]; Katherine E. Free[1]; Jennifer Damicis[1]; Emily Sheikh[1]; Robert Walton[1]; Irina Burd[2]; Peter Napolitano[3]; Nicholas Ieronimakis[1] [1]Madigan Army Medical Center, Tacoma, WA; [2]University of Maryland, Baltimore, MD; [3]University of Washington, Seattle, WA
1:30 PM	57	**Myo-inositol Supplementation to Prevent Pregnancy Complications in Polycystic Ovary Syndrome: a Randomized Controlled Trial** **Anne W.T. Van Der Wel[1]**; Rebekka Bout-Rebel[2]; Chryselle M.C. Frank[3]; Ruben G. Duijnhoven[1]; Bo E. Van Bree[4]; Olivier Valkenburg[4]; Salwan Al-Nasiry[4]; Robbert H.F. van Oppenraaij[5]; Tatjana E. Vogelvang[6]; Michelle E.M.H Westerhuis[7]; Jan Peter de Bruin[8]; Hedwig P. van de Nieuwenhof[8]; Susanne C.J.P. Gielen[9]; Myrthe L. Bandell[10]; Mireille N. Bekker[11]; Maurice G.A.J. Wouters[1]; Velja Mijatovic[1]; Arie Franx[2]; Cornelis B. Lambalk[1]; Frank J.M. Broekmans[11]; Rebecca C. Painter[1]; Bart C.J.M. Fauser[12]; Joop S.E. Laven[2]; Bas B. van Rijn[13]; MYPP Investigator Group[2] [1]Amsterdam UMC, location University of Amsterdam, Amsterdam, Noord-Holland; [2]Erasmus University Medical Center, Zuid-Holland; [3]St. Antonius Ziekenhuis, Utrecht; [4]Maastricht UMC+, Limburg; [5]Maasstad Ziekenhuis, Zuid-Holland; [6]Het Diakonessenhuis, Utrecht; [7]Catharina Ziekenhuis, Noord-Brabant; [8]Jeroen Bosch Ziekenhuis, Noord-Brabant; [9]Franciscus, Zuid-Holland; [10]Albert Schweitzer ziekenhuis, Zuid-Holland; [11]University Medical Center Utrecht, Utrecht; [12]University of Utrecht and University Medical Center Utrecht, Utrecht; [13]Eindhoven University of Technology, Noord-Brabant

Friday, January 31, 2025 • 1:30 PM - 4:00 PM

Time	Abstract	Oral Concurrent Session 5 - Hypertension
1:45 PM	58	**Nifedipine versus Labetalol for Treatment of Postpartum Hypertension: A Randomized Controlled Trial** **Todd R. Lovgren[1]**; Ruofan Yao[2]; Brendan D. Connealy[3]; Robert Bonebrake[1]; Hemant Satpathy[1]; Emily Patel[1]; Matthew Brady[1]; Joshua Dahlke[4] [1]Nebraska Methodist Health System, Elkhorn, NE; [2]Loma Linda University Health, Loma Linda, CA; [3]Methodist Women's Hospital, Omaha, NE; [4]Nebraska Methodist Hospital, Elkhorn, NE
2:00 PM	59	**Defining postpartum cardiovascular physiology: Blood pressure trajectories in patients at risk for new-onset postpartum hypertension** **Ukachi N. Emeruwa[1]**; Minhazur R. Sarker[1]; Elizabeth Nicole Teal[1]; Marni B. Jacobs[2]; Louise C. Laurent[3]; Natalie A. Bello[4]; Timothy Wen[5]; Russell S. Miller[6]; Cynthia Gyamfi-Bannerman[1] [1]University of California, San Diego, San Diego, CA; [2]University of California, San Diego Health, San Diego, CA; [3]University of California, San Diego Medical Center, La Jolla, CA; [4]Cedars Sinai Medical Center, Los Angeles, CA; [5]University of California, San Diego, Irvine, CA; [6]Columbia University Medical Center, New York, NY
2:15 PM	60	**Severe Systolic Hypertension and Adverse Maternal Outcomes** **Yossi Bart[1]**; Hector M. Mendez-Figueroa[2]; Farah H. Amro[1]; Baha M. Sibai[1] [1]McGovern Medical School at UTHealth Houston, Houston, TX; [2]McGovern Medical School at UTHealth, Houston, TX
2:30 PM	61	**Postpartum Diuretics for Hypertensive Disorders of Pregnancy: A Systematic Review and Meta-Analysis** **Emma Trawick Roberts[1]**; Elana Jaffe[1]; Johanna Quist-Nelson[1]; Suneet Chauhan[2]; Baha M. Sibai[3]; Michal Fishel Bartal[4] [1]University of North Carolina, Chapel Hill, NC; [2]Christiana Care, Newark, DE; [3]McGovern Medical School at UTHealth Houston, Houston, TX; [4]UTH Houston & Sheba Medical Center Israel, Houston, TX
2:45 PM	62	**Association of Preeclampsia with Long-Term Risk of Neurodegenerative Disorders** **Maria Bazan[1]**; Ai-ris Y. Collier[2]; Tina Yi Jin Hsieh[2]; James Cheng-Chung Wei[3] [1]Beth Israel Deaconess Medical Center, Brighton, MA; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]Chung-Shan Medical School, Taichung, Taichung
3:00 PM	63	**Comprehensive blood pressure management to improve early postpartum blood pressure parameters: a randomized controlled trial** **Alexandra JD Phelps[1]**; Loveis Jackson[1]; Lilly He[1]; Ashanti E. Griggs-Cooks[1]; Neha Dudipala[2]; Etoi Garrison[1]; Kathryn J. Lindley[1]; Soha S. Patel[1]; Julia C. Phillippi[3]; Megan Webb[1]; Sarah S. Osmundson[1] [1]Vanderbilt University Medical Center, Nashville, TN; [2]Ohio State University College of Medicine, Columbus, OH; [3]Vanderbilt University School of Nursing, Nashville, TN
3:15 PM	64	**Hofbauer cells may mediate PE-associated placental dysfunction via APOE synthesis** **Bani Medegan Fagla**; Cielo Dela Rosa; Savita Sundar; Aswathi Jayaram; Erykah Walton; Jason York; Leon M. Tai; Guomao Zhao; Irina A. Buhimschi University of Illinois at Chicago, College of Medicine, Chicago, IL
3:30 PM	65	**Impact on Severe Maternal Morbidity following Statewide Improvements in Hypertensive Disorders of Pregnancy Care Processes** **Patrick Schneider[1]**; Allison Stevens[2]; Alyssa Antonini[2]; Michelle Menegay[3]; Allison Lorenz[3]; Stephen Afflito[3]; Rashelle Ghanem[4]; Ryan Everett[5]; Justin R. Lappen[6] [1]The Ohio State University, Wexner Medical Center, Columbus, OH; [2]Government Resources Center for the Ohio Colleges of Medicine, Columbus, OH; [3]Ohio Colleges of Medicine, Government Resource Center, Columbus, OH; [4]Ohio Department of Children and Youth, Columbus, OH; [5]Ohio Hospital Association, Columbus, OH; [6]Cleveland Clinic Foundation, Cleveland, OH
3:45 PM	66	**Adverse outcomes during delivery hospitalizations among patients with an intellectual or developmental disability diagnosis** **Manasa G. Rao[1]**; Timothy Wen[2]; Mary E. D'Alton[1]; Alexander M. Friedman[3]; Noelia Zork[3] [1]Columbia University Medical Center, New York, NY; [2]University of California, San Diego, Irvine, CA; [3]Columbia University Irving Medical Center, New York, NY

Friday, January 31, 2025 • 1:30 PM - 4:00 PM

Time	Abstract	Oral Concurrent Session 6 - Prematurity and Newborn
1:30 PM	67	**Azithromycin to prevent stillbirths and infant deaths in Mali: A 2x2 factorial placebo-controlled randomized trial** **Karen Kotloff[1]**; Amanda J. Driscoll[1]; Fadima Haidara[2]; Lawrence Moulton[3]; Jason Bailey[1]; Ousmane Samake[2]; Tiecoura Bocoum[2]; Jane Juma[2]; Awa Traore[2]; Mamadou Diallo[2]; Collins Okello[2]; Uma Onwuchekwa[2]; Mamoudou Kodio[2]; Yuji Chen[1]; Emily Deichsel[1]; Matthew Finholt-Daniel[4]; Robert L. Goldenberg[5]; Fleesie Hubbard[1]; Rebecca Maguire[1]; Melissa Page[4]; David Plotner[4]; Milagritos Tapia[1]; Dilruba Nasrin[1]; Samba Sow[2] [1]University of Maryland, School of Medicine, Baltimore, MD; [2]Centre pour le Développement des Vaccins, Mali, Bamako, Bamako; [3]Johns Hopkins, Bloomberg School of Public Health, Baltimore, MD; [4]RTI International, Durham, NC; [5]Columbia University School of Medicine, New York, NY
1:45 PM	68	**The effect of metformin in women who received betamethasone on maternal hyperglycemia and neonatal hypoglycemia** **Enav Yefet[1]**; Manal Massalha[2]; Gil Talmon[1]; Aminet Labay[1]; Marian matanis[1]; Erez Sleman[1]; Rima nassra[1]; Maya Frank Wolf[3]; Inshirah Sgayer[4]; Lior Lowenstein[4]; Zohar Nachum[2] [1]Tzafon Medical Center, Poriya, HaZafon; [2]Emak Medical Center, Afula, HaZafon; [3]Galilee Medical Center, Naharyia, HaZafon; [4]Galilee Medical center, Nahariya, HaZafon
2:00 PM	69	**Fully Quantitative Cervical Remodeling: Race Group Differences Responsibilities and Cautions** **LeAnn A. Louis[1]**; Sarah M. Dwyer[1]; Methodius G. Tuuli[2]; Adam K. Lewkowitz[2]; Julie Tumbarello[1]; Emily Dively, BSN[3]; Madeline Felske[1]; Wendy Sparks[1]; Anita M. Malone[1]; Peinan Zhao[4]; Molly J. Stout[5] [1]University of Michigan Hospital, Ann Arbor, MI; [2]Women & Infants Hospital of Rhode Island and Alpert Medical School of Brown University, Providence, RI; [3]Washington University School of Medicine, St. Louis, MO; [4]Washington University, St. Louis, MO; [5]University of Michigan Medical Center, Ann Arbor, MI
2:15 PM	70	**Neonatal outcomes after Caesarean versus vaginal birth: population-based cohort study of extremely preterm breech singletons** **Yanchen Wang[1]**; Pasqualina Santaguida[1]; Sameer Parpia[1]; Fabiana Bacchini[2]; Prakeshkumar S. Shah[3]; Kellie Murphy[3]; K. S. Joseph[4]; Sandesh Shivananda[5]; Sarah D. McDonald[1] [1]McMaster University, Hamilton, ON; [2]Canadian Premature Babies Foundation, Toronto, ON; [3]University of Toronto, Toronto, ON; [4]School of Population and Public Health, University of British Columbia, Vancouver, BC; [5]University of British Columbia, Vancouver, BC
2:30 PM	71	**The role of cervical elastography for the prediction of spontaneous preterm birth** **Anne-Sophie Lafortune[1]**; Louise Ghesquiere[2]; Paul Guerby[3]; Marie-Laurence Côté[1]; Genevieve Marcoux[4]; Annie Beaudoin[4]; Emmanuel Bujold[1] [1]Université Laval, PQ; [2]Université de Lille, Lille, Nord-Pas-de-Calais; [3]Université de Toulouse, Midi-Pyrenees; [4]CHU de Québec, CHU de Québec, PQ
2:45 PM	72	**Corticosteroids and Neonatal Hypoglycemia among Pregnant Individuals with Diabetes: Effect of Gestational Age at Delivery** **Ruby Lin**; Cande V. Ananth; Todd J. Rosen On behalf of the MOMPOD Consortium Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ
3:00 PM	73	**Pro-inflammatory vaginal cytokines, early PTB, and infectious morbidity in patients with asymptomatic cervical shortening** **Tracy A. Manuck** On behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units (MFMU) Network University of North Carolina, Chapel Hill, NC

Friday, January 31, 2025 • 1:30 PM - 4:00 PM

Time	Abstract	Oral Concurrent Session 6 - Prematurity and Newborn, continued
3:15 PM	74	**Comparison of Polyester Fiber versus Polypropylene Suture Materials in Physical-Exam Indicated Transvaginal Cerclages** Daniel J. Martingano[1]; Amanda F. Francis Oladipo[2]; **Marwah Al-Dulaimi[3]**; Sandra Kumwong[4]; Andrea Ouyang[5]; Lauren Cue[6]; Ashley Nguyen[3]; Shailini Singh[7]; Alexander Ulfers[8]; Mark Rebolos[3]; Kristin Cohen[9]; Donald Morrish[3]; Iffath A. Hoskins[10]; Francis X. 8:00 AM - 8:15 AM

Objective: Recently, guidelines recommend corticosteroid injection in singleton pregnancy at risk of late preterm birth (34 ~36+6 weeks). However, the effectiveness of antenatal corticosteroid in twin pregnant women at risk of late preterm birth has not been evaluated, and there is a paucity of guideline in this population. In the current study, we evaluated if antenatal betamethasone administration reduces the risk of neonatal respiratory morbidity in late preterm twin neonates.

Study Design: In this multicenter randomized trial, we enrolled twin pregnant women at 34+0 to 36+5 weeks of gestation who were at risk of late preterm birth. The participants received betamethasone or placebo after randomization of 1:1 ratio. Primary outcome was severe neonatal respiratory morbidity, including at least one of the followings: the use of continuous positive airway pressure (CPAP) or high-flow nasal cannula for 12 hours or more, supplementary oxygen administration with a fraction of oxygen of at least 0.3 for 24 hours or more, mechanical ventilation, extracorporeal membranes oxygenation, or perinatal death within 72 hours after birth. The secondary outcome was other neonatal morbidities.

Results: Among 1620 neonates, the primary outcome occurred in 99 neonates with lower risk in the betamethasone group than in placebo group (39/818 [4.8%] vs. 60/802 [7.5%], relative risk (RR) 0.64 [95% CI, 0.42-0.98]) Other respirator morbidities were also lower in the betamethasone group, such as CPAP use for 2 hours or more (RR 0.58 [95% CI 0.35~0.95]) and transient tachypnea of the newborn (RR 0.47 [95% CI 0.25~0.89]). The risk of neonatal hypoglycemia was increased in the betamethasone group (RR 1.33 [95% CI 1.01~1.75]), but the risk of neonatal sepsis or maternal chorioamnionitis were not different between the two groups of cases.

Conclusion: The antenatal betamethasone administration in twin pregnant women at risk of late preterm birth significantly reduced the risk of neonatal respiratory morbidity.

Table. Neonatal respiratory complications

Characteristics	Placebo (n=802 babies)	Betamethasone (n=818 babies)	Relative Risk (reference: Placebo)	P value
Primary outcomes (Severe respiratory morbidities)	**60 (7.5%)**	**39 (4.8%)**	**0.64 (0.42-0.98)**	**0.038**
CPAP ≥12 h	**38 (4.7%)**	**19 (2.3%)**	**0.50 (0.29-0.87)**	**0.013**
High-flow nasal cannula ≥12 h	16 (2.0%)	12 (1.5%)	0.75 (0.35-1.61)	0.456
Fraction of inspired oxygen of ≥0.3 for ≥24 h	4 (0.5%)	5 (0.6%)	1.19 (0.34-4.14)	0.787
Mechanical ventilation	23 (2.9%)	17 (2.1%)	0.73 (0.38-1.40)	0.350
Extracorporeal membranes oxygenation	0 (0%)	2 (0.2%)	9.65 (0.52-178.00)	0.127
Perinatal death	0 (0%)	0 (0%)	-	-
Mild respiratory morbidities	64 (8.0%)	44 (5.4%)	0.68 (0.45-1.02)	0.063
CPAP ≥2 h	**48 (6.0%)**	**28 (3.4%)**	**0.58 (0.35-0.95)**	**0.031**
High-flow nasal cannula ≥2 h	21 (2.6%)	20 (2.4%)	0.94 (0.50-1.76)	0.838
Fraction of inspired oxygen of ≥0.3 for ≥4 h	6 (0.7%)	8 (1.0%)	1.27 (0.46-3.53)	0.646
Other respiratory morbidity	45 (5.6%)	31 (3.8%)	0.68 (0.41-1.13)	0.138
Respiratory distress syndrome	7 (0.9%)	8 (1.0%)	1.11 (0.38-3.19)	0.849
Transient tachypnea of the newborn	**34 (4.2%)**	**16 (2.0%)**	**0.47 (0.25-0.89)**	**0.021**
Apnea	1 (0.1%)	6 (0.7%)	3.71 (0.90-15.27)	0.070
Bronchopulmonary dysplasia	0 (0%)	2 (0.2%)	9.65 (0.52-178.00)	0.127
Pneumonia	0 (0%)	0 (0%)	-	-
Surfactant use	2 (0.2%)	1 (0.1%)	0.64 (0.15-2.75)	0.545
Pulmonary air leak	4 (0.5%)	2 (0.2%)	0.58 (0.16-2.06)	0.396

2 | The Frequency and Severity of Complications after Previable PROM in Texas following SB8

Danna Ghafir[1]; Emily Fahl[1]; Nancy Ukoh[1]; Han-Yang M. Chen[1]; Sean C. Blackwell[1]; Julie Gutierrez[2]; Irene A. Stafford[1]
[1]McGovern Medical School at UTHealth Houston, Houston, TX; [2]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX

8:15 AM - 8:30 AM

Objective: Robust contemporary data concerning previable PROM are limited. The impact of changes in state abortion laws on maternal outcomes also remains unknown. We sought to compare outcomes of pregnant individuals who develop previable PROM at our center before and after the implementation of Texas Senate Bill 8 (SB8).

Study Design: This is a retrospective cohort study across three tertiary care hospitals from January 1, 2018-March 31, 2023. ICD-10 codes were used to identify individuals with previable PROM. Chart review was done by trained research staff. Individuals with singleton or twin gestions and clinical diagnosis of PROM < 22 weeks were studied, excluding those with IUFD and/or active PTL. We compared clinical characteristics and outcomes of individuals before and after the implementation of SB8 on September 1, 2021. Our primary outcome was composite adverse outcome, which included ICU admission, transfusion, and/or sepsis. Multivariable Poisson regression with robust error variance was used to adjust for confounding factors for the primary outcome. Adjusted relative risk (aRR) with 95% CIs was calculated.

Results: Over the 5-year study period, 166 individuals met inclusion criteria (97 pre-SB8 vs 69 post-SB8). There were no differences in baseline characteristics pre- vs post-SB8 (Table 1). Prior to SB8, 49% of individuals opted for immediate delivery. No individuals in the post-SB8 cohort were induced with previable ROM as the sole indication for delivery. There was a higher rate of the composite adverse outcome (20.6% vs 37.7%; aRR 2.02, 95% CI 1.2-3.3), after adjusting for age, race and ethnicity, and gestational age at delivery. Time from rupture to delivery was longer in the post-SB8 cohort (median [IQR]: 1 [1-3] days vs 6 [2-12] days, p< 0.001) and demonstrated a higher incidence of sepsis (6.2% vs 31.9%; aRR 5.15, 95% CI 2.27-11.7).

Conclusion: Prior to SB8, nearly one-half of individuals opted for pregnancy termination due to previable PROM. After SB8, risks of serious adverse outcomes increased nearly 2X, and the risk of sepsis increased over 4X.

8:30 AM - 8:45 AM

Objective: Cell-free DNA (cfDNA) screening for fetal aneuploidy is typically offered beginning at 10 weeks' gestation. Prior to 10 weeks the proportion of placental cfDNA, known as the fetal fraction (FF), is often too low to allow for confident analysis. FF amplification, the preferential enrichment of placental cfDNA based on its shorter fragment size, may sufficiently increase FF to enable screening earlier than 10 weeks with high confidence and a low failure rate. This study aimed to evaluate the feasibility

of cfDNA screening using FF amplification prior to 10 weeks' gestation.

Study Design: Blood samples were collected from pregnant patients with singleton gestations at 6w0d-9w6d and ≥10w0d. Samples were processed using an approach that incorporates FF amplification. Logistic regression was used to evaluate the proportion of samples with low FF (< 4%) as a function of gestational age (GA). Aneuploidy and sex-call concordance were evaluated.

Results: 459 patients completed both blood draws. Additional cohort characteristics are described in the Table. FF ranged from 2.1- 34.7%, with lower GAs corresponding to lower FFs (Figure). Prior to the incorporation of FF amplification, 4.78% of samples at 10w0d had a low FF (< 4%). FF amplification allowed for comparable performance at 7w3d (the earliest date where < 4.78% of samples had FF < 4%). To reflect practical application in a clinical setting, we selected 8w0d through 9w6d as the "early GA" period. Among the 239 samples in the early GA period, one sample failed because of insufficient FF (FF = 2.5%), yielding a no-call rate of 0.42%. Three trisomies (two T21 and one T7) were identified in the early GA period, and each was concordant with the corresponding ≥10w0d call. All 238 passing samples had concordant sex calls in the early GA and ≥10w0d GA periods.

Conclusion: CfDNA screening using FF amplification provided accurate results as early as 8 weeks GA with a low no-call rate in this study population. Earlier prediction of risk for chromosomal abnormalities may provide patients with the option to have diagnostic testing with CVS at 10 weeks' gestation.

Table 1: Cohort Characteristics

Characteristic	Mean [range] or N (%)
All patients	459
Gestational age at 1st draw	
6 weeks 0 days to 6 weeks 6 days	128 (27.9%)
7 weeks 0 days to 7 weeks 6 days	92 (20.0%)
8 weeks 0 days to 8 weeks 6 days	159 (34.6%)
9 weeks 0 days to 9 weeks 6 days	80 (17.4%)
Mean fetal fraction at 1st draw [range]	10.7% [2.1% — 34.7%]
Mean fetal fraction at 2nd draw [range]	19.2% [5.5% — 35.7%]
Mean maternal BMI [range]	27.3 [15.5 — 49.1]
Mean maternal age [range]	32 [19 — 46]

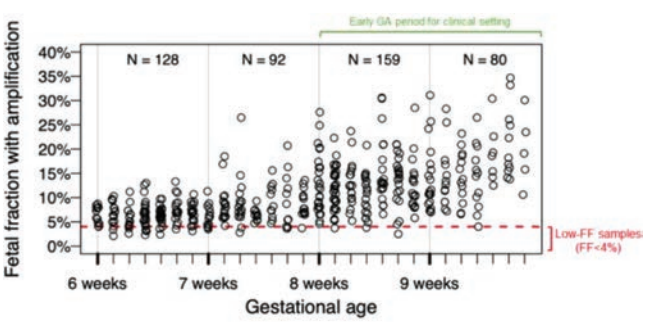

Figure 1: Fetal fraction as a function of gestational age. Dashed red line indicates the 4% FF generally considered to be the threshold below which a sample has "low FF".

4 | AI Significantly Improves Detection of Prenatal Ultrasounds Suspicious for Major Congenital Heart Defects by OBGYN/MFMs

8:45 AM - 9:00 AM

Objective: Congenital heart defects (CHDs) are a leading cause of infant morbidity and mortality partly due to low prenatal detection rates. We evaluated whether an artificial intelligence (AI) system can improve the detection of CHDs on fetal ultrasound exams among both general OBGYNs and MFM specialists.

Study Design: The AI system analyzes all grayscale 2D ultrasound cines of an exam and detects 8 morphological findings associated with severe CHDs. The presence of any such finding should justify patient referral for further examination. The AI system identifies each finding as present, absent or inconclusive, and highlights frames where findings can be assessed.

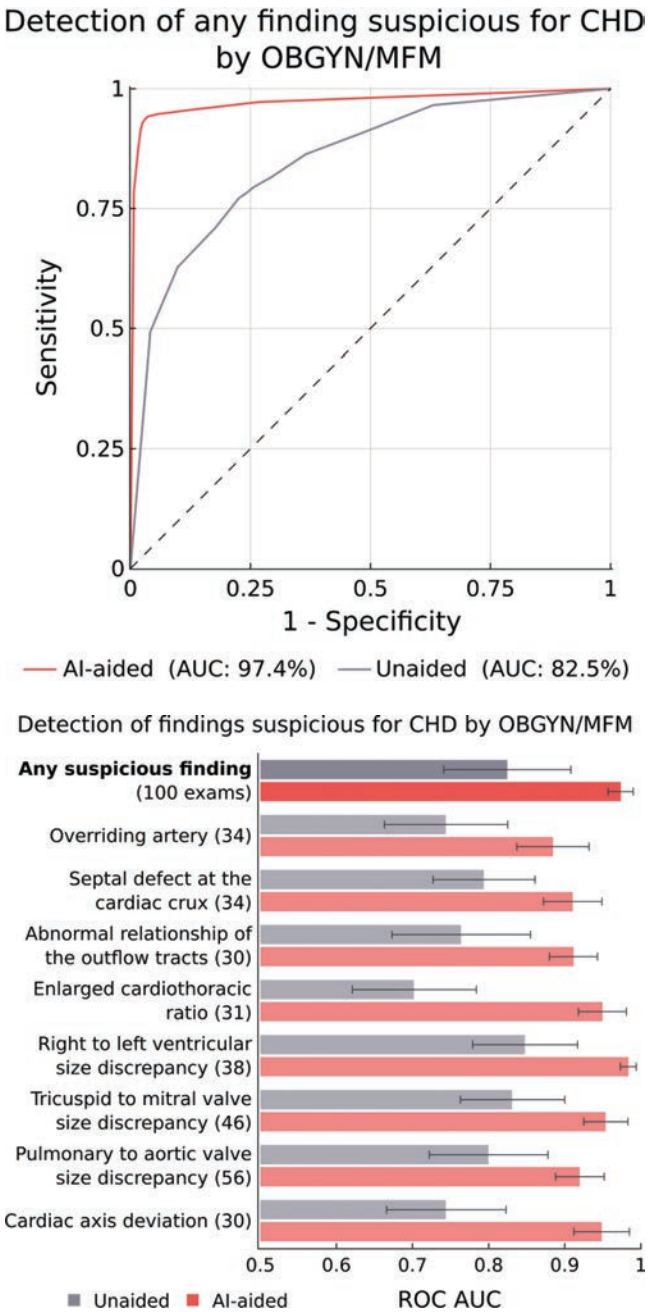
A dataset of 200 ultrasound exams from 11 centers in 2 countries was collected (single pregnancy, obstetric or detailed anatomic ultrasounds, or fetal echocardiograms, at 18-24 weeks gestation), with 100 exams having at least one suspicious finding. The ground truth for presence or absence of each finding was determined by a panel of expert fetal cardiologists. These exams were not used for the training of the AI system.

Fourteen physicians (OBGYNs and MFMs, 1-30+ years' experience) reviewed each exam both aided and unaided by the AI system, in randomized order, and annotated them for the presence or absence of any such finding and of each individual finding, along with confidence scores. Receiver operator characteristics (ROC) area under the curve (AUC), sensitivity and specificity were computed by comparing reviews to the ground truth.

Results: ROC AUC for detection of any finding was significantly higher for aided than unaided reviews: 0.97 (95% CI 0.96-0.99) vs 0.83 (0.74-0.91), p = 0.002 (DBM-OR method). Similar results held for sensitivity: 0.94 (0.89-0.98) aided vs 0.78 (0.69-0.88) unaided and specificity: 0.97 (0.95-0.99) aided vs 0.76 (0.63-0.89) unaided.

Mean reading time was shorter for aided (226 ± 218 s) than unaided (274 ± 241 s) reviews ($p < 0.001$).

Conclusion: Assistance by the AI system significantly improved detection of studies suspicious for CHD by OBGYNS and MFMs. AI may play a pivotal role in improving prenatal detection of CHD.



5 | Atosiban Versus Placebo in Threatened Preterm Birth (APOSTEL 8-study): an International Randomized Controlled Trial

Larissa I. van der Windt[1]; Job Klumper[1]; Ruben G. Duijnhoven[1]; Marjolein Kok[1]; Ben W. Mol[2]; Kate F. Walker[3]; Fionnuala M. M. McAuliffe[4]; Joris A. M. van der Post[5]; Carolien Roos[1]; Martijn A. Oudijk[1]

[1]Amsterdam UMC, location University of Amsterdam, Amsterdam, Noord-Holland; [2]Monash University, Clayton, Victoria; [3]Centre of Perinatal Research University of Nottingham, Queen's Medical Centre, Dublin, England; [4]UCD Perinatal Research Centre, University College Dublin, Dublin 2, Dublin; [5]Amsterdam UMC, location University of Amsterdam, Amsterdam, Noord-Brabant

9:00 AM - 9:15 AM

Objective: In many countries, threatened preterm birth (PTB) is treated with tocolytics to allow for a complete antenatal course of corticosteroids. Although effective in delaying birth, a positive effect on neonatal outcome has never been demonstrated. We assessed the effectiveness of atosiban for women with threatened PTB between 30 and 34 weeks of gestation in improving neonatal outcome.

Study Design: We performed a randomized double-blind placebo-controlled superiority trial in 26 hospitals in the Netherlands, England and Ireland. After informed consent, women with a singleton or twin pregnancy with threatened PTB between 30 and 34 weeks gestation were randomized (stratified by centre, 1:1 ratio) to intravenous atosiban or placebo for 48 hours. Primary outcome was a neonatal composite of perinatal mortality and morbidity. Treatment effect was expressed as relative risk (RR) with 95% confidence intervals (CI). To detect a reduction from 12% adverse perinatal outcome in the placebo group to 6% in the atosiban group with a power of 80%, we needed to randomise 722 women. Assuming a 5% drop-out rate, the sample size was calculated at 760 participants. Analysis was by intention-to-treat principle.

Results: From December 2017 to July 2023, we randomized 755 participants to atosiban (n = 377) or placebo (n = 378). Primary outcome was available for 752 participants with 884 infants. The primary outcome occurred in 37/449 (8.2%) infants in the atosiban group and 40/435 (9.2%) in the placebo group (RR 0.90, 95% CI 0.58 to 1.40). There were two (0.4%) and four (0.9%) perinatal deaths respectively (RR 0.48, 95% CI 0.09 to 2.63). There were no significant differences in other neonatal outcomes. Prolongation of pregnancy > 48 hours was significantly more often achieved in the atosiban group (292/375, 77.5%) compared to placebo (261/377, 69.2%) (RR 1.13, 95% CI 1.03 to 1.24).

Conclusion: We did not demonstrate superiority of atosiban over placebo in improving neonatal outcomes as a treatment for threatened PTB between 30 and 34 weeks of gestation. This questions the widespread use of tocolytics in many countries.

Table: obstetric and neonatal outcomes

	Atosiban mothers n=375 infants* n=449	Placebo mothers n=377 infants* n=435	RR (95% CI)	p-value
Obstetric outcomes				
Median gestational age at birth, weeks	33.9 [32.1 to 37.4]	34.1 [32.2 to 37.6]		0.83
Prolongation of pregnancy (time to delivery)				
Median, days	12.0 [3.0 to 37.0]	11.0 [2.0 to 42.0]		0.72
>48 hours	292 (77.9)	261 (69.2)	1.13 (1.03 to 1.24)	0.01
Neonatal outcomes*				
Median birthweight, grams	2142 [1821 to 2728]	2220 [1820 to 2845]		0.35
Primary adverse perinatal outcome	37 (8.2)	40 (9.2)	0.90 (0.58 to 1.40)	0.63
Perinatal mortality	2 (0.4)	4 (0.9)	0.48 (0.09 to 2.63)	0.40
BPD	1 (0.2)	2 (0.5)	0.48 (0.04 to 5.32)	0.55
NEC > stage 1	2 (0.4)	6 (1.4)	0.32 (0.07 to 1.59)	0.16
IVH > grade 2	3 (0.7)	6 (1.4)	0.48 (0.12 to 1.92)	0.30
PVL > grade 1	8 (1.8)	5 (1.1)	1.55 (0.51 to 4.70)	0.44
ROP > grade 2 or needing laser therapy	1 (0.2)	0	N/A	-
Culture proven sepsis	26 (5.8)	25 (5.7)	1.00 (0.58 to 1.75)	0.98

Outcome data are n (%) or median [IQR]. RR, risk ratio; CI, confidence interval; BPD, bronchopulmonary dysplasia; NEC, necrotising enterocolitis; IVH, interventricular haemorrhage; PVL, periventricular leukomalacia; ROP, retinopathy of prematurity.
Infants can have more than one of the components of the composite outcome.

6 | Prediction of Severely Small-for-Gestational-Age Infants Using a Novel Cell-free RNA Model

9:15 AM - 9:30 AM

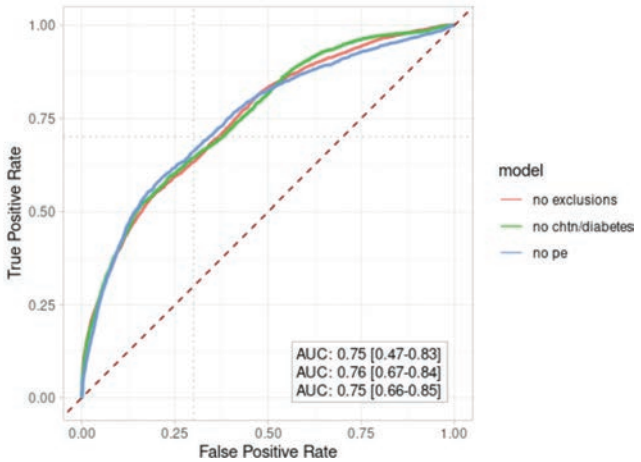
Objective: Pregnancies with suspected severe fetal growth restriction (FGR) require increased surveillance and earlier delivery due to their associated risk of stillbirth and other comorbidities. However, many infants born at < 3rd percentile (SGA3) are not detected until after delivery. We sought to understand the extent to which SGA3 can be predicted with a novel cell-free RNA (cfRNA) model, compared to the antepartum detection rate of SGA3.

Study Design: From a prospective cohort, 5,195 subjects with singleton gestations were enrolled from 11 U.S. sites and direct-to-participant mobile recruitment. Maternal blood was drawn between 17w4d-22w0d and pregnancy outcomes were adjudicated. Growth ultrasounds were performed for usual clinical indications. SGA3 was based on the Fenton growth chart. A cfRNA model was developed with features selected using sure independence screening and fit using cross-validation and L1 to reduce feature count. Rates of antepartum detection of SGA were estimated via the rate of FGR diagnosis.

Results: 115 (2.2%) delivered SGA3 infants, of whom 44.3% (N = 51) were detected antenatally with FGR. SGA3 was associated with preeclampsia, nulliparity, younger age, and Black race. A cfRNA model driven by *COL24A1* for prediction of SGA3 demonstrated an AUC of 0.75 (Fig). Excluding subjects with preeclampsia (N = 624, 22 SGA3) demonstrated comparable performance (AUC = 0.75), as did exclusion of subjects with chronic HTN and T1/T2DM (N = 555, 12 SGA3; AUC = 0.76). The cfRNA model predicted 59.1% (N = 68) of SGA3 infants. 30.4% (N = 35) were predicted to be SGA by cfRNA modeling but not FGR diagnosis vs. 14.8% (N = 17) predicted by FGR diagnosis but not cfRNA.

Conclusion: This large diverse study shows that antenatal detection of FGR is lacking, with the majority of SGA3 infants undiagnosed prior to birth. Improved diagnostic tools are required to identify these high-risk pregnancies. A cfRNA model identified the majority of SGA3 infants, independent of preeclampsia status. This novel cfRNA model represents a promising step toward the improved antepartum prediction and detection of severe FGR.

Fig. Test AUCs of cfRNA models on full population, excluding CHTN & T1/T2DM, and excluding preeclampsia



7 | Metformin Paradoxically Increases Insulin Resistance During Pregnancy in a Rhesus Macaque Model

Enrico R. Barrozo[1]; Tyler Dean[2]; Claire E. Jensen[3]; Melissa A. Suter[1]; Maxim D. Seferovic[1]; Kristin Sauter[2]; Jacob E. Friedman[4]; Maureen Gannon[5]; Stephanie R. Wesoloski[6]; Carrie E. McCurdy[7]; Paul Kievit[2]; Kjersti M. Aagaard[8]
[1]Baylor College of Medicine and Texas Children's Hospital, Houston, TX; [2]Oregon National Primate Research Center, Beaverton, OR; [3]University of North Carolina, Chapel Hill, NC; [4]Harold Hamm Diabetes Center, University of Oklahoma Health Sciences Center, Oklahoma City, OK; [5]Vanderbilt University Medical Center, Nashville, TN; [6]University of Colorado, Anschutz Medical Campus, Aurora, CO; [7]University of Oregon, Eugene, OR; [8]Boston Children's Hospital, Division of Fetal Medicine and Surgery, Boston, MA; HCA Healthcare and HCA Healthcare Research Institute, Nashville, TN; HCA Texas Maternal Fetal Medicine, Houston, TX; Baylor College of Medicine and Texas Children's Hospital, Houston, TX, Boston, MA

9:30 AM - 9:45 AM

Objective: Normal human and non-human primate pregnancy physiology includes mild insulin resistance, which enables appropriate fetal growth & species-specific accumulation of fetal adiposity. With rising diabetes in pregnancy, metformin use has become common despite its inferiority to insulin in managing maternal hyperglycemia. We hypothesized metformin inferiority during pregnancy may be due to differing pathophysiology of insulin resistance in pregnancy and tested this hypothesis in our recent Rhesus macaque model.

Study Design: Dams (n = 75) were randomized to vehicle control (VEH) or metformin (MET, 10 mg/kg twice daily) at pregnancy confirmation by GD30 and allocated to control (CHOW) or an isocaloric 35% fat Western-style diet (WSD). Glucose tolerance tests were conducted pre-pregnancy (Baseline), 3rd trimester, and 3 months postpartum. AUC for glucose and insulin, HOMA-IR, QUICKI, and Matsuda Index were calculated as insulin

resistance (IR) and sensitivity (IS) measures, respectively. Data were analyzed using two-way ANOVA or mixed-effects models and Tukey's test for multiple comparisons ($p < 0.05$).

Results: Consistent with pregnancy physiology, dams were insulin resistant during pregnancy (insulin AUC $p < 0.0001$) but not hyperglycemic ($p = 0.3$; Fig 1). Relative to VEH, initiation of metformin by GD30 resulted in increased IR (HOMA-IR, $p = 0.03$) and decreased IS (QUICKI & Matsuda, $p = 0.001$ & $p < 0.001$), both of which appropriately varied during gestation. Metformin was ineffective at treating IR during pregnancy and postpartum, with a paradoxical effect of significantly increased IR with metformin use compared to VEH (baseline vs 3rd trimester $q < 0.05$, Fig 2). Results were consistent when stratified by fetal sex and lactation status.

Conclusion: In our non-diabetic rhesus macaque model, we found that the pathophysiology and metformin-responsiveness of maternal pregnancy-related IR differ from non-pregnancy IR. These data are consistent with the lack of efficacy in human trials and underscore the need for longitudinal studies on the mechanisms and long-term health risks of metformin exposure during pregnancy.

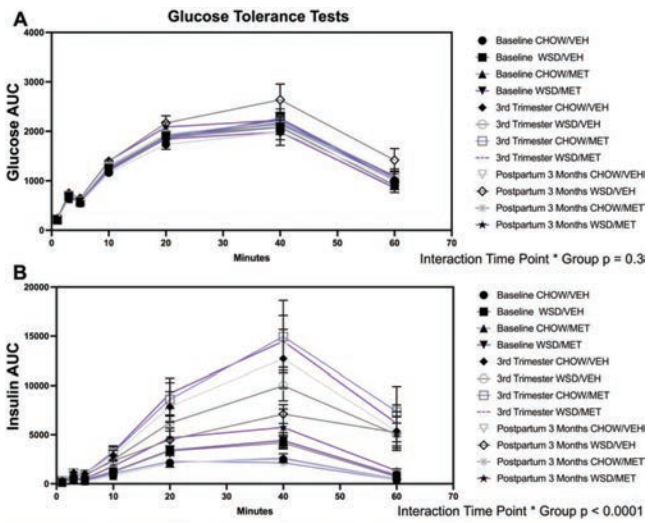


Figure 1. Rhesus Macaque Model for Insulin Resistance in Pregnancy and Not Hyperglycemia Confirmed by Maternal Glucose Tolerance Tests (GTT) Before, During, and After Pregnancy. A, Average glucose (mg/dL) area under the curve (AUC) stratified by time point and grouped by diet (CHOW or WSD) and treatment (VEH or MET). **B**, Average insulin (μU/mL) AUC stratified by time point and group. Significance was determined by two-way ANOVA (significance defined as a p-value < 0.05).

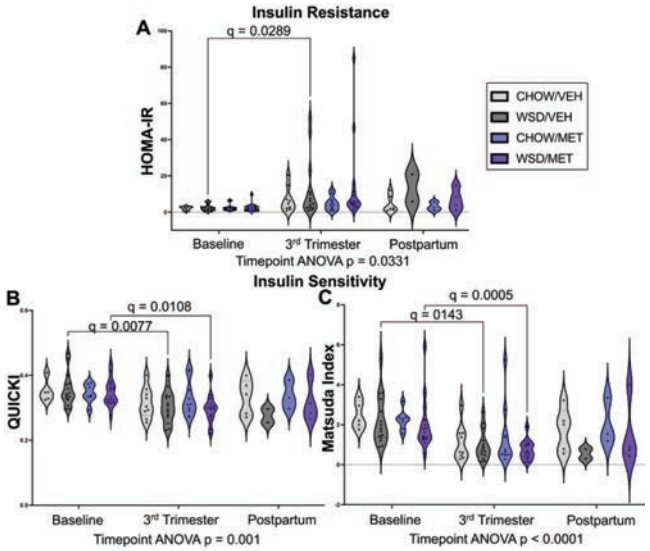

Figure 2. Metformin was Ineffective at Treating Insulin Resistance and Sensitivity Alterations During Pregnancy and 3 Months Postpartum. A-C, Homeostatic model assessment of insulin resistance (HOMA-IR; A), quantitative insulin sensitivity check index (QUICKI; B), and Matsuda index (C) stratified by time point and grouped by diet and treatment. Significance was determined by two-way ANOVA and Tukey's multiple corrections test (significance defined as an adjusted p-value (q) < 0.05).

8 | INTER-ACT Interpregnancy and Pregnancy Lifestyle Intervention for a Healthy Future: a Randomized Controlled Trial

Yael Winter Shafran[1]; Hanne Van Uytsel[2]; Annick Bogaerts[2]; Lieveke Ameye[2]; Roland Devlieger[3]

[1]Kaplan Medical Center and REALIFE Research Group, Rehovot, HaMerkaz; [2]REALIFE Research Group, KU Leuven, Leuven, Vlaams-Brabant; [3]University Hospital Leuven, Leuven, Vlaams-Brabant

9:45 AM - 10:00 AM

Objective: Maternal pre-pregnancy BMI and gestational weight gain (GWG) influence pregnancy outcomes. Interventions during pregnancy show limited success, highlighting the need for pre-pregnancy interventions. This study evaluated a comprehensive lifestyle intervention from the interpregnancy to subsequent pregnancy periods in individuals with a history of excessive GWG, aiming to reduce pregnancy complications.

Study Design: The INTER-ACT trial is a prospective multicenter randomized controlled trial (RCT) conducted from 2017 to 2019. A total of 1,450 participants with were randomized, with 390 experiencing a singleton pregnancy. The intervention included face-to-face coaching and an E-Health app focusing on nutrition, physical activity, and mental well-being. The control group had measurements and surveys. The primary outcome was a composite of pregnancy-induced hypertension, gestational diabetes, cesarean section, and large-for-gestational-age infants.

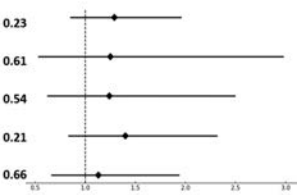
Results: The lifestyle intervention did not significantly reduce the composite outcome overall (OR 1.29, 95% CI 0.85 to 1.96). Adherence dropped substantially during the following pregnancy, with only 55% attending at least one coaching session and 38% using the app. A subanalysis revealed that participants who adhered to either the intervention or control follow-up had

a significantly reduced composite outcome compared to non-adherent participants, with ORs of 0.50 (95% CI: 0.26 to 0.98) and 0.48 (95% CI: 0.26 to 0.90), respectively.

Conclusion: This innovative, inclusive large-scale RCT highlights the potential of lifestyle interventions to improve pregnancy outcomes and underscores the importance of adherence and motivation. While the INTER-ACT intervention did not lower the composite outcome rate, those who maintained adherence either to the intervention or the follow-up showed significant benefits. Future trials should explore the impact of lifestyle interventions across diverse BMI ranges, particularly in the preconception and interpregnancy periods, and examine how to motivate participants to take a more active and aware role in their lifestyle choices.

Primary Outcomes of the INTER ACT study

	Intervention (N-193) n/N (%)	Control (N=197) n/N (%)	Odd ratio (95% CI)	P- value
Composite outcome	80/186	69/187	1.29 (0.85-1.96)	0.23
PIH	12/189	10/195	1.25 (0.53-2.98)	0.61
DM	19/187	16/192	1.24 (0.62-2.50)	0.54
CS	41/193	32/197	1.40 (0.83-2.32)	0.21
LGA	33/184	30/185	1.13 (0.66-1.94)	0.66



This table and forest plot represent the primary outcomes from the INTER-ACT Study following the second pregnancy. Diamond markers the odds ratios, with the 95% confidence intervals. Evaluated outcomes include Pregnancy-Induced Hypertension (PIH), Diabetes Mellitus (DM), Cesarean Section (CS), and Large for Gestational Age (LGA).

9 | Dysregulated Gene Expression in Placentas with Exposure to Persistent Maternal Socioeconomic Disadvantage

Greg E. Miller[1]; Lauren Keenan-Devlin[2]; Alexa A. Freedman[1]; Renee Odom-Konja[3]; Linda M. Ernst[3]; Steve Cole[4]; Ann EB Borders[2]
[1]Northwestern University, Chicago, IL; [2]Endeavor Health, Evanston Hospital, Evanston, IL; [3]Endeavor Health, Evanston, IL; [4]University of California, Los Angeles, Los Angeles, CAMA

1:30 PM - 1:45 PM

Objective: Persistent socioeconomic disadvantage is associated with many adverse health outcomes across the lifespan. One hypothesis is these risks start during gestation from hardship-related changes in placental gene expression. Studies in animal models have yielded results consistent with this hypothesis, but it has yet to be tested in large, diverse human cohorts.

Study Design: 605 patients with singleton pregnancies were recruited during their first trimester. Socioeconomic status (SES) data was collected using a standardized interview, and disadvantage was quantified by educational attainment and occupational prestige. Biopsies from distinct cotyledons of the placenta's chorionic villous layer were collected < 2 hours from delivery and used for genome-wide expression profiling via RNA-Seq on an Illumina NovaSeq X Plus. Data were analyzed with linear mixed models, adjusted for maternal age, race, ethnicity, BMI, obstetric risk, delivery mode, and fetal sex.

Results: 449 participants delivered at term and had complete data. At a threshold of 1.50 fold-change, analyses identified 1,859 transcripts that were differentially expressed across the 4 standard deviation range of SES. 1,311 transcripts were upregulated in conjunction with SES disadvantage and 548 were downregulated. Bioinformatic analyses yielded indications that SES disadvantage was associated with upregulated pro-inflammatory transcriptional pathways (those anchored by GATA, STAT, MAF, and IRF) in fetal myeloid cells, but also with downregulation of trophoblast transcriptional pathways involved in fetal organ maturation (those anchored by PBX, c-ETS, ELK1, PAX, and CREB).

Conclusion: These results suggest molecular correlates of maternal disadvantage during pregnancy are present in mRNA from the placenta chorionic villous layer demonstrating SES disparities in placental biology. Multiple dimensions of placental gene expression were dysregulated with exposure to SES disadvantage. Future work should focus on interventions that reduce SES disadvantage before and during pregnancy, and evaluate their impact on pregnancy outcomes and placental biology.

10 | Association Between Maternal-Fetal Medicine Physician Density and Adverse Pregnancy Outcomes

Tetsuya Kawakita; Rula Atwani; Lindsay S. Robbins; George R. Saade
Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA

1:45 PM - 2:00 PM

Objective: To examine the association between maternal-fetal medicine (MFM) physician density and adverse pregnancy outcomes at the state level.

Study Design: This was a cross-sectional analysis of publicly available state-level birth certificate data from 2018 to 2021. The number of MFM physicians per state each year was obtained from the American Medical Association database. The primary exposure was based on the density of MFM per state categorized by quartiles of the ratio of MFM in each state per 100,000 live births (low, fair, moderate, and high). Our primary outcome was maternal mortality rate during pregnancy and up to 42 days postpartum (MMR). Our secondary outcomes were maternal mortality rate up to 365 days postpartum, stillbirth rate, preterm birth rate, and cesarean delivery rate. We calculated incident rate ratios (IRR) with 95% confidence intervals (95%CI) using generalized estimating equations with Poisson distribution and exchange-correlation structure, accounting for confounders.

Results: The median state MFM density was 31.6 MFM per 100,000 births (interquartile 21.9-42.5). Of 14,803,520 births included in this analysis, 1,683,691 (11.4%) were in low MFM-density states, 5,193,402 (35.1%) births were in fair MFM-density states, 4,557,005 (30.8%) were in moderate MFM-density states,

and 3,369,422 (22.8%) were in the high MFM-density states. There was an inverse relationship between the MFM density in the state and its MMR per 100,000 live births (Figure 1). Compared to the low MFM-density states, high MFM-density states were associated with a lower risk of MMR, PRM, and preterm birth (Table 1). There were no significant differences in outcomes between low MFM-density states and fair or moderate MFM-density states except for stillbirths being lower in the moderate MFM-density states compared to the low MFM-density states.

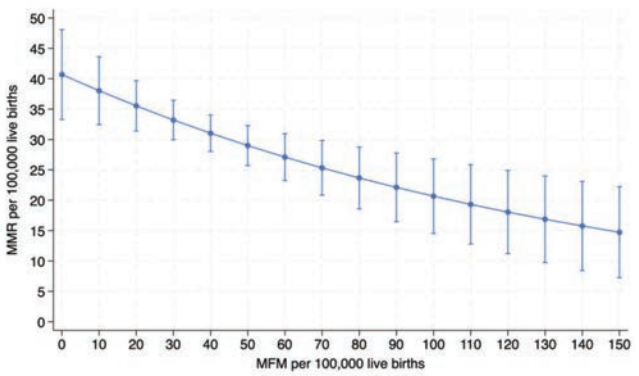
Conclusion: High MFM-density states have a decreased risk of maternal mortality compared to low MFM-density states, suggesting an association between MFM physician availability and decreased maternal mortality.

Table 1. Outcomes

	Low MFM density	Fair MFM density		Moderate MFM density		High MFM density	
	n	n	IRR (95%CI)	n	IRR (95%CI)	n	IRR (95%CI)
Total delivery N (%)	n=1,683,691	n=5,193,402		n=4,557,005		n=3,369,422	
MMR n (per 100,000)	668 (39.7)	1623 (31.3)	0.89 (0.69-1.14)	1302 (28.6)	0.88 (0.70-1.10)	932 (27.7)	0.74 (0.59-0.93)
PRM n (per 100,000)	896 (53.2)	2231 (43.0)	0.90 (0.73-1.10)	1977 (43.4)	0.92 (0.76-1.12)	1405 (41.7)	0.79 (0.65-0.95)
Stillbirth n (per 1,000)	33504 (19.9)	48899 (9.4)	0.68 (0.31-1.46)	30951 (6.8)	0.53 (0.29-0.98)	63010 (18.7)	1.18 (0.66-2.10)
Preterm birth, n (%)	181393 (10.8)	534269 (10.3)	0.96 (0.90-1.01)	462610 (10.2)	0.96 (0.91-1.02)	326276 (9.7)	0.88 (0.84-0.93)
Cesarean delivery, n (%)	534726 (31.8)	1698570 (32.7)	0.97 (0.93-1.02)	1395022 (30.6)	0.96 (0.91-1.01)	1076158 (31.9)	0.98 (0.93-1.04)

IRR: adjusted for race, ethnicity, insurance, chronic hypertension, and pregestational diabetes (low MFM density as referent).
Abbreviations: IRR (incidence rate ratio); MMR (maternal mortality rate during pregnancy and up to 42 days postpartum); PRM (pregnancy-related mortality, defined as maternal mortality rate during pregnancy and up to 365 days postpartum)

Figure 1. Maternal mortality rate according to the density of maternal-fetal medicine physicians.



Maternal-Fetal Medicine (MFM); MMR (maternal mortality rate per 100,000 live births)
Blue bars represent 95% confidence intervals.
Outputs were obtained from the generalized estimating equations.

11 | Black Maternal Morbidity and its Association with Systemic Racism

Sebastian Z. Ramos; Meghan I. Short; Erika F. Werner; Chloe E. Bird; Ndidiamaka Amutah-Onukagha; Michael B. Siegel
Tufts University School of Medicine, Boston, MAMA

2:00 PM - 2:15 PM

Objective: To explore the relationship between systemic racism and Black maternal morbidity using the Systemic Racism Index (SRI), a county-level measure that captures disparities in incarceration, education, economic status, employment, and segregation in Black versus White populations in the United States.

Study Design: Using CDC Vital Statistics data from 2019-2021, a Composite Adverse Maternal Outcome Score (CAMOS)—which included blood transfusion, ruptured uterus, unplanned hysterectomy, and intensive care unit admission—was calculated for Non-Hispanic Black (NHB) and Non-Hispanic White (NHW) patients. The Systemic Racism Index and its relationship to rates of morbidity in NHB and NHW patients were studied. Mixed-effects logistic regression models were fit, adjusting for individual level clinical factors and county-level community vulnerability using the CDC's Social Vulnerability Index (SVI).

Results: There were 5,703,315 births for which covariates were measured in the 1,181 counties with an SRI score. The CAMOS rate in NHB patients was 7.6 vs 4.9 per 1000 in the NHW population. After adjusting for overall community vulnerability using the Social Vulnerability Index and individual level clinical and demographic factors, there was a 20% increase in CAMOS rate in NHB patients for each standard deviation increase in the SRI factor score (aOR 1.20, 95% CI 1.14, 1.26) and an 11% increase for NHW patients (aOR 1.11, 95% CI 1.06-1.15).

Conclusion: There is a significant relationship between systemic racism, as measured by the Systemic Racism Index, and maternal morbidity disparity in NHB and NHW patients. Even after controlling for individual risk factors and overall community vulnerability, there was a strong correlation between the Systemic Racism Index and maternal morbidity, suggesting a mechanism separate from resource allocation and access to a more deeply entrenched system that perpetuates inequity. These findings underscore the profound impact of systemic racism on maternal health outcomes and highlight the need for addressing structural inequalities to reduce racial disparities in maternal morbidity.

Table 1. Results of Mixed-effects Logistic Regression Analyses Using Random Intercept Modeling to Study the Relationship Between Systemic Racism Factor Scores and Non-Hispanic Black and Non-Hispanic White Composite Adverse Maternal Outcome Score Rates in Counties with > 1000 Black residents, 2019-2021 (N= 5,703,315 births, 1,181 counties)

Outcome Variable	Regressors	Percentage Change in CAMOS risk for Each Standard Deviation Increase in Systemic Racism Factor Score	95% CI	p-value
Black CAMOS rate	Multivariate*	20.1%	14.2% to 26.3%	<0.001
White CAMOS rate	Multivariate*	10.7%	6.3% to 15.3%	<0.001
Individual Level Regressors				
Advanced maternal age (≥35 years)		24.8%	21.0% to 28.7%	<0.001
Nulliparity		1.1%	-1.8% to 4.0%	0.464
Number of prenatal visits		0.56%	0.45% to 0.68%	<0.001
Multiple gestations		142%	130% to 155%	<0.001
TOLAC		16.6%	10.9% to 22.5%	<0.001
SVI		-10.1%	-22.6% to 4.4%	0.162

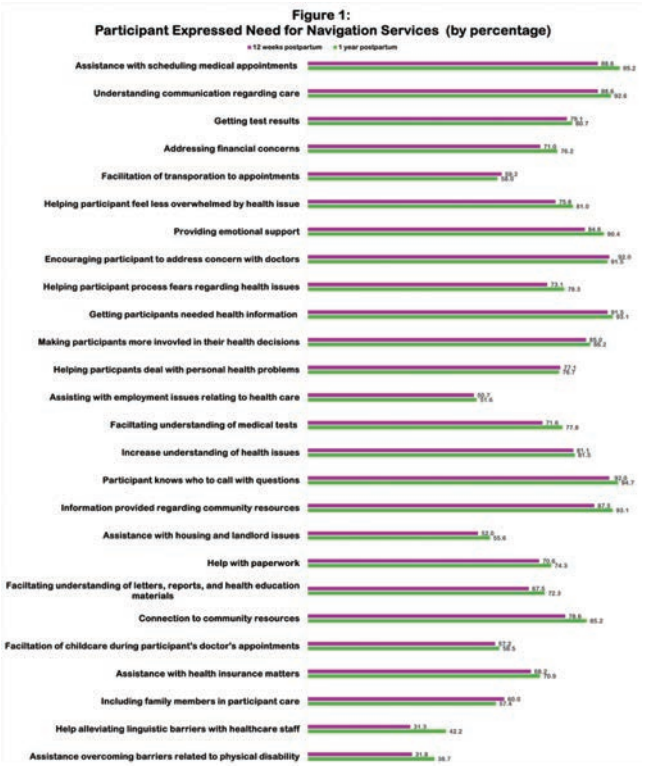
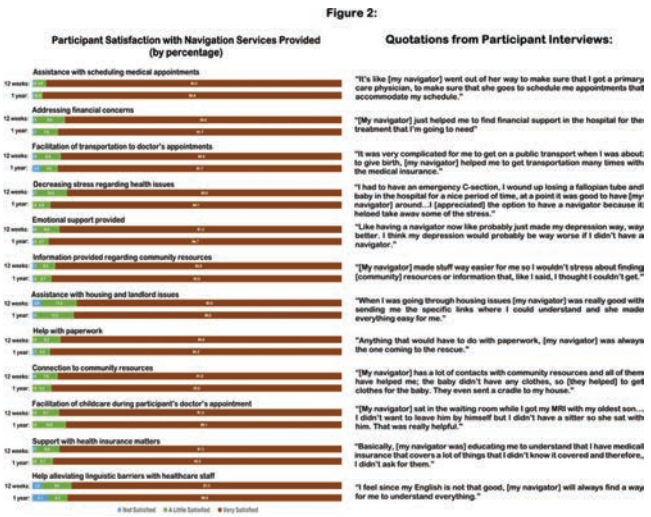
12 | Low-income Birthing Individuals' Need for and Satisfaction with Services in a One-Year Postpartum Navigation Program

Maya J. Daiter[1]; Laura Diaz[1]; Hannah M. Green[1]; Ying Cheung[1]; Viridiana Carmona-Barrera[1]; Brittney R. Williams[1]; Charlotte M. Niznik[1]; Joe M. Feinglass[1]; William A. Grobman[2]; Lynn M. Yee[1]
[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]The Ohio State University, Columbus, OH

2:15 PM - 2:30 PM

Objective: Patient navigation seeks to reduce barriers to care and to overcome adverse social determinants of health. Navigating New Motherhood (NNM) is a trial in which low-income individuals are randomized to receive postpartum navigation for one year. We aimed to understand what services were most needed by participants along with satisfaction with the navigation program.
Study Design: This is a mixed methods analysis of data from NNM participants randomized to navigation. All navigated participants completed study visits at 4-12-weeks ("12 weeks") and 11-13 months ("1 year") postpartum. Visits included the 26-item "Patient Satisfaction with Navigation-Logistical (PSN-L)" measure, which queried about services needed and-for those services that were needed–satisfaction with the services received; the PSN-L is scored from -3.31 to +3.43 (higher scores indicate greater satisfaction). A randomly-selected sample of navigated participants also underwent in-depth qualitative interviews at 4-6 and 11-13 months postpartum. Transcripts from both interviews, which were focused on perception and utilization of navigation services, were analyzed via the constant comparative method. Themes were identified using a concurrent triangulation design using survey and interview data.
Results: Of 203 navigated participants, 201 completed the PSN-L at 12 weeks and 189 at 1 year. On nearly every PSN-L item at both time points, >50% of participants indicated need for navigation service, with similar types of needs at both time points (Fig 1). The mean PSN-L scores were 3.13 (SD 0.62) at 12-weeks and 3.14 (SD 0.59) at 1-year postpartum, revealing high satisfaction overall. Similarly, more than 90% of participants reported on the PSN-L that they were "very satisfied" with most domains (20/26 at 12 weeks and 23/26 at 1 year) of navigation services provided. These findings were corroborated by thematic analysis (Fig 2).
Conclusion: While most participants expressed that they needed many services to optimize their health, they reported they were very satisfied with the capacity of patient navigation to address those needs.





13 | Impact of WIC Enrollment on Adverse Maternal and Neonatal Adverse Outcomes in Medicaid Populations

Reetam Ganguli[1]; Stephen Wagner[2]
[1]Elythea, San Jose, CA; [2]Beth Israel Deaconess Medical Center, Boston, MA

2:30 PM - 2:45 PM

Objective: To evaluate the impact of the Women, Infants, and Children (WIC) program enrollment on severe maternal morbidities and neonatal adverse outcomes among pregnant Medicaid recipients from 2018 to 2022.
Study Design: A retrospective cohort study was conducted using data from the CDC National Vital Statistics System to compare maternal and neonatal outcomes between Medicaid-insured pregnant women enrolled in WIC (n = 4,552,866) and

those not enrolled in WIC (n = 2,948,168). Multivariate logistic regression was used to calculate adjusted odds ratios (aORs) with 95% confidence intervals (CIs) for various outcomes, adjusting for age, ethnicity, marital status, education status, and birth order.

Results: Enrollment in WIC was associated with a statistically significant reduction in several adverse outcomes. Women enrolled in WIC had a lower risk of postpartum hemorrhage (aOR 0.93, 95% CI [0.91-0.95], p < 0.001), unplanned hysterectomy (aOR 0.98, 95% CI [0.92-1.05], p = 0.014), and admission to the ICU (aOR 0.86, 95% CI [0.84-0.89], p < 0.001). Neonatal outcomes also improved among WIC participants, with reduced odds of NICU admission (aOR 0.90, 95% CI [0.90-0.91], p < 0.001) and low birth weight (aOR 0.91, 95% CI [0.91-0.92], p < 0.001). Furthermore, WIC enrollment was associated with higher rates of breastfeeding at discharge (aOR 0.84, 95% CI [0.84-0.84], p < 0.001).

Conclusion: Medicaid-insured pregnant women enrolled in the WIC program demonstrated a significantly lower risk of adverse maternal and neonatal outcomes compared to those not enrolled in WIC. Accessible and innovative outreach and engagement strategies to improve WIC enrollment among pregnant Medicaid members may be vital in reducing preventable preterm labor, NICU admissions, low birth weight infants, and severe maternal morbidities among health insurance plans.

Effect of WIC Enrollment on Adverse Maternal and Neonatal Outcomes Across Pregnant Medicaid Women

Sample Sizes: 4,552,866 on WIC and 2,948,168 not on WIC

Outcome	Odds Ratio	95% CI Lower	95% CI Upper	p-value
Severe Postpartum Hemorrhage	0.928574	0.909872	0.94766	<0.001
Unplanned Hysterectomy	0.979955	0.917968	1.046128	0.014
Admission to ICU	0.863404	0.835527	0.892211	<0.001
Maternal Transfer During Labor	0.814999	0.799727	0.830562	<0.001
Admission to NICU	0.904316	0.899979	0.908674	<0.001
Low Birth Weight Infant	0.91139	0.90693	0.915871	<0.001
Infant Breastfed at Discharge	0.840827	0.837702	0.843964	<0.001
Cesarean Section	1.121718	1.118119	1.125328	<0.001

14 | Homicide and Suicide: The Leading Cause of Maternal Death, and How Firearm Legislation Affects It

Hooman A. Azad[1]; Dana Goin[2]; Lisa Nathan[3]; Dena Goffman[1]; Uma M. Reddy[4]; Danielle Laraque-Arena[2]; Mary E. D'Alton[1]
[1]Columbia University Medical Center, New York, NY; [2]Columbia University Mailman School of Public Health, New York, NY; [3]Columbia University Irving Medical Center, New York, NY; [4]Columbia University, New York, NY

2:45 PM - 3:00 PM

Objective: In medical training, the dogma is this: the leading causes of maternal mortality are bleeding, infection, hypertension, and cardiovascular disease. This is only true when violence against women is excluded. We present the leading causes of death in pregnancy, compare violent death rates in pregnant and non-pregnant people, and investigate firearm legislation's association with these deaths.

Study Design: Case-level data on deaths in US women ages 15-44 (2005-2022) were collected using CDC's Limited Mortality File. Cause of death and pregnancy status were identified by *ICD-10* codes. A "pregnancy checkbox" identified additional deaths in pregnancy. We include the first 42 postpartum days in defining "pregnancy," consistent with national definitions.

We present the leading causes of death in pregnancy. We compare violent death rates among pregnant women and non-pregnant controls. A state-level, cross-sectional, ecologic panel study using negative binomial regressions is used to identify associations between domestic violence (DV) firearm laws and violent deaths in pregnancy.

Results: In 18 years, 20,421 pregnant women died. 2,293 were violent deaths (11%); of these, 1,407 (61%) were homicides and 886 (39%) were suicides. 1,261 violent deaths involved firearms (55%). Violence was the most common cause of death in pregnancy (Figure 1A); the incidence doubled from 2005-2022. Violent death was more frequent in pregnant women than non-pregnant controls (3.2 v 1.2 deaths per 100,000 population) (Figure 1B).

DV laws were associated with reductions in homicide and firearm death in pregnancy (range, 17-32%). Laws requiring relinquishment of firearms among DV perpetrators showed the strongest associations with reduced death rates (Table 1).

Conclusion: More pregnant women die from violence than any medical cause in the US, at higher rates than their non-pregnant counterparts. Firearm legislation is associated with fewer deaths, suggesting lethal means restriction may help curb this alarming trend. As maternal mortality rates rise, addressing violence should be a focus of clinicians and policymakers alike.

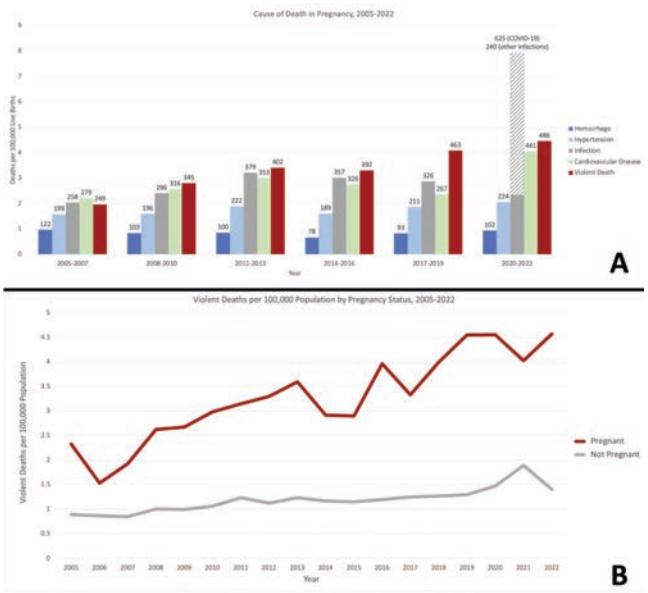


Figure 1: Death rates per 100,000 population are depicted in both panels.
Panel A: Death counts listed above each bar, with 3-year groupings for visual clarity. Covid-19 deaths are depicted separately as a hashed overlay.
Panel B: Population is considered live births for pregnancy and age/sex-specific population for non-pregnant individuals. (*Sources: CDC Natality File, U.S. Census Population Estimates*)

Table 1. Associations between various firearm laws addressing firearm ownership and possession by perpetrators of domestic violence and certain causes of death in pregnancy. Incidence rate ratios and 95% confidence intervals are presented.

		Manner of Death in Pregnancy		
		Violent Death	Homicide	Firearm Death
State-Level Firearm Legislation		IRR [95% CI]		
Misdemeanor Conviction	Ownership Prohibited	0.92 [0.80 - 1.06]	0.88 [0.76 - 1.03]	0.87 [0.74 - 1.03]
	Relinquishment Required	0.88 [0.75 - 1.04]	0.82 [0.67 - 1.01]	0.90 [0.72 - 1.12]
Restraining Order *(spouse/cohabitant only)*	Ownership Prohibited	0.93 [0.81 - 1.07]	0.83 [0.71 - 0.97]*	0.83 [0.70 - 0.97]*
	Relinquishment Required	0.93 [0.80 - 1.07]	0.83 [0.71 - 0.98]*	0.77 [0.65 - 0.92]*
Restraining Order *(any partner)*	Ownership Prohibited	0.86 [0.74 - 1.00]*	0.75 [0.63 - 0.89]*	0.72 [0.60 - 0.87]*
	Relinquishment Required	0.86 [0.71 - 1.04]	0.79 [0.62 - 0.99]*	0.68 [0.53 - 0.88]*
Stalking Offense	Ownership Prohibited	0.89 [0.78 - 1.02]	0.88 [0.76 - 1.02]	0.89 [0.76 - 1.05]
Removal of firearms required by law enforcement responding to domestic violence-related incident		0.77 [0.67 - 0.89]*	0.85 [0.72 - 1.00]*	0.80 [0.67 - 0.95]*

Negative binomial models are used to account for overdispersion. All models control for temporal trends, regional trends, and state-level firearm ownership using a validated proxy (Source: Siegel *et al., Inj. Prev.*, 2014).

*Asterisk and shading demonstrate statistical significance, $p < 0.05$.

15 | Elimination of a Threefold Racial Disparity in Aspirin Recommendation Using Integrated Clinical Decision Support

Melissa S. Wong[1]; Rommy Coutelin Johnson[2]; Karla Gonzalez[1]; Ojiugo Onwumere[3]; Kristin Parrinella[4]; Camelita Thrift[3]; Samira Torna[1]; Matthew Wells[1]; Kimberly D. Gregory[3]
[1]Cedars-Sinai Medical Center, Los Angeles, CA; [2]Cedars-Sinai, Los Angeles, CA; [3]Cedars Sinai Medical Center, Los Angeles, CA; [4]Kaiser-Permanente, Los Angeles, CA

3:00 PM - 3:15 PM

Objective: Low dose aspirin (LDA) for preeclampsia prevention is under-prescribed and Black pregnant people are disproportionately affected. Clinical decision support (CDS) embedded in the electronic health record (EHR) has been shown to improve compliance. The aim of this study was to evaluate whether the presence of a CDS tool (1) increased recommendation of LDA and (2) reduced the racial disparity.

Study Design: We performed a pre/post implementation study comparing two time periods: Oct 2019-Mar 2020 and Oct 2023-Mar 2024; parallel months were chosen to limit seasonal changes. We used manual chart review to assess patient factors (Table 1) and to identify LDA recommendation. Our primary outcome was the rate of LDA recommendation (documented discussion or order placed). We assessed rates of hypertensive disorders of pregnancy, obstetric and neonatal outcomes, and performed subgroup analysis for Black patients to determine whether there were differences in LDA recommendation.

Results: There were 677 patients in the pre-CDS and 649 in the post-CDS period; similar proportions met criteria to receive LDA (Table). A significantly greater proportion received LDA after the implementation of the CDS (pre-23.5%; post-78.1% p = < .0001) (Figure).

In the pre-CDS period, Black race was associated with even fewer recommendations (Black [10.4%] vs. non-Black [26.5%] p = 0.02). After implementation of the CDS, the racial disparity was eliminated (Black [82.1%] vs. non-Black [77.6%]), p = 0.54).

There were no differences in the rates of hypertensive disorders of pregnancy, obstetric or neonatal outcomes.

Despite CDS triggering for only 109 (40%) of those who met criteria, the LDA use increased for all meeting criteria (even those for whom the CDS did not trigger, e.g., a patient already on LDA).

Conclusion: The use of CDS for LDA prophylaxis tripled LDA use, eliminated a threefold racial disparity, did not increase adverse outcomes, and increased LDA use even for those for whom the CDS did not trigger. This suggests physician learning and behavior change contributed to increased compliance in addition to the CDS.

Figure 1: Implementation of clinical decision support (CDS) resulted in a significant increase in aspirin use and eliminated the racial disparity in recommendation.

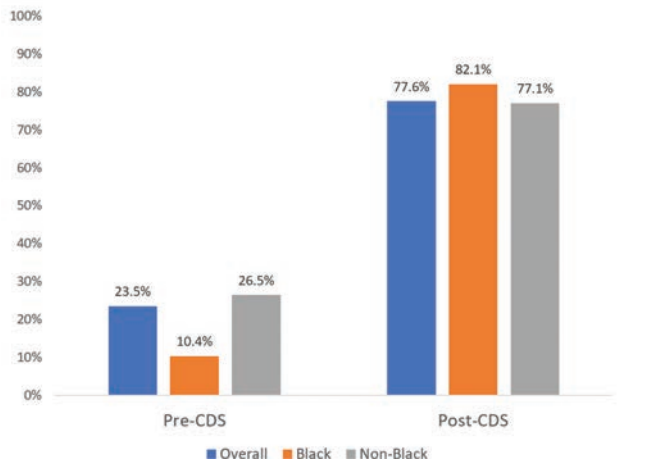

Table 1: Patient characteristics, obstetric, and neonatal outcomes in the pre- and post-implementation time periods among those for whom aspirin was indicated.

	Pre-CDS (n = 263)	Post-CDS (n = 277)	P

16 | Severe Maternal Morbidity Differences by State Medicaid Expansion and Abortion Coverage: National Database Analysis, 2014-2022

Ishana Shetty; Mark C. Valentine; Mark Hoofnagle; Jennifer Reeves; David L. Eisenberg
Washington University, St. Louis, MO

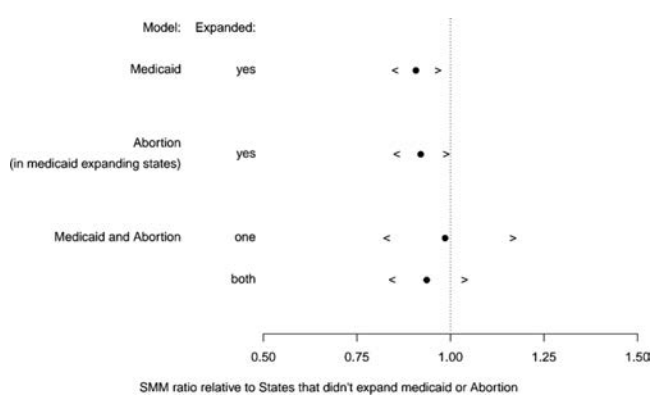
3:15 PM - 3:30 PM

Objective: The objective of this study was to compare the rate of severe maternal morbidity (SMM) state by state stratified by whether that state's Medicaid 1) underwent expansion under the Affordable Care Act (ACA) and 2) had coverage of abortion care beyond Hyde requirements.

Study Design: This was a retrospective cohort study using data on state level SMM rates (reported per 10,000 in-hospital deliveries) from 2014–2022 using the publicly available Healthcare Cost and Utilization Project (HCUP) Fast Stats dataset. We used a negative binomial generalized linear model to analyze SMM as a function of year and state with separate analysis by Medicaid expansion under the ACA and state Medicaid coverage of abortion care beyond Hyde requirements. Categorization of states was based on Kaiser Family Foundation designation.

Results: The rate of SMM was significantly reduced in states expanding Medicaid (0.907, 95% CI 0.852-0.967). Among the states that expanded Medicaid, the rate of SMM was further reduced in states that also expanded abortion coverage (0.920, 95% CI 0.856-0.988). When SMM was modeled as a function of state, year, and Medicaid/abortion expansion (i.e. neither, one, or both), we saw a decrease in SMM for expanding either Medicaid or abortion (0.985, 95% CI 0.829-1.16) and a larger decrease for expanding both (0.936, 95% CI 0.844-1.038), though neither trend reached significance.

Conclusion: The rate of SMM was significantly reduced in states that expanded Medicaid under the ACA compared to states that did not. Medicaid expanded states that additionally provided abortion coverage under Medicaid saw further reductions in the rate of SMM. When modeled simultaneously, Medicaid expansion and abortion expansion both trend towards decreased SMM, with expansion of both showing the largest decrease, although this did not reach significance in this data set. These findings add to growing literature that national policies like abortion restriction and Medicaid expansion significantly impact maternal health outcomes.



17 | Elevated Micro- and Nanoplastics Detected in Preterm Human Placentae

Enrico R. Barrozo[1]; Marcus A. Garcia[2]; Michael D. Jochum, Jr.[1]; Rui Liu[2]; Alex Nihart[2]; Eliseo Castillo[2]; Eliane El Hayek[2]; Jorge Gonzalez-Estrella[3]; Lori Showalter[1]; Cynthia Shope[1]; Melissa A. Suter[1]; Matthew J. Campen[2]; Kjersti M. Aagaard[4]
[1]Baylor College of Medicine and Texas Children's Hospital, Houston, TX; [2]University of New Mexico, Albuquerque, NM; [3]Oklahoma State University, Stillwater, OK; [4]Boston Children's Hospital, Division of Fetal Medicine and Surgery, Boston, MA; HCA Healthcare and HCA Healthcare Research Institute, Nashville, TN; HCA Texas Maternal Fetal Medicine, Houston, TX; Baylor College of Medicine and Texas Children's Hospital, Houston, TX, Boston, MA

3:30 PM - 3:45 PM

Objective: We and others recently demonstrated the widespread presence of micro- and nanoplastics (MNPs) in the environment and their documented absorption by humans, with deposition and bioaccumulation in the placenta. In the current study, we aimed to test the hypothesis that placental MNP concentrations and species differ between term and preterm birth.

Study Design: We analyzed human placentae collected at term (n = 100) and preterm (< 37 weeks gestation; n = 75). Placental specimens were subjected to pyrolysis-gas chromatography/mass spectrometry (Py-GC/MS) to quantify twelve types of MNPs: polyethylene (PE), polypropylene (PP), acrylonitrile butadiene styrene (ABS), styrene-butadiene rubber (SBR), polymethyl methacrylate (PMMA), polycarbonate (PC), polyvinyl chloride (PVC), polyurethane (PU), polyethylene terephthalate (PET), nylon 6 (N6), and nylon 66 (N66). For rigor & reproducibility, duplicate specimens were run & quantified relative to standards.

Results: Highly sensitive Py-GC/MS demonstrated significantly higher levels of PC, PVC & N66 MNPs in preterm placentae compared to term (Fig 1A; q = 0.002, 0.006, 0.013, respectively, by mixed-effects model with Sidak's multiple corrections). Moreover, despite shorter gestations, cumulative MNP concentrations were higher in preterm placentae (Fig 1B; preterm mean 203.0 μg/g tissue ± 19.41 SEM vs term mean 129.8 μg/g tissue ± 14.16 SEM, p< 0.0001 Mann-Whitney). Stratified analyses showed significant differences by fetal sex (Fig 1C) and race/ethnicity (Fig 2A) (q< 0.05), and a significant correlation between social deprivation indices (SDI) and MNP levels (Fig 2B). Total MNP levels in placentae were 121.9 times higher than those reported in human blood (p< 0.0001 Mann-Whitney).

Conclusion: Our findings suggest that MNPs accumulate in placentae from preterm births. Given the established link between MNPs and inflammation, we speculate that MNP bioaccumulation may play a role in modulating inflammatory preterm birth. These novel findings underscore the importance of prioritizing mechanistic studies to explore how MNPs impact fetal development and pregnancy outcomes.

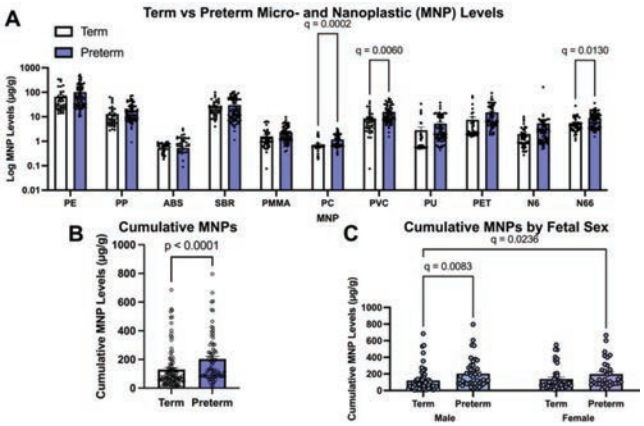


Figure 1. Despite shorter gestations, MNPs significantly bioaccumulate in placentae from preterm deliveries. Human placentae delivered at term (n=100) or preterm (n=75) were analyzed by Py-GC/MS to quantify 12 MNPs species. **A,** MNP data stratified by delivery group and visualizing all MNP types. Significance was determined by mixed-effects models with Sidak's multiple corrections test defined by an adjusted p-value (q) < 0.05. **B,** Cumulative MNPs per placenta stratified by term versus preterm. Significance was determined by Mann-Whitney test comparing ranks defined as p < 0.05. **C,** Cumulative MNPs stratified by fetal sex and term or preterm.

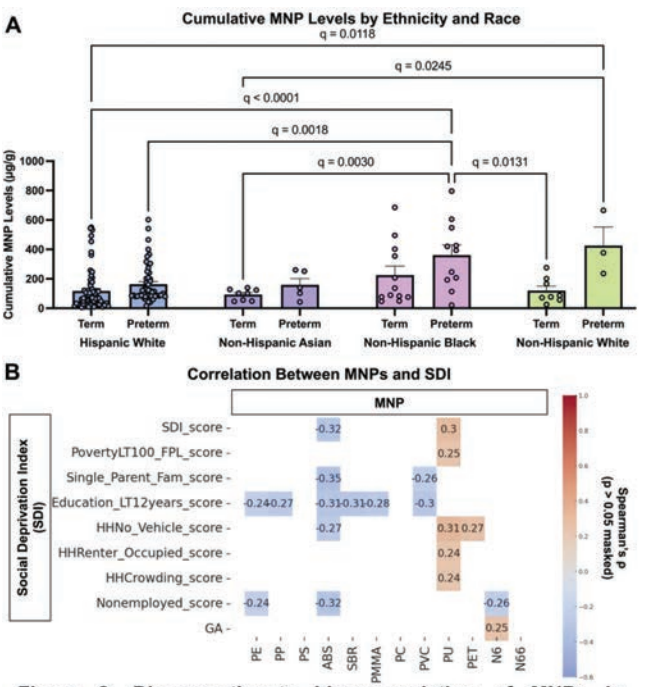

Figure 2. Disproportionate bioaccumulation of MNPs in placentae from preterm and term births in association with social deprivation indices (SDI). A, Cumulative MNP levels were compared by term versus preterm and stratified by ethnicity and race. Significance was determined by mixed-effects models with Sidak's multiple corrections test defined by q < 0.05. **B,** SDI was determined by Zip Code at delivery and compared to MNP levels by Spearson's correlation analysis. Insignificant comparisons (p > 0.05 were masked for clarity.

18 | Severe Maternal Morbidity among Asian and Pacific Islander Parturients in a Contemporary Northern California Cohort

Shalila A. de Bourmont[1]; Janet Alexander[2]; Baiyang Sun[2]; Erica P. Gunderson[2]; Mara Greenberg[1]

[1]Kaiser-Permanente Northern California, Oakland, CA;
[2]Kaiser-Permanente Northern California, Pleasanton, CA

3:45 PM - 4:00 PM

Objective: To compare rates and types of severe maternal morbidity (SMM) among Asian, Native Hawaiian/Pacific Islander (NHPI), and White pregnant individuals in a large integrated health care delivery system.

Study Design: Retrospective cohort study of singleton gestations delivered ≥ 20 weeks in Kaiser Permanente Northern California (KPNC) 2009-2019, self-identified as Asian, NHPI or White. SMM was defined as presence at least 1 of 21 indicators per CDC criteria. Maternal characteristics at time of entry to prenatal care and obstetric comorbidities were compared between groups with White as the referent group. Absolute rates (cases per 10,000 births) of SMM and each SMM indicator at delivery hospitalization were compared between groups using chi-square statistics and logistic regression to estimate the adjusted relative risks for Asian and NHPI relative to the White subgroup.

Results: Among the 164,530 singleton deliveries analyzed, groups significantly differed in all maternal characteristics and obstetric comorbidities. NHPI patients were more likely to have higher rates of chronic and gestational hypertension, preeclampsia and pregestational diabetes (Table 1). SMM rates at delivery were significantly higher for NHPI (284/10,000) and Asian (258/10,000) subgroups than for the White referent group (p< 0.001,Table 2). Rates of SMM indicators differed between groups with higher rates of eclampsia, pulmonary edema/heart failure, shock, hysterectomy and blood products transfusion among NHPI; and higher rates of sepsis and DIC among Asian patients compared to White patients (all indicators p< 0.005, Table 2). Adjusting for covariates, the risk of SMM was higher for NHPI (RR 1.6; 95% CI 1.22-2.1) and Asian (RR 1.41; 95% CI 1.31-1.51) groups compared to the White referent group.

Conclusion: In this large cohort of NHPI, Asian and White patients, risk of SMM was highest for NHPI. Differences in rates of absolute SMM and SMM indicators were significant between groups highlighting the importance of disaggregating them in research and clinical settings to tailor care and reduce the disproportionately high rates of SMM.

19 | Aberrant Fetal Growth in ARRIVE Trial

Bonnie L. Hermann[1]; Cassidy A. O'Sullivan[2]; Fabrizio Zullo[3]; Suneet Chauhan[4]; Hector M. Mendez-Figueroa[5]; On behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units (MFMU) Network

[1]UTHealth Houston, Houston, TX; [2]Christiana Care Health System, Newark, DE; [3]University of Rome La Sapienza, Rome, Lazio; [4]Christiana Care, Newark, DE; [5]McGovern Medical School at UTHealth, Houston, TX

1:30 PM - 1:45 PM

Objective: The primary objective was to compare the rate of cesarean delivery (CD) among individuals with newborns with aberrant growth (i.e. small- or large-for gestational age; SGA or LGA) who were induced versus expectantly managed in the ARRIVE trial. The secondary objectives were to compare the rate of hypertensive disorders of pregnancy (HDP), composite neonatal and maternal adverse outcome (CNAO, CMAO). We hypothesized that the rate of CD would be lower among those with newborns with aberrant growth who were induced versus those expectantly managed.

Study Design: A secondary analysis of the ARRIVE trial was performed, with the inclusion criteria of known gestational age and birthweight (BW). Newborns were classified as SGA (BW < 10%) or LGA (BW > 90%), using the nomogram by Alexander et al. CNAO and CMAO are defined in the Table. Relative risks (RR), 95% confidence intervals (CI) and number needed to treat (NNT) were calculated.

Results: The rate of aberrant growth was 14.0% (430/3,059) in the induced group and 13.9% (423/3,037) in the expectantly managed group (p = 0.17). CD rate among those with SGA or LGA newborns was significantly lower for those induced (21.6%) vs those expectantly managed (28.6%; RR 0.75, 95% CI 0.58-0.99). HDP also differed significantly between the two groups (9.7% vs 16.8%; RR 0.58; 95% CI 0.40-0.85).The NNT for induction to decrease the rate of CD and HDP among SGA or LGA was 14. The rate of CNAO was similar among the two groups: 7.2% in the induced vs. 7.7% in the expectantly managed group. Likewise, the CMAO—22.6% in the induced group versus 22.3% in the expectantly managed group—did not differ between the groups (p = 0.91; Table).

Conclusion: Among low-risk pregnancies with either SGA or LGA, induction at 39 weeks, compared to expectant management, was associated with 25% reduction in the rate of cesarean delivery and 42% reduction in hypertensive disorder, albeit with no difference in composite neonatal or maternal adverse outcomes. This finding provides support for induction of labor at 39 weeks especially for individuals with suspected neonatal aberrant growth.

Table 1. Aberrant growth among induced versus expectantly managed in ARRIVE Trial

	SGA/LGA & Induced (N=430)	SGA/LGA & Expectant Mx (N=423)	P Value	Relative Risk (95% CI)

*Consisted of any of the following: clavicular, skull or other fracture, brachial plexus palsy, other neurologic injury, facial nerve palsy retinal hemorrhage
Bolded if significantly different

20 | Decreased Neuraxial Morphine Dose to Reduce Opioid Side Effects and use After Cesarean Delivery RCT

Ayodeji Sanusi[1]; Yumo Xue[2]; Kevin S. Shrestha[2]; Ayamo Oben[3]; Hanna Hussey[2]; Annalese Neuenschwander[2]; Michelle Tubinis[2]; Mark Powell[2]; Alan T. Tita[2]; Casey Brian[4]

[1]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL; [2]University of Alabama at Birmingham, Birmingham, AL; [3]Maternal Fetal Consultants of Houston, Houston, TX; [4]West Virginia University, Morgantown, WV

1:45 PM - 2:00 PM

Objective: 1 in 300 opioid naive women become persistent opioid users after cesarean delivery (CD). Regional anesthesia with neuraxial morphine (NM) reduces opioid consumption after surgery. However, >70% of patients have pruritus or urinary retention with the standard 150mcg NM dose. We assessed if reduced NM dose decreases opioid side effects while preserving pain control at CD.

Study Design: RCT of 85 patients undergoing scheduled CD at a US tertiary center. Exclusion criteria were quadratus lumborum (QL) block refusal, preeclampsia, insulin-treated diabetes, placental abnormalities or opioid use disorder. Primary exposure was NM dose. The intervention was 50 mcg NM, bilateral ultrasound-guided QL block, spinal 12 mg bupivacaine and 15mcg fentanyl. The control group received 150 mcg NM and adjunctive therapies above. Scheduled acetaminophen/NSAIDS and additional opioid therapy for breakthrough pain were available for both groups. Primary outcomes were opioid use 24hours prior to discharge and opioid side effects (recorded medications or urinary retention). Regression models estimated risk ratios/differences for outcomes between groups. Analyses were intent to treat.

Results: Of 85 eligible patients, 43(50.6%) were randomized to 50mcg NM and 42(49.4%) to 150mcg NM. The mean age and BMI were 30.3 ± 5.6yrs and 36.0 ± 8.1kg/m^2, and >95% had a low transverse hysterotomy. There were no significant differences in baseline characteristics between groups. Lower NM dose did not significantly reduce opioid side effects (itching RR 0.55, 95% CI 0.27-1.10; nausea/vomiting RR 0.90, 95% CI 0.45-1.80), or use 24 hours prior to discharge (RD -1.63, 95% CI -8.47-5.21). Among secondary outcomes, total OMEs were similar between groups. However, intervention group had higher OMEs for parenteral opioids and in the first 24hours, as well as higher recovery room and day of surgery pain scores. No significant differences in other secondary outcomes were noted.

Conclusion: Lower NM dose was not associated with significant reductions in opioid side effects or use 24hours prior to discharge.

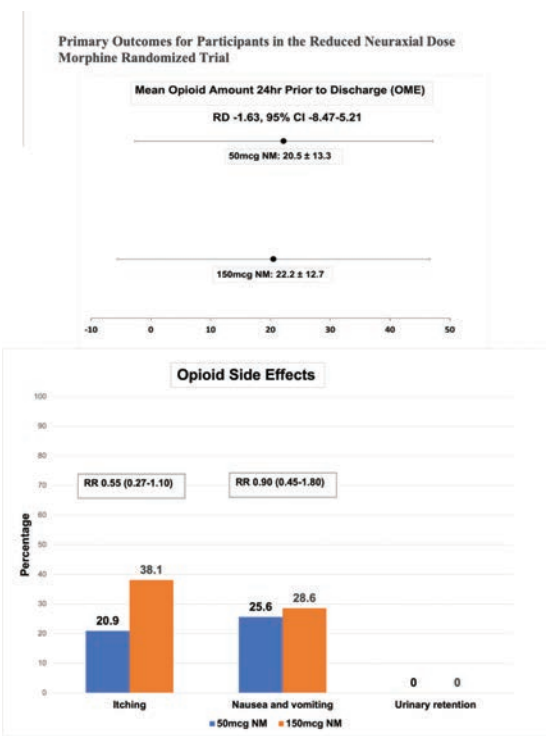

Table: Secondary Outcomes for Participants in the Reduced Neuraxial Dose Morphine Randomized Trial

2:00 PM - 2:15 PM

Objective: To ascertain if the proportion of time spent in Category II fetal heart rate tracing (FHRT) among singleton term (≥ 37 wks) laboring patients was associated with adverse outcomes.

Study Design: Obstetricians—blinded to maternal characteristics and outcomes—reviewed the available FHRT (120 minutes before delivery, at 20 min segments) for all deliveries within a 15-month period. Term, non-anomalous, singleton pregnancies who attempted labor were included. We excluded those that only had persistent category I or any segment with category III. Cohort was divided into 3 groups: Category II for < 33% of the time (Group 1), for 33-66% of the time (Group 2), and > 66% of the time (Group 3). The primary outcome was the rate of composite neonatal adverse outcomes (CNAO); the secondary outcomes were cesarean delivery (CD) for non-reassuring FHRT and

composite maternal adverse outcomes (CMAO). Adjusted odds ratio (OR) with 95% confidence intervals (CI) were calculated.!

Results: Among the 5,160 consecutive deliveries, 2,780 (54%) met the inclusion criteria. Of the 321,980 min of FHRT reviewed, 223,000 min (69%) were category II. Specifically, 10% were in Group 1, 26% in Group 2, and 64% in Group 3. Characteristics of FHRT which differed among the 3 groups were frequency of minimal variability, as well as variable, late and prolonged decelerations (Table 1). CD for non-reassuring FHRT differed significantly between the groups ($p < 0.01$). The rate of CNAO did not differ among the groups ($p = 0.72$), however the CMAO differed significantly ($p = 0.02$). Adjusted OR comparing category II for Group 1 vs. Group 2 and for Group 1 vs. Group 3 indicated that CD for NR-FHRT, CNAO and CMAO did not differ significantly among the groups (Table 2).

Conclusion: Among term deliveries, the majority of FHRTs are category II for over two-thirds of the total time during the last 120 min of labor. The proportion of time fetal heart rate tracing was in category II did not significantly influence cesarean delivery for non-reassuring tracing and adverse outcomes for the neonatal-maternal dyad.

22 | Tranexamic Acid Prophylaxis During Cesarean Delivery Among Patients with and Without Hypertension

Adam K. Lewkowitz[1]; Mariam Ayyash[2]; On behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units (MFMU) Network
[1]Women & Infants Hospital of Rhode Island and Alpert Medical School of Brown University, Providence, RI; [2]Columbia University Irving Medical Center, New York, NY

2:15 PM - 2:30 PM

Objective: Chronic and pregnancy-related hypertension (hereafter "HTN") are associated with increased risk of obstetric hemorrhage and blood transfusion. Should hemorrhage occur among those with HTN, the choice of uterotonics is constrained (methergine is contraindicated). Thus, while prophylactic use of tranexamic acid (TXA) during cesarean delivery (CD) does not alter rates of obstetric hemorrhage or blood transfusion overall, prophylactic TXA during CD may reduce these morbidities among patients with HTN. Our objective was to examine the effect of prophylactic TXA during CD on peripartum bleeding-related outcomes for patients by HTN status.

Study Design: This is a non-prespecified secondary analysis of a multicenter, placebo-controlled trial of patients undergoing CD who were randomized to 1g of TXA or placebo. For this analysis, all participants were included. The study population was split into subgroups on the basis of HTN prior to delivery. The primary outcome was a composite of maternal death or blood transfusion before hospital discharge or seven days postpartum, whichever occurred first. Blood transfusion was defined as the transfusion of packed red cells or whole blood or cell-savor autotransfusion device use. Secondary outcomes are in Table 1. Relative risks (RR) were calculated for categorical and mean differences for continuous outcomes. *P* values for interaction with HTN were calculated.

Results: Of the 10,995 participants randomized in the parent trial, 2707 (24.6%) had HTN (7.1% chronic hypertension and 17.5% pregnancy related). The primary outcome did not differ among those who received TXA versus placebo in either subgroup (HTN: TXA 4.9% vs placebo 6.0%; RR 0.84 (95% CI 0.62, 1.16); no HTN: TXA 3.2% vs placebo 3.7%; RR 0.91 (0.73, 1.14); *p* for interaction 0.64). For all secondary outcomes, the interaction *p* was non-significant (all $p > 0.05$).

Conclusion: The effect of prophylactic TXA during CD on maternal death or blood transfusion within one week postpartum and on other peripartum bleeding-related outcomes does not differ by the presence of HTN.

Table 1: Outcomes among patients with hypertension versus without hypertension who received tranexamic acid or placebo during cesarean delivery

		Hypertension			No Hypertension

23 | Preclinical Development of a Continuous Fetal Lactate Biosensor to Detect Acidosis

Jonathan M. Morris[1]; Arjun Kaushik[2]; Michael Challenor[2]; Lee J. Hubble[2]; Chaitya Shah[2]; Maureen Ross[2]; Ranjusha Rajagopalan[2]; Hassan Mahmood[2]; Allana Gurney[3]; Hayley Powell[3]; Jane Choi[3]; Helen Kershaw[3]; Gabrielle Musk[3]; Jane Pillow[3]

[1]*University of Sydney, New South Wales;* [2]*VitalTrace Pty Ltd, Western Australia;* [3]*University of Western Australia, Crawley, Western Australia*

2:30 PM - 2:45 PM

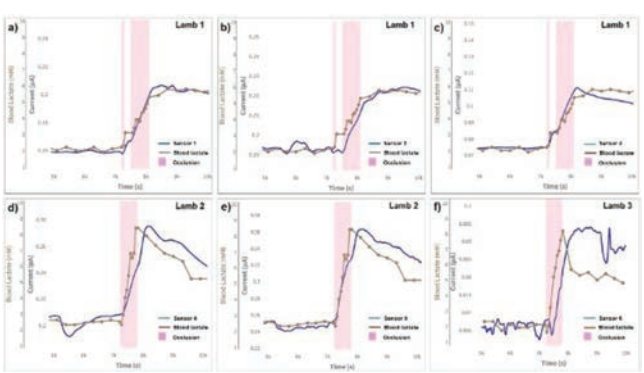
Objective: Accurate detection of fetal acidosis in labor is an unmet clinical need. Objectives of this study are:

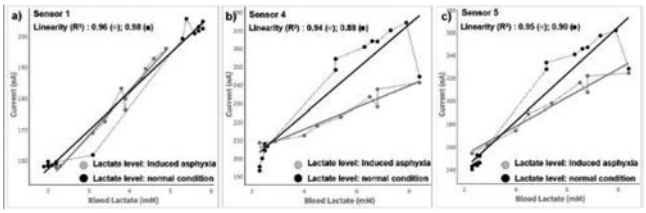
1. To validate a subcutaneous biosensor for continuous lactate monitoring (CLM) to detect acidosis in a fetal lamb model of asphyxia.
2. Assess the utility of the CLM biosensor for intrapartum fetal monitoring, by correlating sensor-detected lactate levels with contemporaneously collected blood lactate values.

Study Design: Ewes (n = 3) with singleton pregnancy were anesthetized and the lamb's head was exteriorised. Multiple biosensors were placed onto the lamb's scalp, with electrical current outputs captured. Venous blood samples were collected at regular intervals across the protocol, and lactate and other physiological parameters recorded. After baseline, the umbilical cord was occluded for ten minutes, with recordings continuing over at least three hours during recovery.

Results: **Figure 1** shows the relationship between biosensor current (μA), venous blood lactate (mM), and time (s) during the fetal lamb model experiments (animal n = 3; biosensor n = 6), highlighting the utility of the biosensor in monitoring in-vivo lactate levels. **Figure 1** illustrates a strong correlation between sensor-measured current and blood lactate levels over time. This is supported by the graphs in **Figure 2 (a-c)**, with the correlation ($R^2 > 0.88$) between sensor current and blood lactate measurements. These results support the capability of the CLM biosensor to detect continuous real-time changes in fetal lamb lactate concentration, crucial for early detection and management of fetal asphyxia during labor and delivery.

Conclusion: This study demonstrates the capability of an innovative subcutaneous biosensor for CLM in detecting early signs of fetal lactic acidosis, highlighted by the strong correlation between sensor-detected lactate levels and venous blood lactate levels. This technology has the potential to enable continuous fetal lactate measurement, with the ability to revolutionize intrapartum care and improve neonatal outcomes. Ethics and governance approvals are in progress to commence first-in-fetus studies.





24 | After Cesarean Time Interval to Exercise (ACTIVE) Trial: A Randomized Controlled Trial

Brittany J. Roser[1]; James Kinderknecht[2]; Brett Toresdahl[3]; Patricia Ladis[4]; Sonali Iyer[5]; Megan Savage[6]; Timothy Dekker[7]; Paul Christos[5]; Robin B. Kalish[8]

2:45 PM - 3:00 PM

Objective: Cesarean delivery (CD) is the most common surgery performed in the United States, accounting for 30% of all births. Currently, there are no clear guidelines on when to initiate exercise after CD. Our objective was to evaluate the impact of early exercise, beginning 2 weeks postpartum, on physical and mental wellbeing.

Study Design: We conducted a prospective, parallel-group, randomized trial (ClinicalTrials.gov NCT04345757) at a single academic center between 2022-2024. Patients ≥ 18 years undergoing CD were included. Significant maternal or neonatal complications were excluded. Patients were randomized 1:1 to either a video-based, structured exercise program beginning 2 weeks postpartum or to routine postpartum care, typically avoiding exercise for 6 weeks. The primary outcome was wellbeing at 6 weeks postpartum, assessed using the Patient-Reported Outcomes Measurement Information System Global Short Form (PROMIS-GSF). Secondary outcomes included PROMIS-GSF physical and mental wellbeing sub-scores, post-operative complications and self-reported breastfeeding (BF) supply. Sample size was calculated to achieve 80% power to detect a 4-point difference in PROMIS-GSF score, with $\alpha = 0.05$. Data was analyzed using two-sample t-test and Fischer exact test as appropriate.

Results: 846 patients were assessed for eligibility: 646 were excluded, 200 were randomized and 63 completed the primary outcome measure. There was no difference in baseline demographics, obstetric characteristics or baseline PROMIS-GSF score between groups (Table 1). While there was no difference in 6 week PROMIS-GSF score, there was a trend towards improved physical health sub-score in the structured exercise group (Table 2). There were no differences in mental health sub-score (Table 2), postoperative complication rates or BF supply.

Conclusion: Structured exercise two weeks after CD appears to be safe and did not adversely impact physical or mental wellbeing. While low survey completion rate was a limitation, this pilot data will help to inform future research powered to measure the impact of early exercise on enhanced recovery after CD.

25 | Intrauterine Resuscitative Maneuvers for Management of Abnormal Fetal Heart Tracings: A Systematic Review and Meta-Analysis

Amanda J. Jones[1]; Fabrizio Zullo[2]; Luis Sanchez-Ramos[3]; Lauren C. Roby[1]; Stephanie Roth[4]; Suneet Chauhan[5]; Matthew K. Hoffman[1]; Anthony C. Sciscione[1]
[1]Christiana Care Health System, Newark, DE; [2]University of Rome La Sapienza, Rome, Lazio; [3]University of Florida College of Medicine, Jacksonville, FL; [4]Christiana Care Health Services, Newark, DE; [5]Christiana Care, Newark, DE

3:00 PM - 3:15 PM

Objective: To evaluate the effectiveness of 7 intrauterine resuscitative maneuvers (IRMs)—amnioinfusion, maternal oxygen supplementation, tocolysis, maternal repositioning, discontinuation of labor stimulation, and treatment of maternal hypotension or tachysystole—in mitigating adverse outcomes in the setting of non-reassuring fetal heart tracings (NRFHT).

Study Design: We conducted a systematic review and meta-analysis of randomized controlled trials (RCTs) of laboring patients with NRFHT randomized to receive one of the 7 IRMs versus no intervention. The primary outcome was Apgar score < 7 at 5 minutes. Secondary outcomes included cesarean delivery rate (CD), CD for NRFHT, relief of NRFHT, umbilical artery (UA) pH < 7.10, UA pH < 7.20, and NICU admission. Summary measures were reported as relative risk (RR) with 95% confidence interval (CI) using the random effects model of DerSimonian and Laird. Higgins I2 > 0% was used to identify heterogeneity.

Results: Of 11,372 abstracts reviewed, 8 RCTs were eligible and included: 682 patients randomized to amnioinfusion vs none; 170 randomized to oxygen supplementation vs. none; and 523 randomized to tocolysis before CD vs. none. Likelihood of relief of NRFHT was significantly higher in the amnioinfusion group (68.0% vs 3.27%; RR 18.9; 95% CI 7.16, 50.26) and CD for NRFHT was significantly lower (37.8% vs 54.2%; RR 0.70; 95% CI 0.60, 0.82) vs none. Likelihood of UA pH < 7.20 was significantly lower in the tocolysis group (18.7% vs 35.4%; RR 0.40; 95% CI 0.17-0.93) vs none. The likelihood of Apgar score < 7 at 5 minutes, UA pH < 7.10, and NICU admission was similar in each group across interventions. We did not identify eligible RCTs for change in maternal position, discontinuation of labor stimulation, or treatment of maternal hypotension or tachysystole.

Conclusion: Amnioinfusion for NRFHT was found to relieve NRFHT and reduce CD. Oxygen for NRFHT did not reduce CD or improve fetal outcomes. Tocolysis for NRFHT reduced the rate of rate of fetal acidosis with UA pH < 7.20. No eligible RCTs were found for other IRMs in the setting of NRFHT.

Table 1: Meta-Analysis of randomized controlled trials of intrauterine resuscitative maneuvers versus no interventions for abnormal fetal heart tracings

[3] *Studies included: Kuller et al J. Perinat. Med. 1997; Briozzo J. Obstet. Gynaecol. et al 2007; Zahar et al Med. J. Malays. 2023*

* To identify studies to include or consider for this systematic review, a medical librarian developed detailed search strategies for each database. The databases included in this search were PubMed (NLM), Embase.com (Elsevier), Cochrane CENTRAL (Wiley) and CINAHL Ultimate (EBSCOHost) using a combination of keywords and subject headings. A grey literature search included clinicaltrials.gov, WHO ICTRP and medRxiv. All final searches were performed on March 22, 2024. A protocol was registered at PROSPERO (CRD42023409756). 8 RCTs were determined to be eligible for data extraction and quality assessment.

NRFHT: non-reassuring fetal heart tracing; CD: cesarean delivery; UA: umbilical artery; NICU: neonatal intensive care unit

26 | Reducing Postpartum Hemorrhage: The Impact of a Standardized High-Dose Oxytocin Protocol

Evan J. Keil[1]; Elizabeth J. Campbell[2]; Joanne M. Bailey[2]; David E. Arnolds[2]; Diana Peacor[2]; Molly J. Stout[2]; Jourdan E. Triebwasser[1]
[1]University of Michigan, Ann Arbor, MI; [2]University of Michigan Medical Center, Ann Arbor, MI

3:15 PM - 3:30 PM

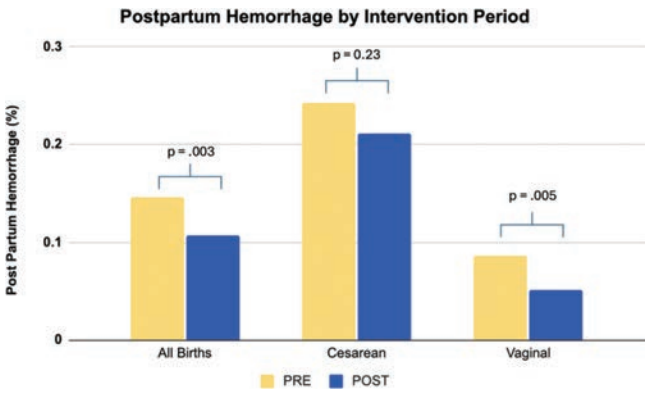
Objective: Oxytocin protocols to prevent postpartum hemorrhage (PPH) vary widely, with limited data suggesting higher doses may reduce PPH. We examined the impact of increasing the dose of oxytocin for active management of the third stage of labor on PPH.

Study Design: We performed a single-center quality improvement project at a large academic medical center. The pre-intervention phase (PRE) was Jan 1 - Apr 6, 2024 and post-intervention phase (POST) was Apr 7 - Jul 6, 2024. Quantitative blood loss (QBL) was routinely used throughout. PRE-oxytocin protocol was 30 units in 500 mL given over 1 h followed by 3.6 units over 1 h. POST-protocol was 60 units in 1 L given over 1 h. Implementation steps included updating medication orders and infusion pumps and providing staff training. Process measures were uterotonic administration between QBL 500mL and 1L and exposure to >18h of oxytocin during labor, which were monitored using weekly control charts. Healthcare rules were applied to detect special cause variation. Relative risks were calculated to assess the intervention's impact.

Results: PPH was less frequent POST (14.6% vs. 10.8%, RR 0.74 [95% CI 0.61-0.90], **Figure**) despite no change in cesarean

birth rate (37.9% vs. 35.3%, p = 0.16) or receipt of any oxytocin during labor (37.0% vs. 38.9%, p = 0.34). Reduction in PPH was most pronounced among vaginal births (8.7% vs. 5.2%, RR 0.60 [95% CI 0.42-0.86]). The magnitude of change in PPH was similar for cesarean births though not statistically significant (24.3% vs. 21.1%, RR 0.87 [95% CI 0.69-1.10]). Reduction in PPH was not attributable to other process measures as there was no special cause variation in uterotonic administration (mean 64%) or Oxytocin for >18h (mean 18%) during the study period.

Conclusion: Implementing an oxytocin protocol of 60 units given over 1 hour reduced overall PPH rates, particularly for vaginal births.



27 | Hysterotomy using Barbed vs. Vicryl Suture for Scheduled Cesarean Delivery: A Randomized Controlled Trial

Ayisha B. Buckley[1]; Nicola F. Tavella[2]; Camila Cabrera[2]; Keisha S. Paul[2]; Mariah McKevitt[2]; Monica J. Patel[2]; Lauren A. Ferrara[2]; Jenny Tang[2]; Joanne Stone[3]; Calvin E. Lambert, Jr.[2]; Luciana A. Vieira[4]; Angela T. Bianco[2]

[1]Weill Cornell Medical Center, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Mt. Sinai Medical Center, New York, NY; [4]Stamford Hospital, Stamford, CT

3:30 PM - 3:45 PM

Objective: Intraoperative reduction of blood loss correlates with reduced morbidity. We examined whether Cesarean Deliveries (CD) had significantly lower quantitative blood loss (QBL) when the hysterotomy was closed with barbed suture.

Study Design: This was a single site randomized controlled trial. Patients with a scheduled term CD gave informed consent and were randomly assigned barbed or vicryl suture for hysterotomy closure. Block randomization controlled for primary or repeat CD. We excluded patients with increased risk of hemorrhage (PPH). The primary outcome was QBL (mL). Secondary outcomes were time for hysterotomy closure, additional hemostatic sutures, and postoperative pain (via numerical scoring system). Among covariates for which we adjusted were provider level (Resident, Fellow, Attending) and provider experience with the suture. Multivariable linear regressions estimated adjusted means. A two-sided $\alpha < 0.05$ indicated significance. An a priori calculation determined 226 subjects were needed to detect a 30% difference in mean QBL with 85% power.

Results: From 2021 to 2023, 226 subjects were assigned barbed (n = 113) or vicryl suture (n = 113). The groups did not differ on demographic or clinical variables. More hysterotomies using barbed suture were done by fellows ($p = 0.02$). The groups differed in provider experience with the suture ($p < 0.001$). Regression models showed a difference in mean QBL between the barbed (521.0 minutes [95%CI: 447.3, 594.7]) and vicryl (558.8 minutes [95%CI: 441.4, 676.2]) groups. There was a shorter time for hysterotomy (4.5 vs 6.1 minutes [95%CI: 4.0, 5.0]) and less postoperative pain (3.3 vs 3.4 [95%CI: 3.0, 3.6]) in the barbed suture group.

Conclusion: Closing hysterotomies with barbed suture at scheduled CDs is associated with decreased QBL, postoperative pain, and hysterotomy closure time. These results suggest potential for reduced surgical morbidity and improved patient experience with use of barbed suture. Further studies are needed to corroborate our findings.

28 | Investigating Selection Bias in Research Using Placental Pathology Samples

Linda M. Ernst[1]; Alexa A. Freedman[2]; Renee Odom-Konja[1]; Lauren Keenan-Devlin[3]; Greg E. Miller[2]; Ann EB Borders[3]
[1]Endeavor Health, Evanston, IL; [2]Northwestern University, Chicago, IL; [3]Endeavor Health, Evanston Hospital, Evanston, IL

3:45 PM - 4:00 PM

Objective: Increasing research interest has focused on placental pathology and pregnancy outcomes. Clinically-requested pathology cases are often used for research due to convenience, which may lead to selection bias. We leveraged a large cohort of prospectively-collected placentas to compare prevalences of placental pathology in cases with and without a clinically-requested pathology exam (CPE) and to quantify potential selection bias.

Study Design: All placentas were prospectively collected from participants in the Stress, Pregnancy, and Health (SPAH) study, including those with and without CPE. In all cases, placental pathology was categorized and graded in 4 major groups: acute inflammation (AI), chronic inflammation (CI), fetal vascular malperfusion (FVM) and maternal vascular malperfusion (MVM). We compared the distribution of placental pathology in cases with and without CPE. Odds ratios (OR) for preterm birth (PTB) and small for gestational age (SGA) infant were calculated in the whole SPAH cohort and compared with the CPE subcohort. Relative odds ratios (ROR) were used to quantify selection bias. Models were adjusted for sociodemographic and pregnancy characteristics.

Results: 575 placentas were collected and examined, 287 with CPE and 288 without CPE. The prevalence of AI, CI and FVM was similar among the 2 groups. However, the prevalence of MVM was significantly higher in CPE placentas, particularly for high grade MVM (15% vs 8%, $p < 0.001$). In adjusted models, high grade MVM was significantly associated with increased odds of PTB and SGA in the whole SPAH cohort and the CPE sub-cohort (PTB: SPAH OR = 5.62, CPE OR = 7.56; SGA: SPAH OR = 8.13, CPE OR = 8.25). RORs show a 30% overestimation of the association between MVM and PTB, and only a 2% overestimation in SGA when using a CPE sample.

Conclusion: MVM was the only placental pathology seen more frequently in the CPE sample. Research using a CPE only sample may overestimate associations, particularly for MVM and PTB. Because we quantified the selection bias, the RORs from our data can be used to adjust estimates in studies using retrospective CPE samples.

Table 1. Pathology distributions

	SPAH sample	NO Clinically requested pathology examination (NO CPE)	Clinically requested pathology examination (CPE)	p-value

29 | Beyond the Fetus: Unveiling Maternal Health Risks Through Prenatal Genome Sequencing

Brittany Arditi[1]; Caitlin D. Baptiste[2]; Jessica L. Giordano[1]; Rachel Herz-Roiphe[2]; Vaidehi Jobanputra[3]; Ronald J. Wapner[4]
[1]Columbia University Irving Medical Center, New York, NY; [2]Columbia University Medical Center, New York, NY; [3]New York Genome Center, New York, NY; [4]Columbia University, New York, NY

1:30 PM - 1:45 PM

Objective: Genome sequencing (GS) has been demonstrated to be of benefit in the evaluation and management of fetal structural anomalies. However, the management of maternal ancillary findings on trio analysis has not been described. Our objective was to evaluate the frequency and clinical impact of maternal genomic variants identified after fetal GS.

Study Design: This is a secondary analysis of all patients undergoing prenatal GS between September 2022-November 2023 at a single institution under a research protocol. 420 fetuses (279 anomalous and 141 non-anomalous) were included. GS was performed in a CLIA certified laboratory and results reported to parents. Genome analysis was performed through a proband-focused trio approach: pathogenic and likely pathogenic variants were identified in the fetus and parental inheritance was subsequently determined. All maternally inherited findings were adjudicated by a multidisciplinary team of maternal fetal medicine physicians, laboratory geneticists, and genetic counselors to determine the impact on pregnancy and postpartum care. Pathogenic and likely pathogenic variants in genes with implications for peripartum management were reported to the care providers.

Results: 3.8% (16/420) of patients had a maternally inherited, reportable, autosomal dominant finding. Among patients with a reportable finding, 9/16 (56.25%) were referred to a subspecialist for further management and/or underwent additional workup aimed at identifying and preventing risk for maternal morbidity (Table 1). Familial cascade testing was discussed with all patients and performed in 4/16 (25.0%) families. Only 2/16 (12.5%) of genes reported in our analysis are on the American College of Medical Genetics and Genomics secondary findings list.

Conclusion: In addition to providing a fetal diagnosis, prenatal sequencing will identify maternal genetic diseases with the potential to cause peripartum maternal morbidity and mortality. Future research is required to understand the clinical impact of these findings and to develop management protocols.

Anomalous Fetus cohort				
Fetal phenotype	**Gene**	**Associated diseases**	**Maternal phenotype**	**Referral/Additional workup**
Cystic hygroma	TEK	Congenital glaucoma	None	- Ophthalmology referral - Glaucoma exam

1:45 PM - 2:00 PM

Objective: Prenatal detection of congenital heart defects (CHD) improves patient outcomes. Despite advances in imaging techniques and equipment, prenatal diagnosis remains low. We evaluated the accuracy of an artificial intelligence (AI) system to detect 2nd trimester (2T) ultrasound studies suspicious for CHD.

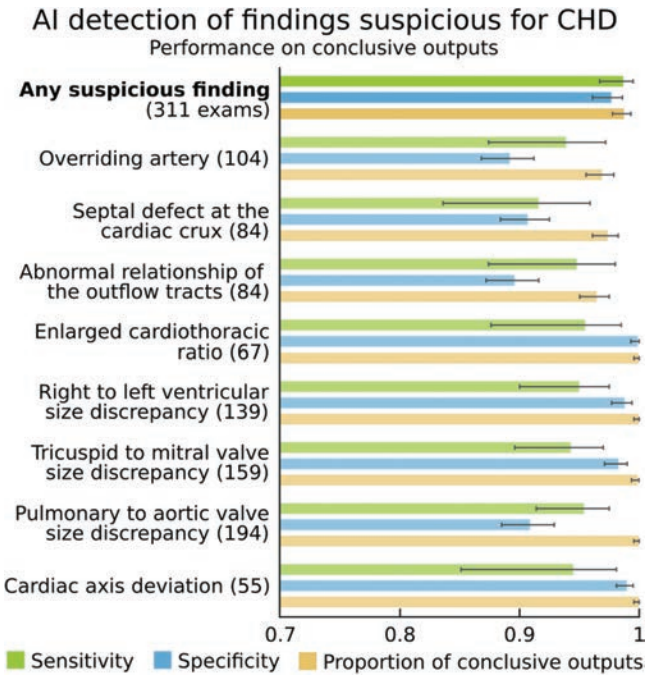
Study Design: The AI system analyzes all grayscale 2D ultrasound cines of a study and detects 8 morphological findings suspicious for CHD. The findings were selected such that most major forms of CHD would feature at least one such finding, and the presence of any of these would flag the study for referral for further examination.

We retrospectively included 877 exams (obstetric or detailed anatomic ultrasounds, or fetal echocardiograms), in singleton pregnancies, between 18-24 weeks gestation from 11 centers, including 311 exams with a major CHD, cardiomegaly or levo/dextrocardia. Each exam included 4-chamber, LVOT and RVOT views documented in cines, and was not used for training of the AI system.

For each exam, 3 expert fetal cardiologists annotated the presence or absence of each finding and majority voting was used as the ground truth. The AI system predicted the presence, absence or inconclusiveness (in case of low confidence) of each finding. An exam was predicted positive if at least one finding was present, negative if all findings were absent and inconclusive otherwise.

Results: Regarding the detection of any finding, the AI system had a conclusive output for 98.8% (95%CI 97.8-99.3) of exams. On exams with a conclusive output, sensitivity was 98.7% (96.7-99.5), and specificity was 97.7% (96.1-98.6). Performance per individual finding is presented in the Figure. To better represent the general low risk population despite the artificially high prevalence of exams with at least one suspicious finding (311/877), per-finding specificity was computed on exams negative to all findings.

Conclusion: The AI system accurately detected 2T ultrasound exams suspicious for CHD consistent with experts in most cases. The AI system may improve the prenatal ultrasound detection of CHD and thereby improve outcomes.



31 | Effect of Home Ultrasound in Patients with Previous Late Pregnancy Loss- A Randomized Control Trial

Liat Mor[1]; Hagit Eisenberg[2]; Liliya Tamayev[3]; Daniel Tairy[1]; Ben Oren[3]; Yael Ganor Paz[1]; Michal Levy[3]; Eran Weiner[2]; Giulia Barda[2]

[1]Edith Wolfson Medical Center, Holon, HaMerkaz; [2]Wolfson Medical Center, Wolfson Medical Center, Tel Aviv; [3]Edith Wolfson Medical center, Holon, HaMerkaz

2:00 PM - 2:15 PM

Objective: We aimed to evaluate the effect of incorporating twice-weekly telemedicine home-ultrasound sessions on maternal anxiety and antenatal attachment in patients with a history of late pregnancy loss.

Study Design: In this randomized controlled trial, patients with a history a pregnancy loss beyond 20 weeks of gestation were recruited during their subsequent pregnancy and randomized into either a control group receiving standard high-risk care or a study group receiving additional twice-weekly home-ultrasound sessions. Home-ultrasound scans were guided by a physician via telemedicine and assessed basic fetal wellbeing using a Pulsenmore device. Two validated questionaries assessed maternal anxiety- the State-Trait Anxiety Inventory Scale (STAI-S) and the Revised Prenatal Distress Questionnaire (NuPDQ). Maternal attachment was evaluated using the Maternal Antenatal Attachment Scale (MAAS-2). All questionnaires were filled in the beginning, mid and end of follow up time. The primary outcome

was the STAI-S score at the final prenatal visit (STAI-3). In order to detect a 20% difference in the primary outcome, a sample size of 50 patients was required.

Results: Fifty patients were recruited and completed the study, 25 in each group. Demographic characteristics were similar between the groups. The home ultrasound group presented significantly decreased STAI-3 scores ($p = 0.022$), a significantly increased MAAS-3 score ($p = 0.022$) and less unscheduled emergency department visits during this time ($p = 0.024$) compared to control. Multivariate regression analyses confirmed significant and independent associations between reduced STAI and improved MAAS and the use of home-ultrasound (Table 1).

Conclusion: Incorporating home-ultrasound visits into prenatal care in patients with prior late pregnancy loss may significantly reduce maternal anxiety and enhance maternal attachment. These findings suggest that home ultrasound technology can be a valuable tool in managing maternal anxiety in this subset of patients.

Logistic regression analyses examining the association between maternal anxiety, antenatal attachment and emergency department visits to home ultrasound follow-up among patients with previous late pregnancy loss

	Unstandardized B	95% CI for B	p-value
STAI-3	-9.45	[-17.11, -1.7]	**0.017**
MAAS-3	4.59	[0.12, 9.06]	**0.044**
Unscheduled ED visits	-1.46	[-3.37, 0.45]	0.130

Values reflect the results of multivariate logistic regression analyses adjusted for parity, gestational age at previous IUFD, assisted reproductive technology, use of anti-depressants. STAI- state-trait anxiety index; MAAS- maternal antenatal attachment scale; ED- emergency department.

32 | Genetic Diagnoses in a National Cohort with Non-Immune Hydrops and Other Fetal Effusions

Natalie B. Gulrajani[1]; Billie R. Lianoglou[2]; Katie Tick[3]; Nuriye Sahin-Hodoglugil[3]; Ugur Hodoglugil[4]; Patrick Devine[4]; Jessica Van Ziffle[4]; Mary E. Norton[2]; Teresa N. Sparks[3]
[1]University of California, San Francisco, School of Medicine, San Francisco, CA; [2]Center for Maternal-Fetal Precision Medicine, University of California San Francisco, San Francisco, CA; [3]University of California, San Francisco, San Francisco, CA; [4]Genomic Medicine Laboratory, University of California, San Francisco, San Francisco, CA

2:15 PM - 2:30 PM

Objective: Many single gene disorders are associated with non-immune hydrops fetalis (NIHF) and other fetal effusions. However, less is known about how these diseases present uniquely in utero. We aimed to characterize how genetic diseases present in utero with NIHF, other single effusions, and concurrent anomalies.

Study Design: This is a prospective national cohort of pregnancies with unexplained NIHF, pleural effusion, pericardial effusion, ascites, skin edema, cystic hygroma, increased nuchal translucency (NT) ≥3.5mm, or a combination of these. All ultrasound reports for each pregnancy were reviewed. A CLIA-approved laboratory performed exome sequencing (ES) and results were provided to patients. Each case was categorized as presenting with NIHF, single effusion (pleural or pericardial effusion, ascites, or skin edema), or increased NT or cystic hygroma, all with or without concurrent structural anomalies.

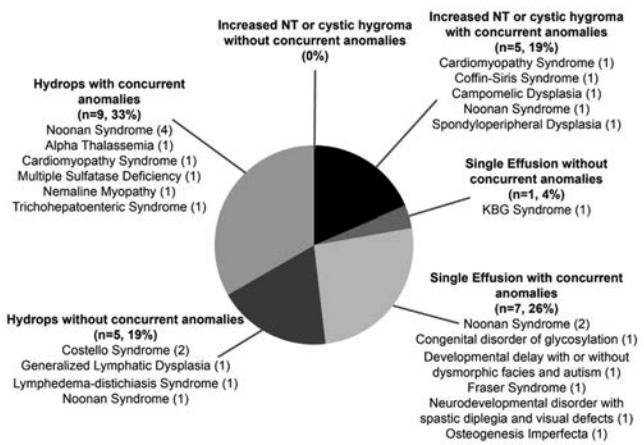
Results: 118 pregnancies underwent ES. There was a high diagnostic yield among cases with NIHF and single fetal effusions (17-36%), both with and without concurrent anomalies (Table 1). For cases with increased NT or cystic hygroma, the diagnostic yield was 42% for cases with concurrent anomalies, but zero in the absence of concurrent anomalies. Genetic diseases identified varied widely (Fig. 1). RASopathies, musculoskeletal disorders, and cardiomyopathies presented variably with and without concurrent anomalies and with all types of fetal effusions. Primary lymphedema syndromes presented later in gestation with NIHF and without concurrent anomalies. Diseases associated primarily with postnatal neurodevelopmental delay were seen with single fetal effusions and increased NT, with and without concurrent anomalies.

Conclusion: ES yielded a diagnosis in a high proportion of cases with NIHF and other single fetal effusions, with the exception of isolated increased NT or cystic hygroma. Certain genetic diseases presented broadly with all types of fetal effusions, while others presented more uniquely. Understanding these patterns informs accurate prenatal diagnosis, clinical counseling, and management.

Table 1. Frequency of genetic diseases presenting with NIHF and other isolated effusions.

Type of fetal effusion	Frequency of genetic disease	p-value
NIHF with concurrent anomalies (n=45) NIHF without concurrent anomalies (n=14)	20% 36%	0.29
Single effusion with concurrent anomalies (n=25) Single effusion without concurrent anomalies (n=6)	28% 17%	>0.99
Increased NT or cystic hygroma with concurrent anomalies (n=12) Increased NT or cystic hygroma without concurrent anomalies (n=16)	42% 0%	<0.01

Figure 1: Genetic diseases identified in positive cases by phenotypic category



33 | Genomewide monogenic Non Invasive Prenatal Genetic Screening based on maternal cfDNA

Dolev Rahat[1]; Ravit Mesika[1]; Lilach Schneor[1]; Noa Liscovitch-Brauer[2]; Tom Rabinowitz[1]; Noam Shomron[1]; Reut Tomashov Matar[3]; Lina Basel-Salmon[3]

2:30 PM - 2:45 PM

Objective: Current methods for prenatal screening using cell-free DNA (cfDNA) for monogenic disorders have significant limitations. They are restricted to a predefined set of variants or genes, require impractically high fetal fractions (FFs) for clinical settings, or focus on paternally-inherited variants. Since paternal genetic material is often unavailable, there is a critical need for a father-independent solution. We present a comprehensive noninvasive prenatal genetic screening method that accurately predicts the fetal genotype at any location in the genome using only a maternal DNA sample.

Study Design: We conducted a study involving nine families with singleton pregnancies, with varying FF values (7-25%) where the parents are carriers for a severe monogenic disorder. We performed whole genome sequencing (WGS) of both maternal genomic DNA and maternal plasma and predicted the fetal genotypes for the pathogenic variants and across the entire genome.

Results: Our study includes seven families with a pathogenic single nucleotide variant (SNV): four families where both parents shared a common recessive pathogenic variant (e.g., congenital chloride diarrhea), two families with suspected compound heterozygous pathogenic variants (e.g., cystic fibrosis), and one family with a dominant pathogenic variant (Treacher collins syndrome). We accurately predicted the fetal disease status in all tested families (Table 1). We also conducted a genome-scale analysis of our algorithm's performance over millions of genomic sites where the mother was a carrier. Our method achieved an area under the curve (AUC) of 0.89 for homozygous variants (Figure 1).

Conclusion: Our study presents a novel approach for genome-wide non-invasive prenatal screening, addressing a critical clinical need. We demonstrate the clinical feasibility of this approach as early as the first trimester. Our genome-wide method can be extended to detect variants of all types and scales, including copy number variations and aneuploidies, and it also allows for the detection of de novo fetal variants.

Family	Condition	Gestational age	FF (%)	Inheritance	Predicted fetal disease status	True disease status
IG01	Cystic fibrosis	12	12.36	Compound	Healthy	Healthy
IG02	Epidermolysis bullosa	33	25.5	AR	Healthy	Healthy
IG03	Congenital chloride diarrhea	11	6.97	AR	Carrier	Carrier
IG04	Propionic acidemia	11	10.57	AR	Affected	Affected
IG05	Infantile convulsions and choreoathetosis (ICCA)	19	10.44	AR	Carrier	Carrier
IG06	Treacher collins	12	12.02	AD	Affected	Affected
IG07	Glutaric acidemia IIC	12	15.18	Compound	Affected	Affected

Table 1: Clinical information, predicted fetal disease status and true fetal disease status (from amnio/CVS) across the study families. AD - autosomal dominant, AR - autosomal recessive, compound - compound heterozygous.

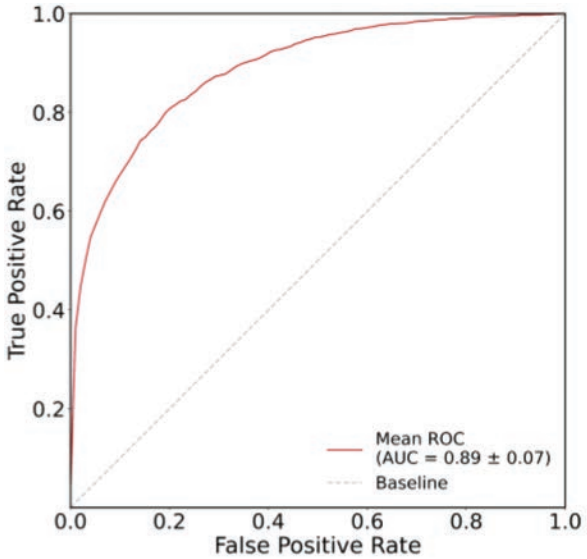

Figure 1: ROC curve showing the performance of our non-invasive prenatal screening algorithm. Values were calculated over variants in the entire genome and the average over families in the study cohort is shown.

34 | AI Assistance Enhances Physician Performance in Identifying Congenital Malformations

Clémentine Morisset[1]; Frédéric Logé-Munerel[1]; Celia Amabile[1]; Louis Chouinard[1]; Vianney Debavelaere[1]; Remi Besson[1]; Nikola Matevski[1]; Guillaume Corda[1]; Julien Stirnemann[2]; Yves Ville[3]; Yinka Oyelese[4]; Andrew Combs[5]

[1]Sonio, Paris, Ile-de-France; [2]Hôpital Necker Enfants Malades, Paris, Ile-de-France; [3]University and Necker-Enfants Malades Hospital, Paris, Ile-de-France; [4]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA; [5]Pediatrix Medical Group, Sunrise, FL

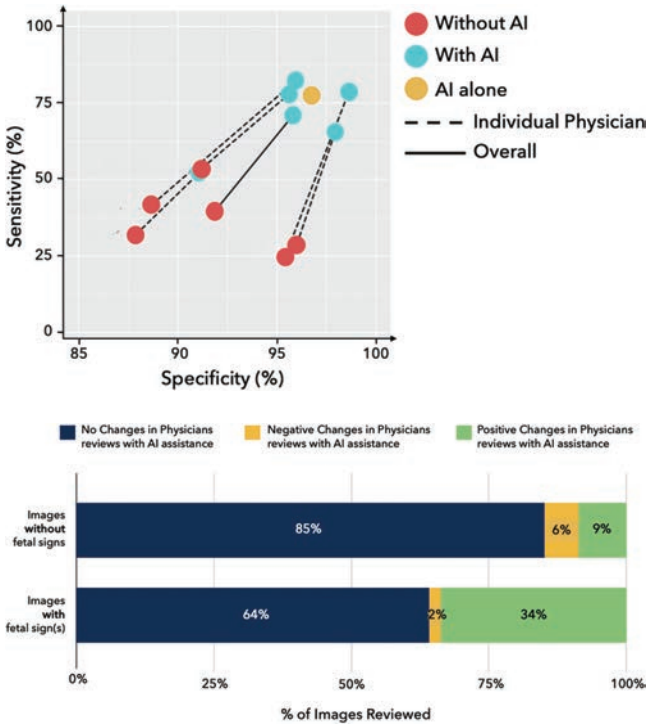
2:45 PM - 3:00 PM

Objective: Accurate sonographic identification of congenital malformations by interpreting Healthcare Practitioners (HCP) is critical for effective prenatal care. An AI software (under development, not FDA cleared) was trained to detect 10 fetal signs on automatically recognized views within its scope. This study aims to evaluate whether physician performance in identifying malformations improves with the assistance of the AI software versus without.

Study Design: A total of 1453 fetal images were labeled by experts and then reviewed by five physicians with varied profiles (Maternal-Fetal Medicine specialists, Obstetricians/Gynecologists, and General Radiologists). The reviews were conducted in two sessions (with and without the AI software), separated by one week to minimize recall bias. Each provider reviewed a mix of pathological and non-pathological images.

Results: There was a clear improvement for each reviewer and in overall performance - from 40% sensitivity (92% specificity) to 70% (96% specificity) with AI support (Figure 1). When assisted by the AI, physicians refined their reviews to more closely match the AI's output, leading to notable enhancements in performance (Figure 2).

Conclusion: AI-powered review of fetal images improves physician identification of signs of fetal malformations, highlighting the potential clinical impact of AI software to support more precise diagnosis.

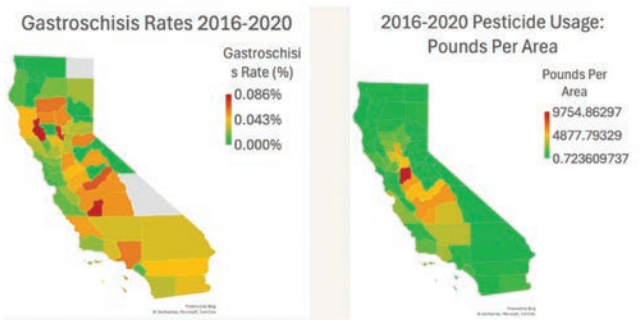


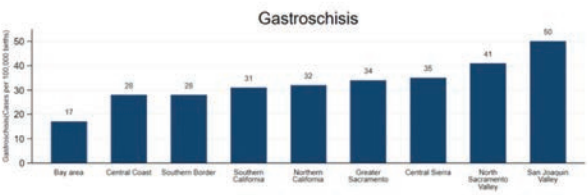
35 | Exploring Gastroschisis Patterns and Pesticide Use in California's Central Valley: A population-based cohort Study

Alejandro Perez[1]; Bharti Garg[2]; Hope Delgado[3]; Joshua F. Robinson[4]; Aaron B. Caughey[2]; Stephanie L. Gaw[4]
[1]University of California, San Francisco, Kerman, CA; [2]Oregon Health & Science University, Portland, OR; [3]University of California, Berkeley, Berkeley, CA; [4]University of California, San Francisco, San Francisco, CA

3:00 PM - 3:15 PM

Objective: The incidence of gastroschisis has been rising in regions with significant agricultural practices. Certain pesticides (e.g. atrazine, mineral oil) have been associated with gastroschisis in epidemiological studies.
Study Design: This is a retrospective cohort study of all California births from 2016-2020 utilizing linked birth certificate and hospital discharge records. We identified gastroschisis cases by ICD-10 code Q79.3 and geographically assessed maternal residence by zip code. Pesticide usage by county was obtained from publicly available databases from California Department of Pesticide Regulation for years 2016-2020. The usage of pesticides by county was calculated by pounds applied per total land area. We analyzed data from the following pesticides previously linked to gastroschisis: atrazine, mineral oil, oxyfluorfen, and glyphosate. We also investigated sulfur, which was the most widely applied pesticide in CA during this time period. Multivariable logistic regression, adjusting for maternal demographics, socioeconomic factors, and birth-related variables was used to identify associations between pesticide application and gastroschisis.
Results: During the study time, there were 2,218,394 births and 656 cases of gastroschisis (0.3 cases/1000 births). Pregnant individuals in the San Joaquin Valley had 1.4 times higher odds of gastroschisis (95% CI: 1.1-1.7) compared to other CA regions (0.5/1000 vs 0.3/1000, respectively). Analysis of the five pesticides of interest revealed higher gastroschisis rates in counties with greater usage of sulfur (aOR = 1.22; 95% CI: 1.00-1.49; p = 0.046) and mineral oil (aOR = 1.24; 95% CI: 1.05-1.45, p = 0.009).
Conclusion: These findings suggest an association between pesticide exposure, particularly sulfur and mineral oil, and risk of gastroschisis. More studies are needed to further illuminate causal relationships and guide targeted preventive strategies and management approaches for reducing gastroschisis incidence in vulnerable populations.





36 | AI Software Demonstrates Strong Performance for Screening of Tetralogy of Fallot and Truncus Arteriosus Communis

Remi Besson[1]; Nicolas Fries[2]; Julien Stirnemann[3]; Yves Ville[4]; Guy Vaksmann[5]
[1]Sonio, Paris, Ile-de-France; [2]Imagyn'Echo, Imagyn'echo Montpellier, Languedoc-Roussillon; [3]Hôpital Necker Enfants Malades, Paris, Ile-de-France; [4]University and Necker-Enfants Malades Hospital, Paris, Ile-de-France; [5]Cabinet Vendôme, Lille, Nord-Pas-de-Calais

3:15 PM - 3:30 PM

Objective: Congenital malformations are under-diagnosed during fetal ultrasound (US) exams. Artificial Intelligence (AI) could make the examination safer by drawing the practitioners eyes to suspicious images. Objective is to evaluate the feasibility to build an AI recognizing the overriding great vessel images of the Tetralogy of Fallot (ToF) or Truncus arteriosus communis (TAC).
Study Design: An AI software (under development, not FDA approved) was trained on tens of thousands annotated US images from 30 major USA and European sites including the images of

102 patients with diagnosed ToF. No cases of TAC were used by the algorithm during the training phase.
A first validation database is composed of 99 overriding aorta from ToF cases and 2153 normal images coming from these same centers. A second validation database was composed of 21 ToF and 7 TAC cases built from literature images between 2001 and 2021. Each exam was reviewed by one fetal US expert responsible for extracting all the images showing an overriding great vessel. The AI software was evaluated on its ability to accurately identify this sign.
Results: On the 99 overriding aorta images of the first validation database, the AI software reached 94.95% sensitivity in raising an alert. On the literature images, respectively on ToF and TAC cases, the algorithm identified an overriding great vessel on resp. 36 and 12 images, reaching a sensitivity of resp. 90% and 92.3%. On the control group, 98.8% specificity was reached (Fig.1).
Conclusion: This study demonstrated the feasibility in building a reliable alert system for screening of ToF along with the performance of such an algorithm in detecting pathologies non-seen during training (TAC) thanks to including well-known ultrasound semiology to guide the AI learning phase. Further tests on independent DBs from new centers are needed to better assess the AI software's robustness.

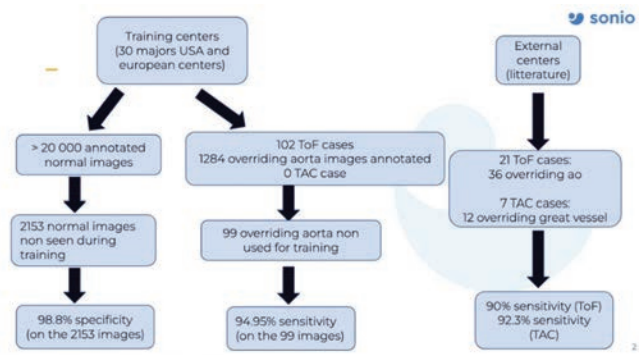


Figure 1: Composition of the different databases and performance of the AI on them

37 | Genetic Etiologies of Bilateral Renal Agenesis

Bobby Brar[1]; Robert Weatherford[2]; Carol Nowlen[1]; Katelynn Sagaser[3]; Ahmet A. Baschat[1]; Karin Blakemore[1]; Jena L. Miller[1]; Angie C. Jelin[1]
[1]Johns Hopkins Medicine, Baltimore, MD; [2]Massachusetts General Hospital, Boston, MA; [3]23andMe, South San Fransisco, CA

3:30 PM - 3:45 PM
Objective: Bilateral renal agenesis (BRA) with anhydramnios due to fetal anuria has a poor prognosis due to severe pulmonary hypoplasia. Although often isolated, BRA may be one feature of a larger, complex genetic disorder. Our objective was to further elucidate the genetic etiologies of fetuses with BRA.
Study Design: We performed a retrospective cohort study of all patients with fetal BRA presenting to an academic medical center for evaluation under the Renal Anhydramnios Fetal Therapy (RAFT) trial over a five-year period. Maternal demographics, ultrasound reports, and genetic screening/diagnostic testing results were reviewed. Pedigrees were also assessed to help inform potential inheritance.
Results: From 2017–2022, 52 patients with fetal BRA presented for evaluation. Extrarenal anomalies were seen in 17 (33%), most commonly cardiac (11), CNS (4), and skeletal (4). Aneuploidy screening was performed in 32 (62%), and none screened positive for the common autosomal aneuploidies. Diagnostic testing, offered to all, was completed in 37 patients (71%) with a 19% testing yield (7/37) (Table 1). 25 of the 37 had isolated BRA. Of 14 karyotypes, 1 case of 47, XXX was appreciated. Chromosomal microarray, performed in 28 patients, identified 3 copy number variants (CNVs): (2q21.1 duplication, 16p13.11 duplication, and 22q11.2 microdeletion). Exome sequencing revealed a pathogenic abnormality in 3 out of 5 patients (heterozygous variants in *GREB1L* and *RET*, compound heterozygous variants in *FREM2*). Of 7 patients with abnormal diagnostic testing, only 3 had extrarenal anomalies. Pedigrees were elicited in 46 patients with 13 (28%) reporting a family history of a genitourinary anomaly.
Conclusion: Approximately 1 in 5 fetuses with BRA have abnormal genetic testing. This highlights the importance of a comprehensive diagnostic testing approach in this population. Future research routinely employing molecular methodologies that interrogate for potentially etiologic CNVs and single gene disorders in pregnancies with BRA is needed to further our understanding of this condition, and to better inform parental counseling.

Case Number	Diagnostic Testing Result	Method of Testing	Extrarenal Anomalies
Case 1	47,XXX	Karyotype	None
Case 2	775 kb duplication of 2q21.1 (includes *CFC1*)	CMA	Pulmonic valve stenosis
Case 3	1.2 mb duplication of 16p13.11	CMA	None
Case 4	2.6 mb deletion of 22q11.21	CMA	Dilated cardiomyopathy, pulmonary atresia with intact ventricular septum
Case 5	Heterozygous variant in *GREB1L* (c.5016G>A)	WES	None
Case 6	Heterozygous variant in *RET* (c.2617C>T)	WES	None
Case 7	Compound heterozygous variants in *FREM2* (c.750_751dupGA and c.5162dupA)	WES	Congenital high airway obstruction, ascites, VSD

38 | Fully Quantitative Cervical Remodeling: Inter-pregnancy interval shows differences in biomechanical characteristics of the cervix

Sarah M. Dwyer[1]; LeAnn A. Louis[1]; Methodius G. Tuuli[2]; Adam K. Lewkowitz[2]; Julie Tumbarello[1]; Emily Dively, BSN[3]; Madeline Felske[1]; Wendy Sparks[1]; Giselle Kolenic[4]; Peinan Zhao[5]; Molly J. Stout[6]
[1]University of Michigan Hospital, Ann Arbor, MI; [2]Women & Infants Hospital of Rhode Island and Alpert Medical School of Brown University, Providence, RI; [3]Washington University School of Medicine, St. Louis, MO; [4]University of Michigan, Ann Arbor, MI; [5]Washington University, St. Louis, MO; [6]University of Michigan Medical Center, Ann Arbor, MI

3:45 PM - 4:00 PM

Objective: Short interval pregnancy is known to confer obstetric risks in subsequent pregnancies. We aimed to examine starting cervical stiffness based on time elapsed since prior pregnancy and mode of delivery in prior pregnancy.

Study Design: We invented fully quantitative cervical elastography (FQ-CES), which modifies a transvaginal ultrasound probe to quantify both pressure applied and tissue deformation, thereby yielding a fully quantified strain-based elastography system that provides a numeric quantification (Young's modulus) of cervical tissue stiffness. This system is operator independent and can be compared across patients and within patients over time. This analysis is a prospective cohort study of people with singleton pregnancies presenting for prenatal care. Exposure is time in years since immediate prior pregnancy and mode of delivery of prior pregnancy. Outcome is fully quantitative cervical stiffness in the first trimester. Mixed regression models were used.

Results: 196 individuals included. Median years since prior pregnancy is 2 years (IQR 1,3 years). Prior vaginal birth shows a progressive hardening (13.8% change in Young's Modulus per year) over the 3 years following birth ($p = 0.18$) whereas cesarean birth shows stable cervical stiffness (1.3% change in Young's Modulus per year; $p = 0.95$).

Conclusion: Cervical tissue remodeling after pregnancy may be differ after vaginal versus cesarean births. First trimester cervical stiffness may be associated with time since last pregnancy. The inter-pregnancy interval is a critically understudied time window which may provide insights into optimizing pregnancy outcomes.

39 | Methylergonovine to Decrease Blood Loss During Cesarean Delivery in Twins: A Triple-Blinded Placebo-Controlled Randomized Trial

Helen B. Gomez Slagle[1]; Shai Bejerano[2]; Russell S. Miller[2]; Dena Goffman[2]; Mary E. D'Alton[2]; Mirella Mourad[2]
[1]*Columbia University Irving Medical Center, New York, NY;*
[2]*Columbia University Medical Center, New York, NY*

8:00 AM - 8:15 AM

Objective: To evaluate whether prophylactic administration of intramuscular (IM) methylergonovine after cord clamping reduces blood loss during cesarean delivery (CD) in twin pregnancies.

Study Design: This single-center randomized placebo-controlled triple-blinded trial compared the effects on blood loss at CD of IM methylergonovine versus saline placebo control. Pregnant individuals with twin gestations at ^{3}34 weeks of gestation undergoing planned CD were enrolled. Methylergonovine or saline placebo was administered immediately after umbilical cord clamping of the second twin in addition to standard care with oxytocin. The primary outcome was change in maternal hemoglobin (Hgb) level from preoperative to postoperative day 1 (POD 1). We planned to enroll 66 patients to detect a standard deviation (SD) greater drop in postoperative maternal Hgb, assuming -1.40 (0.83) g/dL Hgb difference in planned CDs (90% power, alpha 0.05). Pearson chi-square, or Fisher's exact test, and Wilcoxon rank-sum with intent-to-treat principles were performed as appropriate.

Results: From February 2023 through March 2024, 77 patients were eligible and 66 participated. There were no demographic differences between methylergonovine and placebo groups. Median gestational age at delivery was 37 weeks for both groups. Mean Hgb drop at POD 1 was 1.1 g/dL (SD 0.7 g/dL) for methylergonovine and 2.1 g/dL (SD 0.9 g/dL) for placebo ($p< 0.001$). Median quantitative blood loss was significantly lower in patients receiving prophylactic methylergonovine (891cc versus 1017cc, $p = 0.003$). Postpartum hemorrhage rates were lower in the methylergonovine group (18.2% vs 54.5%, $p = 0.002$). There were 7 cases of unblinding due to hemorrhage in the placebo group compared to no cases in the methylergonovine group ($p = 0.01$); unblinded subjects received methylergonovine.

Conclusion: Prophylactic IM methylergonovine administered during twin CD after umbilical cord clamping significantly reduced intraoperative blood loss and hemoglobin drop at POD 1. These data support further study of methylergonovine as a preventative treatment strategy at the time of twin CD.

Table 1: Surgical Characteristics and Outcomes by Randomized Treatment Group

	Methylergonovine (n=33)	Placebo (n=33)	p
Surgical Characteristics			
Indication for cesarean delivery			1.0
Elective	9 (27.3)	10 (30.3)

40 | Management of Postpartum Preeclampsia and Hypertensive Disorders (MOPP): Postpartum Tight Versus Standard Blood Pressure Control

Emily B. Rosenfeld[1]; Deepika Sagaram[1]; Rachel Lee[1]; Ernani Sadural[2]; Richard C. Miller[2]; Ruby Lin[1]; Deshae Jenkins[1]; Kristin Blackledge[3]; Ivana Nikodijevic[4]; Alex Rizzo[2]; Vanessa Martinez[1]; Emily E. Daggett[5]; Olivia McGeough[1]; Cande V. Ananth[1]; Todd J. Rosen[1]

[1]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; [2]Cooperman Barnabas Medical Center, RWJBarnabas Health, Livingston, NJ; [3]Rutgers New Jersey Medical School and Cooperman Barnabas Medical Center, Livingston, NJ; [4]New Jersey Medical School, Newark, NJ; [5]Rutgers Robert Wood Johnson Medical School, Edison, NJ

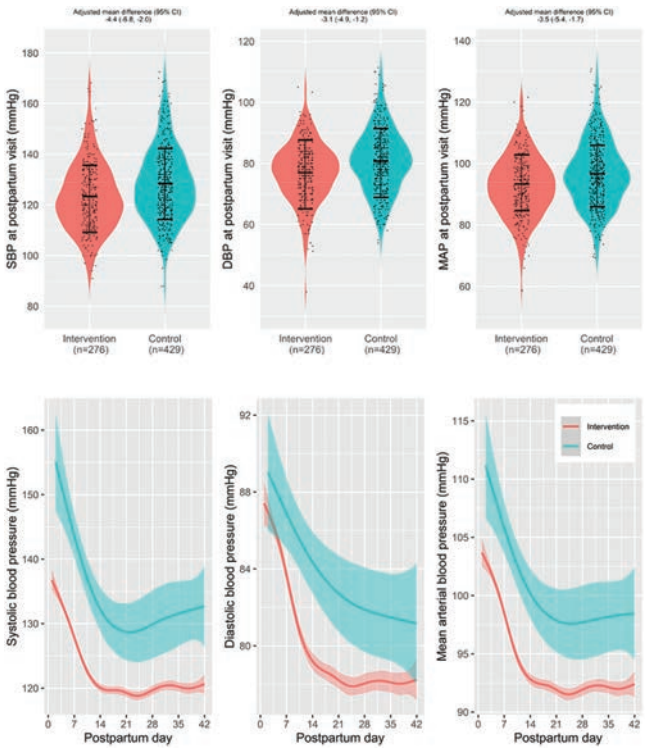
8:15 AM - 8:30 AM

Objective: To assess the effect of lowering the blood pressure (BP) threshold for treatment to 130/80 mmHg from the ACOG standard of 150/100 mmHg, coupled with remote BP monitoring, in managing postpartum patients with hypertensive disorders and reducing Emergency Department (ED) visits.

Study Design: A prospective cohort of postpartum patients was recruited in a multicenter study between March 2023 and March 2024 and treated to maintain BP < 130/80 mmHg for six weeks postpartum. These patients were compared to a retrospective cohort of patients delivered from February 2021 to February 2023 who were treated to maintain BP < 150/100 mmHg. Eligible patients were 18 years or older with a diagnosis of hypertensive disorder. The primary outcome was an ED visit for hypertensive disorders. Secondary outcomes included hospital readmissions and changes in BP at six weeks postpartum. We matched subjects between the interventional and the retrospective cohort through the propensity score method.

Results: There were 392 patients enrolled in the interventional cohort and 1,204 patients in the retrospective cohort. After the propensity score match, 276 and 429 patients remained in the intervention and retrospective cohorts. ED visits for hypertensive disorders occurred in 3.6% (n = 10) in the interventional cohort and 8.5% (n = 36) in the retrospective cohort (risk difference [RD] -4.8, 95% confidence interval [CI] -8.2, -1.3; matched odds ratio [OR] 0.32, 95% CI 0.10, 1.01). There were fewer hospital readmissions for hypertensive disorders (RD -3.2, 95% CI -5.7, -0.8; OR 0.09, 95% CI 0.003, 2.31). Compared to the retrospective group, systolic and diastolic BP at six weeks postpartum in the intervention group were, on average, 4.4 mmHg (95% CI -6.8, -2.0) and 3.1 mmHg (95% CI -4.9, -1.2) lower (**Figure 1**). BP and mean arterial pressure were lower throughout the six weeks in the intervention group (**Figure 2**).

Conclusion: Tighter BP control with remote patient monitoring was associated with a clinically meaningful reduction in postpartum ED visits for hypertensive disorders and lower blood pressure at six weeks postpartum.



41 | Impact of Living in a Food Desert on Prenatal Macro- and Micronutrient Intake

Noor K. Al-Shibli[1]; Anne L. L. Dunlop[2]; Suchitra Chandrasekaran[3]

[1]Emory University, School of Medicine, Atlanta, GA; [2]Emory University School of Medicine, Atlanta, GA; [3]Emory University, Atlanta, GA

8:30 AM - 8:45 AM

Objective: Nutritional deficiencies and associated adverse pregnancy outcomes are emerging threats to public health. Little is known about the impact of the lived food environment on prenatal diet quality. This study aimed to explore the impact of living in a food desert (FD) on macro- and micro-nutrient intake in pregnancy.

Study Design: We performed a single-center prospective pregnancy cohort study from 2014-2024. Participants were a subset of those enrolled in the Atlanta African American Maternal-Child Cohort, which included pregnant people ages 18-40 with a singleton 8-14 weeks' gestation who identified as Black/African American. Block-Bodnar food frequency questionnaires (FFQ) were administered at 8-14 or 24-30 weeks' gestation. Responses were used to estimate dietary intake of macro/micronutrients. Address of primary residence was assigned to a census tract; FD status was assigned to low-income & low-access tracts

according to U.S. Department of Agriculture (USDA) definitions. Descriptive and bivariate statistics were utilized.

Results: Of n = 543 pregnancies, n = 242 (45%) lived in a FD. Median BMI was 28.3 and 27.1 in FD and non-FD, respectively (p = 0.321). FD census tracts had more housing units that utilized Supplemental Nutrition Assistance Program (SNAP) benefits: 586 vs 362 (p< 0.0001). Living in a FD was not associated with significant differences in macro/micronutrient intake (Table 1). However, a large proportion of FD & non-FD cohorts had insufficient micronutrient intake. Rates of insufficient intake were highest for vitamin D, magnesium, folic acid, & iron (Table 2).

Conclusion: Interestingly, our data demonstrates no difference in prenatal intake of macro/micronutrients according to residence in a FD. Both groups had high rates of insufficient micronutrient intake regardless of living in a FD or non-FD. These findings highlight the current prenatal nutritional crisis and support a shift in policy focus to nutrition education, food prescription programs, and diet culture to optimize maternal nutrition status in pregnancy and beyond.

Table 1: Macro- and Micro-nutrient intake by Food Desert Status

Median	Non-Food Desert	IQR [Q1-Q3]	Food Desert	IQR [Q1-Q3]	p-value
Age, years	26	8 [22-30]	24	8 [21-29]	0.005
BMI,* mg/kg^2	27.1	7.79 [23.3-33.7]	28.3	8.18 [23.8-34.5]	0.321
Macronutrients:					
Kcal†	1741	1700 [1103-2803]	1801	1631 [1156-2788]	0.759
Protein, g	62.65	60.28 [41.63-101.9]	62.66	55.29 [40.46-95.75]	0.721
Total fat, g	69.78	67.61 [46.43-114.0]	74.69	67.27 [47.02-114.3]	0.908
Carbohydrates, g	219.23	209.7 [139.7-349.5]	223.4	205.7 [145.6-351.3]	0.667
Micronutrients:

42 | Small for Gestational Age Prediction Using Unsupervised Machine Learning of First Trimester Fetal Cardiac Parameters

Rebecca Horgan[1]; Elena Sinkovskaya[1]; Erkan Kalafat[2]; George R. Saade[1]; Alfred Abuhamad[3]

[1]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [2]Koc University Hospital, Istanbul, Istanbul; [3]Eastern Virginia Medical School, Norfolk, VA

8:45 AM - 9:00 AM

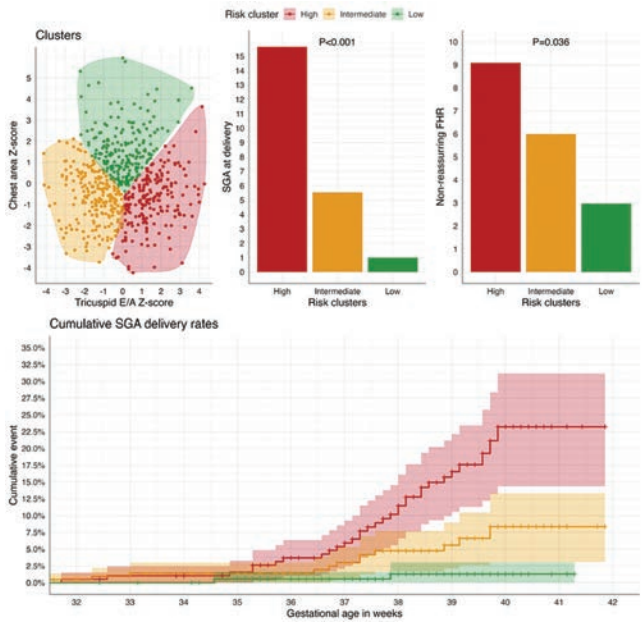
Objective: To use unsupervised machine learning techniques on first trimester fetal cardiac parameters to predict risk of subsequent small for gestational age (SGA) birthweight.

Study Design: This was a prospective cohort study which enrolled patients at ≤ 13+6 weeks' gestation without fetal, umbilical cord or placental abnormalities. At the 1st trimester ultrasound, the chest area, heart area, ventricular inlet lengths, spectral and color Doppler of the atrioventricular valves, valvular regurgitation and myocardial performance index were assessed. K-Medoids clustering was applied to sort fetuses into risk groups for SGA, defined as a birthweight < 10th percentile for gestational age. Candidate variables were selected with regression analyses and the Elbow method was used to determine the optimal number of clusters. Cumulative rates of outcomes were plotted with Kaplan-Meier analysis and model performance was tested with area under the curve values with repeated cross-validation.

Results: 617 pregnancies were included in the analysis, of whom 45 (7.3%) delivered an SGA neonate. Z-scores of chest area (P = 0.027) and tricuspid valve E/A ratio (P< 0.001) showed an independent association with delivery of an SGA neonate and were used in the clustering algorithm. Unsupervised learning algorithm found 3 risk clusters, low (n = 202), intermediate (n = 217), and high (n = 198). The rates of SGA (1.0%, 5.5% and 15.7%, P< 0.001) and non-reassuring fetal heart rate tracings (3.0%, 6.0% and 9.1%, P = 0.036) differed significantly between the three risk clusters (Figure 1). AUC values of the model in cross-validation samples were 0.79 (IQR: 0.76–0.81). Using low risk cluster as a threshold, model sensitivity was 95.5% and specificity was 35.0%. The negative predictive value for ruling out SGA was 99.0%.

Conclusion: Unsupervised machine learning of first trimester fetal cardiac parameters can effectively stratify risk for SGA

neonates. Our findings support the hypothesis that fetal growth trajectory is impacted by early development and may explain the association between fetal growth and programming of adult cardiovascular function.



43 | Pravastatin Dose-Range and Pharmacokinetic Study in a Pregnant Rat Model

Xiao-Yu Wang[1]; Sydney Lammers[2]; Jennifer Reno-Graber[3]; Frederick Reno[3]; Alan Hoberman[4]; George R. Saade[5]; Monica Longo[6]; Victoria L. Pemberton[7]; Ronald J. Wapner[8]; Nicole Abbott[1]; Zhiliang Xie[1]; Joo Young Na[1]; Mitch A. Phelps[1]; Maged M. Costantine[1]

9:00 AM - 9:15 AM

Objective: Pravastatin has biologic plausibility and promising preliminary clinical data for the prevention of preeclampsia. We sought to determine its pharmacokinetic (PK) properties and biodisposition in a Sprague Dawley (SD) pregnant and juvenile offspring rat model.

Study Design: Pregnant female SD rat dams (n = 18/dose) were administered pravastatin by gavage at doses of 0 (ctrl), 15, 45, and 90 mg/kg/day starting on gestation day (GD) 6 through postnatal day (PND) 6. Randomly selected male and female juvenile pups were dosed at 0 (ctrl), 15, 45 and 90 mg/kg/day (n = 18/sex/dose) on PND7 until PND21. Brain, liver, and plasma samples were collected, and pravastatin and its primary metabolite, 3α-hydroxy pravastatin, were measured with validated HPLC assay to calculate PK parameters on GD20 F0 dams, GD20 F1 fetuses (pooled), and PND21 F1 male and female pups.

Results: Pravastatin at all doses was well tolerated in the F0 dams and F1 pups and did not affect growth or development of the F1 pups. Incremental dosing was associated with increasing plasma exposures in F0 dams, F1 fetuses, and F1 pups (AUC and Cmax; Tables 1, 2). Exposure levels in the dams was equivalent to 5- to 67-fold increase over those observed in pregnant women on pravastatin 20mg/day (Table 1). GD20 PK data show very low transfer of pravastatin from dams to fetuses, with F1 fetus exposures ~≤5% that of F0 dams (Table 1). Direct dosing of F1 pups resulted in systemic exposure that was significantly higher than exposure of the dams. Brain PK data show very low brain exposure for both pravastatin and 3α-hydroxy pravastatin in F1 GD20 fetuses and PND21 pups (Tables 1, 2). Liver PK profiles show dose-dependent increased exposure compared with brain at similar doses.

Conclusion: In a rat model, maternal to fetal transfer of pravastatin is minimal and fetal and postnatal juvenile pup brain exposure to pravastatin and its metabolite is limited. Our studies also demonstrate no overt toxicity in the dams or offspring with antenatal pravastatin use and support the continued research in repurposing of pravastatin for preeclampsia prevention.

Table 1: Pravastatin plasma PK of F0 dams, F1 fetuses (pooled) plasma and brain (all GD20)

	Dose (mg/kg/day)	C_{max} (nM)	AUC_{last} (nM*hr)	Ratio of F1 Fetal pooled samples/ F0 Dams plasma*	Plasma AUC in F0 Dams / Pregnant people (dosed 20 mg/day)**

44 | Patterns of Perceived and Everyday Stress, Resilience, and Adverse Placentally Mediated Outcomes

Maura Jones Pullins; Sarah Heerboth; Joy McNeal; Ashlyn Tolbert; Annie Dude; Johanna Quist-Nelson; Rebecca Fry; Tracy A. Manuck

University of North Carolina, Chapel Hill, NC

9:15 AM - 9:30 AM

Objective: Prenatal stress is common. However, the quantity and type of stress throughout pregnancy remains poorly defined, and the magnitude of the association between stress, resilience, and hypertensive disorders of pregnancy (HDOP) remains poorly understood.

Study Design: Primary analysis of 2 prospective cohorts, 2017-2022. Patients were recruited < 28 weeks' and completed the Perceived Stress Scale (PSS, range 0-40; 'high' stress is ≥ 21), Everyday Stress Index (ESI, range 0-60; higher values = higher stress), and the Brief Resilience Scale (BRS, range 1-5; 'low' resilience is < 3) surveys. The primary outcome was plac-comps defined as hypertensive disorders of pregnancy ± birthweight < 10% for GA and sex, ± placental abruption). We evaluated whether survey scores in early pregnancy (< 24 weeks) were associated with the eventual development of plac-comps. Linear regression was used to evaluate whether survey results < 24 weeks assessing stress (by PSS, ESI, or both) and/or resilience were associated with the eventual development of plac-comps.

Results: 1,133 individuals met inclusion criteria; 267 (24%) had plac-comps. Cohort characteristics are shown in Table 1. In general, stress, as quantified by the PSS and ESI, tended to decrease with increasing gestational age, while resilience increased (Figure 1). Overall scores were similar for those with and without plac-comps. However, when considering survey results < 24 weeks, PSS scores were higher and BRS lower among those who developed plac-comps compared to those who did not. In regression models controlling for CHTN, pre-gestational DM, pre-pregnancy BMI, maternal race, and history of PTB, increased resilience (quantified by BRS < 24 weeks) was associated with a reduced odds of plac-comps (aOR 0.73, 95% CI 0.56, 0.95). Neither stress score was associated with plac-comps in regression models.

Conclusion: Overall, stress decreases and resilience increases throughout gestation. Increased resilience in early pregnancy is associated with reduced placentally-mediated adverse outcomes.

Table. Demographic and obstetric characteristics, stratified by those with and without plac-comps [defined as hypertensive disorders of pregnancy (HDOP), small for gestational age at birth (<10% for gestational age and sex), and/or placental abruption). All data presented as n(%) or as median (IQR), as applicable, unless otherwise noted.

Characteristic	Plac comps N=267	No plac comps N=866	P-value

45 | Microfluidic Device Successfully Replaces Traditional Models of Pregnancy Associated Drug Pharmacokinetic Studies

Ana Collins-Smith; Ananth Kammala; Lauren Richardson; Xiao-ming Wang; Ramkumar Menon
University of Texas Medical Branch, Galveston, TX

9:30 AM - 9:45 AM

Objective: Pregnant & lactating people remain therapeutic orphans. To mediate this problem, we evaluated drug propagation using a microphysiologic (MPS) model of the human maternal-fetal interface (FMi-PLA-OOC) with simulation software to see if this could serve as an alternative & more efficient approach to studying pharmacokinetics across the placental barrier during pregnancy surpassing the limitations of traditional placental perfusion systems & animal models.

Study Design: The humanized FMi-PLA-OOC is composed of 7-cell culture chambers & connected by microchannels containing seven different cells from the feto-maternal interface. A physiological dose of indomethacin (15µg/mL) was introduced into the decidual chamber to assess drug pharmacokinetics. Media & supernatants were collected at various time points & analyzed using mass spectrometry. A physiologically based pharmacokinetic (PBPK) pregnancy model was developed using Gastroplus & compared with placental perfusion studies, animal models, and clinical data from the literature.

Results: Cells in the FMi-PLA-OOC maintained viability, metabolism, & did not show cytotoxicity. The drug propagated & reached the placental layers in 4 hours and the fetal membrane cellular layers in 1 hour. Comparing maximum drug concentrations ratios in the fetus and mother (Cmax, fetal/Cmax, maternal) amongst the different platforms demonstrated: 0.45 (placental perfusion), 0.97 (pregnant humans), 0.77 (FMi-PLA-OOC), 0.88 (PBPK). The fold error of FMi-PLA-OOC & PBPK for Cmax ratios compared to human studies were 0.8 and 0.9, demonstrating an acceptable model.

Conclusion: The utilization of the innovative feto-maternal interface MPS model & PBPK simulation yielded data comparable to the current traditional & simulation approaches. Our humanized MPS model can determine other pharmacologic parameters (efficacy, toxicity, metabolism, absorption, excretion), making preclinical trials easier, cheaper, and faster and in compliance with the FDA Modernization Act 2.0.

A. Concentration of indomethacin that propagated across the FMi-PLA-OOC at 4 and 8 hours

FMi-PLA-OOC	4 hours (ng/mL)	8 hours (ng/mL)

46 | Continuous Glucose Monitoring for Gestational Diabetes Diagnosis: A Comparative Effectiveness Randomized Control Trial (PRECISE)

Sarah A. Nazeer[1]; Joycelyn A. Corntwaithe, RD, CDE[1]; Rafael Bravo Santos[1]; Claudia Pedroza[1]; Sean C. Blackwell[2]; Suneet Chauhan[3]; Farah H. Amro[2]; Ghamar Bitar[2]; Jon Tyson[1]; Baha M. Sibai[2]; Michal Fishel Bartal[4]

[1]The University of Texas Health Science Center at Houston (UTHealth), Houston, TX; [2]McGovern Medical School at UTHealth Houston, Houston, TX; [3]Christiana Care, Newark, DE; [4]UTH Houston & Sheba Medical Center Israel, Houston, TX

9:45 AM - 10:00 AM

Objective: Continuous glucose monitoring (CGM) offers innovative strategies to improve outcomes for gestational diabetes (GDM). We aimed to test the utility of new technology in the diagnosis of GDM compared to the 2-step method.

Study Design: Individuals with a singleton pregnancy, at 24-30 weeks gestation were randomly allocated to screening with either CGM (Dexcom G6) for 7 days or 2-step method after stratifying by BMI (≤ 40) and site (03/2023-04/2024). Individuals diagnosed with fetal anomalies or pregestational DM were excluded. Diagnosis of GDM was made by CGM if any of the following: Time above range (TAR) (≥140 mg/dL) ≥ 10%, mean glucose ≥ 130, or any glucose ≥ 200. GDM was diagnosed by 3-hour GTT for the routine group. Following GDM diagnosis, both groups received usual care. Primary outcome was a composite of adverse neonatal outcomes (LGA, shoulder dystocia, birth injury, need for IV/PO glucose, respiratory distress, and fetal/neonatal death). We utilized Bayesian statistics to estimate a sample size of 814 to have a posterior probability of 75% of any reduction of the primary outcome, assuming 90% power with a 30% reduction with CGM. Analysis was done with an intention-to-treat under a Bayesian framework with a neutral informative prior and with frequentist statistical analysis (NCT05430204).

Results: A total of 814 participants were randomized: 405 in the CGM group, and 409 in the 2-step method group. Groups were similar at baseline (Table 1). Primary outcome was unavailable for 34 (4.2%). GDM was diagnosed in 89 (22%) in the CGM group and 63 (15%) in the 2-step group. Primary neonatal outcome was similar between the groups (34% v. 29%; RR 1.13, 95% Credible interval 0.93-1.4, posterior probability 88%, Table 2). There were no differences in secondary outcomes. In a prespecified, secondary analysis, no difference in primary outcome among individuals treated for GDM was found (50% v. 37%; RR 1.13 95% CI 0.96-1.32).

Conclusion: In this RCT, the use of CGM for diagnosis of GDM was associated with an increased rate of GDM and similar rates of adverse outcomes compared to the 2-step method.

1:30 PM - 1:45 PM

Objective: Recent research has identified multiple circulating miRNA biomarkers that may predict neonatal brain injury following hypoxia-ischemia. We hypothesized that quantification of these miRNAs in CNS derived extracellular vesicles (EV) would result in more accurate prediction of subsequent brain injury given that total circulating markers represent miRNAs from multiple organ sources.

Study Design: CNS EVs were purified from serum samples from 35 neonates who underwent therapeutic hypothermia for NE using previously published methods. Neonates were subsequently categorized into 2 groups based on post warming MRI using the Barkovich scoring system: no/mild injury (n = 21) or moderate/severe injury (n = 14). The four most predictive circulating miRNAs were selected and quantified in CNS EVs using standard qPCR techniques at two time points after birth: 0-6 hours and 48 hours. Biomarker levels were compared between no/mild and moderate/severe injury using the Kruskal-Wallis test and ROC curves were constructed for individual and combined miRNAs.

Results: All miRNA biomarkers were significantly different between groups at 48 hours, but miRNAs 328-3p and 342-3p were the most effective at discriminating between the two clinical outcomes (Figure 1a, miRNAs 197-3p and 150-5p not shown). The combination of all 4 miRNAs resulted in an area under the curve of 0.96 (Figure 1b). However, miRNA 328-3p as a single marker had a similar performance (AUC 0.93) and may be a more cost-effective approach.

Conclusion: Predictive biomarkers are critically important in identifying neonates who will have residual neurologic injury following neonatal encephalopathy despite therapeutic hypothermia. Early identification would allow for early implementation of additional neuroprotective interventions in this subpopulation. We present data identifying 1 to 4 miRNAs that appear to be effective biomarkers at 48 hours. Further investigation is required to determine if CNS EV miRNAs are superior to circulating miRNAs in this clinical scenario.

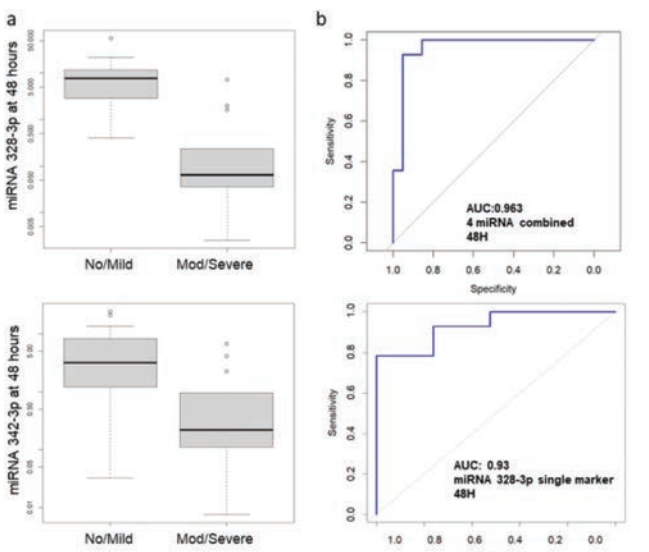

Figure 1. 1a. Median CNS EV miRNA content at 48 hours in neonates with no/mild NE vs moderate severe NE. Significance was determined by Kruskal Wallis testing ($p<0.0001$ for miRNA 328-3p; $p=0.003$ for miRNA 342-3p). 1b. Receiver operator curve (ROC) for the predictive performance of 4 EV miRNA biomarkers vs miRNA 328-3p as a single marker in discriminating between mild/no NE and moderate/severe NE on post warming MRI.

48 | 3D-Printed Humanized Feto-Maternal Interface Tests Exosomal Delivery of Anti-Inflammatory Interleukin-10 (IL-10) to Reduce Infection-Associated Inflammation

Leah Saylor[1]; Rahul Cherukuri[2]; Ananth Kammala[1]; Marc Ferrer[3]; Cristina Antich Acedo[3]; Arum Han[2]; Lauren Richardson[1]; Ramkumar Menon[1]

[1]*University of Texas Medical Branch, Galveston, TX;* [2]*Texas A&M University, College Station, TX;* [3]*National Center for Advancing Translational Sciences, National Institute of Sciences, Bethesda, MD*

1:45 PM - 2:00 PM

Objective: Spontaneous preterm birth (PTB) is linked to fetal inflammatory responses (FIR), typically caused by infections. Current treatments are limited because drugs often cannot cross the feto-maternal interface (FMi). This study uses New Approach Methods (NAMs), like extracellular vesicles (EVs) for drug delivery and a high-throughput 3D-printed organ-on-chip (OOC) model to test efficacy.

Study Design: Recombinant IL-10 was delivered in extracellular vesicles (eIL-10) via electroporation and through THP1 cells transfected with an IL-10 plasmid (tIL-10). A two-chambered 3D scaffold mimicking the feto-maternal interface was used for high-throughput screening. The scaffold, made from biocompatible polymer resin via 3D printing, features microchannels for fluidic communication and a mix of cells and gelatin methacrylate hydrogel in the lower chamber, with cell-specific medium in the upper chamber. We assessed cell viability (LDH), metabolic activity (AlamarBlue), and cytoskeletal markers (cytokeratin-18 and vimentin). Maternal infection was simulated using Lipopolysaccharide (LPS), and the efficacy of eIL-10 and tIL-10 (500ng/mL) in reducing inflammation was evaluated by measuring IL-6 and IL-8 concentrations at 6 and 24 hours.

Results: Our 3D-printed OOC FMi model supported cell growth, viability, and metabolic activity. LPS, eIL-10, and tIL-10 successfully moved between the interconnected chambers. LPS increased IL-6 ($p< 0.001$) and IL-8 ($p< 0.001$) in both decidua and amnion compared to controls. Co-treatment with IL-10, in any form, significantly reduced cytokines on both maternal ($p< 0.05$) and fetal sides ($p< 0.05$).

Conclusion: We developed a 3D-printed feto-maternal interface that effectively tested and showed that exosomal encapsulated IL-10 reduces FMi infectious inflammation. We propose two NAMs: (1) exosomal drug delivery and (2) a 3D-printed device for high-throughput drug screening. These approaches could significantly improve perinatal medicine by reducing inflammation that leads to preterm birth.

49 | Decoy Peptide to (pro)renin Receptor as a Potential Therapeutic Target for Preeclampsia: a Translational Study

Michelle Harris[1]; Ahmed F. Pantho[2]; Kelsey R. Kelso[1]; Jessica C. Ehrig[3]; Ram R. Kalagiri[1]; Niraj Vora[1]; Thomas J. Kuehl[2]; Steven R. Lindheim[1]; Mohammad N. Uddin[4]

2:00 PM - 2:15 PM

Objective: Preeclampsia (preE), a syndrome of hypertension, proteinuria, and end organ damage, is a leading cause of maternal and fetal morbidity and mortality. Circulating levels of soluble (pro)renin receptor (PRR) and placental (pro)renin (PR) have been shown to be elevated in a preE rat model and preE human subjects with a decoy peptide based on this handle-region peptide (HRP) that can block binding of PR to PRR. The goal of this study was to develop and characterize HRP as an innovative treatment for preE and PRR as a novel biomarker for preE.

Study Design: The human extravillous cytotrophoblasts (CTBs) incubated with PRR in medium with the receptor-expressing CTBs followed by renin activity assay to determine the percent binding and activation of PRR. Renin activity assay was performed to determine the percent binding and activation of PRR. Pregnant female rats were randomly assigned to three pregnant groups: 1) NP: normal rats; 2) PDS: rats injected desoxycorticosterone acetate (DOCA) whose drinking water was replaced with saline; and 3) PDS-HRP: rats administered DOCA and saline and given HRP during pregnancy. Additionally, placental and blood samples were collected from pregnant women (40 NP and 30 preE) and analyzed by WB and IHC and s(P)RR ELISA in an IRB approved study.

Results: PR was activated by binding to PRR on the cell membrane of CTB cells, while HRP inhibited binding (100% vs 20%, $p< 0.05$) and activation of PRR (100% vs 30%, $p< 0.05$). HRP administration normalized blood pressure, proteinuria, and birth numbers in the DOCA preE rat model. The placental expression of PRR and soluble PRR were higher ($p< 0.05$) in human preE compared to NP women, respectively.

Conclusion: Our data suggests that increased expression of PRR in the placenta is associated with elevated levels of soluble PRR and is related to preE in the rat model and human subjects. Given HRP appears to inhibit binding of PR to PRR, its use may serve as a potential therapeutic intervention in preE.

Table. HRP normalizes proteinuria and pup numbers in DOCA model

Groups	Protein (mg/24h)	No. Pups	% Malfunctioned Pups
NP	2.8 ± 1.1	14.0 ± 1.8	0
PDS	5.7 ± 1.6 *	10.2 ± 1.5 *	16
NPM	6.4 ± 1.8 *	9.5 ± 1.3 *	18
PDS-HRP	2.6 ± 1.2	13.9 ± 1.4	0

50 | Longitudinal Changes in Epigenetic Aging in Pregnant Versus Non-Pregnant People: a Prospective Cohort Study

Danielle M. Panelli; Nicole Gladish; Nicola C. Perlman; Andres Cardenas; Katherine Bianco

Stanford University, Palo Alto, CA

2:15 PM - 2:30 PM

Objective: Higher parity has been linked with accelerated biologic aging, yet the direct effects of pregnancy itself on epigenetic aging biomarkers are unknown. We compared changes in epigenetic aging across gestation between pregnant and non-pregnant people.

Study Design: This was a prospective cohort of nulliparous people aged 18-50 years seeking obstetric or gynecologic care in 2020. Pregnant people were enrolled between 10 and 14 weeks gestation and age-matched to the next eligible non-pregnant person. Blood samples were collected at enrollment (Time 1) and again either on postpartum day 1 (pregnant) or approximately 7 months later (non-pregnant, Time 2). The primary outcome was biological age, determined from epigenetic clocks using Illumina EPIC Human Methylation BeadChips. Biologic ages at specific time points were compared using t-tests. Changes in biologic age over time were analyzed using mixed effects linear regression models, adjusting for confounders and interaction between time and pregnancy status. Results focus on the two strongest clocks: GrimAge (biologic age in years) and DunedinPACE [aging acceleration (≥ 1) or deceleration (< 1)].

Results: 75 people enrolled, of whom 61 (81.3%) completed both timepoints. While the sample interval differed by cohort, their chronologic ages were similar (Table 1). By Time 2, the pregnant cohort had an older GrimAge than the non-pregnant cohort [mean (SD) 56.7 (3.5) versus 52.9 (6.0) years, p = < 0.01). Additionally, DunedinPACE indicated faster aging in the pregnant cohort at Time 2 [1.2 (0.1) pregnant versus 1.0 (0.1) non-pregnant, p = < 0.001]. Significant interaction between time and pregnancy status was detected for both GrimAge (p< 0.01) and DunedinPACE (p< 0.01, Figure 1).

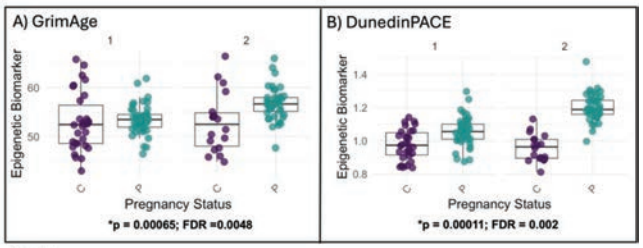
Conclusion: We found significant epigenetic aging acceleration in nulliparous pregnant people compared to their non-pregnant counterparts, highlighting gestation as a key period for epigenetic changes. Further characterizing these epigenetic aging trajectories may inform future interventions to improve maternal and child health.

Table 1. Demographics compared between pregnant and non-pregnant study participants, 2020-2021, N=75.

Characteristic	Pregnant N=45	Non-Pregnant N=30	p-value[a]
Mean chronologic age at Time 1 (years)	31.1 (3.4)	32.6 (7.4)	0.72
Mean chronologic age at Time 2 (years)	32.4 (3.4)	32.9 (7.0)	0.59
Mean body mass index at enrollment (kg/m^2)	23.1 (3.7)	24.9 (4.7)	0.12
Race			
Asian or Pacific Islander	19 (42.2%)	8 (25.7%)	
Black	2 (4.4%)	0	0.29
White	21 (46.7%)	19 (63.3%)	
Other or unknown	3 (6.7%)	3 (10.0)	
Hispanic ethnicity	5 (11.1)	2 (6.7)	0.70
Highest level of education			
Completed high school	3 (6.7%)	1 (3.3%)	
Completed college	10 (22.2%)	11 (36.7%)	0.20
Pursuing or completed higher degree	30 (66.7%)	14 (46.7%)	
Unknown or missing	2 (4.4%)	4 (13.3%)	
Spontaneous conception	39 (86.7%)	-	-
Comorbidity at time of enrollment			
None	24 (53.3%)	15 (50.0%)	0.81
Neurologic or psychiatric	9 (20.0%)	5 (16.7%)	0.77
Chronic hypertension	0	2 (6.7%)	0.16
Type 1 or 2 Diabetes	1 (2.2%)	0	1.00
Hypo- or hyperthyroid	5 (11.1%)	1 (3.3%)	0.39
Other	13 (29.9%)	11 (36.7%)	0.61
Enrolled prior to COVID-19 lockdown (March 17, 2020)	23 (51.1%)	18 (60.0%)	0.49
Number with both timepoints (%)	43 (95%)	18 (60%)	0.02
Mean number of days between Time 1 and Time 2	196.7 (12.6)	242.0 (50.7)	<0.01

[a] Shown as mean (standard deviation) for continuous variables and N (%) for categorical.
[b] Wilcoxon rank sum for continuous variables or Fisher's exact test for categorical.

Figure 1. Changes in selected biologic clocks over time in prospective cohort of pregnant (P) versus non-pregnant (C) people, 2020-2021



Legend:
GrimAge biologic clock is interpreted in years, similar to chronologic age.
DunedinPACE [(P)ace of (A)ging (C)alculated from the (E)pigenome] biologic clock reflects aging acceleration (≥1) versus deceleration (<1).
C = Control, non-pregnant.
P = Pregnant.
Time 1 = enrollment, Time 2 = postpartum day 1 or scheduled date approximately 7 months later in non-pregnant cohort.
P-values from the following mixed linear effects model: Biomarker ~ Pregnancy*Timepoint + Chronologic Age + Cell Types + (1|Participant).
FDR = correction for false discovery rate multiple testing.

51 | Lactobacillus Crispatus Mitigates Group B Streptococcus-Induced Inflammation in the Cervicovaginal Epithelium

Briana Ferguson; Aaron Loder; Lauren Anton; Kristin D. Gerson
University of Pennsylvania Perelman School of Medicine, Philadelphia, PA

2:30 PM - 2:45 PM

Objective: Group B *Streptococcus* (GBS) is a common vaginal microbe involved in adverse perinatal outcomes, including preterm birth, chorioamnionitis, and neonatal sepsis. Features of vaginal ecosystems may modify GBS pathogenicity. Previous work has shown that *Lactobacillus crispatus* (LC), a marker of reproductive health, mitigates proinflammatory cytokines in response to select vaginal pathogens. We sought to investigate the effect of LC on GBS-mediated inflammation in the cervicovaginal epithelium.

Study Design: We leveraged an *in vitro* epithelial-microbial coculture model. Ectocervical, endocervical, and vaginal epithelial cells were treated with 10^5 CFUs of LC for 24h. Cells were then treated with 10^4 CFUs of GBS clinical isolates (serotypes IA, III, and IV) for an additional 24h. Concentration of proinflammatory cytokine IL-8 was measured in cell culture media by ELISA. Cytotoxicity was assessed using LDH assays. Outcomes were compared by one-way ANOVA with correction for multiple comparisons. Microbial count (CFU/well) was measured on De Man-Rogosa-Sharpe and Granada agar plates to select for GBS growth.

Results: LC had no effect on IL-8 expression, while all GBS serotypes induced IL-8 across cells ($p < 0.05$ for all, Fig. 1). LC rescued GBS induction of IL-8 to near basal levels ($p < 0.05$ for all, Fig. 1). LC did not alter LDH in GBS-treated cells (data not shown), indicating that IL-8 reduction was not attributable to cell death. To test if immune mitigation occurred due to LC outcompeting GBS growth, we assessed microbial counts at the time of IL-8 measurement. LC did not alter the number of viable GBS colonies, and unexpectedly no live LC was detected (Table 1).

Conclusion: LC mitigates host inflammatory response to a vaginal microbe implicated in adverse pregnancy outcomes. Microbial competition does not appear to underlie this protective effect, suggesting that immune-mediated mechanisms are at play. Whether LC microbial components or secreted factors, such as metabolites, modify GBS-epithelial interactions warrants future

investigation. University of Pennsylvania Research Foundation Award (KDG)

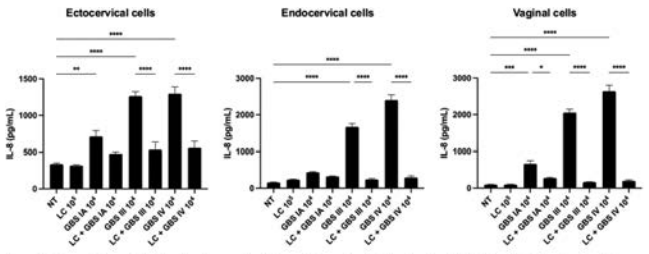


Figure 1. Concentrations of IL-8 in cell culture media of ectocervical, endocervical, and vaginal epithelial cells after treatment with three Group B *Streptococcus* (GBS) serotypes +/- pretreatment with *Lactobacillus crispatus* (LC). *p<0.05, **p<0.01, ***p<0.001, ****p<0.0001

52 | Expression of CD300E in Human Myometrium and its Impact on Parturition

Meera M. Thakkar[1]; William E. Ackerman, IV[1]; Guomao Zhao[1]; Zoe B. Strong[1]; Elizabeth Feoktistov[2]; Ekaterina Snegovskikh[2]; Catalin S. Buhimschi[1]; Irina A. Buhimschi[1]

[1]*University of Illinois at Chicago, College of Medicine, Chicago, IL;* [2]*University of Illinois at Chicago, Chicago, IL*

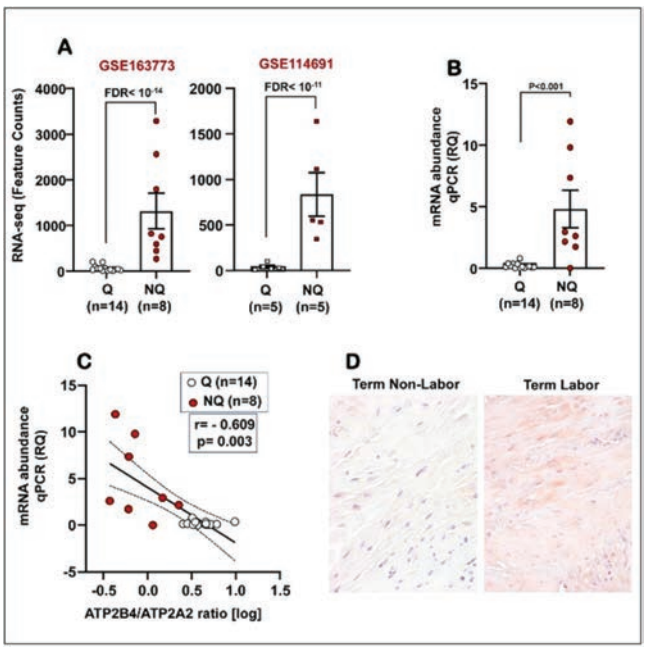
2:45 PM - 3:00 PM

Objective: CD300 glycoproteins are a newly identified family of 7 receptors with paired inhibitory and activating cellular functions. CD300 receptors have recently emerged as therapeutic targets. CD300E is expressed in myocardial smooth muscle and has been linked to cardiac arrythmia. Our novel study sought to examine if CD300E is expressed in the human myometrium and if its levels of expression vary in relationship to the uterine contractile status.

Study Design: RNA sequencing was performed on myometrial biopsies of 22 patients in the following clinical groups (dataset GSE163773): 1) spontaneous preterm birth (PTB) with clinical and/or histologic chorioamnionitis (HCA, n = 6, GA 29±3w); 2) PTB without labor (PTNL, n = 6, GA 29±3w); 3) term birth in absence of labor (TNL, n = 5, GA: 39±1w) and 4) spontaneous term labor (TL, n = 5, GA 40±1w). An external RNAseq dataset (GSE114691) was used for validation. The combined dataset comprised 20 term and 12 preterm samples further stratified by uterine contractile status as quiescent (Q, n = 19) and non-quiescent (NQ, n = 13). qPCR and immunohistochemistry (IHC) for CD300E were performed for confirmation.

Results: *CD300E* mRNA was significantly upregulated in NQ vs. Q myometrium in both datasets (Fig. **A**). This was confirmed by qPCR (Fig. **B**), which was strongly correlated with the RNAseq expression data in matched samples ($r = 0.8$, $p < 0.001$). Moreover, *CD300E* expression was significantly correlated with *ATP2B4*/*ATP2A2*, a previously characterized ratio of Ca^{2+} transporters genes used for molecular classification of myometrial contractile status (Fig. **C**), independent of GA, amniotic fluid culture results or membrane status. By IHC we validated CD300E was present in myometrial cells with a stronger labeling in labor (Fig. **D**).

Conclusion: CD300E is expressed in human myometrium and significantly upregulated in laboring myometrium. CD300E may prove to be future therapeutic targets for prevention of preterm birth.



53 | Personalized Models of fetal Brain Development as Biomarkers of Offspring Neurodevelopmental Outcomes After Maternal SARS-CoV-2

Lydia L. Shook; Liam T. McCrea; Olyvia Jasset; Steven D. Sheridan; Roy H. Perlis; Andrea G. Edlow

Massachusetts General Hospital, Boston, MA

3:00 PM - 3:15 PM

Objective: Maternal immune activation from viral infection in pregnancy is associated with adverse neurodevelopmental (ND) outcomes in offspring, mediated at least in part by *in utero* programming of fetal brain microglia resulting in aberrant synaptic pruning. We have shown the feasibility of using human cord blood mononuclear cells (CB-MNCs) to model the impact of maternal viral infection on fetal brain development. In a large cohort, we examined associations between CB-MNC models and offspring adverse ND outcomes at 3 years of age using linked electronic health records (EHR).

Study Design: CB-MNCs were selected from 119 unvaccinated individuals enrolled in a COVID-19 biorepository (April 2020 - August 2022): 74 with maternal SARS-CoV-2 infection in pregnancy (N = 38 1st or 2nd trimester infection, N = 36 3rd trimester infection) and 45 uninfected controls. We induced CB-MNCs to acquire microglia-like morphology and function (cord blood induced microglia or CB-iMG) using IL-34, GM-CSF, and serum withdrawal. CB-iMG phagocytosis of iPSc-derived neural synaptosomes-a proxy for microglial synaptic pruning behavior-was quantified using real-time pHrodo fluorescence-based imaging. ND outcomes of offspring at 3 years were determined using an EHR-based algorithm to identify ICD-10 codes associated with ND in an integrated statewide health system.

Results: CB-iMG exhibited typical microglial morphology and marker expression (Fig 1A). Synaptosome phagocytosis was greater ($p< 0.001$) in the CB-iMG of offspring exposed to 3rd trimester maternal SARS-CoV-2 with an adverse ND outcome (N = 6) compared to exposed offspring with no ND outcome (N = 30) (Fig 1B). Among unexposed offspring (N = 45), phagocytosis scores between groups were not significantly different. Phagocytosis in models derived from 1st and 2nd trimester infection did not differ significantly from controls.

Conclusion: Although additional validation is needed, personalized models using CB-MNCs available at birth show promise for identifying offspring at greatest ND risk after exposure to maternal viral infection *in utero*.

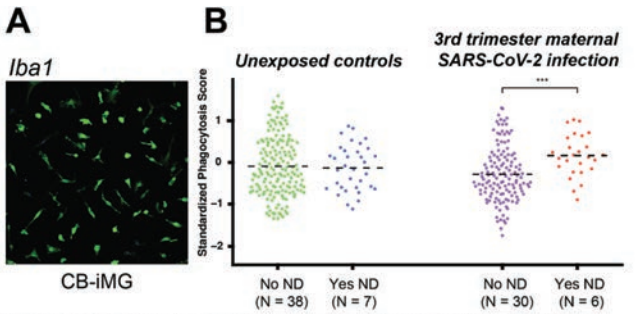


Figure 1. A. Cord blood induced microglia-like cells (CB-iMG), demonstrating ramified morphology and canonical microglia marker *Iba1* (green). B. Phagocytosis scores of CB-iMG from offspring exposed to 3rd trimester maternal SARS-CoV-2 infection (N=36) and unexposed controls (N=45) by presence or absence of neurodevelopmental diagnosis (ND) at 3 yrs of age. ***p<0.001. N=26-159 image fields per group.

54 | The Placental Vascular Transcriptome in Pregnancies Resulting in Low vs. Normal Birth Weight Neonates

Samantha Carson[1]; Morgan E. Wasickanin[1]; Emily Sheikh[1]; Hillary Kinsman[1]; Lydia Bettridge[1]; Katherine E. Free[1]; Jennifer Damicis[1]; Robert Walton[1]; Peter Napolitano[2]; Nicholas Ieronimakis[1]

[1]Madigan Army Medical Center, Tacoma, WA; [2]University of Washington, Seattle, WA

3:15 PM - 3:30 PM

Objective: Placental vascular dysfunction may be associated with fetal growth restriction (FGR). Although not all Low Birth Weight (LBW) neonates are identified as FGR in the prenatal period, it is believed that abnormal placental blood flow is a contributing factor. We hypothesize that molecular differences within placental vessels underly vascular impairment in LBW neonates without known FGR etiologies (e.g. genetic or other congenital anomalies). The objective of this pilot study was to compare the vascular transcriptome within placentas delivered from normal birth weight neonates to those born with LBW.

Study Design: Chorionic arterial and venous vessels were dissected from unlabored placentas delivered by cesarean (Figure 1). Vessels were stripped to remove the membrane and plate along with any blood. Gene expression analysis from normal (n = 8) and LBW neonates (n = 10) was performed using mRNA-seq. Alignment and differential gene expression (DEGs) analysis was conducted using Illumina's Dragen software. We considered DEGs significant based on a Benjamini-Hochberg FDR adjusted p-value of < 0.05.

Results: Between LBW vs. normal, 15,204 DEGs were identified in arteries and 14,667 in veins. Among these, 5 were significantly upregulated and 1 downregulated in LBW arteries (Figure 2). In LBW veins, 1 DEG was significantly upregulated (not shown). Notably, zinc finger protein (ZNF)365 was downregulated in LBW arteries while ZNF358 was upregulated in veins.

Conclusion: The vascular transcriptome in placental vessels from LBW neonates appears different from those with normal birth weights. Expression of ZNF365 is lower in the placental arteries of LBW baby's and ZNF358 is greater in placental veins of LBW babies. ZNF365 is involved in DNA repair and in colon cancer its correlated with poor prognosis. Little is known about ZNF358 but it may be related to vascular dysfunction. Further investigation is warranted to understand the role of these factors in regulating vascular function in relation to fetal growth.

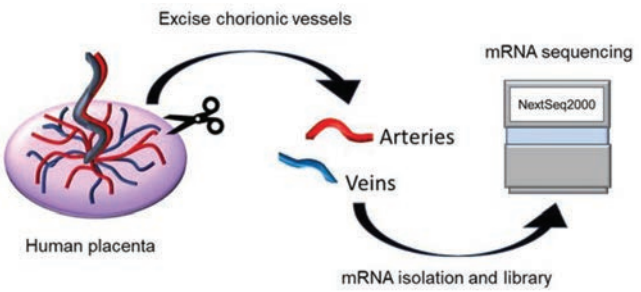

Figure 1. Experimental design illustration. Arteries and veins were excised from the chorionic plate of human placentas and processed for mRNA sequencing using an Illumina system.

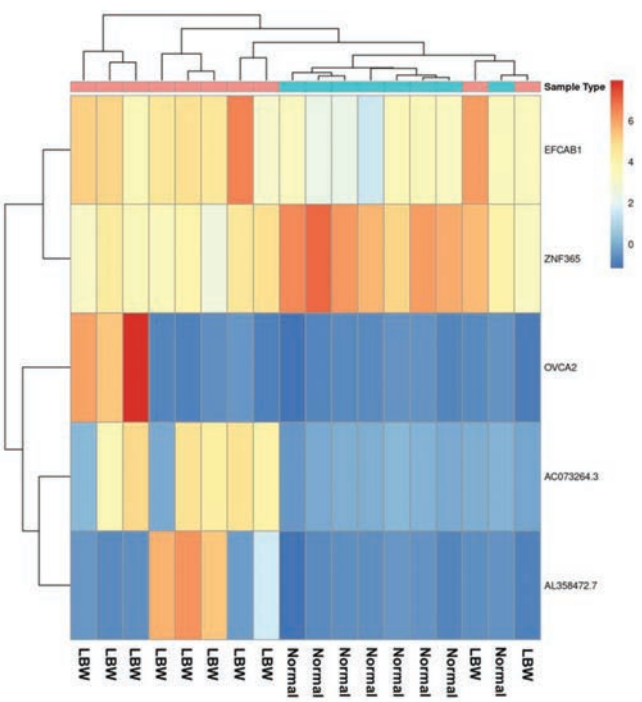

Figure 2. Hierarchically clustered heatmap from mRNA-seq comparing placental arteries from Low Birth Weight (LBW) and normal weight neonates. Represented are genes with adj p<0.05. Color intensities correspond to fold changes between LBW vs. normal samples, red for the upregulation and blue for downregulation of genes across individual placentas.

55 | Commonly Used Non-Steroidal Anti-Inflammatory Drug (NSAIDs) in Obstetrics & Associated Placental Cytotoxicity

Ana Collins-Smith
University of Texas Medical Branch, Galveston, TX

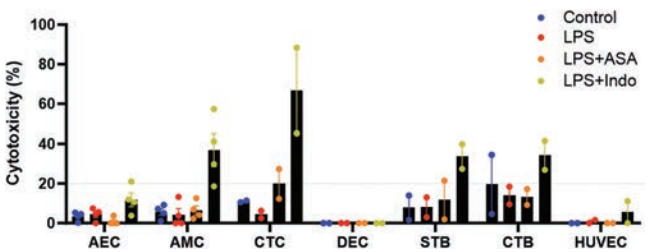
3:30 PM - 3:45 PM

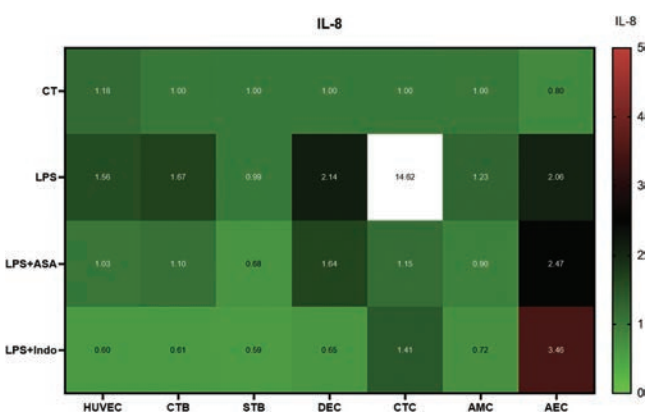
Objective: To determine if commonly used non-steroidal anti-inflammatory drugs have a cytotoxic effect and their ability to reduce inflammation at the cellular level of the feto-maternal interface.

Study Design: A microfluidic fetal membrane-placental feto-maternal interface on-chip (FMi-PLA-OOC) composed of seven different cell types was used to analyze the effects of cell cytotoxicity at the placental-maternal interface with therapeutic concentrations of commonly used NSAIDs in obstetrics. Therapeutic concentrations of aspirin (2µg/mL corresponding to 81mg) and indomethacin (15µg/mL) were applied to the FMi-PLA-OOC with the supernatants analyzed for LDH levels and cytokine levels in both a diseased state, non-diseased state (simulated with lipopolysaccharide (LPS)), and a diseased state with treatment of the NSAIDs.

Results: Cell cytotoxicity in the control group was approximately 20% in AEC, AMC, CTC, and STB cell lines. After application of LPS, the cell cytotoxicity increased in five cell types. Aspirin decreased cell death by approximately 84% in AEC & 48.7% in STB. While indomethacin increased cell death across all cell lines. A three-way ANOVA was conducted with p-value < 0.0001. Pro-inflammatory cytokine IL-8 was decreased with aspirin use.

Conclusion: Indomethacin demonstrates cell cytotoxicity at all layers of the feto-maternal interface. On the other hand, aspirin demonstrated an improvement in cell death in a diseased state which can support the continued use of aspirin for the promotion of placental angiogenesis. Aspirin also demonstrated a decrease in pro-inflammatory cytokines at the placental cellular level.





56 | Evaluating Semaglutide in Human Fetal Neural Stem Cells: Could Early Exposure Impact Neurodevelopment?

Morgan E. Wasickanin[1]; Samantha Carson[1]; Hillary Kinsman[1]; Katherine E. Free[1]; Jennifer Damicis[1]; Emily Sheikh[1]; Robert Walton[1]; Irina Burd[2]; Peter Napolitano[3]; Nicholas Ieronimakis[1]
[1]Madigan Army Medical Center, Tacoma, WA; [2]University of Maryland, Baltimore, MD; [3]University of Washington, Seattle, WA

3:45 PM - 4:00 PM

Objective: Semaglutide (Ozempic/Wegovy) use for diabetes and weight loss management has exploded, especially in reproductive age females. Due to its long half-life and possibility of crossing the placenta, discontinuation of use is recommended prior to conception. Anecdotally, unintentional pregnancies with semaglutide appear to be on the rise. Semaglutide may signal within the adult brain and reduce neuroinflammation, yet it remains unknown if this occurs in the fetal brain. We hypothesize semaglutide exposure early in pregnancy may impact neurodevelopment and/or infer anti-inflammatory properties. We examined if semaglutide alters the phenotype and proinflammatory response of human fetal derived neural stem cells (NSCs) *in-vitro*.

Study Design: Commercially available fetal NSCs (ReNcells) were exposed to either semaglutide or the vehicle. In parallel they were given PBS as a control or Interleukin-1 beta (IL-1B) to stimulate inflammatory responses. Cells were harvested 24-hours post exposure (n = 5-6 per condition) and examined for gene expression.

Results: The expression of genes associated with stem cell maintenance (NESTIN, SOX2) and neural differentiation (MAP2, GFAP) was not different with semaglutide exposure alone. The neuronal gene Beta-III-tubulin (TUBBIII) was significantly downregulated with semaglutide alone and in combination with IL-1B (Fig. 1A). Semaglutide did not impact the upregulation of proinflammatory genes by IL-1B. Though IL-1B exposure did downregulate the expression of the signaling receptor (GLP-1R), this was not related to semaglutide exposure (Fig. 1B).

Conclusion: Semaglutide impacts the NSCs phenotype by down-regulating TUBBIII. Beta-III-tubulin plays an important role in neurodevelopment and has been implicated across a spectrum of long-term brain disorders. The clinical significance of these findings are unclear but support the need for further research and careful monitoring in exposed offspring.

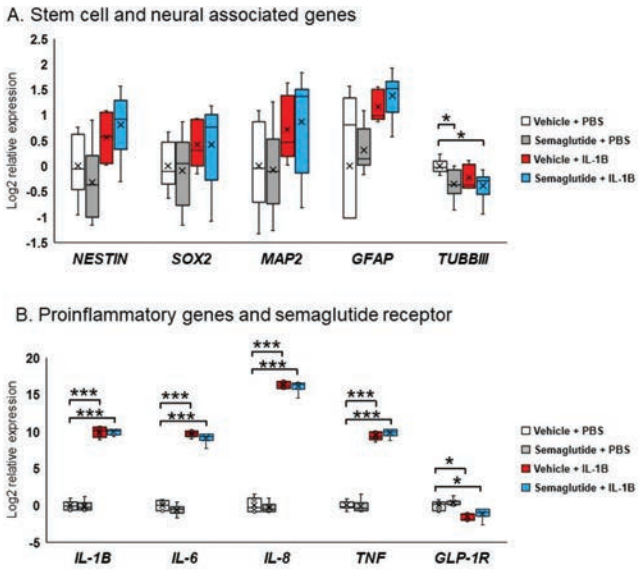


Figure 1. Box and whisker plots show gene expression results from Neural Stem Cells (NSCs) collected 24-hours following exposure to the vehicle or semiglutide in combination with PBS as a control or IL-1B to invoke inflammatory responses. For each treatment combination n=5-6 technical replicates were analyzed. Errors bars reflect the standard deviation, center lines within each box the medians, x's denote means. The horizontal axis specifies each gene examined, the vertical axis depicts the log2 relative expression normalized to *ribosomal protein 18s*. **Panel A.** Expression for stem cell (NESTIN and SOX2) and neural (MAP2, GFAP, TUBBIII) associated genes. * $p<0.05$ by student's *t* test. **Panel B.** Expression for proinflammatory genes (IL-1B, IL-6, IL-8, TNF) and the semiglutide signaling receptor (GLP-1R). * $p<0.05$ and * * * $p<0.0005$ by student's *t* test.

1:30 PM - 1:45 PM

Objective: To assess whether daily myo-inositol supplementation reduces a composite of gestational diabetes mellitus, preeclampsia and/or preterm birth in pregnant persons with polycystic ovary syndrome.

Study Design: In this double-blind, multicenter randomized placebo controlled trial, pregnant persons with polycystic ovary syndrome received daily supplementation of 4 grams of myo-inositol, or matching placebo, from between 8 and 16 weeks gestation until delivery. The primary outcome was a composite of gestational diabetes mellitus, preeclampsia or preterm birth. Key secondary outcomes included obstetric, maternal and neonatal outcomes. The analysis was performed according to the intention-to-treat principle.

Results: A total of 464 individuals, recruited at 13 hospitals in the Netherlands, underwent randomization. Characteristics at baseline were similar between groups, except for a higher proportion of biochemical hyperandrogenism in the myo-inositol group (29.0% vs. 18.5% in the placebo group). Two-thirds (67.5%) of participants conceived after assisted reproductive technology. The primary outcome occurred in 56 out of 224 participants (25.0%) in the myo-inositol group and in 61 out of 228 participants (26.8%) in the placebo group (relative risk, 0.93; 95% confidence interval, 0.68 to 1.28; P = 0.67). No substantial between-group differences were observed for secondary outcomes, except for a higher incidence of primary caesarean section in the placebo group (11.6%, versus 5.9% in the myo-inositol group; relative risk 0.51; 95% confidence interval 0.27 to 0.97; P< 0.05). In the preplanned sub group analysis, no interactions were observed for participants with biochemical hyperandrogenism or obesity.

Conclusion: Myo-inositol supplementation in pregnant individuals with polycystic ovary syndrome does not appear to lower the incidence of a composite outcome of gestational diabetes mellitus, preeclampsia or preterm birth compared with placebo. (Funded by The Netherlands Organisation for Health Research and Development [project number 848016013]; Research with human participants [CCMO] ID NL67329.078.18)

58 | Nifedipine versus Labetalol for Treatment of Postpartum Hypertension: A Randomized Controlled Trial

Todd R. Lovgren[1]; Ruofan Yao[2]; Brendan D. Connealy[3]; Robert Bonebrake[1]; Hemant Satpathy[1]; Emily Patel[1]; Matthew Brady[1]; Joshua Dahlke[4]

1:45 PM - 2:00 PM

Objective: Postpartum hypertensive disease is a significant cause of maternal morbidity and mortality, and the optimal treatment is uncertain. The purpose of this study was to determine if medication choice affects the incidence of postpartum readmission for hypertensive complications.

Study Design: This is a single institution, open-label randomized trial comparing nifedipine and labetalol for treatment of postpartum hypertension. Patients with at least two hypertensive blood pressures (>140 systolic or >90 diastolic) four hours apart during their admission for delivery were identified. Once enrolled, patients were randomized to nifedipine or labetalol, irrespective of any prior treatment. The primary outcome was readmission for postpartum treatment of hypertension. Clinical characteristics evaluated included, frequency of severe hypertension, acute treatment of hypertension during hospitalization, magnesium sulfate use, and hypertension within 12 hours of discharge. Trial Registration: NCT05309460

Results: During the study period, 3015 patients met inclusion criteria and 324 patients were enrolled and randomly allocated to nifedipine or labetalol. The labetalol group had a higher BMI (35.3 vs 33.5), later GA at delivery (38 vs 37 weeks) and higher prevalence of CHTN (n = 17 vs 7). After controlling for the significant clinical characteristics, the incidence of readmission was 88% lower in the nifedipine arm (1.2% vs 8.1%); aOR of 0.12 (95% confidence interval [CI] 0.026 to 0.57). The frequency of severe HTN, acute treatment of HTN during hospitalization, use of magnesium sulfate and HTN within 12 hours of discharge was similar between groups.

Conclusion: The primary outcome was statistically significant, representing a significant decrease in readmission in those taking nifedipine. Coupled with published observational studies demonstrating similar results, this study supports Nifedipine as the initial agent of choice in the ongoing management of hypertension in the postpartum period.

Table 1 Cohort Characteristics

2:00 PM - 2:15 PM

Objective: Though de novo postpartum hypertension (dnPPHTN) accounts for up to two thirds of PPHTN cases, the physiologic and pathophysiologic cardiovascular changes after delivery are poorly understood. We sought to define longitudinal PP blood pressure (BP) patterns in patients at risk for PPHTN.

Study Design: We analyzed data from a negative randomized trial (PMID 38641089) of 82 normotensive patients at high risk for dnPPHTN randomized to daily furosemide or placebo from PP day 1-5. BPs were monitored every 4-8 hours from delivery to discharge, then by Bluetooth-enabled remote monitoring twice-daily for 6 weeks. The primary goal of this secondary analysis was discovery of distinct patterns of longitudinal BP trajectories in the placebo group. Secondary goals included exploring differences in early PP BP trends between those who developed dnPPHTN and those remaining normotensive; and timing of peak BPs. Trends were assessed using local polynomial regression fitting. Linear mixed-effects models were used to examine temporal BP trajectories, including polynomial time effects, linear spline, and random intercepts and slopes. An interaction term for the time trend and dnPPHTN diagnosis was included.

Results: We included all 40 placebo participants from the parent trial, contributing 2235 PP BP readings. SBP and DBP rose until days 10 and 12 PP, respectively, before declining. Mean peak SBPs and DBPs were 120.7 ± 13.4mmHg and 81.0 ± 10.3mmHg. There were significant differences in BP trajectories between participants with (n = 3; 167 BP readings) and without (n = 37; 2068 BP measurements) dnPPHTN (**Figure 1**). Those with dnPPHTN had a significantly steeper rise in SBP preceding dnPPHTN diagnosis, which occurred at a median of 5 days [IQR 5,5.5 days]. SBPs rose by 1.6mmHg/day more to its PP day 9 peak in dnPPHTN compared to normotensive participants, while DBP rose by 0.3mmHg/day more and peaked later (PP day 14 vs 12) (**Table 1**).

Conclusion: Using innovative technology, we defined distinct trends in PP cardiovascular physiology that distinguish physiologic from pathophysiologic BP changes in patients at risk for dnPPHTN.

60 | Severe Systolic Hypertension and Adverse Maternal Outcomes

Yossi Bart[1]; Hector M. Mendez-Figueroa[2]; Farah H. Amro[1]; Baha M. Sibai[1]

[1]McGovern Medical School at UTHealth Houston, Houston, TX; [2]McGovern Medical School at UTHealth, Houston, TX

2:15 PM - 2:30 PM

Objective: Severe hypertension (sHTN) in pregnancy is associated with maternal morbidity. The specific role of sHTN based on isolated severe systolic blood pressure has not been well studied. We aimed to examine whether sHTN diagnosed by elevated systolic BP (SBP) alone is associated with adverse maternal outcomes.

Study Design: We conducted a secondary analysis of the Assessment of Perinatal Excellence (APEX) database. We included all the patients who had hypertension at the time of delivery, defined as SBP ≥ 140 mmHg or diastolic BP ≥ 90 mmHg on two occasions at least 30 minutes apart. We excluded individuals with diastolic BP ≥ 110 mmHg. Our reference group were those with mild HTN, defined as: systolic BP 140-159 and/or diastolic BP 90-109. We had 3 comparison groups; group I: SBP 160-179, group II: SBP 180-199, and group III: SBP ≥ 200 mmHg. The primary outcome was defined as a composite of maternal outcomes, including hypertensive stroke, pulmonary edema, acute kidney injury, disseminated intravascular coagulation, cardiopulmonary arrest, and death. Poisson regression was applied to address possible confounders.

Results: Overall, 38,245 individuals met the inclusion criteria, of which 32,277 (84%) had mild HTN and 5,968 (16%) had severe systolic HTN. Of those, 3,790 (63%) had SBP 160-179, 1,903 (32%) had SBP 180-199, and 275 (5%) had SBP ≥ 200 mmHg. Higher SBP was associated with higher rates of advanced maternal age, obesity, preterm birth, and chronic HTN. Following adjustment, higher systolic BP was associated with higher rates of the composite outcome, driven mainly by higher rates of pulmonary edema and acute kidney injury. The relative risk for composite maternal outcome was 2.93 (95% CI 2.24-3.85) for SBP 160-179 mmHg, 3.92 (95% CI 2.88-5.33) for SBP 180-199, and 6.74 (95% CI 4.01-11.31) for SBP ≥ 200 mmHg. Further stratification to 10 mmHg intervals of SBP demonstrate the dose-dependent association with the composite outcome (Figure).

Conclusion: Compared to mild HTN, severe HTN diagnosed by SBP alone was associated with maternal morbidity in a dose-dependent fashion.

Table – The association between severe hypertension diagnosed by systolic blood pressure only and maternal outcomes

Outcomes	Group	N (%)	Adjusted RR [a] (95% CI)
Composite maternal outcome	Mild HTN	198 (0.6)	1.00
	SBP 160-179	88 (2.3)	**2.93 (2.24-3.85)**
	SBP 180-199	63 (3.3)	**3.92 (2.88-5.33)**
	SBP ≥ 200	18 (6.5)	**6.74 (4.01-11.31)**
Hypertensive stroke	Mild HTN	18 (0.1)	1.00
	SBP 160-179	5 (0.1)	2.30 (0.83-6.38)
	SBP 180-199	7 (0.4)	**6.26 (2.55-15.36)**
	SBP ≥ 200	1 (0.4)	5.96 (0.77-45.94)

61 | Postpartum Diuretics for Hypertensive Disorders of Pregnancy: A Systematic Review and Meta-Analysis

Emma Trawick Roberts[1]; Elana Jaffe[1]; Johanna Quist-Nelson[1]; Suneet Chauhan[2]; Baha M. Sibai[3]; Michal Fishel Bartal[4]

[1]University of North Carolina, Chapel Hill, NC; [2]Christiana Care, Newark, DE; [3]McGovern Medical School at UTHealth Houston, Houston, TX; [4]UTH Houston & Sheba Medical Center Israel, Houston, TX

2:30 PM - 2:45 PM

Objective: To systematically review postpartum use of diuretics to reduce persistent hypertension (HTN) among individuals with hypertensive disorders of pregnancy (HDP).

Study Design: A systematic review was conducted in MEDLINE, OVID, Scopus, World Health Organization International Clinical Trials Registry Platform, ClinicalTrials.gov and the Cochrane Central Register of Controlled Trials from inception to 4/2024 (PROSPERO CRD42021288277). Randomized controlled trials (RCTs) investigating postpartum use of diuretics in individuals with HDP were included. Clinical characteristics and outcome measures were extracted. The primary outcome was persistent HTN postpartum. Secondary postpartum outcomes were use of additional antihypertensive drugs, length of stay, readmission/emergency visits, and breastfeeding. Meta-analysis was performed using a random effects model to estimate treatment effects in terms of risk ratios (RR) or mean difference with 95% confidence interval (CI).

Results: Of 571 studies reviewed, eight RCTs with 1368 individuals (767 intervention, 771 control) met inclusion criteria. Interventions included furosemide (3 RCTs), torsemide (1 RCT), combined furosemide/antihypertensive drug (3 RCTs), and combined thiazide/angiotensin-converting enzyme inhibitor (1 RCT). There was a significant reduction in persistent HTN between intervention and control groups (4 RCTs, N = 955, RR 0.53, 95%CI 0.35-0.80, I^2 = 70%, Figure 1). The number needed to treat (NNT) to reduce persistent HTN was 4. There was no difference in the need for additional antihypertensives during admission (7 RCTs, N = 1209, RR 0.79, 95%CI 0.61-1.02, I^2 = 7%) or at the time of discharge (5 RCTs, N = 905, RR 1.00 95%CI 0.82-1.21, I^2 = 53%). There was no difference in length of stay, readmission/emergency visits, or breastfeeding between groups.

Conclusion: Diuretics were associated with a reduction in persistent HTN postpartum in individuals with HDP (NNT = 4). Heterogeneity in study interventions and outcomes suggests that the optimal postpartum dosing and timing of diuretics in HDP warrants further study.

Data are presented as intervention vs control as n/N (percentage) or as mean ±standard deviation
Abbreviations: NR, not reported; vs, versus
Persistent hypertension was defined as the earliest postpartum time point reported across studies: 48 hours (Reyna-Villasmil), within 5 days or at time of discharge (Viteri), 7 days (Lopes Perdigao), and 7-10 days (Fishel Bartal).
Bolded if significantly different.

62 | Association of Preeclampsia with Long-Term Risk of Neurodegenerative Disorders

Maria Bazan[1]; Ai-ris Y. Collier[2]; Tina Yi Jin Hsieh[2]; James Cheng-Chung Wei[3]

[1]Beth Israel Deaconess Medical Center, Brighton, MA; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]Chung-Shan Medical School, Taichung, Taichung

2:45 PM - 3:00 PM

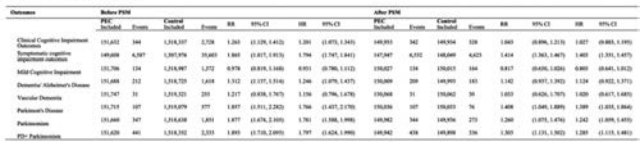
Objective: Preeclampsia (PE) is a common complication of pregnancy linked to increased lifetime risk of cardiovascular disease. The link between PE and development of adverse neurologic conditions is poorly understood. Our objective was to describe the rates of neurodegenerative disorders occurring 3 or more years following complications from PE compared to those without PE.

Study Design: We utilized the TriNetX database including diagnoses codes from 66 healthcare organizations to identify women 18+ years old with last birth between 1/2000-12/2023. PE was defined using ICD-10 codes occurring before delivery up until December 2020. The comparator group included pregnant women in the same period without PE diagnosis. After 1:1 propensity score matching (PSM) on age at index pregnancy, demographics, health utilization, comorbidities, depression, reproductive factors, and BMI, hazard ratios (HR) and 95% confidence intervals (CI) for cognitive disorders were estimated between the PE and comparator group using a Cox proportional hazard regression model. Cognitive outcomes were identified by ICD-10 codes and censored until one of the following conditions was met: 1) development of an outcome, 2) July 26, 2024, or 3) loss to follow-up in the system.

Results: The cohort included 163,296 pregnant women with PE and 1,647,539 without PE. In those with prior PE, 8,012 (4.9%) developed neurodegenerative outcomes, compared to 46,337(2.8%) in the control group. After PSM, the PE exposure group demonstrated an increased risk of symptomatic cognitive impairment outcomes (HR 1.4, CI 1.351-1.457), Parkinson's disease (HR 1.389, CI 1.035-1.864), Parkinsonism (HR 1.242, CI 1.059-1.455), and combined Parkinson's disease and Parkinsonism (HR 1.285, CI 1.115-1.481) compared to those without PE (Table 1).

Conclusion: Our findings show a higher risk of cognitive impairment, Parkinson's disease, and Parkinsonism in those with a history of PE. Obstetrical health is a window to lifelong neurocognitive health. This study supports enhanced surveillance and monitoring of neurodegenerative diseases.

Table 1. Event number, risk ratio and hazard ratio of neurodegenerative outcomes among women with preeclampsia compared to those without preeclampsia who had a delivery



63 | Comprehensive Blood Pressure Management to Improve Early Postpartum Blood Pressure Parameters: a Randomized Controlled Trial

Alexandra JD Phelps[1]; Loveis Jackson[1]; Lilly He[1]; Ashanti E. Griggs-Cooks[1]; Neha Dudipala[2]; Etoi Garrison[1]; Kathryn J. Lindley[1]; Soha S. Patel[1]; Julia C. Phillippi[3]; Megan Webb[1]; Sarah S. Osmundson[1]
[1]Vanderbilt University Medical Center, Nashville, TN; [2]Ohio State University College of Medicine, Columbus, OH; [3]Vanderbilt University School of Nursing, Nashville, TN

3:00 PM - 3:15 PM

Objective: To determine whether comprehensive vs clinician-directed blood pressure (BP) management and tight vs standard BP control improves BP parameters at 7-10 days postpartum.

Study Design: Postpartum patients with cHTN, gHTN, or preeclampsia were randomized to two interventions (four arms): 1) comprehensive BP management with remote monitoring, daily BP reporting, and algorithm-based treatment by an MFM-supervised nurse practitioner vs clinician-directed BP monitoring and 2) tight (goal BP < 140/90) vs standard (goal BP < 150/100) control. All participants received a BP cuff, directions how to monitor BPs twice daily, and instructions to attend an in-office BP check 7-10 days postpartum. The primary outcome was in-office BP check. Secondary outcomes included reporting any BPs either remote or in person, mean BPs, and the frequency of BPs > = 140/90 or > = 160/110 within 7-10 days postpartum.

Results: Between 5/9/2023 and 7/26/2024, 644 patients were eligible, 327 (51%) enrolled and were randomized, and 323 participants available for the final analysis after 4 withdrawals. Demographic and clinical characteristics of the population are presented in Table 1. Comprehensive management increased the frequency of attending an in-office, 7-10 day BP check compared to clinician management, but the results were not statistically significant (62% vs 51%, aOR 1.53 [0.94-2.50]). Comprehensive management significantly increased the frequency of reporting any BP either remote or in person (94% vs 85%, aOR 2.43 [1.05-5.63]). Findings did not vary by race or insurance status. Other secondary outcomes were not statistically significant and were unchanged after accounting for interaction between the two interventions.

Conclusion: Compared to clinician-directed management, comprehensive BP management did not increase the frequency of attending an in-office BP check but did increase the frequency of reporting any BP between 7-10 days. These findings suggest a comprehensive program to intensely monitor BPs in the early postpartum period increases patient engagement with BP management.

Table 1: Clinical characteristics and blood pressure (BP) outcomes at 7-10 days postpartum

Management program	Comprehensive Management		Clinician Management		
Blood pressure goals	Tight BP Control	Standard BP Control	Tight BP Control	Standard BP Control	P for Interaction[5]
Sample Size	N=81	N=80	N=81	N=81	
Clinical Characteristics					
Age at delivery	30 (26-35)	30.0 (24-35)	30.0 (27-34)	29.0 (22-33)	–
Nulliparity	52 (64)	48 (60)	45 (56)	36 (44)	–
Black race self-identified	22 (27)	23 (29)	20 (25)	20 (25)	–
High school education or less	6 (7)	4 (5)	9 (11)	7 (9)	–
BMI[1] at delivery (kg/m^2)	34 (43)	31 (40)	25 (33)	42 (53)	–
Public health insurance	37 (32-44)	35 (31-41)	36 (30-46)	37.9 (33-46)	–
Antepartum HTN[2] medications	36 (44)	34 (43)	29 (36)	45 (56)	–
Chronic HTN	22 (27.2)	12 (15.0)	23 (28.4)	31 (38.3)	–
PreE[3] w/o severe features or gHTN	38 (47)	36 (45)	39 (48)	40 (49)	–
PreE[3] with severe features	31 (38)	28 (35)	26 (32)	35 (43)	–
Discharged on HTN[2] medications	31 (38)	34 (43)	35 (44)	39 (48)	–
Study Outcomes					
Attended an in-person visit[4]	54 (67)	45 (56)	43 (53)	40 (49)	–
Reported any BP[4]	76 (94)	75 (94)	70 (86)	68 (84)	–
Mean systolic BP	128 (120-137)	128 (124-136)	132 (125-138)	130 (122-140)	0.43
Mean diastolic BP	84 (78-90)	84 (78-89)	82 (78-90)	84 (78-90)	0.50
Any BP ≥140/90	23 (30)	22 (29)	26 (37)	27 (40)	0.77
Any BP ≥160/110	2 (3)	0 (0)	4 (6)	2 (3)	0.46

Comprehensive Management involved daily blood pressure (BP) reporting with advanced practice nurse (APRN) monitoring and physician supervision. Clinician monitoring was done by individual physicians or APRNs. Tight BP goal was <140/90. Standard BP goal was <150/100
All data are presented as n (%) or mean (interquartile range)

64 | Hofbauer Cells May Mediate PE-Associated Placental Dysfunction via APOE Synthesis

Bani Medegan Fagla; Cielo Dela Rosa; Savita Sundar; Aswathi Jayaram; Erykah Walton; Jason York; Leon M. Tai; Guomao Zhao; Irina A. Buhimschi
University of Illinois at Chicago, College of Medicine, Chicago, IL

3:15 PM - 3:30 PM

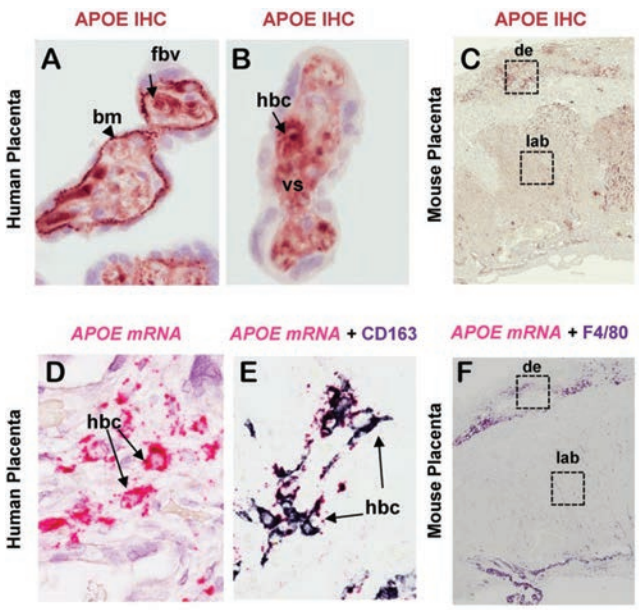
Objective: Preeclampsia (PE) was recently described as a protein misfolding disorder of pregnancy sharing pathophysiological processes with Alzheimer's disease (AD). Among these, amyloid-beta (Aβ) accumulation, characteristic for AD brain, was also identified in PE placenta. Apolipoprotein E (ApoE), a key lipid regulator synthesized in the brain by astrocytes, neurons, and microglia mediates Aβ accumulation and clearance. To our knowledge, in situ synthesis of ApoE mRNA by human placental cells has not been investigated. Herein, we aimed to identify ApoE producing cells in the human and mouse placenta.

Study Design: Immunohistochemistry (IHC) was performed on human placentas from pregnancies with (n = 10, GA: 30.6±3.3 wks) and without (n = 9, GA: 33.6±3.3 wks) PE. Placentas of humanized *ApoE* transgenic mice were also studied (n = 16

mice). Dual RNA in situ hybridization (ISH)+IHC was conducted to localize ApoE RNA relative to macrophage markers CD163 (human) and F4/80 (mouse). In transgenic mice, we also quantified F4/80 signal intensity after Reduced Uteroplacental Perfusion Pressure (RUPP), a validated surgical procedure that induces PE-like symptomatology. Control mice underwent sham procedures (n = 5-11/group).

Results: 1) In human placenta, IHC identified ApoE in fetal blood vessels (fbv), basement membrane (bm), villous stroma (vs) and Hofbauer cells (hbc) which stained conspicuously (Figs. A&B); 2) In mice, ApoE was diffusely present throughout the labyrinth (lab) and decidua (de) (Fig. C); 3) In human placenta, ApoE mRNA was selectively present in Hofbauer cells identified by co-expression of CD163 (Fig. D&E); 4) Similarly, in mice, ApoE mRNA co-localized with the macrophage marker F4/80 (Fig. F); 5) F4/80 expression decreased in response to RUPP in mouse placenta (p = 0.001 vs. sham).

Conclusion: Placental HBCs, which are known to share common embryologic origin with brain microglia, synthesize ApoE and may contribute to clearance or accumulation of misfolded proteins in the placenta and thus to PE pathogenesis.



65 | Impact on Severe Maternal Morbidity following Statewide Improvements in Hypertensive Disorders of Pregnancy Care Processes

Patrick Schneider[1]; Allison Stevens[2]; Alyssa Antonini[2]; Michelle Menegay[3]; Allison Lorenz[3]; Stephen Afflito[3]; Rashelle Ghanem[4]; Ryan Everett[5]; Justin R. Lappen[6]

[1]The Ohio State University, Wexner Medical Center, Columbus, OH; [2]Government Resources Center for the Ohio Colleges of Medicine, Columbus, OH; [3]Ohio Colleges of Medicine, Government Resource Center, Columbus, OH; [4]Ohio Department of Children and Youth, Columbus, OH; [5]Ohio Hospital Association, Columbus, OH; [6]Cleveland Clinic Foundation, Cleveland, OH

3:30 PM - 3:45 PM

Objective: Hypertensive disorders of pregnancy (HDP) are a major cause of severe maternal morbidity (SMM). While statewide quality improvement (QI) projects have significantly improved HDP care processes, their impact on SMM remain unclear.

Study Design: As part of a statewide QI project initiated during the COVID-19 pandemic, 30 maternity hospitals implemented an HDP care bundle which included timely treatment of severe hypertension (HTN) and subsequent care management. Monthly patient data was collected on all new cases of sustained severe HTN. Hospital SMM rates defined by CDC criteria were obtained from the state hospital association. Data were analyzed for periods before (10/2018-9/2020) and after (10/2020-9/2023) implementation. R (4.3.3) was used to conduct a controlled interrupted time series analysis. The primary outcomes were the difference in HDP SMM trends overall, by race, and Medicaid status at participating hospitals before/after bundle implementation. Secondary outcomes included the difference in HDP SMM trends overall, by race, and Medicaid-status at participating vs. non-participating hospitals and change in timely treatment of severe HTN among participating hospitals before/after bundle implementation.

Results: Timely treatment increased after bundle implementation (baseline 56.9% to 77.1%; p< 0.001). Though the increase in rates appeared attenuated, no statistically significant change in the overall, Black, and Medicaid HDP SMM rates before/after implementation were found (p = 0.43; 0.67; 0.82; Table 1). Similarly, no statistically significant change in the overall, Black, and Medicaid HDP SMM rates among participating vs. non-participating hospitals before/after implementation were found (p = 0.52; 0.30; 0.46; Figure 1).

Conclusion: In this statewide HDP QI project, no significant changes in HDP SMM rates were detected despite improvements in HDP care processes. While this demonstrates that improvements in HDP care processes may not be the sole driver of HDP SMM reductions, it supports further exploration of non-clinical and contextual factors impacting SMM, such as the COVID-19 pandemic.

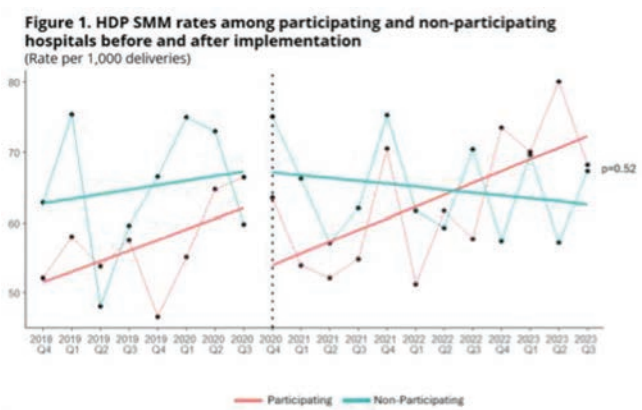


Table 1: Primary Outcome Measures - Trends in HDP SMM Rates at Participating Hospitals Pre/Post-Implementation

Primary Outcome Measures Among Participating Hospitals	p-value
HDP SMM rate trend pre/post-implementation	0.43
Black HDP SMM rate trend pre/post-implementation	0.67
White HDP SMM rate trend pre/post-implementation	0.40
Medicaid HDP SMM rate trend pre/post-implementation	0.82
Commercially-insured HDP SMM rate trend pre/post-implementation	0.26

66 | Adverse Outcomes During Delivery Hospitalizations Among Patients with an Intellectual or Developmental Disability Diagnosis

Manasa G. Rao[1]; Timothy Wen[2]; Mary E. D'Alton[1]; Alexander M. Friedman[3]; Noelia Zork[3]
[1]Columbia University Medical Center, New York, NY; [2]University of California, San Diego, Irvine, CA; [3]Columbia University Irving Medical Center, New York, NY

3:45 PM - 4:00 PM

Objective: People with intellectual and developmental disabilities (IDD) have higher risk for obesity, diabetes, asthma, and cardiovascular disease. There is limited contemporary data on pregnancy outcomes in the setting of IDD. The objective of this study was to evaluate whether IDD is associated with adverse perinatal outcomes in a large national sample.

Study Design: Delivery hospitalizations to patients aged 15-54 were analyzed using the 2000-2021 Nationwide Inpatient Sample. Primary exposure of interest was IDD, defined using ICD9/ICD10 codes. Temporal trends in proportion of deliveries with IDD were analyzed with joint point regression to determine average annual percent change (AAPC) with 95% confidence intervals. Adjusted logistic regression models were performed for outcomes accounting for hospital, demographic, and clinical factors with IDD as the exposure of interest.

Results: Of 83.6 million births, 23,347 (0.03%) had an associated IDD diagnosis. Deliveries to patients with IDD increased from 1 per 10,000 in 2000 to 6 per 10,000 in 2021 (AAPC 7.7%, 95% CI: 1.0%-8.8%, p< 0.01). IDD deliveries were more likely to have a diagnosis of obesity (p< 0.01), asthma (p< 0.01), chronic hypertension (p< 0.01), pregestational and gestational diabetes (p< 0.01), or a mental health condition (p< 0.01). In adjusted analyses, IDD deliveries were more likely to have preterm birth at < 37 (aOR 1.5, 1.3-1.7), < 34 (aOR 1.7, 1.4-2.0), < 32 weeks (aOR 1.7, 1.4-2.1), cesarean delivery (aOR 1.6, 1.5-1.8), operative vaginal delivery (aOR 1.6, 1.4-1.8), non-transfusion severe maternal morbidity (aOR 1.7, 1.4-2.1), transfusion (aOR 1.34, 1.09-1.65), hypertensive disorders of pregnancy (aOR 1.2, 1.1-1.3), postpartum hemorrhage (aOR 1.2, 1.1-1.4), infection (aOR 1.2, 1.0-1.4), and stillbirth (aOR 2.3, 1.9-2.8). Likelihood of placental abruption and infection were not significantly different between groups.

Conclusion: IDD among delivery hospitalizations is increasing and is associated with adverse perinatal outcomes. Additional resources and surveillance may be warranted for patients with IDD to optimize outcomes.

Table. Unadjusted and adjusted models for adverse outcomes

	Intellectual and Developemenal Disability				Unadjusted model		Adjusted model	
	Absent		Present					
	N	%	N	%	OR	95% CI	aOR	95% CI
Gestational age at delivery								
<37 weeks	2,082,379	9.8%	1,870	17.5%	1.95	1.74, 2.17	1.49	1.33, 1.67
<34 weeks	580,555	2.7%	680	6.4%	2.42	2.04, 2.87	1.68	1.40, 2.01

67 | Azithromycin to Prevent Stillbirths and Infant Deaths in Mali: A 2x2 Factorial Placebo-Controlled Randomized Trial

Karen Kotloff[1]; Amanda J. Driscoll[1]; Fadima Haidara[2]; Lawrence Moulton[3]; Jason Bailey[1]; Ousmane Samake[2]; Tiecoura Bocoum[2]; Jane Juma[2]; Awa Traore[2]; Mamadou Diallo[2]; Collins Okello[2]; Uma Onwuchekwa[2]; Mamoudou Kodio[2]; Yuji Chen[1]; Emily Deichsel[1]; Matthew Finholt-Daniel[4]; Robert L. Goldenberg[5]; Fleesie Hubbard[1]; Rebecca Maguire[1]; Melissa Page[4]; David Plotner[4]; Milagritos Tapia[1]; Dilruba Nasrin[1]; Samba Sow[2]
[1]University of Maryland, School of Medicine, Baltimore, MD; [2]Centre pour le Développement des Vaccins, Mali, Bamako, Bamako; [3]Johns Hopkins, Bloomberg School of Public Health, Baltimore, MD; [4]RTI International, Durham, NC; [5]Columbia University School of Medicine, New York, NY

1:30 PM - 1:45 PM

Objective: To determine if oral azithromycin (AZ) delivered to pregnant women and infants in a high mortality setting reduces stillbirths and infant deaths up to 12 months, compared to placebo.

Study Design: We conducted a randomized 2x2 factorial placebo-controlled trial in 3 districts of Mali, West Africa, to evaluate the efficacy of 2 AZ regimens to prevent stillbirths and/or infant deaths. Pregnant women were recruited at antenatal care (ANC) visits and randomized 1:1:1:1 to one of 4 treatment arms: maternal and infant AZ (AA), maternal AZ and infant placebo (AP), infant placebo and maternal AZ (AP), or maternal and infant placebo (PP). They received up to 3 single 2g doses of AZ or placebo: upon enrolling at ≥14 weeks gestation, at the next routine ANC visit, and at delivery. Their infants received two single 20mg/kg doses of AZ or placebo at routine vaccination visits at approximately 6 and 14 weeks of age. The primary outcome for the maternal intervention was a composite of stillbirth and infant death to up 12 months of age. The primary outcome for the infant intervention was infant death from the time of the first infant dose up to 12 months of age.

Results: We enrolled 49,675 pregnant women between Sep 24, 2020, and Feb 27, 2023. The hazard ratio (HR) for stillbirths and infant deaths was 0.94 (95% CI 0.89, 1.00; p-value = 0.058) in the maternal AZ arms compared to the maternal placebo arms, and 0.90 (0.72, 1.12) for the infant mortality outcome comparing the infant AZ arms to placebo arms. In subgroup analyses, maternal AZ was associated with reduced stillbirth and infant deaths in women with height < 160 cm (0.87; 95% CI 0.79, 0.96) with parity ≥4 (0.86; 95% CI 0.78, 0.95), and for those in Kignan district (0.77; 95% CI 0.65, 0.90). In Kignan, stillbirths were reduced by 19% (risk ratio 0.80; 95%CI 0.65, 0.99) and neonatal deaths 0-27d by 40% (HR 0.60; 95%CI 0.43, 0.82).

Conclusion: Maternal AZ could reduce stillbirths and infant deaths if targeted to high-risk groups in high mortality settings. The benefit of AZ delivered to infants at routine vaccination visits is uncertain.

68 | The Effect of Metformin in Women Who Received Betamethasone on Maternal Hyperglycemia and Neonatal Hypoglycemia

Enav Yefet[1]; Manal Massalha[2]; Gil Talmon[1]; Aminet Labay[1]; Marian matanis[1]; Erez Sleman[1]; Rima nassra[1]; Maya Frank Wolf[3]; Inshirah Sgayer[4]; Lior Lowenstein[4]; Zohar Nachum[2]
[1]Tzafon Medical Center, Poriya, HaZafon; [2]Emak Medical Center, Afula, HaZafon; [3]Galilee Medical Center, Naharyia, HaZafon; [4]Galilee Medical center, Nahariya, HaZafon

1:45 PM - 2:00 PM

Objective: While betamethasone reduces complications of prematurity, it can cause maternal hyperglycemia and neonatal hypoglycemia. Metformin effectively treats maternal hyperglycemia and has been shown to decrease neonatal hypoglycemia in women with gestational diabetes mellitus.

This study examines metformin's impact on maternal hyperglycemia and neonatal hypoglycemia in preterm deliveries in women administered betamethasone.

Study Design: This multicenter, open-label, randomized controlled trial was conducted from 2020 to 2024 at three medical centers. Women with diabetes were excluded. Pregnant women receiving betamethasone between 24 and 36.5 weeks of gestation due to increased preterm delivery risk were randomly assigned

to either metformin (425 mg three times daily before meals and 850-1700 mg at 10 p.m.) or no treatment. The treatment lasted up to 48 hours following the first betamethasone dose. Capillary glucose was measured before meals (pre-prandial), 90 minutes after starting meals (post-prandial), and at 10 p.m.

Primary outcomes were the mean maternal daily glucose values and neonatal hypoglycemia in preterm deliveries. To show a reduction in neonatal hypoglycemia from 40% in the control group to 15% in the metformin group, 98 neonates were needed (two-tailed alpha = 0.05, power of 80%). To demonstrate a mean difference of 5 mg% with a 10 mg% standard deviation in daily glucose levels, 156 women were required (two-tailed alpha = 0.025, power of 80%).

Results: A total of 84 and 85 women in the metformin and control groups, respectively, were analyzed. Preterm neonates included 48 from the metformin group and 58 from the control group.

In the metformin group, mean maternal daily and postprandial glucose values were significantly lower than in the control group. The rate of neonatal hypoglycemia was lower in the metformin group compared to the control group (10 (21%) vs. 23 (40%), P = 0.037, relative risk 0.53, 95% CI 0.28-0.99). Mild adverse effects were reported by 14% of women.

Conclusion: Metformin is safe and effective in preventing steroid-induced maternal hyperglycemia and neonatal hypoglycemia.

Table: Study outcomes

Maternal outcomes			
	Metformin N=84	Controls N=85	P value
Mean daily glucose (mg%)	121±15	127±17	0.01
Mean pre-prandial daily glucose (mg%)	115±13	119±16	0.1
Mean postprandial daily glucose	129±22	138±26	0.009
%Abnormal glucose values at the daily glucose chart	66±24%	73±21%	0.1
%Abnormal pre-prandial glucose values at the daily glucose chart	83±27%	88±20%	0.42
%Abnormal postprandial glucose values at the daily glucose chart	43±35%	54±36%	0.052

69 | Fully Quantitative Cervical Remodeling: Race Group Differences Responsibilities and Cautions

LeAnn A. Louis[1]; Sarah M. Dwyer[1]; Methodius G. Tuuli[2]; Adam K. Lewkowitz[2]; Julie Tumbarello[1]; Emily Dively, BSN[3]; Madeline Felske[1]; Wendy Sparks[1]; Anita M. Malone[1]; Peinan Zhao[4]; Molly J. Stout[5]

[1]University of Michigan Hospital, Ann Arbor, MI; [2]Women & Infants Hospital of Rhode Island and Alpert Medical School of Brown University, Providence, RI; [3]Washington University School of Medicine, St. Louis, MO; [4]Washington University, St. Louis, MO; [5]University of Michigan Medical Center, Ann Arbor, MI

2:00 PM - 2:15 PM

Objective: We aimed to examine fully quantitative cervical tissue stiffness patterns in pregnancy by race groups across 3 academic centers.

Study Design: We invented fully quantitative cervical elastography (FQ-CES), which yields a numeric value of cervical tissue stiffness (Young's modulus) and allows comparison within and across patients over time.

This is a prospective longitudinal cohort of singleton pregnancies at 3 academic centers. We measured FQ-CES in all trimesters in asymptomatic individuals. We defined starting cervical stiffness and softening rate over pregnancy by term and preterm birth (PTB) in the total cohort and across race groups using mixed regression models. Race was self-reported.

Results: 380 individuals were included. Those with PTB start pregnancy with softer cervixes (29.2% lower Young's modulus, p = 0.03). Among Black individuals, the cervix started firmer (33.5% higher Young's modulus in the first trimester, p = 0.03) and had a faster softening rate (8.0% vs 6.5% per week, p = 0.002) compared to non-Black individuals. Within those with PTB, Black individuals start pregnancy with firmer cervixes compared to non-Black individuals (240% higher in Young's modulus, p = 0.01) meaning that even with a firmer cervix Black individuals still had increased risk for PTB.

Conclusion: PTB differentially affects minoritized populations. While those with PTB generally start pregnancy with softer cervixes, racial differences exist, with Black individuals starting firmer and softening faster. This may be due to racial differences in environmental factors and their impact on the pathway to PTB. If normative values were defined from the total cohort, estimates could underestimate risk in Black individuals (starting pregnancy firmer, placing them in a lower risk category). While differential interpretation of screening and diagnostic tests has perpetuated racism and risk in minoritized groups, we caution that overlooking differences mediated by racism and related

factors may have unintended consequences of underestimating risk in at risk groups.

Center	Black Race	Non-Black Race

70 | Neonatal Outcomes After Caesarean Versus Vaginal Birth: Population-based Cohort Study of Extremely Preterm Breech Singletons

Yanchen Wang[1]; Pasqualina Santaguida[1]; Sameer Parpia[1]; Fabiana Bacchini[2]; Prakeshkumar S. Shah[3]; Kellie Murphy[3]; K. S. Joseph[4]; Sandesh Shivananda[5]; Sarah D. McDonald[1]
[1]McMaster University, Hamilton, ON; [2]Canadian Premature Babies Foundation, Toronto, ON; [3]University of Toronto, Toronto, ON; [4]School of Population and Public Health, University of British Columbia, Vancouver, BC; [5]University of British Columbia, Vancouver, BC

2:15 PM - 2:30 PM

Objective: To determine the association of Caesarean (versus vaginal) birth with neonatal outcomes among extremely preterm breech singletons admitted into a neonatal intensive care unit.
Study Design: This retrospective population-based cohort study included all breech singletons between 23 and 27 weeks' gestation, who received active resuscitation and were admitted to one of 30 level-III neonatal intensive care units within the Canadian Neonatal Network from 2010 to 2022. We excluded outborn singletons and those with major congenital anomalies. The primary outcome was a composite of neonatal death, birth trauma, or severe neurological complications. The primary analysis to compare those born by Caesarean section versus vaginally was carried out using a generalized estimating equation based Poisson regression model with propensity score and instrumental variable analyses as sensitivity analyses.
Results: Of the 3332 extremely preterm breech singletons included in the study population, 2778 (83.4%) were born by Caesarean section. The adjusted incidence of the neonatal composite outcome was 26% following Caesarean section, versus 34% following vaginal birth (adjusted relative risk [aRR]: 0.77, 95% confidence interval [CI]: 0.63, 0.95). The reduction in the neonatal outcome following Caesarean section persisted after propensity score matching (aRR: 0.69, 95% CI: 0.53, 0.89) and instrumental variable analysis (aRR: 0.81, 95% CI: 0.67, 0.98). In the subgroup of singletons receiving optimized perinatal care (including antenatal corticosteroids, magnesium sulfate, and deferred cord clamping), the adjusted reduction in the neonatal composite outcome was 0.63 (95% CI: 0.41, 0.98), and in those without optimized perinatal care (aRR: 0.80, 95% CI: 0.63, 1.01).
Conclusion: Most (83%) extremely preterm breech singletons were born by Caesarean section with an associated reduction in mortality/serious morbidity. This association was robust and consistently observed in analyses addressing potential confounding through different methods, and in those receiving optimized care or not.

Table 1. Association of neonatal mortality/serious morbidity with Caesarean section among extremely preterm breech singletons who received active resuscitation

Neonatal composite outcome [a]	Incidence (95% confidence interval %)		Adjusted relative risk (95% confidence interval)
	Vaginal birth group	Caesarean section group	
Primary analyses			
Univariable analysis [b]	262/554 (47.3%)	651/2778 (23.4%)	0.50 (0.42, 0.58)
Multivariable Poisson regression [c]	**33.7%** (22.5%, 50.6%)	**26.1%** (18.1%, 37.6%)	**0.77 (0.63, 0.95)**
Sensitivity analyses			
Propensity score matching [d]	**30.3%** (13.7%, 67.2%)	**20.9%** (9.4%, 46.4%)	**0.69 (0.53, 0.89)**
Instrumental variables analyses [e]	**32.6%** (21.7%, 48.9%)	**26.4%** (18.5%, 37.5%)	**0.81 (0.67, 0.98)**
Subgroup analyses [c]			
Optimized perinatal care [f]	**34.2%** (20.8%, 56.2%)	**21.5%** (14.4%, 32.2%)	**0.63 (0.41, 0.98)**
Non-optimized perinatal care	32.5% (19.2%, 54.8%)	25.9% (16.6%, 40.4%)	0.80 (0.63, 1.01)

Footnote of Table 1

[a] **The neonatal composite outcome** was defined as neonatal mortality, birth trauma (including intracranial hemorrhage, subarachnoid hemorrhage, subdural hemorrhage, or other birth injuries), or severe neurological complications (including grade 3 or higher intraventricular hemorrhage or cystic periventricular leukomalacia)
[b] **The crude incidence** was reported. **Crude relative risk** was predicted by univariable Poisson regression estimated by the generalized estimating equations.
[c] **Adjustment for pre-specified confounders** including year at birth, age in pregnant patients, assisted reproductive technology, nulliparity, diabetes in pregnant patients, hypertensive disorders in pregnant patients, preterm premature rupture of membranes, clinical chorioamnionitis, antenatal corticosteroids, antenatal magnesium sulfate, intrauterine growth restriction, gestational age at birth, deferred cord clamping, and infant sex.
[d] **Exposed and unexposed groups were matched** by propensity score, which was estimated using logistic regression with Caesarean section as the dependent variable and pre-specified confounders as independent variables (including year at birth, age in pregnant patients, nulliparity, diabetes in the pregnant patients, preterm premature rupture of membranes, antenatal magnesium sulfate, gestational age at birth, infant sex, and deferred cord clamping). **Multivariable Poisson regression** was used after further adjustment for assisted reproductive technology, hypertensive disorders in pregnant patients, clinical chorioamnionitis, antenatal corticosteroids, and intrauterine growth restriction.
[e] **Multivariable Poisson regression using generalized estimating equations approach** was used after control for the mode of birth, the hospital rate of Caesarean section among extremely preterm breech singletons **(instrumental variable)**, and the pre-specified confounders.
[f] **Optimized perinatal care** was defined as inborn singletons who received all three following antenatal interventions: antenatal corticosteroids, magnesium sulfate, and deferred cord clamping.

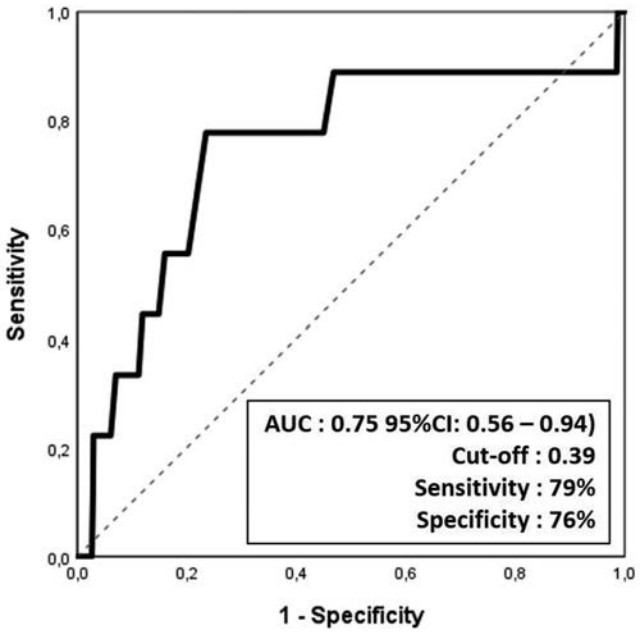
71 | The Role of Cervical Elastography for the Prediction of Spontaneous Preterm Birth

Anne-Sophie Lafortune[1]; Louise Ghesquiere[2]; Paul Guerby[3]; Marie-Laurence Côté[1]; Genevieve Marcoux[4]; Annie Beaudoin[4]; Emmanuel Bujold[1]
[1]Université Laval, PQ; [2]Université de Lille, Lille, Nord-Pas-de-Calais; [3]Université de Toulouse, Midi-Pyrenees; [4]CHU de Québec, CHU de Québec, PQ

2:30 PM - 2:45 PM

Objective: Cervical elastography is a tool for the prediction of spontaneous preterm birth (sPTB). We aimed to estimate its role in addition to cervical length (CL) in low-risk pregnancies.
Study Design: We performed a prospective study including nulliparous participants who underwent transvaginal ultrasound at 20-23 weeks. Among those with CL >25 mm, stiffness of the cervix using strain elastography was evaluated using the following parameters: internal os strain (IOS), external os strain (EOS), and the hardness ratio (HR). Operators and patients remained blinded to the results. Receiver operator characteristics (ROC) curves along with non-parametric statistical analyses were used to estimate the predictive values of each parameter.
Results: Among 991 eligible participants with CL >35mm, 32 (3.2%) had sPTB including 9 (0.9%) with sPTB before 35 weeks. Among all parameters, we observed that EOS was highly associated with sPTB< 35 weeks (p< 0.001; figure) with an optimal cut-off of 0.39, along with a HR< 40% (p = 0.01) and CL< 35 mm (p = 0.02). The combination of a CL< 35mm and EOS >0.39 was associated with a greater risk of sPTB (RR: 5.5; 95%CI: 1.6–18.5) and mainly sPTB< 35 weeks (RR: 12.6; 95%CI: 1.4–112; p< 0.01).

Conclusion: Mid-trimester cervical elastography (EOS and HR) is highly associated with the risk of sPTB and particularly sPTB< 35 weeks when CL is >25 mm. Its use in addition to CL should be rapidly considered in clinical practice.



72 | Corticosteroids and Neonatal Hypoglycemia among Pregnant Individuals with Diabetes: Effect of Gestational Age at Delivery

Ruby Lin; Cande V. Ananth; Todd J. Rosen; On behalf of the MOMPOD Consortium
Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ

2:45 PM - 3:00 PM

Objective: While antenatal steroids have been linked to neonatal hypoglycemia (NNH) among pregnant patients with diabetes, the impact of gestational age is unclear. We hypothesize that ACS for fetal lung maturity for patients with pregestational and early gestational diabetes is associated with a higher risk of NNH, but early preterm delivery < 34 weeks mediates this risk.

Study Design: This is a secondary analysis of MOMPOD, a multicenter, a randomized control trial of 831 pregnant patients with preexisting T2DM or diabetes diagnosed before 23 weeks gestation treated with insulin alone or insulin and metformin. All participants exposed to ACS were compared to those who were not. The primary outcome was NNH defined as blood glucose < 40 mg/dl or need for IV dextrose treatment. We undertook a causal mediation analysis to disentangle the effects of steroids on neonatal hypoglycemia that operate through early preterm delivery (< 34 weeks) versus the effect that is independent of early preterm delivery. We estimated the confounder-adjusted relative risk (RR) with a 95% confidence interval (CI) through log-binomial regression models.

Results: Of the 765 patients with available data, 115 received ACS. Two-thirds (68%, n = 78) of those who received ACS had NNH compared to 42% (n = 273) of those who did not receive ACS (Table 1). ACS exposure was associated with a 1.82-fold (95% CI 1.40-2.51) increased risk of NNH. 82% of this increased risk of NNH associated with corticosteroid exposure was mediated through delivery at < 34 weeks (Table 2).

Conclusion: ACS exposure is associated with a 1.8-fold adjusted risk of NNH, but the majority of this effect is mediated through preterm delivery < 34 weeks. Efforts to design secondary clinical interventions and protocols to reduce the burden of NNH associated with ACS exposure among neonates < 34 weeks born to pregnant patients with diabetes would be of benefit.

Table 1: Neonatal Hypoglycemia and Gestational age characteristics

	Corticosteroids (n=115)	No Corticosteroids (n=650)
Neonatal hypoglycemia*	78/115 (68%)	273/650 (42%)
<34 weeks	42/63 (67%)	12/16 (75%)
≥34 weeks	35/50 (70%)	258/628 (41%)
Gestational age at birth, median (IQR), wk	33.2 (30.9-34.6)	37.5 (37.0-38.7)
Delivery at <34 weeks	63/115 (54%)	16/650 (2%)

*Gestational age data was missing for 8 patients

Table 2: Association between antenatal corticosteroids and risk of neonatal hypoglycemia: mediation effects by preterm delivery <34 weeks

	Relative risk (95% confidence interval)			Proportion mediated (%)
	Total Effect	Natural direct effect	Natural indirect effect	
Unadjusted	1.82 (1.40-2.51)	1.26 (0.84-2.72)	1.45 (0.70-2.04)	69
Adjusted	1.81 (1.38-2.45)	1.14 (0.72-2.05)	1.59 (0.77-2.21)	82

*Adjusted for age, BMI, treatment with insulin with or without metformin, pregestational vs early gestational diabetes, HgbA1c early in pregnancy, and total daily insulin dose at the end of pregnancy

73 | Pro-inflammatory Vaginal Cytokines, Early PTB, and Infectious Morbidity in Patients with Asymptomatic Cervical Shortening

Tracy A. Manuck; On behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units (MFMU) Network
University of North Carolina, Chapel Hill, NC

3:00 PM - 3:15 PM

Objective: There is a critical need to improve risk-stratification of individuals with an asymptomatic short cervical length (CL).

Study Design: Secondary analysis of a multicenter, unmasked RCT of pessary vs. usual care, 2017-2021. Participants with singleton pregnancies, an asymptomatic CL ≤20mm (16+0-23+6 wks), no prior PTB, and a vaginal swab at enrollment were included. 12 cytokines were quantified using a Luminex assay. The primary outcome was PTB < 35 wks. Secondary outcomes were PTB < 32, < 28, and < 24 wks and maternal (chorio) and neonatal (sepsis ± pneumonia) infectious morbidity. Each cytokine was classified as 'high' or 'low' using a numeric cut point that optimized the sensitivity and specificity for PTB < 35 wks. A pro-inflammatory cytokine score was calculated for each patient by adding +1 point per ***high* pro**-inflammatory (IL-1**α**, IL-1β, IL-2, IL-6, IL-8, GM-CSF, TNF-**α**, VEGF) and +1 point per ***low* anti**-inflammatory (IL-1RA, IL-4, IL-10, G-CSF) cytokine. Data were analyzed by logistic regression; AUC analyses evaluated outcome prediction of clinical-only, cytokine-only, and clinical+cytokine models.

Results: 531 of 544 RCT participants met inclusion criteria; 37% had PTB < 35 wks; 7% had maternal and 22% had neonatal infectious morbidity. Cytokines were collected at a median 21.7 (IQR 20.7, 23.0) wks. Cytokine scores ranged 1-9 [median 4, IQR (3,5)] and were higher for those with PTB < 35 wks vs. >35 wks (4.7 vs. 4.0, p< 0.001). In regressions, the composite cytokine score was associated with PTB < 35, < 32, < 28, and < 24 wks and maternal and neonatal infectious morbidity. Outcome prediction in clinical+cytokine models did not statistically improve vs.

clinical-only models (Table). In Kaplan-Meier analysis, higher cytokine scores were associated with earlier delivery (Figure; log-rank $p< 0.001$).

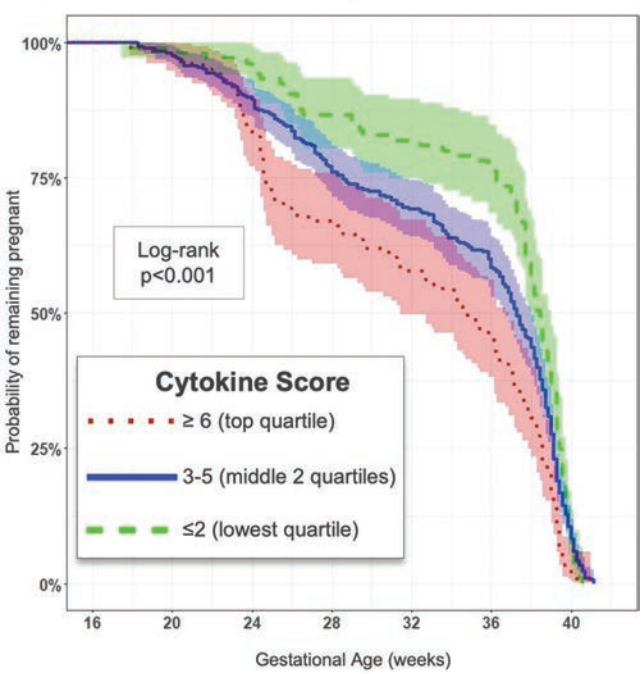
Conclusion: A mid-trimester pro-inflammatory vaginal cytokine milieu is associated with PTB and infectious morbidity in patients with asymptomatic short CL. Non-invasive vaginal cytokine quantification may be an additional way to identify which individuals have pathologic vs. incidental CL shortening.

Table. Clinical-only, cytokine-only, and clinical+cytokine prediction models for each primary and secondary outcome. Shown are the Area Under the Receiver Operating Curve (AUC), unadjusted odds ratios (OR), and adjusted OR (aOR) as appropriate, together with 95% confidence intervals (CI). All models including cytokine data show the increased odds (OR or aOR, as appropriate) of each outcome per 1-point increase in the composite pro-inflammatory cytokine score. Clinical + cytokine models did not statistically improve the prediction of any of the evaluated outcomes compared to clinical-only models (all p>0.05).

Outcome		Clinical-only* models	Cytokine-only models		Clinical* + Cytokine models	
		AUC (95% CI)	OR (95% CI)	AUC (95% CI)	aOR (95%CI)	AUC (95%CI)
PTB or fetal demise	< 24+0 weeks	0.87 (0.82, 0.91)	1.24 (1.07, 1.45)	0.62 (0.54, 0.69)	1.29 (1.07, 1.57)	0.89 (0.84, 0.92)
	<28+0 weeks	0.78 (0.74, 0.83)	1.18 (1.06, 1.32)	0.59 (0.53, 0.65)	1.18 (1.04, 1.34)	0.79 (0.74, 0.84)
	<32+0 weeks	0.76 (0.71, 0.80)	1.21 (1.09, 1.34)	0.60 (0.55, 0.65)	1.20 (1.07, 1.35)	0.77 (0.72, 0.81)
	<35+0 weeks	0.77 (0.73, 0.81)	1.24 (1.12, 1.37)	0.61 (0.56, 0.66)	1.25 (1.12, 1.41)	0.78 (0.74, 0.82)
Maternal infectious morbidity (chorioamnionitis)		0.67 (0.58, 0.76)	1.24 (1.04, 1.49)	0.62 (0.54, 0.70)	1.23 (1.02, 1.48)	0.69 (0.61, 0.77)
Neonatal infectious morbidity (sepsis ± pneumonia)		0.68 (0.63, 0.74)	1.18 (1.05, 1.32)	0.58 (0.52, 0.64)	1.16 (1.03, 1.31)	0.69 (0.63, 0.74)

* Models containing clinical factors adjusted for cervical length at screening (in mm), GA at randomization (weeks, considered continuously), progesterone use at the time of vaginal swab collection (yes/no), and initial pregnancy BMI (kg/m^2, considered continuously).

Figure. Kaplan-Meier survival curve, evaluating the probability of remaining pregnant by mid-trimester pro-inflammatory composite cytokine score. Individuals are grouped by cytokine score quartile [lowest quartile (score ≤ 2) vs. middle two quartiles (score 3-5) vs. highest quartile (score ≥6)]. Log-rank p<0.001.



74 | Comparison of Polyester Fiber versus Polypropylene Suture Materials in Physical-Exam Indicated Transvaginal Cerclages

[1]St. John's Episcopal Hospital-South Shore and William Carey University College of Osteopathic Medicine, Far Rockaway, NY; [2]Hackensack University Medical Center, Hackensack, NJ; [3]St. John's Episcopal Hospital-South Shore, Far Rockaway, NY; [4]Touro College of Osteopathic Medicine-Harlem Campus, New York, NY; [5]William Carey University, Hattiesburg, MS; [6]Rutgers University and the Jersey City Medical Center, Jersey City, NJ; [7]AtlantiCare Regional Medical Center, Pamona, NJ; [8]Walter Reed National Military Medical Center, Bethesda, MD; [9]RWJBarnabas Health - Trinitas Regional Medical Center, Elizabeth, NJ; [10]Albert Einstein College of Medicine - Montefiore Medical Center, New York, NY; [11]NYU Grossman School of Medicine - NYU Brooklyn, New York, NY

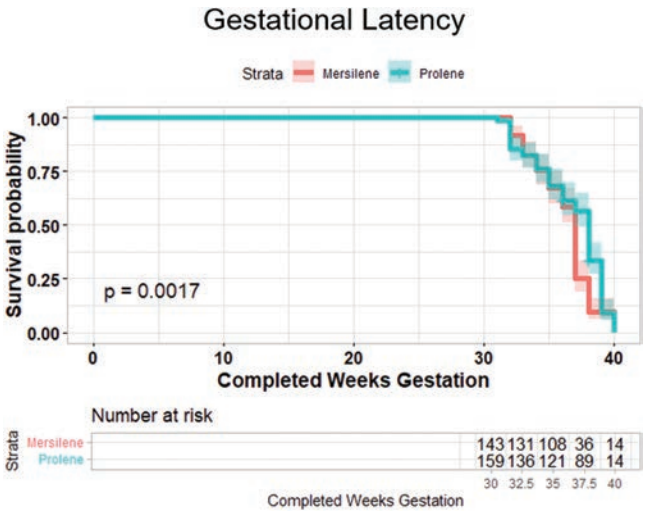
3:15 PM - 3:30 PM

Objective: Polyester fiber (Mersilene) and polypropylene (Prolene) suture materials are the most common type used when performing transvaginal physical-exam indicated cerclages, yet there is insufficient evidence regarding their comparative effectiveness in prolonging gestational latency. This study sought to determine and compare this effectiveness in pregnancies requiring a physical-exam indicated transvaginal cerclage using either Mersilene or Prolene suture material.

Study Design: We conducted a multi-center, prospective observational study from 7/2022 to 7/2024 comparing all pregnancies complicated by cervical insufficiency requiring physical-exam indicated transvaginal cerclage at a gestational age range of 160/7 to 236/7 weeks. Patients with multiple gestations, prior vaginal progesterone, and concurrent antibiotic administration apart from perioperative use were excluded. All patients received perioperative cefazolin and postoperative indomethacin. The primary outcomes included completed weeks gestation at time of delivery, early-preterm (306/7–336/7 weeks), late-preterm (340/7–366/7 weeks), early-term (370/7–386/7 weeks), and full term deliveries (390/7–406/7), as respective, discrete events.

Results: The study included 302 patients with 143 receiving Mersilene and 159 receiving Prolene. Demographic factors were not significantly different. Kaplan-Meier survival analysis noted increased gestational latency in patients receiving Prolene (p = 0.002, Figure 1). Patients receiving Mersilene had higher rates of early-preterm deliveries (46.4% v. 29.3%, p = 0.001) with a 21% increased risk in confounder adjusted models (RR = 1.21, 95% CI 1.01-1.39, p = 0.021) and lower rates of full-term deliveries (10.5% v. 31.1%, p = 0.003) with a 11% decreased likelihood in confound adjusted models (RR = 0.89, 95%CI 0.81-0.98, p = 0.004). Rates of late-preterm and early-term deliveries were not significantly different.

Conclusion: Prolene suture may be a more beneficial choice of suture material for improving gestational latency with physical-exam indicated transvaginal cerclages.



75 | Antimuscarinic Receptor Blockade Reduces Uterine Muscle Contractions Potentially Providing A Novel Treatment For Preterm Labor

Anthony G. Visco[1]; Zachary Visco[2]; Chad Grotegut[3]; Cristina Linde[4]; Timothy Westfall[4]; Friederike Jayes[5]
[1]NinoMed, LLC, Chapel Hill, NC; [2]University of North Carolina, Chapel Hill, NC; [3]Wake Forest University, Wake Forest, NC; [4]Reprocell, Beltsville, MD; [5]Duke University, Durham, NC

3:30 PM - 3:45 PM

Objective: The bladder and the uterus have striking physiologic and anatomic similarities. Anticholinergic medications are commonly used to treat "overactive bladder" by targeting muscarinic receptors. The uterus also contains M2 and M3 muscarinic receptors; however, current management of preterm labor does not target these receptors. We assessed whether muscarinic blockade with oxybutynin reduces both spontaneous and oxytocin-induced uterine muscle contractions.

Study Design: Longitudinal strips of uterine muscle from pregnant rats (17-19 days gestation) were mounted on isometric test apparatuses to directly measure uterine muscle contractions. The effect of oxybutynin on both spontaneous and on oxytocin-induced (1nM) uterine muscle contractility was tested. We measured both the area under the curve (integral) and frequency of the uterine muscle contractions with cumulatively higher concentrations of oxybutynin (100nM, 300nM, 1uM, 3uM, 10uM, 30uM, 100uM) compared to water vehicle control. Measurements are presented as % of baseline. Two-Way ANOVA with Dunnett's post hoc test was performed.

Results: Uterine muscle strips harvested from pregnant rats consistently showed spontaneous muscle contractions. Oxybutynin, at concentrations ≥10μM, resulted in a statistically significant decrease in both spontaneous uterine muscle strength (integral) and contraction frequency compared to vehicle controls. (See Figures 1 and 2).

Oxytocin-induced uterine muscle contractions were also affected by oxybutynin. At concentrations ≥10μM, uterine muscle strength (integral) was reduced ($p < 0.01$), but no difference was observed in contraction frequency compared to controls. (Data not shown).

Conclusion: Oxybutynin significantly reduces spontaneous uterine muscle strength (integral) and contraction frequency. It reduces oxytocin-induced uterine muscle strength (integral) but not contraction frequency. Antimuscarinic blockers warrant future clinical investigation and may represent an exciting new paradigm in the treatment of preterm labor and "overactive uterus".

3:45 PM - 4:00 PM

Objective: To identify microbiota signatures of preterm labor and premature rupture of membranes (PPROM).

Study Design: A prospective cohort study in Paris, France. Four groups were enrolled, a control group and 3 groups at risk of intrauterine infection or preterm birth: prelabor rupture of membranes at term, preterm labor, and PPROM. Vaginal swabs were collected at admission and were analyzed using culturomics. The main outcome was preterm birth.

Results: 2476 women were enrolled, including 1068 controls, 477 with prelabor rupture of membranes at term, 495 with

preterm labor, and 436 with PPROM. Several vaginal microbiota signatures were identified as correlated with pregnancy outcome. In multivariable analysis adjusted for maternal and obstetrical risk factors, lactobacilli depletion and enterobacteria were risk factors for preterm birth, especially in singleton pregnancies (aOR 1.54, 95% CI 1.05-2.28 and aOR 1.62, 95% CI 1.11-2.36, respectively, figure). Additionally, preterm labor was associated with lactobacilli depletion (aOR 1.49, 95% CI 1.08-2.06), enterobacteria (aOR 1.86, 95% CI 1.36-2.53) and G. vaginalis (aOR 4.62, 95% CI 1.86-13.34); PPROM with lactobacilli depletion (aOR 2.04, 95% CI 1.49-2.80) and enterobacteria (aOR 2.38, 95% CI 1.74-3.24). Prelabor rupture of membranes at term was associated with enterobacteria (aOR 1.97, 95% CI 1.46-2.65) and Gardnerella vaginalis (aOR 5.19, 95% CI 2.22-13.78).

Conclusion: In this large cohort, *G. vaginalis* was associated with preterm labor and prelabor rupture of membranes at term, while lactobacilli depletion and enterobacteria were risk factors for PPROM and preterm birth. The supports the need for further studies of adapted antibiotics and probiotics to restore a healthy microbiota for preventing preterm birth.

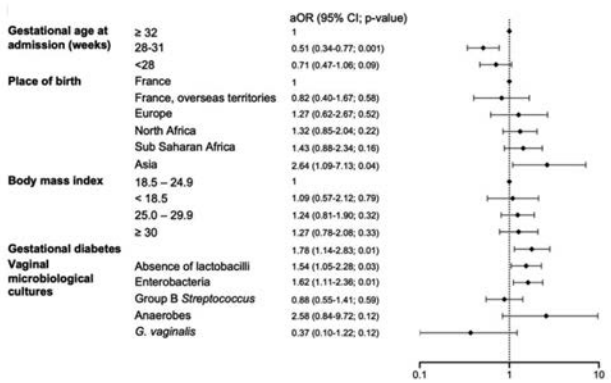

Figure. Multivariable analysis of risk factors for preterm birth in women admitted for preterm labor or preterm premature rupture of membranes in singleton pregnancies.

77 | Does Large for Gestational Age and/or Polyhydramnios Warrant Rescreening for Gestational Diabetes Mellitus?

Henry Lesser; A. Dhanya Mackeen; David Chromey, II; Amanda J. Young; Celia Gray; Michael J. Paglia
Geisinger Medical Center, Danville, PA

8:00 AM - 8:15 AM

Objective: Gestational diabetes mellitus (GDM) screening is often repeated in the 3rd trimester when large for gestational age (LGA) and/or polyhydramnios is diagnosed. We aimed to assess whether patients who did not rescreen in the 3rd trimester had any worse outcomes when compared to those that did.

Study Design: This is a retrospective cohort study from 1/1/11-3/1/24 of term, singleton pregnancies diagnosed with LGA and/or polyhydramnios after a normal GDM screen at 24-30 weeks. Patients with diabetes mellitus, fetal growth restriction, or fetal anomalies were excluded. Non-inferiority analyses were conducted to compare outcomes of individuals who underwent rescreening with those who did not. Noninferiority was established if the lower limit of the one-sided 95% confidence interval (CI) for the event rate in the 'did not rescreen' group did not exceed the relative margin of error from the event rate in the 'did rescreen' group. The lower bound of the 95% CI and corresponding p-values were reported. A p-value of < 0.05 was considered significant.

Results: 1693 pregnancies were included: 1317 did not rescreen and 376 rescreened. In patients that rescreened, 13.6 % were diagnosed with GDM, of which 22% required medication. Outcomes were not worse for those who did not rescreen than those that did rescreen for birthweight (BW) (3758.8g vs 3813.6g p< 0.01), BW ≥4000 (31.9% vs. 34.1%, p< 0.01), obstetric anal sphincter injuries (3.2% vs. 2.1%, p< 0.01), preeclampsia (3.6% vs 5.3%, p< 0.01), neonatal intensive care unit admission (7.6% vs 7.4%, p< 0.01), or GDM in future pregnancies (2.3% vs. 2.4%, p< 0.01).

Conclusion: Patients that did not rescreen for GDM following the diagnosis of LGA and/or polyhydramnios in the 3rd trimester did not have worse birth outcomes than those that did rescreen. This may demonstrate that despite diagnosing GDM in the 3rd trimester, there is insufficient time to intervene and change outcomes and therefore rescreening all patients with LGA and/or polyhydramnios may not be beneficial.

Table 1: Maternal and neonatal outcomes for all patients by no repeat screen versus rescreen

	Complete Rescreen		Margin of Error (%)	Lower Bound of 95% Confidence Interval[1]	Non-Inferiority P-value[1]

Data is described using frequencies and percents unless otherwise noted, n (%).
OASIS: obstetric anal sphincter injury
GDM: Gestational diabetes mellitus
A1: diet-controlled
A2: medication-controlled
NICU: Neonatal intensive care unit
[1] Lower Bound of 95% Confidence interval and respective p-value are from a least square means estimate from a mixed model using the reported margin of error as the test value.
[2]Birthweight has been adjusted for gestational age at delivery.
[3]GDM has been adjusted for history of GDM.

78 | Breastfeeding Patterns Among Parturients with Diabetes: A secondary Analysis of the MOMPOD Randomized Clinical Trial

Minhazur R. Sarker[1]; Marni B. Jacobs[2]; Kim Boggess[3]; Ashley N. Battarbee[4]; Gladys (Sandy) A. Ramos[1]
[1]University of California, San Diego, San Diego, CA; [2]University of California, San Diego Health, San Diego, CA; [3]University of North Carolina, Chapel Hill, NC; [4]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL

8:15 AM - 8:30 AM

Objective: Insulin resistance is associated with decreased milk supply in those lactating. Metformin is hypothesized to increase breast milk production by presumptively improving insulin resistance, suggesting use in pregnancy may increase breastfeeding (BF) success. We aimed to determine the association between metformin use for treatment of preexisting type 2 diabetes mellitus (T2DM) or DM diagnosed in early pregnancy (early DM) and BF patterns.

Study Design: This was a planned secondary analysis of the MOMPOD randomized controlled trial of metformin versus placebo in insulin treated T2DM or early DM. We included parturients who delivered a living neonate, received at least one dose of study treatment, endorsed an intention to BF, and completed a BF survey. BF intentions and BF outcomes were collected utilizing a BF questionnaire at 24-30 weeks and 30 days postpartum (PP) respectively. The primary outcome was immediate BF, defined as any BF on PP day 1-3. Secondary outcomes included time to milk production, exclusive or partial BF at 30 days PP, breast size and issues with BF. Baseline characteristics and outcomes were compared using either chi-square, t-test, or Wilcoxon tests, as appropriate.

Results: Among the 794 women randomized and receiving medication in the primary trial, 378 (47.6%) met inclusion criteria with 194 (51.3%) in metformin and 184 (49.7%) in placebo groups. There were no significant differences in baseline demographics (Table 1). Immediate BF was comparable between groups (91.1% vs 88.9%, p = 0.53) and there was no difference in time to milk production (Table 2). Thirty days PP, BF was lower in both groups but there was no difference between metformin and placebo groups (76.0% vs 66.7%, p = 0.11). There were also no differences in partial or exclusive BF, in breast cup or bra size, or issues with BF (Table 2).

Conclusion: Our data suggest no association between metformin use and BF patterns in those with T2DM or early DM. Antepartum metformin should not be recommended to improve BF success. Further studies should focus on methods to improve sustained BF in this population.

Table 1. Demographics of the study groups

	Metformin n = 194 (51.3%)	Placebo n = 184 (49.7%)	p-Value
Maternal Age, mean (SD)	32.9 (5.2)	33.6 (5.9)	0.28

79 | Predicting Future Diabetes: Impact of Abnormal Pregnancy OGTT Patterns

Yael Winter Shafran[1]; Tal Schiller[2]; Alena Kirzhner[2]; Edi Vaisbuch[2]
[1]Kaplan Medical Center and REALIFE Research Group, Rehovot, HaMerkaz; [2]Kaplan Medical Center, Rehovot, HaMerkaz

8:30 AM - 8:45 AM

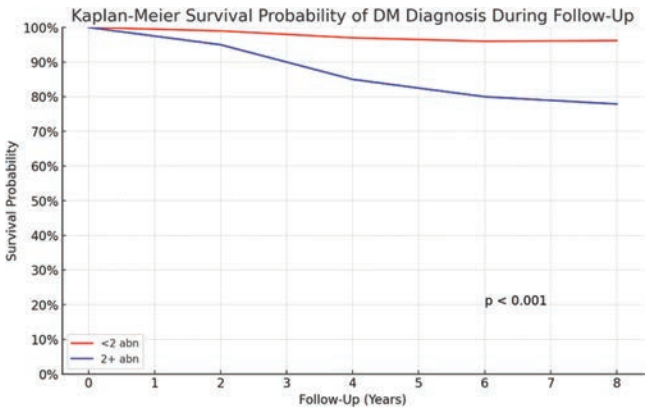
Objective: Evidence suggests that glucose challenge tests during pregnancy can predict long-term metabolic abnormalities. We evaluated the predictive value of Oral Glucose Tolerance Test (OGTT) patterns during pregnancy for future diabetes mellitus (DM) development.

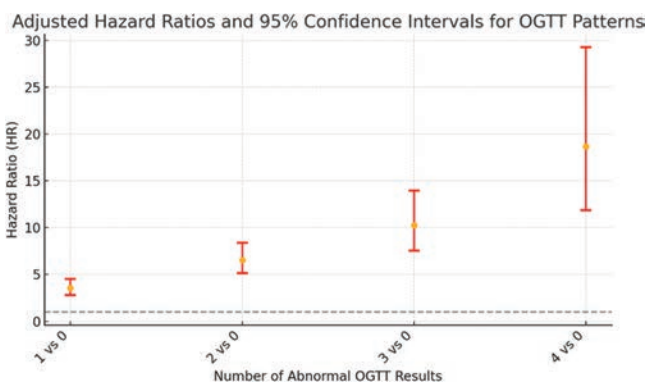
Study Design: This retrospective cohort study included pregnant people who performed a 100-gram OGTT. Those with pre-existing diabetes, recent diabetic medication or steroid use, and incomplete OGTT results were excluded. The predictive value of the OGTT for future DM was assessed using a large healthcare system database, with a follow-up of at least 8 years. Two models were analyzed, one comparing two or more abnormal results to less than two abnormal results in OGTT and the second analyzing the predictive value by the number of abnormal results and the "location" of a single abnormal result (i.e. fasting, one-hour, two-hour, and three-hour post glucose ingestion).

Results: Of the 10,372 individuals identified, 8,157 met the inclusion criteria. Those with a pathological OGTT were older, more obese, and had higher rates of hypertension and dyslipidemia. During follow-up, 22.1% of people with $^{3}2$ abnormal results

developed DM compared to only 3.8% in the group with < 2 abnormal results (HR 5.22, 95% CI 4.33-6.30). Compared to those with all four results normal, the hazard ratio (HR) for developing DM with one, two, three, or four abnormal results were 3.45 (95% CI 2.77-4.53), 6.55 (95% CI 5.12-8.36), 10.26 (95% CI 7.54-13.96), and 18.63 (95% CI 11.87-29.25), respectively. Among people with only one abnormal result, abnormal fasting glucose showed the highest risk (HR 4.01, 95% CI 2.7-5.92).

Conclusion: This study demonstrates that even one abnormal result (with the fasting glucose posing the highest risk) in the 100-gram OGTT is a risk factor for the future development of DM. The risk further increases with each additional abnormal result. These findings underscore the importance of postnatal follow-up and early modifiable interventions even for individuals with one abnormal OGTT result to potentially mitigate future DM risks.





80 | Effect of Breastfeeding on the Early Postpartum Lipid Profile in Women with Gestational Diabetes Mellitus

Harumi Kanzawa[1]; Hiroshi Yamashita[1]; Ichiro Yasuhi[2]
[1]NHO Nagasaki Medical Center, Omura City, Nagasaki; [2]NHO Nagasaki Medical Center, Omura-City, Nagasaki

8:45 AM - 9:00 AM

Objective: Women with a history of gestational diabetes mellitus (GDM) are at high risk for developing type 2 diabetes and metabolic syndrome. Although breastfeeding is recognized as effective in preventing these diseases, its effect on postpartum lipid metabolism remains unclear. This study aimed to investigate the association between breastfeeding and early postpartum lipid profiles in Japanese women with GDM.

Study Design: This prospective cohort study included singleton pregnant women with GDM enrolled during pregnancy. An oral glucose tolerance test (OGTT) was conducted at 6 to 9 weeks postpartum. Fasting lipid profiles, including total cholesterol (T-cho), triglycerides (TG), high-density lipoprotein (HDL), and low-density lipoprotein cholesterol (LDL-cho) levels, were measured. Breastfeeding intensity was categorized into six levels, from exclusive breastfeeding (Level 1) to formula feeding only (Level 6). Breastfeeding of 80% or more (Levels 1-3) was defined as high-intensity breastfeeding (HIB). Adjusted odds ratios (aOR) of hypertriglyceridemia (≥150 mg/dL) and hyper LDL cholesterolemia (≥140 mg/dL) were calculated.

Results: A total of 501 participants underwent a OGTT at 7.3 weeks postpartum. Lipid levels were T-cho 210 ± 33 mg/dL, TG 73 ± 49 mg/dL, HDL 72 ± 17 mg/dL, and LDL 127 ± 30 mg/dL. Breastfeeding intensity levels were 55%, 14%, 9%, 10%, 10%, and 3% from Levels 1 to 6, respectively, resulting in 77% for HIB. All lipids, except T-cho, were significantly associated with breastfeeding intensity (**Table**). Compared to women with non-HIB, those who engaged in HIB showed significantly lower prevalence of hypertriglyceridemia and hyper LDL cholesterolemia, with aORs of 0.21 (95% CI: 0.11-0.40) and 0.48 (0.31-0.76), respectively.

Conclusion: Breastfeeding significantly improved the early postpartum lipid profiles of women with GDM as breastfeeding intensity increased.

Table: The Association Between Breastfeeding Intensity and the Early Postpartum Lipid Profile in Women with GDM

Breastfeeding intensity level	Level 1 (n=274)	Level 2 (n=71)	Level 3 (n=44)	Level 4 (n=49)	Level 5 (n=50)	Level 6 (n=13)	P value
T-cho (mg/dL)	209 ± 34	214 ± 34	210 ± 30	212 ± 31	221 ± 35	208 ± 59	0.29
TG (mg/dL)	65 ± 39	73 ± 48	84 ± 63	105 ± 63	133 ± 80	110 ± 50	<0.0001
HDL-cho (mg/dL)	75 ± 17	73 ± 18	67 ± 17	66 ± 15	61 ± 13	60 ± 15	<0.0001
LDL-cho (mg/dL)	124 ± 32	129 ± 27	130 ± 26	132 ± 31	140 ± 32	137 ± 45	0.018

T-cho, total cholesterol; TG, triglycerides; HDL, high-density lipoprotein; LDL, low-density lipoprotein cholesterol

81 | Rates of Risk Appropriate Postpartum Care within Six Months after Delivery

Jennifer F. Culhane; Anna Denoble; Olivia Paoletti; Caitlin Partridge; Lisbet S. Lundsberg
Yale School of Medicine, New Haven, CT

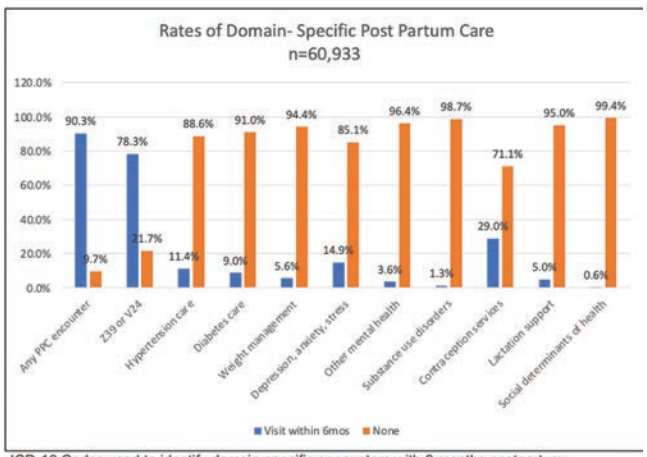
9:00 AM - 9:15 AM

Objective: Pregnancy is a "stress test", providing a window into future health risk. Enthusiasm for postpartum (PP) care (PPC) to mitigate maternal mortality and long-term adverse health outcomes is growing. We aimed to evaluate domain-appropriate 6-month PPC utilization by maternal antenatal risk factors.

Study Design: This was a retrospective study of delivery admissions occurring at a health system from 2013-2023 with evidence of ≥1 prenatal care visit. All encounters from delivery through 6-months PP were identified. Iterative review of PP encounters among random samples of 10,000 patients allowed selection of ICD-10 codes associated with PPC and 11 condition-based care domains. PPC rates were calculated by 1) any encounter, 2) traditional PPC (Z39 or V24), and 3) domain-specific PPC (Figure). Patients with risk factors (chronic hypertension (cHTN), hypertensive disorders of pregnancy, type 1 or 2 diabetes, gestational diabetes, depression/anxiety, and substance use disorder (SUD)) were identified based on ICD-10 codes. Rates of domain-appropriate PPC by risk factors were compared using Chi-square tests.

Results: N = 60,933 were included. 90% of patients had any encounter within 6 months PP and 78% had a traditional PPC visit (Figure). Across specific domains, 6-month PPC rates ranged from 0.6% for problems with social determinants of health (e.g. inadequate housing, lack of adequate foods, extreme poverty) to a high of 29.0% for contraception care. Exploring rates of domain-specific PPC by maternal risk factors, cHTN had the highest rate of appropriate PPC follow-up (54.5%), while patients with SUD had the lowest (16.6%) (Table). With the exception of cHTN, < 50% of patients with antenatal risk factors obtained domain appropriate PPC within 6 months of delivery.

Conclusion: Although we observed high rates of PPC overall, care specific to maternal risk factors was lacking, with rates mostly under 50%. Care for depression/anxiety and SUD treatment was particularly low. Major improvements are needed if PPC is to be a target to combat increasing rates of maternal mortality and improve health over the life course.



ICD-10 Codes used to identify domain-specific encounters with 6 months postpartum:
Traditional postpartum care: Z39, V24
Hypertension: I10, I11, I12, I13, I15, I67, O10, O11, O13, O14, O15, O16, R03, Z01.3, Z01.31

82 | Metformin Use in Pregnancy Decreases Neonatal Fat Free Mass

Claire E. Jensen[1]; Ashley N. Battarbee[2]; Kim Boggess[1]; Kjersti M. Aagaard[3]; On behalf of the MOMPOD Consortium

[1]University of North Carolina, Chapel Hill, NC; [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL; [3]Boston Children's Hospital, Division of Fetal Medicine and Surgery, Boston, MA; HCA Healthcare and HCA Healthcare Research Institute, Nashville, TN; HCA Texas Maternal Fetal Medicine, Houston, TX; Baylor College of Medicine and Texas Children's Hospital, Houston, TX, Boston, MA

9:15 AM - 9:30 AM

Objective: Murine and primate models treated with maternal metformin exhibit fetal bioaccumulation, leading to reduced muscle and retroperitoneal fat mass with fetal growth restriction. In clinical trials, maternal metformin use during pregnancy results in smaller neonates with reduced LGA risk, alongside a variable increased risk for SGA births. We hypothesized that the observed decreased prevalence of LGA births with maternal metformin use during pregnancy results from reduced accumulation of fetal fat free mass (FFM, i.e., muscle accretion) rather than diminished adiposity.

Study Design: Secondary analysis of a large multicenter RCT (MOMPOD) of metformin 1000mg BID vs. placebo in singleton pregnancies at 11-23 weeks with insulin-treated early diabetes or pre-existing T2DM. We included all participants who took ≥ 1 dose of study drug and had neonatal anthropometry. Multivariable linear regression estimated the association between metformin use and neonatal FFM and evaluated for effect modification by key covariates.

Results: Of n = 794 participants, 437 (55%) completed comprehensive neonatal anthropometry. They were demographically similar to the full cohort and balanced between treatment groups. Mean FFM was 2786 g (SD 408.15g, 86.2% of birth weight). FFM was 81.8g less in neonates exposed to metformin (95% CI -157.59, -4.56). The association between metformin exposure and FFM did not vary by neonatal sex, maternal race/ethnicity, pregestational diabetes diagnosis, nor excess maternal weight gain (Table 1). There was a trend toward effect modification by duration of exposure (Figure 1), indicating that the metformin-associated decline in muscle accretion increased with gestational age (p = 0.21).

Conclusion: Metformin is associated with lower neonatal muscle accretion, measured as FFM. Our finding of decreased FFM among metformin-exposed neonates adds to the mounting evidence raising concern for transplacental transfer and bioaccumulation in the fetus, which may restrict healthy physiologic growth patterns and potentially increase risk for adverse long-term cardiometabolic outcomes.

83 | Interaction between Metformin and Baseline Insulin Requirements on Neonatal Outcomes in Pregnancies with Type-2 Diabetes

Kevin S. Shrestha[1]; Claire E. Jensen[2]; Kim Boggess[2]; Gladys (Sandy) A. Ramos[3]; Ashley N. Battarbee[4]
[1]University of Alabama at Birmingham, Birmingham, AL; [2]University of North Carolina, Chapel Hill, NC; [3]University of California, San Diego, San Diego, CA; [4]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL

9:30 AM - 9:45 AM

Objective: Metformin did not improve composite neonatal morbidity among insulin-treated preexisting type 2 diabetes (T2D) in two recent RCTs. Although metformin reduced insulin requirements in the MiTy trial, there was no difference observed in the MOMPOD trial. Given trial heterogeneity, we aimed to determine if baseline insulin requirements modified the effect of metformin on neonatal outcomes.

Study Design: Secondary analysis of the MOMPOD trial, an RCT of metformin versus placebo in insulin-treated T2D or diabetes diagnosed in early pregnancy. Our primary outcome was the composite of neonatal complications from the parent trial (Table). Total daily dose (TDD) of insulin at randomization was evaluated as an effect modifier of the relationship between metformin and the primary outcome using a likelihood ratio test with p< 0.10 as significant. To further investigate effect modification, we evaluated the association between metformin and outcomes among subgroups with TDD < 30U, >60U, and >90U using multivariable Poisson regression with robust error variance and ordinary least squares regression.

Results: Of the 794 participants included, the median baseline TDD was 62 units (IQR 35, 88). There was significant interaction between metformin and TDD in relation to the primary outcome (Figure). In subgroup analyses of TDD< 30, metformin was associated with lower risk of composite neonatal outcome, LGA, neonatal fat mass, preterm birth, and NICU admission (Table). However, there were no differences in outcomes with metformin vs placebo among participants with TDD >60, with exception for smaller increase in insulin TDD during pregnancy (Table). Findings were similar for participants with TDD >90U.

Conclusion: The effect of metformin on neonatal outcomes in the MOMPOD trial cohort differed by baseline insulin requirements. Contrary to our hypothesis, metformin was associated with fewer adverse neonatal outcomes among those with low, not high, TDD. Further studies are needed to confirm our findings and evaluate the reason why metformin is beneficial for pregnancies with low insulin requirements.

Figure. Interaction between metformin and baseline insulin requirements in relation to composite neonatal outcome

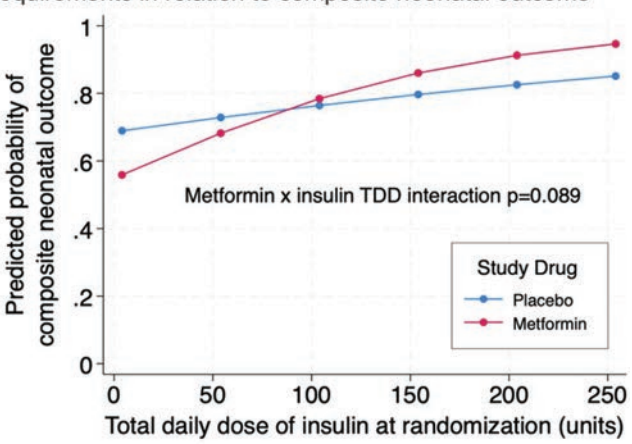

Table. Primary and secondary outcomes by metformin use among subgroups of persons with baseline total daily dose of insulin <30 units and >60 units

84 | The Placental Transcriptome in Pregnancies Complicated by A2 Gestational Diabetes Mellitus

Morgan E. Wasickanin[1]; Samantha Carson[1]; Hillary Kinsman[1]; Lydia Bettridge[1]; Katherine E. Free[1]; Jennifer Damicis[1]; Emily Sheikh[1]; Robert Walton[1]; Peter Napolitano[2]; Nicholas Ieronimakis[1]
[1]Madigan Army Medical Center, Tacoma, WA; [2]University of Washington, Seattle, WA

9:45 AM - 10:00 AM

Objective: Adverse obstetric and fetal outcomes are increased in pregnancies complicated with A2 gestational diabetes mellitus (A2GDM) compared to non-diabetic pregnancies. Placental dysfunction is thought to be attributed to some of the complications in A2GDM, yet the underlying molecular mechanisms remain unknown. We hypothesized that transcriptional differences in human placentas from A2GDM pregnancies may relate to tissue dysfunction. To test our hypothesis, we compared the transcriptome within placentas delivered from A2GDM versus uncomplicated pregnancies.

Study Design: Intervillous biopsies were dissected from unlabored placentas delivered by cesarean. The extracted RNA was depleted for both adult and fetal globin transcripts prior to transcriptional analysis by mRNA-seq (n = 10/condition). Alignment and differential gene expression (DEGs) analysis was conducted using Illumina's Dragen software. DEGs were considered statistically significant based on a cut-off adjusted p-value of < 0.05 using Benajamini-Hochberg false discovery rate correction.

Results: Between A2GDM versus uncomplicated placentas 14,825 DEGs were identified. Among these 1092 had a p < 0.05. When p-values were adjusted, the following 3 DEGs were significantly upregulated with A2GDM: AC068547.1, MMRN1, and ZNF780A (Figure 1).

Conclusion: The intervillous transcriptome in placentas from pregnancies complicated by A2GDM appears different than those from uncomplicated pregnancies. AC068547.1, a gene that codes for the calcium voltage-gated channel auxiliary subunit beta 4 (CACNB4) protein, was upregulated in a subset of placentas from A2GDM pregnancies. MMRN1 and ZF780A, proteins that function in coagulation and transcription regulation respectively, were more consistently upregulated in A2GDM samples. Further investigation is warranted to understand the role of these factors in placentas complicated by gestational diabetes mellitus.

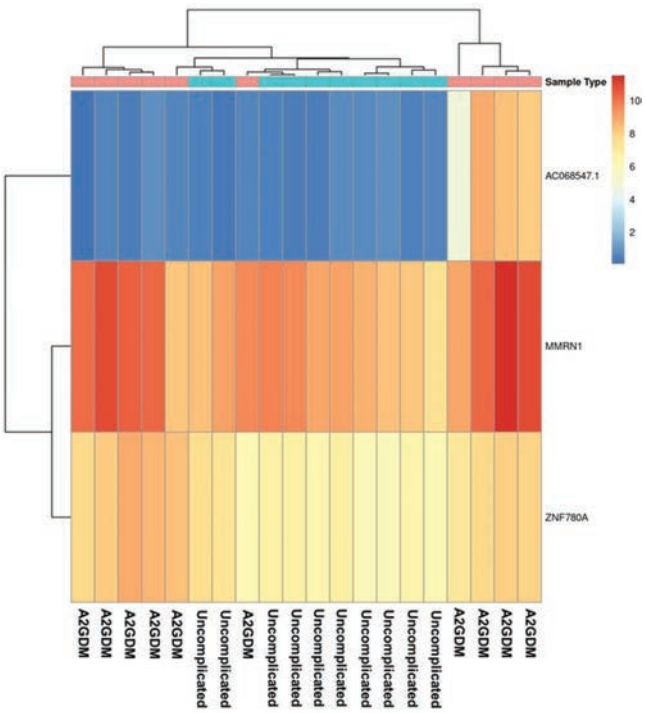

Figure 1. Hierarchically clustered heatmap from the mRNA-seq comparison of intervillous samples from A2GDM and uncomplicated placentas (n=10/condition). Represented are genes with FDR adjusted p<0.05. Color intensities correspond to fold changes between A2GDM vs. uncomplicated samples, red for the upregulation and blue for downregulation of genes across individual placentas.

85 | Childhood Sexual and Emotional Maltreatment are Associated with Increased Gestational Weight Gain

NATALIE E. POLIEKTOV[1]; Mariana Rocha[1]; Kaitlyn Stanhope[2]; Lauren Holt[1]; Alicia Smith[1]; Vasiliki Michopoulos[1]; Suchitra Chandrasekaran[3]
[1]Emory University School of Medicine, Atlanta, GA; [2]Rollins School of Public Health, Atlanta, GA; [3]Emory University, Atlanta, GA

10:00 AM - 10:15 AM

Objective: Gestational weight gain (GWG) is associated with adverse metabolic outcomes (AMO) for a mother & infant. Prior research suggests an association between maternal childhood trauma (CT) and increased GWG; however, little is known about how different domains of CT (e.g., sexual abuse (SA), emotional abuse (EA) & physical abuse (PA)) influence GWG. We aimed to study the association between CT & its domains with GWG.

Study Design: This is a prospective longitudinal cohort study investigating associations between trauma exposure & pregnancy

outcomes at an urban safety net hospital. CT was assessed using the Childhood Trauma Questionnaire (CTQ), a validated measure of 5 trauma domains, as a continuous score & dichotomized as CT (CTQ score >/ = 35) or no CT (CTQ score < 35). Adult trauma was assessed using the Traumatic Experiences Inventory. Weight & body mass index (BMI) were recorded during each trimester. Excessive GWG (EGWG) was defined as GWG exceeding BMI-based recommendations from ACOG. Multivariable linear regression and logistic regression were performed controlling for maternal age, pre-pregnancy BMI, & gestational age at delivery.

Results: N = 335 subjects were enrolled in the study. CTQ total, SA, & EA scores were positively correlated with increased GWG *(b = 0.24, 95% CI 0.02-0.46, p = 0.033; b = 0.07, 95% CI 0.01-0.1, p = 0.034; b = 0.06, 95% CI 0.00-0.12, p = 0.049, respectively)* (Figure 1). Mean GWG was 9 pounds (lb) higher in those with SA vs. no SA *(30.5 lb vs. 21.5 lb)* whereas mean GWG was 4 lb higher in those with EA vs. no EA *(27.5 lb vs. 23.4 lb)*. Further, there was 1.5-fold higher odds of having EGWG with CT vs. no CT *(OR 1.47, 95% CI 0.94–2.33, p = 0.092).* Childhood PA & adult trauma were not associated with GWG.

Conclusion: Using detailed trauma exposure measures, our data indicate that childhood SA & EA, but not PA or adult trauma, are associated with increased GWG during pregnancy. Further research is needed to understand the complex interactions between specific domains of trauma exposure & AMO in order to improve maternal & infant health.

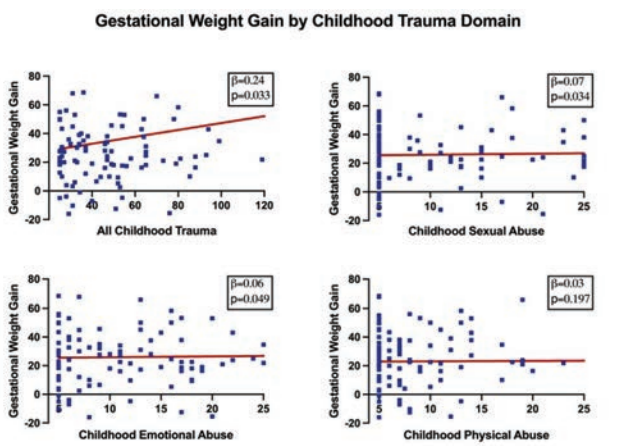

Figure 1. Gestational weight gain (lbs) by childhood trauma domain (points measured by the Childhood Trauma Questionnaire). Beta coefficients and p-values listed correspond to multivariable linear regressions controlling for maternal age, pre-pregnancy body mass index, and gestational age at delivery.

Oral Concurrent Session 8

Fetus and Fetal Intervention

8:00 AM - 8:15 AM

Objective: Direct femoral and carotid access is not possible in fetuses, limiting options for prenatal treatment of high flow life-threatening anomalies (Vein of Galen Malformation, sacrococcygeal teratoma). Direct fetal cardiac puncture is used for intra-uterine transfusion and fetal valvuloplasty. We hypothesized that direct cardiac catheterization would enable access to the fetal arterial system for diagnosis/treatment. Aim: develop a fetal sheep model to study feasibility and safety prior to human trials.

Study Design: 5 ewes at 120 days' gestation (30-week human equivalent) with 8 fetuses, underwent laparotomy with uterine exteriorization. Using ultrasound guidance (US) an 18G needle was placed through the uterine wall into the fetal heart via the apex of the left ventricle, and positioned under the aortic valve. A glidewire was advanced into the aortic arch. The needle was replaced with a 4F dilator. A 1.3F microcatheter was advanced over the glidewire into the aortic arch, and under fluoroscopy to (i) just proximal to the rete mirabile (vessel meshwork supplying the Circle of Willis) via the common carotid and internal maxillary arteries, or (ii) down the descending aorta to the femoral artery. N-butylcyanoacrylate glue was then deposited occluding the target vessel. Sacrifice occurred 30 minutes after occlusion with CT and MRI assessment followed by autopsy (Fig1).

Results: All fetuses tolerated the procedure and survived 30 minutes. Intraoperative digital subtraction angiography and postmortem high-resolution CT showed on-target glue delivery in 7/8 (88%) cases. Postmortem MRI confirmed absence of focal brain and pelvis/limb ischemia/hemorrhage (Fig2).

Conclusion: This study demonstrates, in fetal lambs, feasibility/safety of a new procedure using direct cardiac catheterization (US guided) to access the arterial circulation in the brain and pelvis (fluoroscopy guided). This paves the way for other multiple-method imaging guided procedures, including devascularization of high-flow lesions, diagnostic blood sampling, biopsy, and drug and cell delivery and represents a new space for fetal research/therapy.

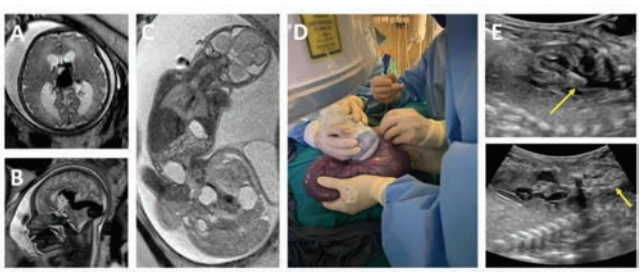

Figure 1 – Human target populations: severe fetal vein of Galen malformation (A-B) and high-risk sacrococcygeal teratoma (C). Intraoperative images in the fetal lamb model: fetal cardiac access under ultrasound guidance (D) with the needle tip (arrow) positioned in the left ventricle under the aortic valve (E) followed by advancement of the flexible sheath (arrow) through the aortic valve terminating in the ascending aorta and aortic arch (F).

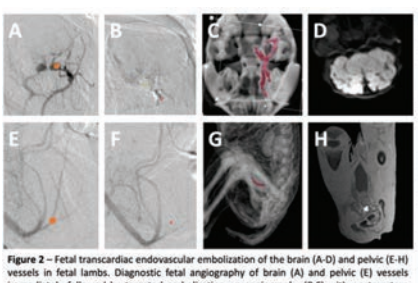

Intraoperative outcomes	Median (SEM)
Gestational Age at procedure (days)	120 (0)
Weight at harvesting (g)	2250 (350)
Duration of fetal cardiac access (m:s)	22:49 (08:51)
Time to final positioning of the microcatheter (m:s)	08:00 (04:28)
Total fluoroscopy time (m:s)	08:02 (03:38)
Total X-ray exposure (Gy/cm²)	31.3 (23.2)
Cumulative contrast dose (mL)	21.0 (7.7)
Fetal heart rate - prior to cardiac puncture (/min)	126 (12)
- after embolization (/min)	121 (16)
- 10 min after embolization (/min)	125 (36)
- 20 min after embolization (/min)	132 (14)
- 30 min after embolization (/min)	120 (17)
Pericardial effusion requiring drainage (number; %)	2/8 (25%)
Fetal resuscitation (number; %)	3/8 (38%)
Successful target embolization on postmortem CT (n; %)	7/8 (88%)
Non-target embolization on postmortem CT (number; %)	0/8 (0%)
Hemorrhage or ischemia on postmortem MRI (number; %)	0/8 (0%)

Figure 2 – Fetal transcardiac endovascular embolization of the brain (A-D) and pelvic (E-H) vessels in fetal lambs. Diagnostic fetal angiography of brain (A) and pelvic (E) vessels immediately followed by targeted embolization on angiography (B,F) with postmortem confirmation of absence of non-target embolization on CT scan (C,G) and absence of hemorrhagic or ischemic complications on MR imaging (D,H). Table (I).

87 | Predicting Outcomes in Congenital Diaphragmatic Hernia with Discordant Fetal MRI and Ultrasound Prognostic Indices

Lamia A. Alamri[1]; Jason Gien[1]; Payton Moody[1]; Blair W. Weikel[2]; Mariana Meyers[1]; Michael V. Zaretsky[1]; Sarkis C. Derderian[1]; Henry L. Galan[3]
[1]University of Colorado, School of Medicine, Aurora, CO; [2]University of Colorado, School of Medicine and Colorado Fetal Care Center, Aurora, CO; [3]University of Colorado, School of Medicine, Children's Hospital of Colorado, Aurora, CO

8:15 AM - 8:30 AM

Objective: Prognosis and management of prenatally diagnosed congenital diaphragmatic hernia (CDH) is reliant on ultrasound (US) observed-to-expected lung-to-head ratio (O/E LHR) and MRI indices (percent predicted lung volume; PPLV). These indices can conflict with one another (e.g. severe by MRI and moderate by US, or vice versa), creating a clinical dilemma. Our objective was to determine whether discordant prognostic indices are more predictive of a moderate or a severe case.

Study Design: This retrospective study included all severe and moderate CDH cases managed at a single fetal care center from 2012-2023. Severe parameters were defined as a MRI PPLV < 15% and U/S O/E LHR value < 25%. Discordant MRI and US indices (DIS) were defined as either one falling into the severe category and the other into the moderate category, and they were grouped together. Concordant Severe (CSev) and Concordant Moderate (CMod) were defined as MRI and US both falling into the severe or moderate category, respectively. The primary outcome was extracorporeal membrane oxygenation (ECMO) use. Categorical and continuous variables were compared using chi-square or Fisher's exact tests or Wilcoxon rank sum test as appropriate. Differences between groups were assessed with pair-wise comparisons and a Bonferroni correction ($p < 0.017$).

Results: Of 82 CDH cases, 27 were in the DIS group, 36 in the CMod group and 19 in the CSev group. Primary and secondary outcomes are shown in the Table 1a. ECMO use was similar for DIS (78%) and CSev (95%) groups, and both were significantly higher (Table 1b) than the CMod group (45%). Survival was highest and mechanical ventilation was lowest in the CMod group (Table 1 & Figure 1). Duration on ECMO and hospital length of stay were similar among all groups.

Conclusion: Discordant prenatal MRI and US CDH indices can lead to uncertainty and affect optimal patient counseling and management. Our results suggest that MRI and US modalities which show discordant CDH prognostic indices, predict a severe CDH phenotype.

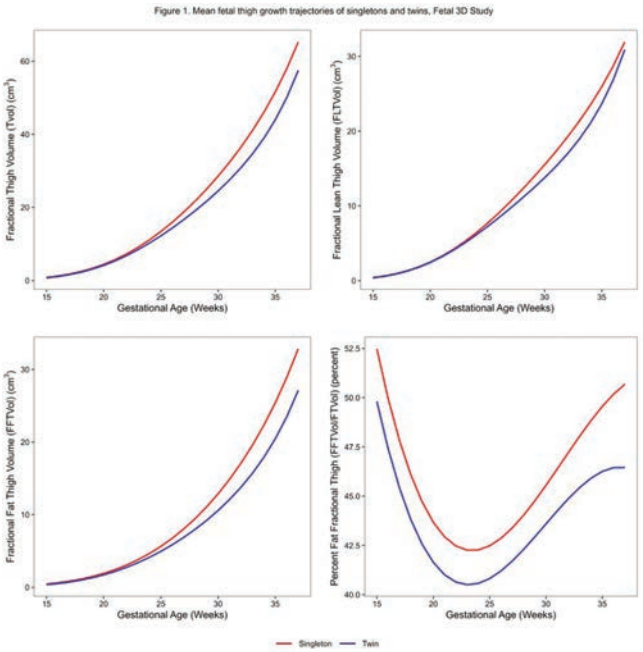
8:30 AM - 8:45 AM

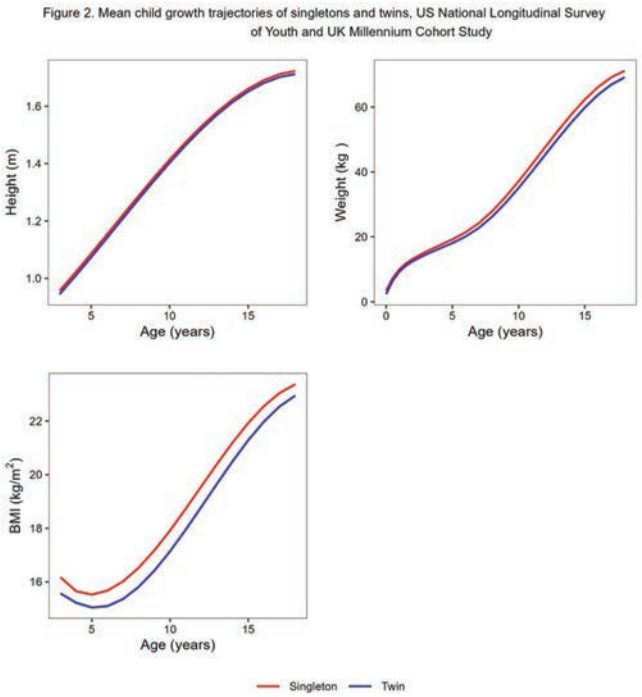
Objective: An emerging paradigm attributes 3rd trimester deceleration in fetal growth in uncomplicated twin pregnancies to a normal evolutionary adaptive process rather than pathologic growth restriction. However, long-term studies tracking child growth are needed since growth restriction in singletons is associated with increased risk for obesity and cardiometabolic dysfunction later in life. Few such studies exist, and none continue through adolescence or have evaluated fetal fat body composition which may provide important insights.

Study Design: In the NICHD-Fetal 3D Study (n = 2919), we compared marginal means of total, fat, and lean fractional thigh volumes between twins and singletons between 15-37 weeks' gestation (wks) estimated from linear mixed models. Additionally, in US and UK nationally representative prospective datasets (n = 30,854), we similarly compared growth trajectories of twins and singletons between 0-18 years (y) and estimated adjusted risk ratios (aRR) of obesity overall and at different stages of development, based on typical ages of puberty for boys and girls.

Results: *In utero*, twins had smaller thigh volumes beginning at 15 wks (difference = -0.12 cm^3; 95% CI -0.16, -0.08) through 37 wks (difference = -7.8 cm^3; CI -11.9, -3.8), with 2.7-4.2% less thigh fat (15-37 wks) and less lean tissue by 0.18-1.85 cm^3 (23-37 wks) than singletons (Figure 1). From birth through age 18y, twins never catch up to singletons, remaining consistently 1 cm shorter, 1-2 kg lighter, and a lower BMI (Figure 2). Accordingly, twins' risk of obesity was 25% lower between age 3-18y; 27% lower (aRR = 0.73; CI 0.54, 0.99) before puberty, 29% lower (aRR = 0.71; CI 0.51, 0.99) during puberty, and 10% lower (aRR = 0.90; CI 0.55, 1.04) after puberty.

Conclusion: Twins had proportionally less fat tissue accumulation *in utero* compared to singletons starting at 15 weeks and were not at an increased risk of childhood obesity. Rather, twins had shorter stature and were thinner through age 18y. Persistent differences in twin size across gestation and through age 18y supports the concept of an early adaptive programming mechanism.





89 | Proteomic Analysis of Monochorionic Pregnancies with twin-to-twin Transfusion Syndrome and Selective Fetal Growth Restriction

Jessian L. Munoz; Cara Buskmiller; Ahmed A. Nassr; Magdalena Sanz Cortes; Michael A. Belfort; Roopali V. Donepudi
Texas Children's Hospital and Baylor College of Medicine, Houston, TX

8:45 AM - 9:00 AM

Objective: One third of monochorionic twin pregnancies are complicated by twin-to-twin transfusion syndrome (TTTS) and/or selective fetal growth restriction (sFGR). While standard treatment of TTTS is fetoscopic laser photocoagulation (FLP),

concomitant sFGR results in greater rates of fetal demise and adverse pregnancy outcomes. Our objective was to characterize the molecular pathophysiology of TTTS, sFGR and the relationship when both are present.

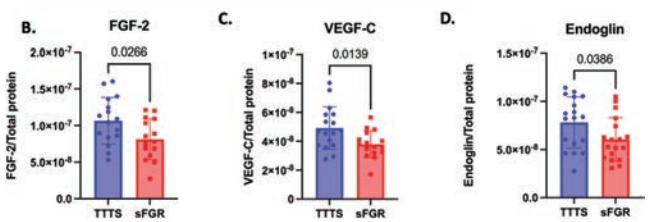
Study Design: This study was a prospective cohort analysis at our Fetal Center from 2022-2024. Maternal plasma specimens and amniotic fluid samples were collected from patients undergoing FLP for TTTS with and without sFGR. Amniotic fluid total protein was assessed by Bradford assay and quantitative proteomic pathway analysis was performed using the Luminex platform. Maternal plasma proteins were then analyzed by ELISA to assess for possible circulating biomarkers.

Results: Amniotic fluid specimens were analyzed from 36 subjects (18 isolated TTTS and 18 TTTS + sFGR). No differences were noted in gestational age of FLP. Proteomic analysis (figure 1) showed significant downregulation of Fibroblast Growth Factor (FGF-2, p = 0.02), Endoglin (Eng, p = 0.04) and Vascular Endothelial Growth Factor C (VEGF-C, p = 0.01) in pregnancies complicated by TTTS with sFGR when compared to isolated TTTS. No differences were noted in other vascular or growth factors. Pathway interaction analysis revealed a linear relationship among these proteins in neovascularization and cell growth pathways. Maternal plasma proteomic analysis showed no difference in protein expression among groups.

Conclusion: In this cohort of monochorionic pregnancies complicated by TTTS and TTTS with sFGR, the pro-vascular and pro-growth pathway of FGF-2/Endoglin/VEGF was significantly downregulated, suggesting these may contribute to the sFGR pathology beyond TTTS. These findings were limited to the amniotic cavity and not identified in maternal circulation. Further research on the downstream molecular mechanism of this proteomic pathway may provide additional targets to assess and treat underlying pathology.

A.

Factor	Isolated TTTS (n=18)	TTTS + sFGR (n=18)	p-value
Age (years)	30.9 ± 5.8	30.1 ± 4.8	0.64
BMI (kg/m²)	29.9 ± 6.6	30.2 ± 8.9	0.94
Gestation age at diagnosis	18.7 [17.4, 22.4]	19.2 [16.7, 21.3]	0.58
Gestational age at FLP	18.9 [17.4, 22.5]	19.2 [17.1, 21.4]	0.67



90 | Chronotropic Rescue Prior to Cord Clamping in Fetal Complete AV Block and Severe Bradycardia

Samantha Holmes[1]; Emily Bucholz[1]; Camila Londono-Obregon[1]; Jason Gien[1]; Nicholas Behrendt[1]; Michael V. Zaretsky[1]; Henry L. Galan[2]; Bettina Cuneo[3]

[1]University of Colorado, School of Medicine, Aurora, CO; [2]University of Colorado, School of Medicine, Children's Hospital of Colorado, Aurora, CO; [3]University of Arizona, Tucson, AZ

9:00 AM - 9:15 AM

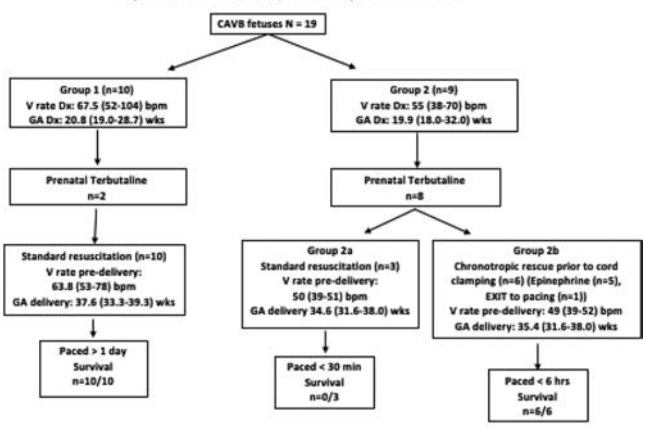
Objective: Fetal complete AV block (CAVB) occurs in 2% of pregnancies with Anti-Ro antibodies or inherited arrhythmias. Only about 10% have a ventricular (V) rate of < 50 beats per minute (bpm) but case mortality rate is 42%. We hypothesized that survival of fetal CAVB with V ≤52 bpm prior to delivery would improve with chronotropic rescue using epinephrine (epi) or ventricular pacing at or after cesarean delivery and prior to cord clamping.

Study Design: Single center retrospective series of fetal CAVB divided into 2 groups based on V rate at time of delivery. Group 1 consists of V rates > 52bpm receiving standard delivery room (DR) resuscitation at delivery. Group 2 consists of V rates ≤52 bpm receiving either standard resuscitation or chronotropic rescue prior to cord clamping and delivery. Maternal, fetal and neonatal medical records and echocardiograms were reviewed for atrial/ventricular rates, cardiac function and survival or demise. We calculated median for both groups.

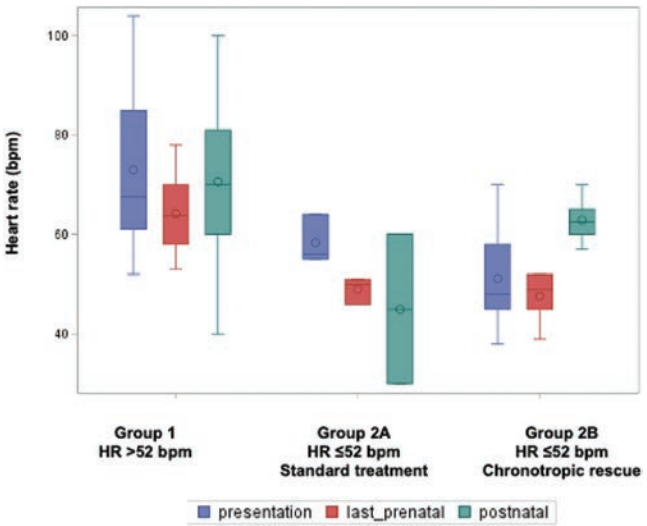
Results: From 2013-2024, 19 fetal CAVB subjects (10 in group 1, 9 in group 2), 18 with maternal Anti-Ro antibodies and one with an inherited arrhythmia, were delivered (Figure 1). Group two delivered and presented at an earlier gestational age (GA), had lower V rates at presentation and received more in utero terbutaline than in group one. All in group one survived after standard DR resuscitation. In group 2a, three died after standard DR resuscitation and pacing within 30 minutes of birth because of pulseless electrical activity: their V rates decreased 50 (39-51) bpm and cardiac function became severely depressed after cord clamping. In group 2b, 6/6 survived after receiving high dose epinephrine (n = 5) or EXIT to pacing prior to cord clamping (n = 1); their V rate increased 63 (57-70) bpm and cardiac function was normal after cord clamping (Figure 2). All with chronotropic rescue were successfully paced at < 6 hours.

Conclusion: Chronotropic rescue prior to cord clamping may improve survival by increasing V rate and maintaining cardiac function in CAVB with ventricular rates ≤52 bpm and a history of in utero terbutaline treatment.

Figure 1. Flow chart of CAVB patient management and survival



Data for FHR and GA data are shown as median (range).
FHR, fetal heart rate; GA Dx, gestational age at diagnosis; bpm, beats per minute
Standard resuscitation: resuscitation per NRP guidelines



91 | Impact of a Synthetic Amniotic Fluid Upon Fetal Lung Development

Stephanie Finoti[1]; Braxton Forde[2]; Samuel Martin[3]; Marc Oria[1]; Jose L. Peiro[4]
[1]University of Cincinnati, Cincinnati, OH; [2]University of Cincinnati College of Medicine, Cincinnati, OH; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [4]Cincinnati Children's Fetal Care Center, Cincinnati, OH

9:15 AM - 9:30 AM

Objective: Serial amnioinfusions in the setting of anyhydramnios seek to promote fetal lung development, however these procedures can be fraught with complications, and the fluid infused (Normal Saline-NS or Lactated Ringer's-LR) is not designed for the in-utero environment. We previously designed a synthetic amniotic fluid (Amnio-well - AW), which minimizes reactive oxygen species damage to the amniotic membrane. Given the interplay between the amniotic fluid and fetal lungs, we sought to evaluate the impact of AW on fetal lung development.

Study Design: At E17.5, pregnant rats underwent laparotomy to amniotic fluid replacement with either NS, LR, AW, or AW plus epidermal and fibroblast growth factor (AW++), with sham surgery as a control. Fetal lungs were harvested at E20.5. Histology was evaluated by H&E staining, using morphometric measurement of fractional airspace to estimate growth. Gene expression for surfactant A, B, and C (SP-A, SP-B, SP-C) was compared between groups via reverse transcriptase PCR and immunofluorescence. Inflammatory gene panels were run to identify patterns in abnormal inflammation in the various treatment groups.

Results: Fetal lungs from NS and LR were noted to have increased edema, macrophage infiltration, and decreased airspace ($p < 0.001$) (Figure 1). When evaluating surfactant expression, there was increased SP-B, SP-C expression with AW relative to control, significantly decreased SP-A, SP-B, SP-C expression with both NS and LR, and mildly decreased SP-A, SP-B, SP-C with AW++ (Figure 2). Inflammatory gene profiling revealed marked alterations in histamines, annexins, phospholipase, and immune cell recruitment in NS and LR, indicating abnormal cell membrane integrity (Figure 2). The closest profile to control was AW, with altered gene expression in 10/94 genes (9 upregulated, 1 downregulated), vs 41 genes with NS (22 up, 19 down), 33 with LR (14 up, 19 down), and 12 with AW++ (10 up, 2 down).

Conclusion: A synthetic amniotic fluid leads to decreased lung inflammatory profiles and improved surfactant expression compared to commercially available fluids when used for amnioinfusion.

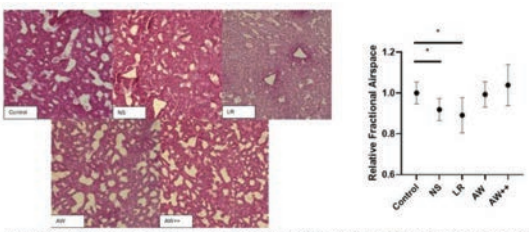


Figure 1. H&E staining of fetal lung tissue at E20.5 at 10x. Increased tissue edema and macrophage/neutrophil infiltration. Decreased relative airspace is noted in NS and LR relative to control, a finding not seen with AW and AW++.

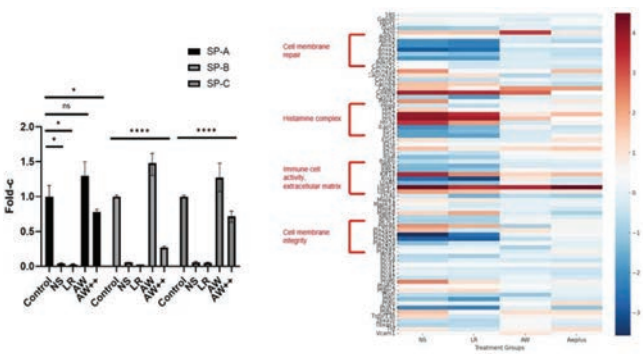

Figure 2. Gene expressions for Surfactant A, B, and C and inflammatory profiles of the various treatment groups. There was significantly decreased SP-A, SP-B, and SP-C expression in lungs exposed to NS and LR. SP-A, SP-B, and SP-C expression in lungs exposed to AW++ was also decreased relative to control, and SP-B, SP-C only were increased relative to control with AW.

92 | Effect of Very Preterm Delivery on Outcomes Following in-Utero Spina Bifida Repair

9:30 AM - 9:45 AM

Objective: In-utero fetal spina bifida repair decreases the risk for ventriculoperitoneal shunt (VP shunt) placement, reverses hindbrain herniation, and improves motor function with a higher likelihood of independent ambulation. The goal of this project was to assess pregnancy and neonatal outcomes among individuals who delivered very preterm (< 30 weeks of gestation (wk)) from the fMMC Consortium Registry sponsored by the North American Fetal Therapy Network (NAFTNet).

Study Design: The NAFTNet fMMC registry includes prospectively collected data from 2011 to 2024. Three cohorts of patients were categorized by gestational age (GA) of delivery and compared: < 30 wk, 30-34 wk, and > 34 wk. Comparisons between groups for maternal and delivery outcomes were completed for the entire cohort and then analyzed for those with available shunt data. Chi-square or Fisher's exact tests were used to compare categorical variables, and Kruskal-Wallis tests were used to compare continuous variables. p-values < 0.05 were considered significant.

Results: A total of 1,213 patients were available for analysis (< 30 wk n = 111, 30-34 wk n = 323, >34 wk n = 779). Overall mortality was 2.2%, 85% of which occurred in the < 30 wk cohort (Table 1) in which perinatal mortality was 21%. Latency from fetal surgery to delivery averaged 2.6 wks for the < 30 wk group. Rates of abruption, chorioamnionitis, and spontaneous labor were higher compared to later GA cohorts. Neonatal morbidity was also significantly higher for sepsis, apnea, respiratory distress, patent ductus arteriosus, and periventricular leukomalacia in the < 30 wk cohort. VP shunt data was available for 677 patients (< 30 wk n = 53, 30-34 wk n = 186, >34 wk n = 438). A similar rate of VP shunt placement was seen between GA groups (Table 2).

Conclusion: Very preterm birth following in-utero spina bifida repair results in significant perinatal mortality and neonatal morbidity. Despite very preterm birth, the reduction in VP shunt rates, a benefit of in utero repair, appears to be preserved. Further data is required to analyze the impact on ambulation and developmental outcomes.

9:45 AM - 10:00 AM

Objective: Irreversible brain damage due to congenital hydrocephalus may be improved with prenatal intervention. While ventriculosubgaleal shunting (VSGS) is commonly performed postnatally in premature infants, in-utero placement is unexplored.

For the first time, we evaluate the feasibility of VSGS in-utero using a lamb model.

Study Design: Hydrocephalus was induced in 14 fetal lambs by injecting 1.5 mL of BioGlue® into the cisterna magna (Fig 1a-1d) between days 80-90 of gestation. Ten to 16 days later, ultrasound was performed to confirm hydrocephalus. Afterward, VSGS was placed by creating a subgaleal pocket (Fig 1e), inserting a standard ventricular catheter (Fig 1f), tunnelling under the scalp (Fig 1g), and securing with a silk suture (Fig 1h), with the other end in a lateral ventricle (Fig 1i). Near term, the ewes were sacrificed. Hysterotomy was performed to extract the lambs. Lambs were evaluated through gross inspection, and postmortem MRI was performed. Neuropathology is pending.

Results: Ten ewes with 14 fetuses underwent hydrocephalus induction (median 86 days) by either hysterotomy (2/14) or transuterine (12/14) methods. Two fetuses were macerated, but hydrocephalus was confirmed in 11/12 surviving fetuses (3 severe, 4 moderates, 4 mild). A VSGS was successfully placed in all 12 (median 104 days) (Fig 1e-1h). One with severe hydrocephalus died after the procedure, 3 were aborted and 1 was macerated at hysterotomy. All 7/14 lambs that survived to near term showed scalp healing (Fig 1l). All 7 VSGS remained under the scalp without migration (Fig 1j-1k) (Table 1). Postmortem MRI showed improved hydrocephalus in 4/7 cases (Table 1).

Conclusion: Prenatal placement of VSGS proved feasible in this animal model. The procedure resulted in a 50% fetal loss, which may be due to procedural factors or stress from repeated procedures. Improved hydrocephalus occurred in 57% of survivors. To improve success, future studies will investigate the efficacy and safety of VSGS using less invasive approaches, including fetoscopic placement of VSGS.

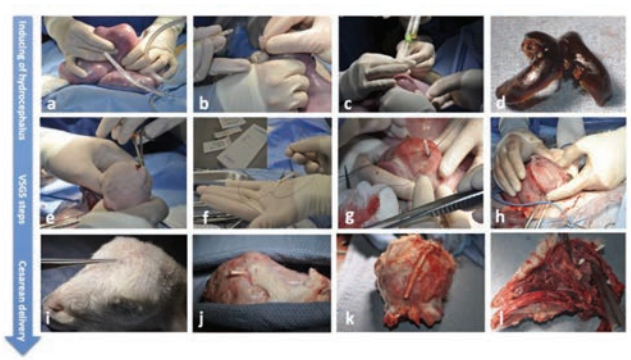

Figure 1: Steps involved in inducing hydrocephalus: placing the head of the fetus in favorable position and fixing it (a), finding the cisterna magna and placing the catheter (b), inserting the BioGlu (c). The BioGlu casting the shape of the ventricles, as seen after harvesting the head (d). The VSGS was implanted by creating a subgaleal pocket (e), inserting a standard ventricular catheter tunneled under the scalp (f-g), and suturing it (h). In gross examination after the hysterotomy, skin healing was observed (i) and shunt position under the scalp was confirmed (j-k). Gross inspection for brain injury/ hemorrhage and the two ends of the shunt placement (k,l).

Sheep No	GA at the time of shunt	Twin/Singleton	Method (Hysterotomy /mini hysterotomy)	Shunt placement during (minutes)	Pre-shunt Ventricle sizes (Normal/Mild/Moderate/Severe)	Right frontal/Left frontal	Type of shunt (catheter or reservoir)	Size of the pocket on scalp (cm)	shunt placement successful (yes/NO)	Post-shunt ventricles sizes	Note
499	104	Twin	Hysterotomy	18	Mild	Right frontal	catheter	4	Yes	Normal	Evaluated upon delivery
			Hysterotomy	15	Mild	Left frontal	catheter	4	Yes	Normal	Evaluated upon delivery
955	99	Singleton	Hysterotomy	10	Moderate	Right frontal	catheter	4	Yes	Moderate	Evaluated upon delivery
617	99	Singleton	Hysterotomy	13	Moderate	Left frontal	catheter	4-5	Yes	Normal	Evaluated upon delivery
409	94	Singleton	Hysterotomy	8	Normal	Right frontal	catheter	4-5	Yes	Normal	Evaluated upon delivery
968	95	Singleton	Mini Hysterotomy (2-3 cm)	10	Severe	Right frontal	catheter	4	Yes	Normal	Evaluated upon delivery
890	107	Twin	Hysterotomy	10	Mild	Right frontal	catheter	5	Yes	Severe	Evaluated upon delivery
			Hysterotomy	10	Severe	Right frontal	catheter	4	Yes	-	Macerated
577	105	Singleton	Hysterotomy	8	Mild	Right frontal	catheter	4	Yes		Abortion - 40 days after shunt placement
300	95	Twin	Mini Hysterotomy (2-3 cm)	8	Moderate	Right frontal	catheter	4	Yes		Abortion - 23 days after shunt placement
			Mini Hysterotomy (2-3 cm)	10	Moderate	Right frontal	catheter	4	Yes		
254	104	Singleton	Hysterotomy	15	Severe	Right frontal	reservoir	4	Yes		Baby passed away right after shunt placement
58	98	Twin	Babies were macerated before shunt placement								

Table 1: Summary of shunt placement procedures and outcomes. The first six sheep (Tag 499-890) underwent hysterotomy and fetuses were evaluated upon delivery. Sheep with Tag 577-300 experienced abortion after shunt placement. One case (Tag 254) passed away immediately after shunt placement, possibly due to severe hydrocephalus. Additionally, case 58 was found to be macerated during the hysterotomy for shunt placement.

94 | Role of Placental Superficial Anastomoses in Twin-Twin Transfusion Syndrome (TTTS)

Ramen H. Chmait[1]; Lisa M. Korst[2]; Arlyn Llanes[1]; Kristine R. Rallo[1]; Andrew H. Chon[3]; Martha A. Monson[4]; Ruben A. Quintero[5]

[1]Keck School of Medicine, University of Southern California, Los Angeles, CA; [2]Childbirth Research Associates, North Hollywood, CA; [3]Oregon Health & Science University, Portland, OR; [4]Intermountain Healthcare, University of Utah Health, Salt Lake City, UT; [5]The Fetal Institute, USFETUS Research Consortium, Miami, FL

10:00 AM - 10:15 AM

Objective: To test whether the type and number of superficial anastomoses [arterio-arterial (AA) and veno-venous (VV)] were associated with twin survival.

Study Design: This is a post hoc analysis of data collected in the Sequential Trial, a randomized controlled trial (RCT) comparing the sequential and selective laser techniques for TTTS patients at 16-26 gestational weeks. Patients received either the original (selective) or a modified selective (sequential) laser surgery, in which arteriovenous (AV) anastomoses with unidirectional blood flow from donor to recipient are laser-ablated first, followed by ablation of AV anastomoses from recipient to donor. This theoretically allows for a net intraoperative blood transfer from the hypervolemic recipient to the hypovolemic donor twin. Those with only 1 AA (AA-1) vs 2 or more AA (AA-2) were identified, and we tested for association for twin survival at birth.

Results: Of 642 patients in the RCT, 466 (72.6%) had AV anastomoses only (donor survival 90.3%) and 176 (27.4%) had both AV and superficial anastomoses (donor survival 70.5%) ($P < .0001$). Of the 176 with superficial anastomoses, 112 (63.6%) had AA only, 40 (22.7%) had both AA and VV, and 24 (13.6%) had VV only. For the 152 patients who had at least 1 AA, donor survival differed based on type and number of superficial anastomoses (Figure). In logistic regression models for donor survival controlling for surgical technique, donor critical abnormal Dopplers, and donor middle cerebral artery peak systolic velocity multiples of the median $\geq$1.5, patients with AA-2 vs AA-1 were less likely to have donor survival (OR 0.26 [0.08-0.81], $P = .0206$). Specifically, patients with 2 or more AA and no VV were at risk (Table). The presence of fetal growth restriction was non-contributory. No differences in recipient survival were noted.

Conclusion: The type and number of superficial anastomoses was associated with donor but not recipient twin survival after laser surgery for TTTS. Poor donor twin survival was associated

with presence of AA, particularly in cases lacking a corresponding VV.

Table. Results of a logistic regression model for donor survival by arterio-arterial (AA) anastomosis group (n=152), after controlling for surgical technique, Quintero stage, the presence of donor critical abnormal Dopplers, and preoperative donor middle cerebral artery peak systolic velocity multiples of the median >=1.5. Reference group: 1 AA and at least 1 venovenous (VV) anastomosis.

AA anastomosis group	Odds Ratio (95% Confidence Interval)	*P*-value
AA1 and no VV	0.37 (0.11-1.28)	.1147
AA2 and VV	0.31 (0.05-1.91)	.2064
AA2 and no VV	0.02 (0.00-0.25)	.0018

95 | Prevention Of Methamphetamine Use among Postpartum People (PROMPT): A Pilot Randomized Controlled Trial

Marcela C. Smid[1]; Jasmin E. Charles[1]; Amanda A. Allshouse[2]; Stephanie Castro[1]; Grace Humiston[1]; Elysha Cash[2]; Adam G. Gordon[2]; Kristi Carlston[1]; Marie Gibson[1]; Gerald Cochran[1]
[1]University of Utah Health, Salt Lake City, UT; [2]University of Utah, Salt Lake City, UT

8:00 AM - 8:15 AM

Objective: In the US, methamphetamine use disorder (MUD) is a leading contributor to postpartum deaths. Our objective was to determine feasibility, safety, and preliminary estimate of efficacy of oral micronized progesterone, a neurosteroid with effects on reward-reinforcement brain circuitry, to reduce postpartum methamphetamine use (MU).

Study Design: We conducted a double-blind, randomized controlled trial of people with MUD within 12 weeks postpartum comparing oral micronized progesterone to placebo. We excluded those with MU within 4 weeks of enrollment, severe depression/anxiety symptoms or suicidality at screening, taking sedating medications, or < 2 weeks medication for opioid use disorder (MOUD). Block randomization occurred 1:1 stratified for opioid use disorder (OUD). Weekly study visits assessed MU, defined as self-reported MU or positive urine toxicology, and MU craving. The primary outcome was feasibility, defined as enrollment of 80% planned sample (n = 32/40). Safety was assessed by number of adverse events (AEs) between treatment arms. Preliminary estimate of efficacy was determined by MU and craving scores. Logistic regression accounting for time was used to assess change in craving scores by arms, adjusting for confounders.

Results: From November 2021 to January 2024, 253 individuals were screened and 34/46 eligible individuals enrolled and randomized (74%) with 88% retention. At baseline, demographics and craving scores were similar between arms (Table 1). AEs did not differ by arm. For MU, there was no difference between groups by intent to treat (11% vs 0%, p = 0.49) or as treated (6% vs 6%, p = 0.99). Craving reduced for both arms, with a larger, but not significant, decrease in progesterone group (Table 2, Model 1). There was a significant interaction by OUD or MOUD, with progesterone increasing cravings for those without OUD and with OUD taking buprenorphine but reducing cravings for those with OUD taking methadone (Models 5, 6).

Conclusion: Promising results of this feasibility and safety trial inform the design of a multi-center trial of progesterone for prevention of postpartum MU.

Table 1. Demographic, baseline assessments and serious adverse events by randomization arm (n=34)

96 | Postpartum VTE risk by CHA2DS2-VASc Score in Patients with Atrial Fibrillation or Flutter During Pregnancy

Virginia Y. Watkins[1]; Miriam L. Estin[2]; Sarah C. Snow[1]; Cary C. Ward[1]; Marie-Louise Meng[1]; Jerome J. Federspiel[1]
[1]Duke University School of Medicine, Durham, NC; [2]Duke university School of Medicine, Durham, NC

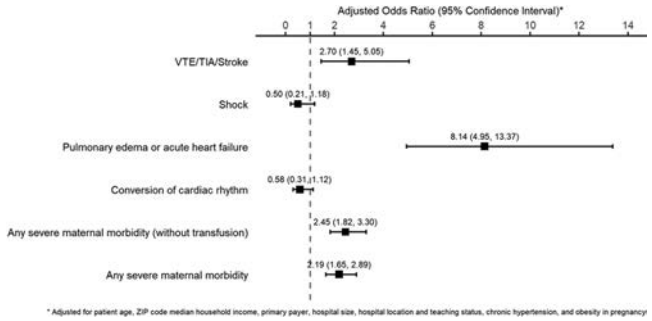
8:15 AM - 8:30 AM

Objective: In nonpregnant individuals with atrial fibrillation (AF) or flutter (AFL), the CHA_2DS_2-VASc score guides candidacy for anticoagulation (AC), with AC commonly recommended for a score $\geq$2. Whether the CHA_2DS_2-VASc score can guide AC candidacy in pregnant populations with AF/AFL is unclear. In this study, we determined whether rates of postpartum venous thromboembolism (VTE), transient ischemic attack (TIA), and cerebrovascular accident (CVA) among patients with a history of AF/AFL differ based on CHA_2DS_2-VASc < 2 and $\geq$2.

Study Design: This retrospective cohort study used the 2016-2021 National Readmissions Database to identify patients with a diagnosis of AF/AFL on delivery hospitalization encounter. The primary outcome was rates of VTE/TIA/CVA during delivery hospitalization or within 42 days following hospital discharge. Secondary outcomes included rates of severe maternal morbidity (SMM) and cardiovascular-related SMM. CHA_2DS_2-VASc scores were calculated for each patient at the index hospitalization and scores compared as < 2 and $\geq$2. After adjusting for facility characteristics and obesity, weighted logistic regression analyses were used to produce relationships between groups.

Results: The cohort consisted of 3,574 delivery hospitalizations with AF/AFL, corresponding to a national estimate of 6,816. Of those, 5,178 (76.0%) had a CHA_2DS_2-VASc < 2 and 1,638 (24.0%) had a CHA_2DS_2-VASc $\geq$2. After adjusting for facility and patient characteristics, patients with a CHA_2DS_2-VASc $\geq$2 were more likely to experience an acute VTE/TIA/CVA (3.9% vs 1.5%, aOR 2.09 [1.17, 3.73]), SMM (23.5% vs 11.4%, aOR 2.00 [1.59, 2.51]), and pulmonary edema or acute heart failure (11.4% vs 1.3%, aOR 7.56 [4.85, 11.78]). No association was observed between CHA_2DS_2-VASc score and conversion of cardiac rhythm or shock.

Conclusion: Pregnant patients with a history of AF/AFL and a CHA_2DS_2-VASc score $\geq$2 are significantly more likely to experience a VTE/TIA/CVA following delivery than those with a CHA_2DS_2-VASc < 2. CHA_2DS_2-VASc score at delivery should be considered when determining appropriate candidates for postpartum VTE prophylaxis.



97 | A Technology Enabled Solution for Perinatal Mental Health Collaborative Care Models: A Randomized Controlled Trial

Emily S. Miller[1]; David Mohr[2]; Dinah Williams[3]; Melissa Shikany[2]; Tracy Walsh[2]; Nathan W. Winquist[2]; Zara Mir[2]; Elizabeth L. Gray[2]; Shannon R. Smith[2]; Charles Krause[2]; Lara M. Baez[2]; Madhu C. Reddy[4]
[1]Women & Infants Hospital of Rhode Island and Alpert Medical School of Brown University, Providence, RI; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Women and Infants Hospital of Rhode Island, Providence, RI; [4]University of California, Irvine, Irvine, CA

8:30 AM - 8:45 AM

Objective: Myriad barriers obfuscate optimal care for perinatal mood and anxiety disorders (PMADs). Collaborative care models (CCMs) integrate mental health into primary care. While CCM offer a promising approach to improving PMAD care, implementation challenges persist, suggesting a need for innovative solutions such as technology-enabled services (TES) to optimize care delivery.

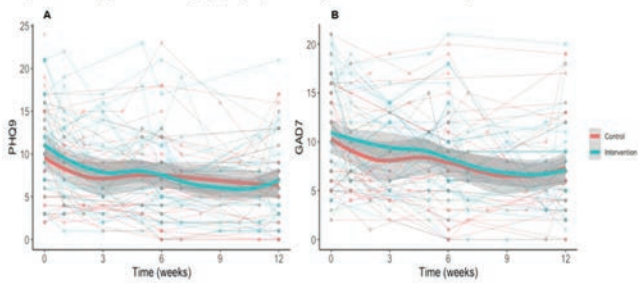
Study Design: Randomized controlled trial (RCT) comparing the impact of a TES to treatment as usual within a CCM on PMAD symptoms. The TES included a cognitive behavioral therapy skills-based mobile app adapted to the perinatal context with adjunctive SMS-based coaching. Individuals were eligible to participate in the RCT if they were pregnant or within 3 months postpartum, experiencing ongoing symptoms of PMADs, enrolled in a CCM, and owned a smart phone. The primary and principal secondary outcomes were depression (PHQ9) and anxiety (GAD7) symptoms, respectively, measured serially over the 12-week intervention. PMAD symptom trajectories were analyzed via generalized linear mixed modeling and as symptom response (50% reduction in symptoms from baseline) and remission (PHQ9 and GAD7 < 4). Satisfaction and engagement with the TES were measured using the Satisfaction Index-Mental Health and TWente Engagement with Ehealth Technologies Scale, respectively.

Results: Of the 75 women enrolled, 38 were randomized to the TES. Depression [β = -0.24 (95% CI -0.45, -0.03)] and anxiety [β = -0.24 (95% CI -0.46, -0.03)] symptom improvement were

identified in the total study sample, but no differences were observed between groups in depression [β = -0.06 (95% CI -0.06, 0.17)] or anxiety [β = -0.06 (95% CI -0.30, 0.19)] symptoms (Figure 1). Response and remission analyses identified no differences across groups (Table 1). Satisfaction was high but not different between groups whereas participant engagement was higher in the TES group at the mid-point evaluation.

Conclusion: Utilization of a TES to support CCM implementation led to increased engagement in perinatal mental health care but did not result in significant improvements in PMAD symptoms.

Depression (A) and anxiety (B) symptom trajectories stratified by randomization arm



Depression and anxiety response, treatment satisfaction and engagement stratified by randomization arm

	Treatment as Usual	TES	p-value
Depression			
Response	16 (43%)	20 (53%)	0.4
Remission	17 (46%)	12 (32%)	0.2
Anxiety			
Response	13 (35%)	21 (55%)	0.08
Remission	12 (32%)	12 (32%)	0.9
Treatment Satisfaction (SIMH)			
Week 6	62 (50-67)	58 (47-68)	0.9
Week 12	60 (52-66)	62 (47-68)	0.6
Treatment Engagement (TWEETS)			
Week 6	26 (22-32)	38 (30-43)	0.007
Week 12	27 (24-36)	35 (28-42)	0.2

TES = Technology Enabled Solution; SIMH = Satisfaction Index-Mental Health; TWEETS = TWente Engagement with Ehealth Technologies Scale

Response: 50% reduction in symptoms from baseline
Remission: PHQ9 and GAD7 < 5

98 | Risk of Severe Maternal Morbidity Among Pregnant People with Colorectal Cancer using a Population Database

Shriddha Nayak[1]; Kristin C. Darwin[2]; Arthur J. Vaught[2]; Marika Toscano[1]
[1]*Johns Hopkins University, School of Medicine, Baltimore, MD;* [2]*Johns Hopkins University, Baltimore, MD*

8:45 AM - 9:00 AM

Objective: Colorectal cancer is among the top three leading causes of new cancer diagnosis as well as cancer death for females in the United States. The purpose of this study was to determine the odds of severe maternal morbidity (SMM) in patients with colorectal cancer in pregnancy using TriNetX, a research network containing real-time data from 93 health care organizations and > 131 million patients.

Study Design: This retrospective cohort study queried TriNetX from inception to 8/2024 for subjects 12-55 years with a pregnancy diagnosis. Two cohorts were derived: (1) individuals with an active diagnosis of colorectal cancer 1 year prior to, or up to 1 month after, first instance of pregnancy and (2) those without a history of any cancer type in pregnancy. Cohorts were propensity score matched 1:1 by demographics and comorbidities by TriNetX built-in analysis tools. SMM was defined as CDC's 21 indicators and corresponding ICD-10 codes. The primary outcome was odds ratio (OR) between cohorts of composite SMM occurring up to 1 year after first instance of pregnancy. Secondary outcomes were odds of individual indicators of SMM. All statistical analyses were conducted in the TriNetX platform.

Results: After propensity score matching, 7570 individuals were included in each cohort (Table). Subjects with colorectal cancer in pregnancy had significantly higher odds of composite SMM with OR 4.43 (95% confidence interval (CI) 3.77-5.22, p< 0.001) compared to those without cancer history in pregnancy. The odds of disseminated intravascular coagulation (DIC) were highest (OR 4.29, 95% CI 3.38-5.43), followed by acute respiratory distress syndrome (ARDS) (OR 3.73, 95% CI 3.12-4.46) and hysterectomy (OR 3.03, 95% CI 1.66-5.56).

Conclusion: Patients with colorectal cancer in pregnancy have more than four-fold increased odds of composite SMM compared to those without cancer history, with considerably higher risk of DIC, ARDS and hysterectomy.

TABLE. Severe maternal morbidity (SMM) in pregnant people with colorectal cancer

SMM Indicator	Rate of SMM		Odds Ratio	95% Confidence Interval (lower limit, upper limit)	p value
	Colorectal Cancer in Pregnancy (n=7570)	Pregnancy without Cancer History, (n=7570)			
Composite	17.2%	4.5%	4.43	(3.77, 5.22)	<0.001

Ventilation	0.3%	0.3%	0.90	(0.48, 1.67)	0.734

99 | Impact of Breastfeeding on Estimated Risk of Postpartum Cardiovascular Disease

Christine P. Field[1]; William A. Grobman[1]; Jiqiang Wu[1]; Anna Palatnik[2]; Mark B. Landon[1]; Denise Scholtens[3]; William Lowe[3];

Nilay S. Shah[4]; Jami Josefson[3]; Sadiya S. Khan[5]; Kartik K. Venkatesh[1]
[1]The Ohio State University, Columbus, OH; [2]Medical College of Wisconsin, Milwaukee, WI; [3]Northwestern University, Northwestern University/Chicago, IL; [4]Northwestern University, Chicago, IL; [5]Northwestern University Feinberg School of Medicine, Chicago, IL

9:00 AM - 9:15 AM

Objective: To determine whether breastfeeding is associated with the estimated risk of long-term atherosclerotic cardiovascular disease (ASCVD) as assessed 10-14 years after delivery.

Study Design: This is a secondary analysis of the prospective Hyperglycemia and Adverse Pregnancy Outcome Follow-up Study (HAPO FUS). The exposure was any breastfeeding (yes/no). The primary outcomes were estimated ASCVD risk (composite of fatal and non-fatal coronary heart disease and stroke) over the subsequent 10- and 30-year time periods measured separately. The Framingham Risk Score was used to calculate ASCVD risk 10-14 years after delivery. ASCVD risk was calculated as a continuous percentage. Multivariable linear regression models were used and adjusted for baseline covariates: field center, age, BMI, height, smoking and alcohol use, parity, and time from delivery to ASCVD risk assessment. Secondarily, we examined whether the association between breastfeeding and ASCVD varied by gestational diabetes mellitus (GDM) status (effect modification).

Results: Of 4,540 assessed individuals, the median age was 30.6 years at baseline. Over three-fourths (79.7%) of individuals reported breastfeeding in this multi-site international cohort, which did not vary by GDM status (79.5% vs 81.0%). At 10-14 years after delivery (median 11.6 years), individuals who had breastfed had a lower estimated risk of ASCVD over the subsequent 10 years (adj. Beta: -0.13; 95% CI: -0.25, -0.02) as well as over the subsequent 30 years (adj. Beta: -0.36; 95% CI: -0.66, -0.05). The association between breastfeeding and estimated ASCVD risk varied significantly by GDM status (interaction p< 0.01): the protective effect of breastfeeding for estimated ASCVD risk was over 5-fold greater for individuals with GDM (TABLE).

Conclusion: Individuals who breastfed-and particularly those with prior GDM-had a lower estimated risk of long-term ASCVD. These findings suggest the beneficial impact of breastfeeding for long-term maternal cardiovascular health, especially among those with GDM.

Table. Association between breastfeeding and estimated 10- and 30-year risk of ASCVD

	ASCVD estimated risk[1]	Unadjusted analysis[2]	Adjusted analysis[2,3]
	Age-adjusted Least Square Mean (SE)	Beta coefficient (95% CI)*	Beta coefficient (95% CI)*
10-year estimated ASCVD risk

Yes GDM + breastfeeding	8.7 (0.3)	-1.42 (-2.97, 0.13)	-1.33 (-2.53, -0.14)

[1]Atherosclerotic cardiovascular disease (ASCVD) estimated risk calculated using Framingham Risk Score.
[2]Linear regression was used.
[3]Models adjusted for maternal variables at oral glucose tolerance test during pregnancy: study field center, age (continuous), BMI (continuous), smoking status (yes/no), alcohol use (yes/no), parity (0, >1), and time in years from delivery to ASCVD risk assessment (continuous).
*Interpreted as the difference in ASCVD risk (%) for those who breastfed. For the primary analysis, those who breastfed had an ASVCD estimated risk that was 0.13% lower than those who did not breastfeed.

100 | Intravenous Ferumoxytol versus Oral Ferrous Sulfate for Iron-Deficiency Anemia in Pregnancy: A Randomized Controlled Trial

Irogue I. Igbinosa; Stephanie A. Leonard; Ijeoma Iweakogwu; Elizabeth B. Sherwin; Caroline Berube; Deirdre J. Lyell
Stanford University, Palo Alto, CA

9:15 AM - 9:30 AM

Objective: Iron deficiency anemia (IDA) affects 1 in 10 pregnancies in the U.S. and contributes to maternal and neonatal morbidity. However, the most effective route for iron supplementation in pregnancy is debated. Our objective was to assess the effectiveness of intravenous (IV) ferumoxytol vs. oral ferrous sulfate on hemoglobin (Hb) for the treatment of IDA in pregnancy.

Study Design: We conducted a randomized controlled trial of IV ferumoxytol vs. oral ferrous sulfate. Pregnant women 24-34 weeks' gestation with IDA (ferritin < 30ng/dL or transferrin saturation < 20%, and Hb < 11g/dL) were eligible; hereditary anemias or malabsorptive disorders were excluded. Patients were computer block randomized: 1) Hb 9-10.9 g/dL received either Ferumoxytol (510mg) or ferrous sulfate (325mg); 2) Hb 7-8.9g/dL received Ferumoxytol (1020mg) or ferrous sulfate (650mg). The primary outcome was change in Hb from enrollment to week 4. We estimated that 80 patients were needed, assuming an effect size of 0.5 g/dL, 90% power, 5% type I error rate, and loss to follow-up rate of 20%. Secondary outcomes included change in Hb by 8 weeks, anemia resolution, and postpartum Hb. Intention-to-treat (ITT) analyses were conducted using Wilcoxon rank sum and Fisher's exact tests.

Results: Of the 80 enrolled patients, 40 were randomized to oral ferrous sulfate and 40 to IV ferumoxytol. Except for the distribution of BMI categories, baseline characteristics were similar between groups (Table 1). Treatment with IV ferumoxytol resulted in a greater change in Hb at a 4-week follow-up than oral ferrous sulfate (median 1.05 (Q1-Q3 0.68-1.70) vs 0.40 (Q1-Q3 0.10-0.80), p< 0.001) (Table 2). The IV ferumoxytol group also had greater change at 8 weeks (median 1.80 (Q1-Q3 1.23-2.48) vs 0.70 (Q1-Q3 0.20-1.28), p< 0.001), greater anemia resolution (37/40 (93%) vs. 26/40 (65%), p = 0.005), and postpartum Hb (median 10.25 (Q1-Q3 9.28-10.90) vs 9.65 (Q1-Q3 8.85-10.05), p = 0.013) (Table 2).

Conclusion: Treatment of IDA with IV ferumoxytol improved hemoglobin at delivery and reduced the prevalence of anemia to a greater extent than oral ferrous sulfate.

101 | Neurodevelopmental Outcomes of 3-year-old Children of Mothers with SARS-CoV-2 Infection in Pregnancy

Lydia L. Shook; Victor Castro; Laura Ibanez-Pintor; Roy H. Perlis; Andrea G. Edlow
Massachusetts General Hospital, Boston, MA

9:30 AM - 9:45 AM

Objective: Large epidemiologic studies have demonstrated an increased risk for neurodevelopmental diagnoses (ND) after maternal viral infection in pregnancy. We previously reported an increased risk of ND in offspring exposed to SARS-CoV-2 *in utero* up to 18 months after birth. We sought to determine whether increased risk of offspring ND after maternal SARS-CoV-2 infection persisted at 3 years of age.

Study Design: Retrospective cohort study of live offspring of all mothers who delivered between March 1, 2020 and May 31, 2021 at 8 hospitals across 2 health systems in Massachusetts. The exposure of interest is a positive SARS-CoV-2 PCR during pregnancy. The primary outcome is electronic health record documentation of one or more ICD-10 diagnostic codes corresponding to ND in offspring. Linear regression models were constructed adjusting for race/ethnicity, insurance status, hospital type, maternal age, and preterm birth.

Results: The cohort included 18,124 live births including 861 (4.8%) with maternal SARS-CoV-2 in pregnancy-Table 1. In regression models, maternal SARS-CoV-2 was associated with a statistically significant elevation in risk for offspring ND at 3 years (139/861 [16.1%] exposed vs 1653/17,263 [9.6%] unexposed); adjusted odds ratio (aOR) 1.30 [95% CI 1.06-1.58]; P = .01 - Figure 1. The most common NDs were speech/language and motor function disorders. In sex-stratified models, effects were larger in males (aOR 1.38 [1.06-1.77]; p = .01) compared to females (aOR 1.20 [0.86-1.64]; p = .3). Effect was larger in 3rd-trimester exposure (aOR 1.36 [1.06-1.71]; p = .01) vs 1st and 2nd trimester exposures (aOR 1.15 [0.83-1.58]; p = .38).

Conclusion: In this large cohort, maternal SARS-CoV-2 infection was associated with significantly increased risk for ND among 3-year-old children, with a stronger impact on male compared to female offspring and greater effects noted after 3rd-trimester exposure. Larger cohorts and longer-term follow-up with more ND accrued will be required to reliably estimate risk and examine impact of trimester of infection and prior vaccination.

Adjusted regression model accounted for maternal age, race and ethnicity, insurance type, delivery hospital type, and preterm birth in association with maternal SARS-CoV-2 positivity.

102 | Maternal Gestational Weight Gain in GLP-1 Agonist Exposed and Unexposed Patients

Nishita Pondugula[1]; Jennifer F. Culhane[1]; Lisbet S. Lundsberg[1]; Caitlin Partridge[1]; Audrey A. Merriam[2]
[1]Yale School of Medicine, New Haven, CT; [2]Yale New Haven Hospital, New Haven, CT

9:45 AM - 10:00 AM

Objective: To understand the effect of GLP-1 agonist use in the year prior to conception on gestational weight gain (GWG).

Study Design: All patients delivering between 2014-2024 with evidence of GLP-1 exposure in the year prior to conception were identified through electronic medical record (EMR) query with hand review to confirm exposure. GLP-1 exposed patients were classified by indication for GLP-1: 1) pregestational diabetes mellitus (PGDM) or 2) weight management (WM) for increased body mass index (BMI). Control groups for each indication cohort were identified from 2021-2022 delivery EMR data. PGDM controls were patients with pregestational DM1 or DM2 managed with medication other than GLP-1 agonist in the year prior to conception. WM controls were a stratified random sample of patients without PGDM not on antihyperglycemic medication in the year prior to conception with BMIs between 30 < 40 kg/m^2 (n = 100) and ≥40 kg/m^2 (n = 100). Demographic and clinical characteristics and obstetrical outcomes were compared. Logistic regression was employed to assess the crude (OR) and adjusted odds ratios (aOR) for GWG controlling for covariates significant in bivariate tests at < 0.05.

Results: 246 patients had GLP-1 exposure in the year prior to conception. Of these, 104 were exposed for PGDM and 142 for WM. 175 PGDM controls were identified from the two years of EMR data interrogated. Random sampling yielded 200 WM controls.

Bivariate tests for race/ethnicity, pre-pregnancy BMI, and chronic hypertension identified significant differences between exposed and unexposed patients in the PGDM cohort. For the WM cohort, exposed and unexposed patients had significant differences in PCOS diagnosis, gestational weight gain, and HDP. Within the PGDM group, GLP-1 agonist exposure did not significantly affect GWG (Table 2). Those exposed to a GLP-1 in the WM cohort had significantly decreased risk of GWG below recommendations (aOR = 1.32 (0.71-2.48)).

Conclusion: GLP-1 agonist use in the year prior to conception decreases risk of GWG under recommendations, which may reflect rebound weight gain during pregnancy after GLP-1 cessation.

103 | Placental Pathology Findings by Timing and Amount of Maternal Cannabis Exposure

Shilpa S. Tummala[1]; Amanda A. Allshouse[2]; Gwendolyn A. McMillin[1]; Jessica M. Comstock[2]; Elizabeth S. Doughty[2]; Robert M. Silver[2]; Torri D. Metz[2]
[1]University of Utah Health, Salt Lake City, UT; [2]University of Utah, Salt Lake City, UT

10:00 AM - 10:15 AM

Objective: We aimed to evaluate the association between the timing and amount of maternal cannabis use and placental abnormalities associated with insufficiency.

Study Design: We conducted a secondary analysis of individuals enrolled in the nuMoM2b study. Maternal cannabis use was identified by urine immunoassay for delta-9-tetrahydrocannabinol (THC-COOH) and confirmed by liquid chromatography-mass spectrometry. Exposure was categorized as only 1st trimester or

ongoing into 2nd or 3rd trimester. In a secondary analysis, cumulative exposure was calculated using quantitative THC-COOH values across serial urine samples. Outcomes for above-median and below-median exposure were compared. The primary outcome was a composite of maternal vascular malperfusion from placental pathology, including retroplacental clot or hematoma, infarction, accelerated villus maturation, syncytial knots, and decidual hemorrhage. Secondary outcomes were fetoplacental weight ratio, fetal vascularization, or chorioamnionitis. Multivariable modeling adjusted for maternal age, hypertension, diabetes, and nicotine use.

Results: Placental pathology was available for 179 participants who used cannabis. Of these, 73 (41%) had only 1st-trimester exposure, and the rest had ongoing exposure. Maternal cannabis use in late pregnancy compared with early was not associated with pathologic findings of maternal vascular malperfusion (Table). The median cumulative exposure to THC-COOH across pregnancy was 332 ng/mL (Figure). Above-median cumulative exposure was not associated with maternal malperfusion (Table). There were no differences in secondary outcomes.

Conclusion: Maternal cannabis use in late pregnancy was not associated with changes in placental vascularization suggestive of insufficiency when compared with 1st-trimester use alone. Differences in cumulative exposure to cannabis during pregnancy may not correlate with abnormalities in placental vascularization. Further studies are needed to understand the pathophysiology underlying maternal cannabis exposure, placental pathology, and fetal growth restriction.

Figure. Cumulative THC-COOH exposure

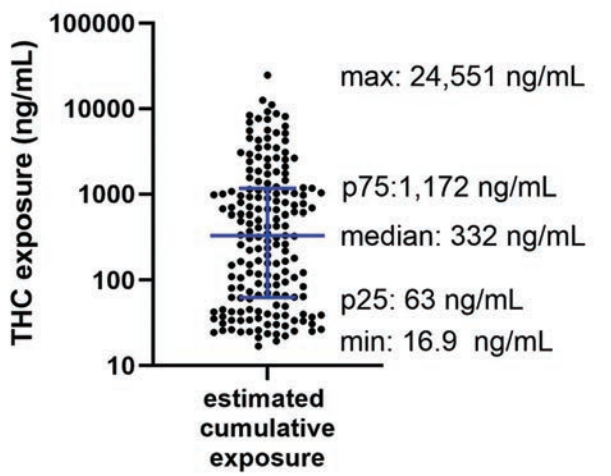

Table. Primary and Secondary Outcomes from Placental Pathology Reports

Outcome	Timing of exposure			Amount of exposure		
	Late	Early only	P-value	Higher	Lower	P-value
	N=106	N= 73		N=90	N= 89	
Maternal vascular malperfusion	27 (27.8)	21 (31.8)	0.584	23 (26.7)	25 (32.5)	0.424
Fetal vascular malperfusion	38 (38.0)	19 (27.9)	0.176	30 (35.3)	27 (32.5)	0.705

104 | The Impact of a Facilitated Postpartum-to-Primary Care Transition on Care Utilization within One Year Postpartum

Arlin Delgado[1]; Pichliya Liang[1]; Tierra Bender[1]; Kaitlyn E. James[1]; Alaka Ray[1]; Ishani Ganguli[2]; Jessica L. Cohen[3]; Mark A. Clapp[1]

[1]Massachusetts General Hospital, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Harvard T.H. Chan School of Public Health, Boston, MA

10:15 AM - 10:30 AM

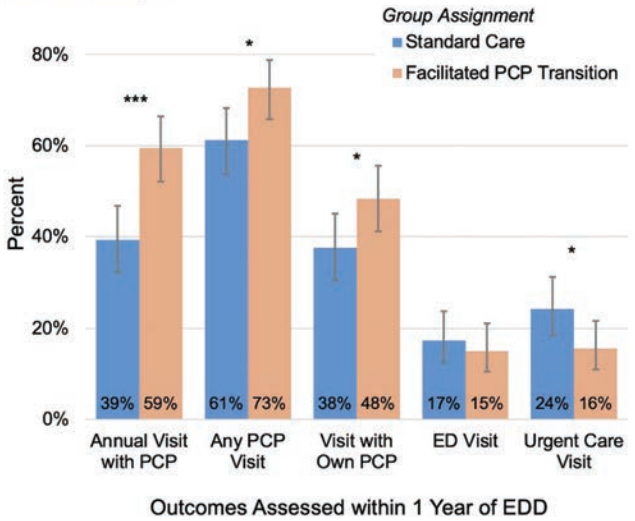
Objective: Postpartum to primary care transitions are important for individuals with ongoing care needs after pregnancy, but there are many barriers to effective transitions in practice. This study's objective was to assess if an intervention, which increased PCP visits within four months postpartum by 2-fold, had a sustained impact on PCP visits and reduced unscheduled care utilization in the first year postpartum.

Study Design: This was a planned secondary analysis of an RCT of a behavior economics-informed intervention, including default visit scheduling, nudge reminders, and tailored messaging, designed to increase PCP engagement within 4 months postpartum versus standard care. The primary outcome in this secondary analysis was receiving an "annual exam" by a PCP within 1 year postpartum. Other outcomes included visits for any reason with a PCP, urgent care visits, and ED visits. Outcomes were compared between the groups with chi-square testing. Odds ratios with and without adjustment for original randomization strata with robust standard errors were reported.

Results: 360 patients were randomized in the original trial (176 control, 184 intervention). 75.4% had anxiety/depression, 19.5% had preexisting/gestational diabetes, and 16.1% had chronic/pregnancy-related hypertension. Figure 1 shows the outcome comparisons between the two groups. Table 1 lists the unadjusted and adjusted odds and demonstrates that the intervention increased all measures of PCP visits within the first year postpartum, including an increased odds of 2.78 (95% CI 1.75, 4.40) for receipt of an annual exam by a PCP.

Conclusion: An intervention designed to facilitate the postpartum-to-primary care transition among individuals with chronic conditions resulted in higher rates of PCP visits within the first year after delivery compared with standard care. There were no differences in urgent care or ED visits, though the comparisons may be underpowered. This relatively low-resource intervention may be an effective strategy for transitioning postpartum individuals' care back to their PCP.

Figure 1: Rates of the Primary and Secondary Outcomes related to Care Utilization between the Standard Care and Facilitated PCP Transition Groups



*Level of Significance: * p<0.05, ** p<0.01, *** p<0.001*

Table 1: Unadjusted and Adjusted Odds Ratios of the Primary and Secondary Outcomes comparing the Facilitated PCP Transition to the Standard Care Group

Outcomes	Unadjusted Odds Ratio (95% CI)	Adjusted Odds Ratio (95% CI)*
Primary		
Annual Exam Visit with a PCP	***2.26 (1.48, 3.47)***	***2.77 (1.75, 4.40)***
Secondary		
Visit for Any Reason with Any PCP	***1.69 (1.08, 2.64)***	***1.91 (1.20, 3.04)***
Visit for Any Reason with Own PCP	***1.55 (1.02, 2.38)***	***1.74 (1.12, 2.69)***
Emergency Department Visit	0.84 (0.48, 1.49)	0.81 (0.46, 1.44)
Urgent Care Visit	***0.57 (0.34, 0.98)***	0.59 (0.34, 1.01)

Odds ratios are reported for the Facilitated PCP Transition Group in reference to the Standard Care Group.

** Logistic regression models adjusted for the two randomization strata: 1) any primary care visit within the prior 3 years and 2) receipt of prenatal care at the main hospital campus vs. satellite clinic.*

10:30 AM - 12:30 PM

Objective: To investigate the relationship of maternal anemia in labor before delivery with abnormal fetal heart rate tracing characteristics (FHRT) and composite neonatal and maternal adverse outcomes (CNAO/CMAO).

Study Design: FHRTs of all deliveries over a 15-month period at a level IV center were reviewed by physicians blinded to maternal and neonatal outcomes. In 20-minute segments, the last hour of available FHRT was analyzed. Term, singleton, non-anomalous deliveries who underwent a trial of labor were included. Anemia was defined as hematocrit < 30% at admission. Each FHRT feature was independently categorized as present if noted greater than 50% of the time in the hour before delivery. The primary outcome was the rate of CNAO or CMAO, with secondary outcomes including rates of FHRT abnormalities as defined by ACOG. The chi-square test was used to compare groups, with p-value < 0.05 considered significant.

Results: Of 5,160 consecutive deliveries, 3,166 (61%) met the inclusion criteria, of which 391 (14.1%) had anemia. There were no differences in oxytocin induction/augmentation rate or neuraxial anesthesia. Anemia was not associated with an increased proportion of any individual FHRT features. There was an increase in CMAO (6.8 vs 15.1%; p < 0.001), driven by an increase in the rate of blood transfusion (1.7 vs 11.5%; p < 0.001). Anemia was not independently associated with increased CNAO, or umbilical artery pH < 7.0. There was a lower rate of cesarean delivery for abnormal FHRT (9.6% vs 6.4%; p = 0.04).

Conclusion: Anemia in labor was not associated with any individual FHRT abnormalities or ACOG FHT Category. There was no change in CNAO, but there was an increased rate of CMAO driven by higher rates of maternal blood transfusion. Our findings provide additional support to other studies that found that maternal anemia was not associated with adverse neonatal outcomes.

Table 1 Intrapartum Characteristics

	No Anemia (N=2775)	Anemia[1] (N=391)	p-value

106 | Hemodynamic Monitoring of Aortic and Mitral Stenosis in Pregnancy

Abra Guo[1]; Katelyn M. Tessier[2]; Connor Demorest[3]; Selma Carlson[4]; Bethany Sabol[2]; Sarah A. Wernimont[2]; Jessica Schultz[5]
[1]University Of Minnesota Medical Center, University of Minnesota Medical Center, MN; [2]University of Minnesota, Minneapolis, MN; [3]Masonic Cancer Center, University of Minesota, University of Minnesota/Minneapolis, MN; [4]University of Minnesota Medical Center/ Minneapolis VA Healthcare System, University of Minnesota Medical Center, MN; [5]University of Minnesota Medical Center, Minneapolis, MN

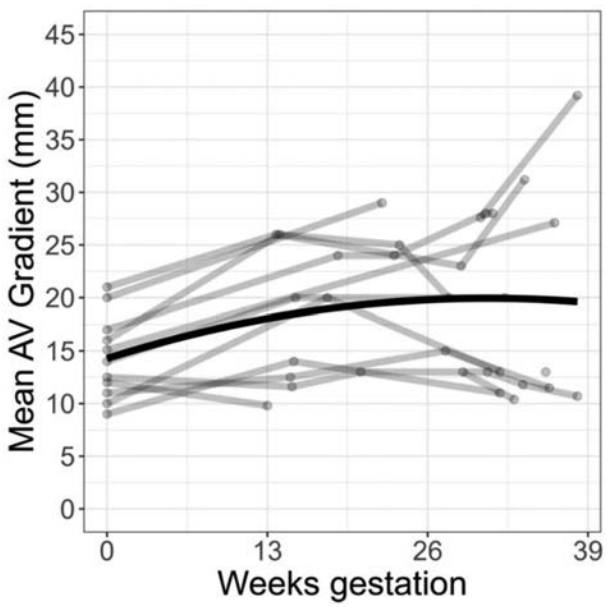
10:30 AM - 12:30 PM

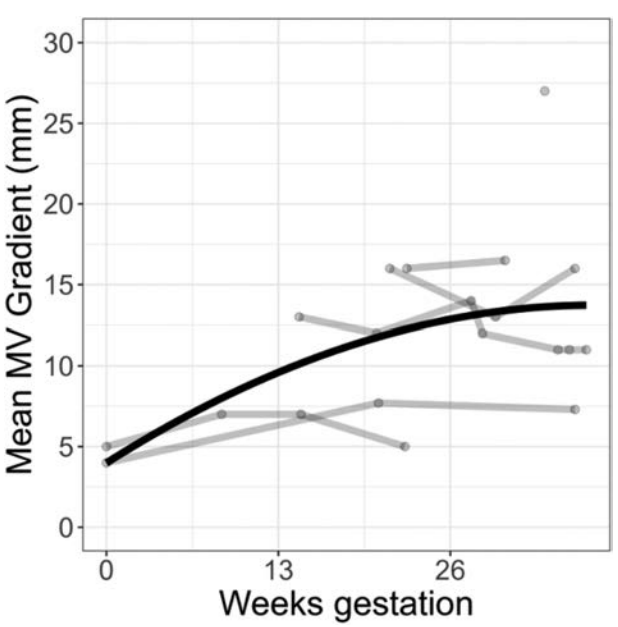
Objective: Valvular heart disease accounts for one-third of heart disease in pregnant individuals with stenotic valvular lesions, particularly left-sided lesions, increasing the risk of adverse maternal outcomes. A major challenge is the lack of normative data describing the echocardiographic changes in this population throughout pregnancy. We sought to establish how peak velocity and mean gradient across stenotic native aortic and mitral valves change with increased hemodynamic volumes throughout pregnancy.

Study Design: This was a single-center retrospective cohort study using a large community-academic health outcomes database. Individuals with aortic and mitral valve stenosis who had at least one echo during pregnancy were identified via ICD-10 diagnosis and procedures codes from an access-protected database of pregnant patients who received care at our center between 2012 and 2023. Mean gradients were identified from transthoracic echocardiogram data throughout pregnancy. Clinical characteristics and differences in gradients were compared within the groups.

Results: Twenty-three patients were identified; 16 with aortic stenosis (AS) and 7 with mitral stenosis (MS). Clinical characteristics were similar amongst groups. The medians of aortic valve mean gradients (mmHg) were as follows: pre-pregnancy (14), second trimester (20), third trimester (13). The medians of peak aortic velocity (m/s) were as follows: pre-pregnancy (2.5), second trimester (3.0), third trimester (2.8). The medians of mitral valve mean gradients (mmHg) were as follows: pre-pregnancy (4.5), first trimester (7.0), second trimester (12.5), third trimester (12.0). No patients in this cohort progressed in degree of severity during pregnancy with most achieving term delivery (median gestational age at birth 38.64 (37.68, 39.51).

Conclusion: To our knowledge this is the first retrospective investigation of longitudinal changes in valve hemodynamics in pregnant patients with native valve stenosis. We demonstrate that peak velocity and mean gradient across native aortic and mitral valves increase in a predictable manner during pregnancy.





107 | Pregnancy Outcomes in Patients with type-2 Diabetes Treated with Semaglutide: A Multi-Center Observational Cohort Study

Emily N. Adams[1]; Ernie Shippie[2]; Ahizechukwu C. Eke[3]
[1]Johns Hopkins University, Baltimore, MD; [2]Vizient Center for Advanced Analytics, Chicago, Illinois, Vizient Center for Advanced Analytics, Chicago, IL; [3]Johns Hopkins University School of Medicine, Baltimore, MD

10:30 AM - 12:30 PM

Objective: Patients with type-2 diabetes face higher risks of adverse pregnancy outcomes, including preeclampsia, preterm birth, and neonatal complications. Semaglutide, a GLP-1 receptor agonist, is effective for managing hyperglycemia in type-2 diabetics, but its safety and efficacy during pregnancy are underexplored. This study evaluates pregnancy outcomes in patients with type-2 diabetes treated with Semaglutide compared to controls.

Study Design: This multi-center observational cohort study used data from 192 hospitals in 38 US states, sourced from the Vizient Clinical Database. We included pregnant individuals with type-2 diabetes who delivered between January 2021 and April 2024. The primary outcome was preterm birth, with secondary outcomes including hypertensive disorders, intrahepatic cholestasis, and neonatal outcomes. We performed standard tests and multivariable logistic regression to adjust for confounders, yielding adjusted odds ratios (aOR) as the measure of treatment effect.

Results: The cohort included 4,606,975 pregnancies, with 8,060 patients (0.2%) exposed to Semaglutide and 4,598,915 controls. At study entry, the mean maternal age was 29.5 years (IQR 25.9-34.3) for the Semaglutide group and 30.3 years (IQR 24.8-33.9) for controls–*Table 1*. Most patients (63.4%) identified as Black. Patients exposed to Semaglutide were 26% less likely to deliver preterm (aOR 0.74, 95% CI 0.67-0.81; P< .001). Conversely, patients exposed to Semaglutide were more likely to develop preeclampsia (aOR 1.16, 95% CI 1.11-1.23; P< .001), HELLP syndrome (aOR 1.88, 95% CI 1.38-2.56; P< .001) and eclampsia (aOR 2.74, 95% CI 2.17-3.47; P< .001) compared to those unexposed to Semaglutide during pregnancy–*Table 2*.

Conclusion: In pregnant patients with type-2 diabetes, exposure to Semaglutide was associated with reduced risk of preterm birth but increased risks of preeclampsia, HELLP syndrome, and eclampsia. This underscores the need for prospective validation and careful monitoring of patients exposed to Semaglutide in pregnancy.

Table 1: Pregnancy outcomes according to Semaglutide use in pregnancy in women with type 2 diabetes

Variable	Semaglutide use in pregnancy (n = 8,060)	Non-Semaglutide use in pregnancy (n = 4,598,915)	P-value
GA at delivery in weeks (mean, SD)	37.1 (3.27)	37.3 (3.42)	<.001

Models were adjusted for maternal age, gestational age at study entry, obesity at baseline, pre-gestational diabetes, and chronic hypertension.

108 | Leveraging Machine Learning Models to Identify Predictors of RSV Immunization During the 2023-24 Season

Ethan Litman; Tina Yi Jin Hsieh; Anna M. Modest; Kathleen Clarke; Melissa Dzinoreva; Valerie Perrinez; Esther Apraku Bondzie; Lydia Gallup; Eleanor Schonberg; Marjorie Rowe; K'ara locke; Oluwaseyi Oginni; Robert Jones; Chloe Zera; Ai-ris Y. Collier
Beth Israel Deaconess Medical Center, Boston, MA

10:30 AM - 12:30 PM

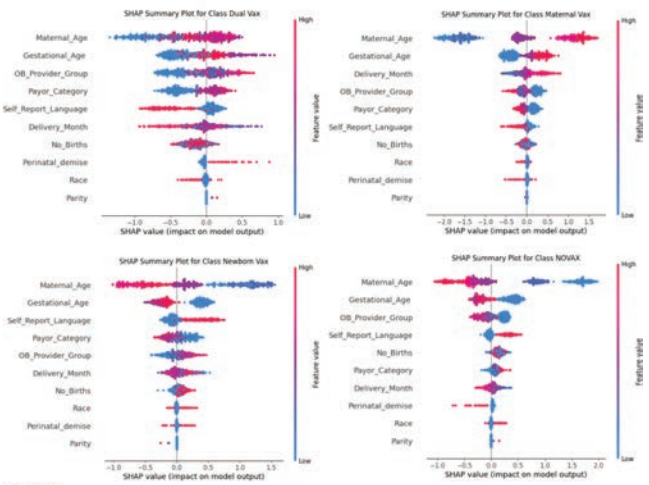
Objective: In 2023, the FDA approved maternal RSVpreF vaccines and infant nirsevimab immunization for prevention of infant respiratory syncytial virus (RSV) disease. This study aims to use unsupervised machine learning to identify key predictors of RSV immunization.

Study Design: Maternal-infant dyad demographic and clinical data was obtained from the electronic medical record. RSV immunization status was abstracted from a state-wide database. The outcome variables were RSV immunization status (maternal, infant, dual, or unvaccinated). Predictors were maternal age, gestational age at birth, delivery month, obstetric provider group, payor category, parity, self-reported race, language, perinatal demise, infant number, and sex. Eleven machine learning classification models (logistic regression, LASSO, RIDGE, Random Forest, SVM Radial and Linear, XGBoost, BNB, MLP, KNN, Catboost) were compared using the AUC-ROC One vs Rest (OvR) score. SHAP analysis was employed to identify the most important features.

Results: 1899 births (1940 live born infants) from September 2023 to January 2024 were included. The Catboost model demonstrated the best performance (AUC-ROC OvR score: 0.75). Maternal age, gestational age, provider group, delivery month, and language ranked highest in SHAP summary plots (Figure 1). Higher maternal age and gestational age were associated with maternal vaccination; lower maternal and gestational age were associated with infant immunization and unvaccinated status. Maternal vaccination was more likely later in the season. Private practice was associated with maternal/dual vaccination, while community or academic practices were associated with infant immunization. English speakers were more likely to receive maternal vaccination, whereas non-English speakers were more likely to receive newborn or no immunization.

Conclusion: Results from this model suggest that increasing vaccine availability in all practice settings throughout the season and providing language-concordant education could improve equitable implementation of RSV immunization.

Figure. SHAP beeswarm summary plots - feature importance for dual, maternal, infant, or no vaccination



Footnotes:

1. OB Provider group (low-high): Private - Community - Academic Practice
2. Payor category (low-high): Commercial - Government
3. Delivery Month (low-high): September - October -November - December - January
4. Self-reported languages (low-high): "English speaker" -"non-English: speaker

109 | Leveraging Machine Learning to Identify Predictors of Passive and Active Influenza Immunity in Infants

Tina Yi Jin Hsieh; Catherine Jacob-Dolan; Alejandra Waller-Pulido; Samuel Nangle; Eleanor Schonberg; Valerie Perrinez; P. Alejandra Barrero-Castillero; Ai-ris Y. Collier
Beth Israel Deaconess Medical Center, Boston, MA

10:30 AM - 12:30 PM

Objective: The optimal conditions for inducing durable infant immunity to influenza virus are unclear. This study aims to identify predictors of infant serum influenza antibodies using unsupervised machine learning.

Study Design: We enrolled infants for serial infant capillary blood collection. Samples collected at 3-5 months of age (prior to pediatric influenza vaccine recommendation) were used to study passive immunity from maternal antibody transfer. Samples collected at 6-12 months (age when pediatric vaccines recommended) were used to evaluate infant immunity after vaccination or natural infection. Serum IgG antibodies specific to influenza A and B virus were quantified using an electrochemiluminescence assay. Thirteen covariates, including maternal and infant health and demographic data, vaccine and infection history were obtained by self-report. Continuous variables were imputed using a random forest imputer and normalized with the Yeo-Johnson method. Machine-learning models (Random Forest, boosted tree, RIDGE, LASSO linear regression) were compared using mean squared error values, and predictors were identified with the best-performing model based on the mean decrease in impurity.

Results: Twenty-three infant serum samples at 3-5 months and 57 serum samples from 6-12 months were analyzed. The Random Forest model had the lowest mean squared error. Top predictors for passive immunity included: infant age, days since the last maternal influenza vaccination/infection, maternal age, and infant weight. Predictors for later infant immunity included: days since the last infant influenza vaccination/infection, total number of infant vaccinations/infections, infant age, infant weight, and days since the last parent vaccination/infection.

Conclusion: Unsupervised machine-learning techniques can be utilized to identify clinical factors for early and late infant immunity. Future studies should integrate more longitudinal samples to develop a more comprehensive understanding of flu immunity and evaluate for maternal antibody inhibition.

110 | Expectant Management of Diet Controlled Gestational Diabetes Mellitus

Alesha M. White[1]; Donald D. McIntire[1]; Anne M. Ambia[2]; Elaine L. Duryea[1]
[1]*University of Texas Southwestern Medical Center, Dallas, TX;* [2]*University of Texas Southwestern, Dallas, TX*

10:30 AM - 12:30 PM

Objective: Gestational diabetes is one of the most common diseases in pregnancy and is associated with increased maternal and neonatal morbidity. There is not enough data to support or discourage a specific delivery time for patients with diet controlled gestational diabetes mellitus (A1GDM). Our objective was to compare differences in outcomes for patients with A1GDM based on increasing gestational age.

Study Design: This is a retrospective cohort study that included deliveries of singleton live born term infants to patients with A1GDM. Diagnosis and treatment of A1GDM, including expectant management until 42 wks, was uniform. Delivery and neonatal outcomes for patients with A1GDM were compared with advancing gestational age and were then compared to the non-diabetic population. Neonates with known anomalies were excluded from analysis of neonatal outcomes. The Mantel-Haenszel and Breslow-day tests were used for statistical analysis.

Results: 4467 patients with A1GDM at 39 wks or greater delivered between November 2010 and February 2024. The rate of primary cesarean delivery (CD) increased with increasing gestational age ($p < 0.001$). Rates of forceps delivery, 3rd and 4th degree lacerations and shoulder dystocia demonstrated a worsening trend with advancing gestational age but did not reach significance. Neonatal outcomes were not significantly different. When compared to non-diabetic patients, all examined outcomes were increased in the A1GDM cohort except for forceps deliveries, hyperbilirubinemia and TTN (Table). The rates of increase for each outcome were not substantially higher in the A1GDM cohort when compared to non-diabetics, except in the case of primary CD (Breslow-day $p = 0.03$).

Conclusion: In patients with A1GDM and advancing gestational age, there are increased risks for the mother and neonate when compared to non-diabetics. The rate at which these risks increase is not more rapid than in patients without diabetes, except in the case of rate of primary CD. Although expectant management does

not result in a greater overall incremental risk, delivery at 39 wks may be associated with lower rates of CD.

Table. Delivery and Neonatal Outcomes based on advancing gestational age in patients with diet controlled gestational diabetes (A1GDM)

111 | Outcomes in Prenatally Suspected Focal Placenta Accreta

Alesha M. White[1]; Jessica E. Pruszynski[2]; Quyen N. Do[1]; Jennifer D. Smith[1]; Catherine Y. Spong[1]; Christina L. Herrera[1]
[1]*University of Texas Southwestern Medical Center, Dallas, TX;* [2]*University of Texas Southwestern, Dallas, TX*

10:30 AM - 12:30 PM

Objective: Placenta Accreta Spectrum (PAS) is associated with increased maternal morbidity and mortality and is the leading cause of peripartum hysterectomy. Morbidity has been shown to correlate with PAS severity. The purpose of this study is to describe the outcomes in cases of prenatally suspected focal placenta accreta.

Study Design: This is a retrospective cohort study evaluating focal accreta cases between 2020-2024. Focal accreta was defined as less than 25 mm by the greatest dimension of invasion on magnetic resonance imaging, an established threshold for hysterectomy. Delivery and neonatal outcomes were evaluated for the entire group and then compared between patients who delivered at less than 37 weeks and at or greater than 37 weeks to evaluate optimal delivery timing. Prior to 2022, there was no standardized timing for delivery of these cases. In 2022, we standardized delivery of focal accreta to ≥37 weeks.

Results: Of 29 focal accreta cases, 14 (48%) delivered <37 weeks and 15 (52%) delivered ≥37 weeks. Twenty-one (72%) had postpartum hemorrhage (PPH), 8 (28%) received a transfusion. Twenty-one (72%) deliveries were scheduled. Six (21%) met FIGO clinical criteria for PAS. Hysterectomy was performed in 2 (7%) cases and 4 (14%) cases required oversewing of the placental bed. Pathology was negative in 25 (89%) patients. Median APGARs at 1 minute were 8 (8-8); no neonate had a pH < 7; and median birthweight was 2910g (2780-3055g). Six (21%) infants were admitted to the NICU. When comparing patients delivering <37 weeks to those delivered ≥37 weeks, there were no differences in maternal outcomes. Neonatal length of stay was longer for those delivered <37 weeks (p = 0.031) (Table).

Conclusion: Patients with prenatally suspected focal accreta had favorable delivery and neonatal outcomes. Delivery at 37 weeks can safely be considered in cases of focal placenta accreta.

Table. Maternal and Neonatal Outcomes in Cases of Focal Placental Accreta

Data reported as N (%), median (interquartile range), and median (range) for gestational age.
*P-value is a comparison of delivery before and after 37 weeks; *EBL* estimated blood loss; *PPH* postpartum hemorrhage (defined as >1000cc at any delivery); *WB* Whole blood; *LOS* length of service; *NICU* neonatal intensive care unit; *CPAP* continuous positive airway pressure.

112 | PPAR Gamma Involvement in Trophoblast Cell Differentiation and Placenta Development

Alex Finlinson[1]; Esteban M. Dominguez[2]; Ayelen Moreno-Irusta[2]; Marc Parrish[1]; Michael J. Soares[2]
[1]*University of Kansas, University of Kansas, KS;* [2]*University of Kansas Medical Center, University of Kansas Medical Center, KS*

10:30 AM - 12:30 PM

Objective: To investigate the role of peroxisome proliferator-activated receptor gamma (PPARG) in invasive extravillous trophoblast (EVT) cell development and establishment of the uterine-placental interface.

Study Design: PPARG expression was evaluated in rat and human placentation sites at different time points using in situ hybridization. PPARG expression was assessed by RT-qPCR in human trophoblast stem (TS) cells in stem and EVT states. Human TS cell development was investigated following PPARG silencing with short hairpin RNAs. Global and specific cell lineages utilizing the Cre-LoxP system were used to investigate the physiology of PPARG at the placentation site and in the invasive trophoblast cell lineage of the rat placenta.

Results: PPARG transcripts were expressed in the EVT cell column and increased in abundance following differentiation of human TS cells to EVT cells. PPARG knockdown impaired human TS cell differentiation to EVT cells. In the rat, PPARG transcripts were localized primarily to trophoblast cells within the uterine-placental interface and the labyrinth zone. In addition, PPARG positive cells within the uterine-placental interface co-localized with cells expressing transcripts for Prl7b1, an invasive trophoblast cell marker. Global PPARG disruption in the rat resulted in prenatal lethality. Conditional disruption of PPARG in the invasive trophoblast cell lineage of the rat has been established and is under evaluation.
Conclusion: PPARG is a conserved driver of placentation and the invasive EVT cell lineage.

113 | Outcomes in Symptomatic Versus Asymptomatic Cesarean Scar Pregnancy

Alexa L. Cohen[1]; Georgios Doulaveris[2]; Eliane Shinder[2]; Leeann Dar[2]; Fatima Estrada Trejo[2]; Ohad Rotenberg[2]; Pe'er Dar[2]
[1]University of Miami Health System, Miami, FL; [2]Montefiore Medical Center, Albert Einstein College of Medicine, New York, NY

10:30 AM - 12:30 PM
Objective: Aim was to examine outcomes in patients who were symptomatic at initial diagnosis of cesarean scar pregnancy (CSP), compared to those who were asymptomatic.
Study Design: This is a retrospective analysis of all patients who had a CSP at a tertiary referral academic institution from 2010-2013. We excluded patients who elected to continue the pregnancy after counseling. Symptomatic patients (vaginal bleeding, abdominal/pelvic pain) at initial CSP diagnosis, were compared to asymptomatic patients. Primary outcome was complete resolution of CSP not requiring hysterectomy. Secondary outcomes were use of minimally invasive interventions (ultrasound-guided feticide and/or transcervical balloon catheter), time to bHCG and sonographic resolution, need for secondary interventions for persistent bleeding, and other intervention-related complications (including infection, hemorrhage and blood transfusion).
Results: Of 110 patients diagnosed with CSP during the study period, 15 (13.6%) elected to continue the pregnancy and were excluded. Of the 95 patients included: 33 (34.7%) were symptomatic, 91% with vaginal bleeding and 9% with pelvic pain, whereas 62 (65.3%) were asymptomatic. Symptomatic patients were less likely to have a live CSP compared to asymptomatic (42.4% versus 66.1%, $p = 0.03$) and more likely to be of Hispanic race (66.7% versus 35.5%, $p = 0.01$). Groups were similar for sac location within the scar niche and level of color Doppler. Similarly, there was no difference between the two groups in rate of CSP resolution, complications, use of interventional therapies, and time to bHCG and sonographic resolution.
Conclusion: Patients who were symptomatic at the time of CSP diagnosis were more likely to have a failed CSP. However, no differences were seen in rate of therapeutic interventions as well as rate and time to complete resolution.

114 | Subsequent Pregnancy Outcomes in Patients with a History of Cesarean Scar Pregnancy

Alexa L. Cohen[1]; Eliane Shinder[2]; Leeann Dar[2]; Chloe Porigow[2]; Fatima Estrada Trejo[2]; Ohad Rotenberg[2]; Pe'er Dar[2]; Georgios Doulaveris[2]
[1]University of Miami Health System, Miami, FL; [2]Montefiore Medical Center, Albert Einstein College of Medicine, New York, NY

10:30 AM - 12:30 PM
Objective: We aimed to report on the reproductive outcomes of patients with a history of cesarean scar pregnancy (CSP) who retained their fertility.
Study Design: A retrospective review of CSP cases treated at a tertiary academic center from 2010 to 2023. Cases treated with hysterectomy or electing pregnancy continuation leading to placenta accreta spectrum (PAS) and hysterectomy were excluded. Reproductive follow-up data was recorded for patients who retained their fertility. The primary outcome evaluated was the recurrence of CSP or PAS. Secondary outcomes included rates of live birth, postpartum hemorrhage (defined as >1L blood loss), preterm delivery, and uterine rupture.
Results: Out of 111 CSP cases identified, 92 qualified for the study. Among these, 37 patients (40.2%) had 54 subsequent pregnancies. The average maternal age was 32.9 ± 0.8 years. The average inter-pregnancy interval following the CSP was 16.6 ± 2.4 months. Elective pregnancy termination occurred in 5.5% of cases. The recurrence rate for CSP and PAS combined was 5.8%. Early pregnancy loss occurred in 18 (35.3%) subsequent pregnancies, with an overall live birth rate of 64.7%. Spontaneous preterm birth occurred in 9.6% of cases, and 29.0% experienced postpartum hemorrhage during repeat cesarean delivery. One patient (3.1%) suffered a uterine rupture at 28 weeks' gestation.
Conclusion: Patients with a history of CSP have a 5.8% risk for recurrent CSP or PAS, which underscores the need for early ultrasound assessment in these cases. The live birth rate in pregnancies after CSP is 64.7%.

115 | Intrapartum Glucose Metrics and Associated Neonatal Adverse Outcomes Among People with GDM

Alexandra C. Gallagher[1]; Alyssa R. Hersh[2]; Lucy Ward[2]; Christian Huertas-Pagán[2]; Monica Rincon[2]; Amy M. Valent[2]
[1]Stanford University, Palo Alto, CA; [2]Oregon Health & Science University, Portland, OR

10:30 AM - 12:30 PM
Objective: Hyperglycemia is a risk factor for adverse neonatal outcomes. However, the role of glycemic control during labor for the risk of adverse neonatal outcomes is not well understood among people with gestational diabetes (GDM). Therefore, we sought to compare continuous glucose monitoring (CGM) metrics between laboring GDM pregnancies complicated by adverse neonatal outcomes compared to those without complications.
Study Design: Secondary analysis of pregnant people with GDM randomized to using CGM versus capillary blood glucose (CBG) for management of GDM. We compared participants whose pregnancies were complicated by a significant neonatal outcome as defined by a composite including ≥1 of the following: hypoglycemia, hyperbilirubinemia, respiratory distress syndrome

or NICU admission to determine if there are glycemic differences during labor as characterized by CGM metrics. Pregnancy-specific glycemic range in labor was defined by 70-110, 70-120, and 70-140 mg/dL. The intrapartum period was defined starting midnight on the day of admission and until delivery time or eight hours prior to delivery. We excluded those with a scheduled cesarean and those without CGM data during labor.

Results: Of the 111 in the primary trial, 62 were included in the analyses; 62.9% underwent induction of labor (IOL) and 80.6% delivered vaginally. The cohort with adverse neonatal outcomes spent less time-in-range (TIR) and more time-above-range (TAR) compared to those with no adverse neonatal outcome, with a statistically significant difference between groups for glycemic range 70-120 mg/dL. The mean glucose for those with adverse neonatal outcomes was higher than those without (Table 1).

Conclusion: In this study, we found that patients with a composite adverse neonatal outcome spent less time in range, more time above range, with a higher mean glucose in labor than those without a composite adverse outcome. These findings help inform future evidence-based protocols for glycemic targets in labor for those with GDM, suggesting tighter glycemic control and more time spent in range may mitigate adverse neonatal outcomes.

Table 1. Association between continuous glucose monitoring parameters stratified by composite adverse neonatal outcome (neonatal hypoglycemia, hyperbilirubinemia, respiratory distress syndrome, NICU admission).

	Adverse neonatal outcome (n=21)	No adverse neonatal outcome (n=41)	P

116 | Amplifying the Experience: a Qualitative Analysis of Black Birthing People'S Experiences Within a Doula Program

Alexandria Williams[1]; Tierra Bender[2]; Maria Fradinho[3]; Allison S. Bryant[2]; Elizabeth Janiak[4]; Nicole A. Smith[4]
[1]Brigham and Women's Hopsital, Boston, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Newton Wellesley Hospital, Wellesley, MA; [4]Brigham and Women's Hospital, Boston, MA

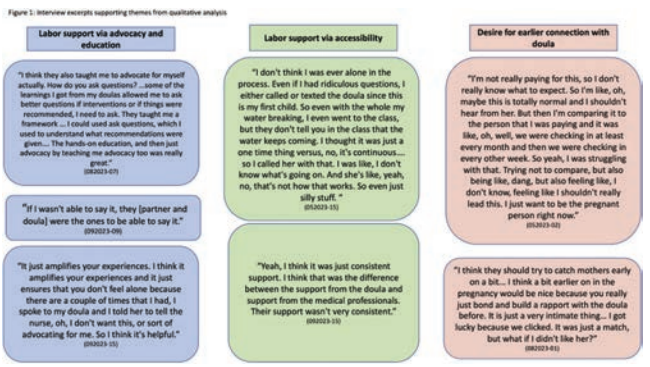
10:30 AM - 12:30 PM

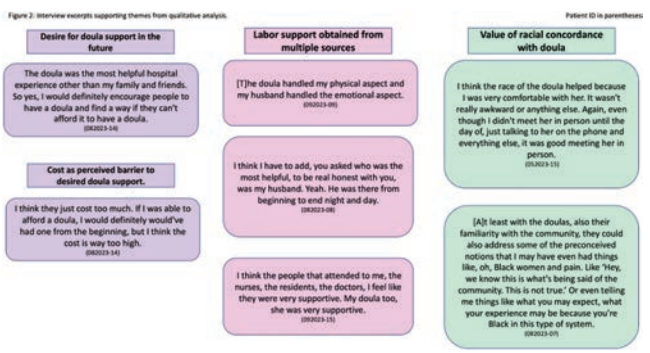
Objective: This qualitative study aimed to understand Black birthing people's support and experiences during labor after being paired with a doula through a program within an urban academic medical system.

Study Design: We recruited patients who participated in a program that pairs nulliparous self-identified Black birthing people with community doulas in the third trimester. Patients were eligible if they were >18 years old, delivered within the academic medical center within a year prior to the interview, and were successfully paired with a doula through the program. This study was exempt after IRB review. One on one semi-structured interviews (n = 10) were preformed virtually after consent was obtained. Interview questions probed general birth experience, interactions with the doulas, and role of racial concordance among doulas. Interviews were recorded and transcribed. We used a combination of deductive and inductive approaches to group coded excerpts into emergent themes.

Results: All participants where nulliparous Black birthing people. The median age was 29.5 (range 28-40) and all were privately insured. Themes that emerged were: labor support through advocacy and education, labor support through presence and accessibility, desire for earlier connection with doula, desire for doula support in the future, labor support from multiple sources, value of racial concordance with doula, and cost as perceived barrier to desired doula support. Example quotes for each theme are listed in figures 1 and 2.

Conclusion: Overall, Black birthing people paired through a system wide program had positive experiences with racially concordant doulas and identified multiple methods of labor and antenatal support from various groups in addition to their paired doula. Many desired increased labor education and contact with their doulas earlier and more frequently, and the rare negative experiences were related to ability to develop a patient-doula relationship. Programs to increase access to doulas should aim to optimize the amount of covered doula meetings and quality of doula care.





117 | Evaluation of Evidence-Based, Plain Language Marijuana Health Education

Megan L. Young[1]; Alicia Mastronardi[2]; Basma Ouddi[3]; VICKI L. BRADFIELD[4]; Jill M. Maples[5]; Heather Moss[6]; Nikki B. Zite[6]; Tara Burnette[7]
[1]University of Tennessee Medical Center, Center for Women and Infants, Knoxville, TN; [2]University of Tennessee Graduate School of Medicine, Department of OB/Gyn, Knoxville, TN; [3]The University of Tennessee Graduate School of Medicine, Memphis, TN; [4]UTMCK, Knoxville, TN; [5]University of Tennessee Health Science Center, College of Medicine, Knoxville, TN; [6]University of

Tennessee Graduate School of Medicine, Knoxville, TN; [7]University of Tennessee Medical Center, Department of OB/GYN and Neonatology, Knoxville, TN

10:30 AM - 12:30 PM

Objective: To assess the impact of patient education on perceived safety of marijuana use in pregnancy and breastfeeding, intended future marijuana use, and perception of stigmatizing language.

Study Design: An evidence-based, plain language one-page handout was created to educate patients regarding marijuana use in pregnancy. Patient feedback was gathered to determine if the material was perceived as helpful or stigmatizing. Patients were identified through self-reported use or a positive urine test in pregnancy. Pre- and post-intervention surveys gauged perceived safety of marijuana use during pregnancy and breastfeeding. Perceived stigmatizing language was assessed post-intervention. Demographics were collected. Wilcoxon signed-rank tests assessed pre- and post-intervention perceptions of marijuana use safety for significant differences.

Results: Twenty-two patients consented into the study and completed the intervention and surveys. After the intervention, a significantly higher percentage of patients disagreed that fetal exposure to marijuana was safe (Table 1). However, perceptions of maternal risks and breastfeeding success with marijuana use did not change significantly. Post-intervention, 50.0% of patients indicated less likelihood of using marijuana in future pregnancies and 71.4% felt the education made them feel the provider was "on their team." The majority (90.9%) found the education helpful and 72.7% learned something new (Figure 1).

Conclusion: Though statistically significant differences were only noted around perceptions of fetal risk and marijuana use, consideration for decreased marijuana use in future pregnancies and feelings of destigmatization were promising. It seems possible to provide non-stigmatizing education addressing potential dangers of marijuana use to maternal and infant health, which is becoming more important as providers address higher self-reported marijuana use during pregnancy in our communities.

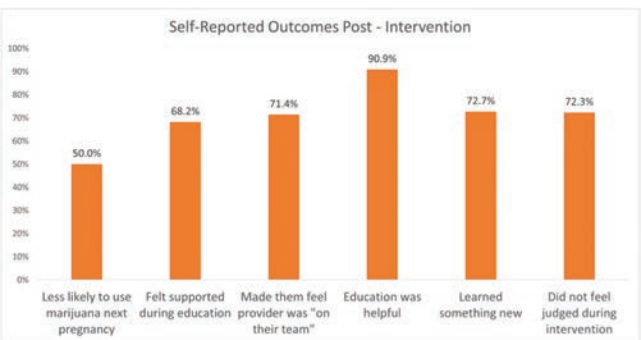


Table 1. Survey responses pre- and post-marijuana health education intervention regarding maternal risk, fetal risk, and breastfeeding

	Pre-Intervention Median (IQR)[A] (Percent Strongly Disagree/Disagree)	Post-Intervention Median (IQR)[A] (Percent Strongly Disagree/Disagree)	p-value[B]
Using marijuana while pregnant....			
... is safe for my health.	4.00 (3.75, 5.00) (18.2%)	4.50 (2.00, 5.00) (27.3%)	.443
... is safe for my unborn baby's health.	4.00 (3.00, 4.00) (18.2%)	3.75 (2.00, 4.00) (27.3%)	**.026**
...poses no threats to my unborn baby's long-term health.	4.00 (3.00, 5.00) (13.6%)	3.00 (2.00, 4.00) (36.4%)	**.013**
Using marijuana while breastfeeding....			
...has no effect on my breastmilk supply.	2.50 (2.00, 4.25) (50.0%)	2.00 (2.00, 4.00) (54.5%)	.208
...is safe for my baby's health.	3.00 (2.00, 4.25) (27.3%)	3.00 (2.00, 4.00) (40.9%)	.258

[A] Six-point Likert scale answer choices were as follows: (1) strongly disagree, (2) disagree, (3) slightly disagree, (4) slightly agree, (5) agree, (6) strongly agree.

[B] Differences in survey answers pre vs. post intervention were assessed using Wilcoxon signed-rank tests with an alpha <0.05 for significance.

118 | Technical and Maternal Factors Associated with Fetal Anatomic Survey Completion in Higher Bmi Groups

Alina Tvina; Meredith Cruz; Rachel Knoebl; Faith Bobholz; madalynn Welch; Anna Palatnik
Medical College of Wisconsin, Milwaukee, WI

10:30 AM - 12:30 PM

Objective: To describe the proportion of completed fetal anatomic survey (FAS) at first attempt in patients with Body Mass Index (BMI) ≥40 kg/m^2, and to identify maternal and sonographic factors affecting FAS completion rates.

Study Design: A retrospective single academic center study that included pregnant individuals with singleton gestation, presenting for a detailed FAS in 2019-2023 between 17 and 25 weeks' gestation and are ^{3}18yo with BMI^{3}40 kg/m^2. Maternal and sonographic characteristics were compared between three BMI groups, 40-45.9, 46-49.9, and ≥50 kg/m^2, using adjusted and unadjusted analyses.

Results: A total of 574 patients met inclusion criteria with 53% at BMI 40-45.9, 26% at BMI 46-49.9, and 21% at BMI ≥50. The groups did not differ in gestational age at detailed FAS, placental location, fetal position, machine type, duration of scan, time of day and sonographer experience (Table 1). Completion of the anatomy at first attempt for all BMI groups was less than 50%, with significant reduction as BMI category increased ($p < 0.001$ for all comparisons). The number of suboptimal anatomic systems did not differ between BMI groups, with the heart being the most common suboptimal system followed by spine and extremities (Table 1). The rate of fetal anomalies was 2%. After controlling for gestational age at anatomic survey, sonographer experience, placental location, fetal position, type of ultrasound machine, and time of day the scan was done, higher BMI remained significantly associated with lower rates of anatomy completion (aOR of 0.57, 95% CI 0.37-0.88 for BMI 45-49.9, and aOR of 0.34, 95% CI 0.20-0.56 for BMI≥50, both compared with BMI 40-44.9).

Conclusion: Anatomy scan completion rates were low among individuals with BMI ≥40 kg/m2 and progressively decreased among BMI 45-49 and BMI ≥50. This could lead to potential delays in diagnosing fetal anomalies, necessitating alternative strategies such as advanced imaging technology, specialized

training, pre-scan preparation and patient education, to ensure comprehensive prenatal care for individuals with higher BMIs.

Table 1: Demographic and Sonographic Characteristics

119 | Maternal Outcomes in the Postpartum Period by Timing of Diagnosis of Hypertensive Disorder of Pregnancy

Alisse Hauspurg[1]; Lara S. Lemon[2]; Kripa Venkatakrishnan[3]; Malamo Countouris[3]; Beth Quinn[3]; Jacob Larkin[4]; Anna B. Binstock[5]; Sarah Rogan[3]; Arun Jeyabalan[6]; Hyagriv Simhan[3]
[1]Alpert Medical School of Brown University, Providence, RI; [2]University of Pittsburgh, Pittsburgh, PA; [3]University of Pittsburgh Medical Center, Pittsburgh, PA; [4]Magee-Womens Hospital University of Pittsburgh Medical Center, Pittsburgh, PA; [5]UPMC Magee-Womens Hospital, Pittsburgh, PA; [6]University of Pittsburgh School of Medicine, Pittsburgh, PA

10:30 AM - 12:30 PM

Objective: We sought to assess whether intrapartum or new-onset postpartum hypertensive disorders of pregnancy (HDP) are associated with similar maternal outcomes as HDP with antepartum onset.

Study Design: This cohort study uses data from our institution's remote blood pressure (BP) management program. Included individuals delivered between 9/2019-4/2024, were enrolled in our remote monitoring program at the time of delivery and had no pre-pregnancy HTN. We compared outpatient BP measures, need for initiation of post-discharge anti-hypertensive medications and care utilization outcomes between individuals with antepartum HDP and those with intrapartum or postpartum HDP first diagnosed during the delivery hospitalization.

Results: Of 7071 individuals with HDP, 1045 (15%) had new-onset intrapartum or postpartum HDP and 6026 (85%) had antepartum HDP. Compared to those with antepartum HDP, individuals with intrapartum or postpartum HDP had similar rates of severe HTN after hospital discharge (13.9% vs. 13.7%; $p = 0.87$). Overall, individuals with antepartum HDP were more likely to require anti-hypertensive medications at any point postpartum (46.5% vs. 32.7%; $p < 0.001$) compared with those with intrapartum or postpartum HDP. However, outpatient initiation of anti-hypertensive medications was equally likely across groups. Rates of ER visits (12.7% vs. 11.4%; $p = 0.22$) and postpartum readmissions (5.1% vs. 5.1%; $p = 0.98$) were similar among individuals with intrapartum and postpartum HDP compared to those with antepartum HDP, respectively.

Conclusion: Hypertension with onset intrapartum or postpartum is often dismissed or attributed to other etiologies. Our data suggest that individuals with intrapartum and postpartum-onset HDP have similar rates of severe HTN, post-discharge medication initiation and care utilization in the postpartum period as individuals with antepartum HDP and highlights the importance of ongoing BP monitoring after hospital discharge in these individuals.

Table. Demographic and obstetric characteristics by timing of onset of hypertensive disorder of pregnancy (HDP).

	Antepartum HDP n=6026	Intra- or post-partum HDP n=1045	p value

120 | Understanding and Addressing Antenatal Depression Management in the High Risk Obstetrics Care Setting

Allison Chu; Alexis French; Sarah K. Dotters-Katz; Nathan Copeland; Gary Maslow
Duke University School of Medicine, Durham, NC

10:30 AM - 12:30 PM

Objective: Maternal fetal medicine specialists are uniquely poised to manage mental health in high-risk pregnancies given the compounded effects of depression on maternal and fetal outcomes. However, without supportive systems in place, effective care is difficult to achieve. We characterized depression screening and management practices to inform policy change for perinatal depression care.

Study Design: Retrospective cohort study evaluating pregnancy episodes from a single academic high-risk obstetrics clinic between 1/2021-12/2023. Primary outcome was percentage of patients screened for depression during pregnancy. Secondary outcomes were frequencies and categories of interventions provided for patients with a positive PHQ-9(≥10) screen. Frequencies and percentages calculated to describe patient characteristics and management for pregnancy episodes. All analyses were performed using IBM SPSS Statistics (Version 27).

Results: 5,313 patients met initial study criteria; only 1,421(26.7%) patients had any PHQ-9 screen during pregnancy; of 1,421, 74(5.2%) patients had positive screenings, for a total of 76 unique pregnancy episodes (Figure 1). Of these 76 episodes, 81.6%(n = 62) had a pre-existing mental health diagnosis, including 27.6%(n = 21) with a history of pregnancy-related mood disorder (Table 1). Interventions were provided in 65.8%(n = 50) of pregnancies. Antidepressants were started in 14.5%(n = 11) of pregnancies; of that group, 54.5%(n = 6) and 90.9%(n = 10) did not have a validated screening completed before starting medication and during follow-up, respectively.

Conclusion: Current practice suggests gaps in utilization of validated screening tools to manage depression during pregnancy, which does not reflect standard of care outlined by the American College of Obstetricians and Gynecologists (ACOG). Our study revealed a concerning low rate of depression screening and suboptimal practices regarding antidepressant use in this high-risk population. An evidence-based collaborative care model has emerged as a potential solution to address gaps and align current practice with ACOG guidelines.

121 | Impact of Obesity Class on Severe Maternal Morbidity in Pregnancies with Postpartum Hemorrhage

Allison N. Akers[1]; Lilla Markel[1]; Shreya Arora[2]; Sydney Stewart[3]; Jose R. Duncan[4]; Judette M. Louis[5]
[1]Department of Obstetrics & Gynecology, University of South Florida Morsani College of Medicine, Tampa, FL; [2]University of South Florida Morsani College of Medicine, TAMPA, FL; [3]University of South Florida Morsani College of Medicine, Tampa, FL; [4]Department of Obstetrics and Gynecology, University of South Florida, Morsani College of Medicine, Tampa, FL; [5]Department of Obstetrics & Gynecology, University of South Florida Morsani College of Medicine, University of South Florida, FL

10:30 AM - 12:30 PM

Objective: Prior studies have reported a need for more doses of uterotonic agents when managing postpartum hemorrhage in patients with obesity. We sought to evaluate the association between obesity severity on postpartum hemorrhage interventions and associated severe maternal morbidity (SMM).

Study Design: We conducted a retrospective cohort study including all singleton gestations among women who delivered at a safety net quaternary care center from January 2019-December 2021. Medical charts were reviewed for clinical and sociodemographic data. Patients with multiple gestation or incomplete data

were excluded. Obstetric hemorrhage was defined as quantitative blood loss ≥1000 mL in vaginal or cesarean deliveries. CDC severe morbidity indicators and nonsurgical and surgical hemorrhage interventions were assessed. There were three comparative groups based on prepregnancy BMI: BMI ≤29kg/m^2 (Group 1), 30-39 kg/m^2 (Group 2), and ≥ 40kg/m^2 (Group 3). The data were analyzed using chi-square, student's t-test, Kruskal-Wallis, and logistic regression where appropriate. $p < 0.05$ was significant.

Results: During the study period there were 18,937 deliveries and 393 met criteria for inclusion in this analysis. Within the study cohort, 57.0% (n = 224) were in Group 1, 28.0% (n = 111) in Group 2, and 14.8% (n = 58) in Group 3. Patients in each group were similar in demographic characteristics but were more likely to have hypertensive disease (Table 1). After controlling for confounding variables, obesity class (OR. 0.7[95% CI 0.5-1.0]) was not associated with an increased odds of SMM. Higher admission hemoglobin (OR 0 .7 [95%CI .65-.9] was protective against SMM. In contrast, preterm delivery (OR 2.3 [95%CI 1.3-4.4] and number of hemorrhage risk factors (OR1.5 [95%CI 1.2-1.9]) were associated with a higher odds of SMM.

Conclusion: In this cohort of patients managed with a standardized hemorrhage management protocol, obesity severity was not associated with severe maternal morbidity.

Table 1: Patient Demographics by Obesity Group

	Group 1 BMI ≤29kg/m^2 (N=224)	Group 2 BMI 30-39 kg/m^2 (N=111)	Group 3 BMI ≥ 40kg/m^2 (N=58)	P value

122 | Reexamining a Paradigm of Maternal Syphilis Management when Fetal Ultrasound Findings are Present

Allison Kurzeja[1]; Heath Yancey[1]; Jessica E. Pruszynski[2]; Emily H. Adhikari[1]

[1]*University of Texas Southwestern Medical Center, Dallas, TX;*
[2]*University of Texas Southwestern, Dallas, TX*

10:30 AM - 12:30 PM

Objective: To characterize pregnancies with abnormal ultrasound findings of congenital syphilis and compare management and outcomes among pregnancies with and without ultrasound findings following current management protocols.

Study Design: Retrospective chart review of maternal syphilis cases diagnosed after 20 weeks from 2021 through 2023 at a large public hospital with uniform management of maternal syphilis, including 24 hours of fetal monitoring following initial benzathine penicillin dose if abnormal ultrasound was documented. A detailed fetal evaluation for congenital syphilis included assessment of placentomegaly, polyhydramnios, hepatomegaly, ascites, and elevated MCA systolic velocity. We compared demographics, syphilis stage, RPR titers, delivery outcomes, and neonatal outcomes among individuals with and without an abnormal detailed ultrasound prior to initiation of treatment.

Results: 97 individuals diagnosed after 20 weeks had a detailed ultrasound for congenital syphilis prior to treatment. Of those, 43 (44%) had abnormal findings, most commonly placentomegaly (63%) or hepatomegaly (53%). Syphilis stage and RPR titer were not associated with abnormal findings. Substance use disorder was prevalent in both groups. Consistent with our practice, individuals with abnormal findings were more likely to have received treatment with fetal monitoring on L&D. Despite being more likely to have monitoring, gestational age at delivery and cesarean rates were similar in both groups. There were no cases of stillbirth. Neonatal outcomes, including NICU admission and syphilis treatment, were not significantly different.

Conclusion: Delivery for fetal indication during maternal syphilis treatment remains a rare event, even in the setting of abnormal sonographic findings. Even in high resource settings, the added value of detailed ultrasound or prolonged fetal monitoring may not outweigh the benefit of immediate treatment initiation in pregnancy.

Table 1: **Demographics and Clinical Characteristics of Maternal Syphilis Cases**

123 | Outcomes Associated with Subsequent Diagnosis of Gestational Diabetes Following a Pregnancy Without Gestational Diabetes

Alyssa R. Hersh; Bharti Garg; Wendy Tian; Kristin C. Prewitt; Amy M. Valent; Aaron B. Caughey
Oregon Health & Science University, Portland, OR

10:30 AM - 12:30 PM

Objective: Gestational diabetes (GDM) affects more than 200,000 people annually in the U.S., with prevalence continuing to rise. GDM is associated with adverse perinatal outcomes. We sought to assess how a new diagnosis of GDM after a pregnancy without GDM impacts perinatal outcomes.

Study Design: This was a retrospective cohort study of pregnant persons in California between 2008-2020 with two births that were both singleton, non-anomalous, gestational ages 23-42 weeks. Included persons did not have pre-existing or gestational diabetes during an index pregnancy. We assessed perinatal outcomes associated with development of GDM in a subsequent pregnancy compared to those who did not develop GDM. Statistical analyses were performed utilizing chi squared and multivariable logistic regression with a p-value of 0.05.

Results: There were 849,908 people that met inclusion criteria, of which 58,403 (6.9%) had GDM in a subsequent pregnancy. New GDM in a subsequent pregnancy was associated with increased rates of hypertensive disorder (4.8% vs 10.5%, $p < 0.001$), preterm delivery < 37 weeks (5.4% vs 7.8%, $p < 0.001$), maternal ICU admission (0.07% vs 0.13%, $p < 0.001$) and severe maternal morbidity (0.9% vs 1.2%, $p < 0.001$). Cesarean delivery was higher among those that had no history of cesarean delivery (7.2% vs 11.5%, $p < 0.001$) and there were lower rates of operative vaginal delivery (3.9% vs 3.6%, $p = 0.009$). Neonatal outcomes were also worse with GDM in the subsequent pregnancy, including macrosomia (10.5% vs 12.3%, $p < 0.001$), APGAR < 7 at 5 minutes (0.6% vs 0.7%, $p < 0.001$), neonatal ICU admission (8.1% vs 9.2%, $p < 0.001$), and respiratory distress syndrome (0.8% vs 1.2%, $p < 0.001$).

Conclusion: We found that GDM diagnosis in a subsequent pregnancy without prior GDM is associated with a higher rate of adverse outcomes. Our findings impact inter-pregnancy diabetes prevention, affect perinatal counseling, and clarify focus for maternal intervention for those with new GDM. Future studies should assess whether prevention of the interval development of GDM among a population without a prior diagnosis may improve pregnancy outcomes.

124 | Outcomes Among Low-Risk Term Multiparous Births in California Pre- and Post-Arrive Trial Publication

Alyssa R. Hersh; Bharti Garg; Megha Arora; Aaron B. Caughey
Oregon Health & Science University, Portland, OR

10:30 AM - 12:30 PM

Objective: Following publication of the ARRIVE trial, term pregnancy management has changed for all patients. Although the ARRIVE trial included only nulliparous patients, its results may have been extrapolated to multiparous patients. Therefore, we assessed the differences in obstetric management and outcomes pre- and post-ARRIVE trial publication among multiparous patients who would have otherwise fit study criteria.

Study Design: This was a retrospective cohort study of singleton, non-anomalous, low-risk multiparous patients between 39-42 weeks of gestation in California. We excluded patients with a prior cesarean delivery, chronic hypertension, diabetes, breech presentation, advanced maternal age, oligohydramnios, polyhydramnios, and placental conditions requiring cesarean delivery. The pre- and post-ARRIVE trial publication cohorts were two years before and after 2018, 2016-2017 and 2019-2020, respectively. We assessed utilization of induction of labor and clinically relevant maternal and neonatal outcomes in the overall cohort, then stratified by week of gestation. Chi squared and multivariable logistic regression were used for statistical analyses.

Results: There were 149,214 births in 2016-2017 and 118,653 births in 2019-2020 that met our inclusion criteria. In the post-ARRIVE trial publication time period, induction of labor increased (24.2% vs. 29.5%, $p < 0.001$) and cesarean deliveries decreased (5.2% vs. 4.9%, $p < 0.001$). There were lower rates of NICU admission (7.3% vs. 6.3%, $p < 0.001$) and respiratory distress syndrome (0.25% vs. 0.21%, $p = 0.018$). The adjusted odds of stillbirth were significantly lower at 39 weeks of gestation (aOR 0.52, 95% CI 0.48-0.96).

Conclusion: In this study, we found increased utilization of induction of labor and decreased rates of cesarean delivery, NICU admission, and respiratory distress syndrome pre- and post-publication of the ARRIVE trial. There was also a reduction in stillbirth at 39 weeks' gestation. These results demonstrate that

similar to nulliparas, a trend of increased delivery at 39 and 40 weeks' gestation may improve perinatal outcomes in multiparas.

125 | Development of Physiologically Based Pharmacokinetics Model of Aspirin in Pregnancy

Ana Collins-Smith; Ananth Kammala; Ramkumar Menon
University of Texas Medical Branch, Galveston, TX

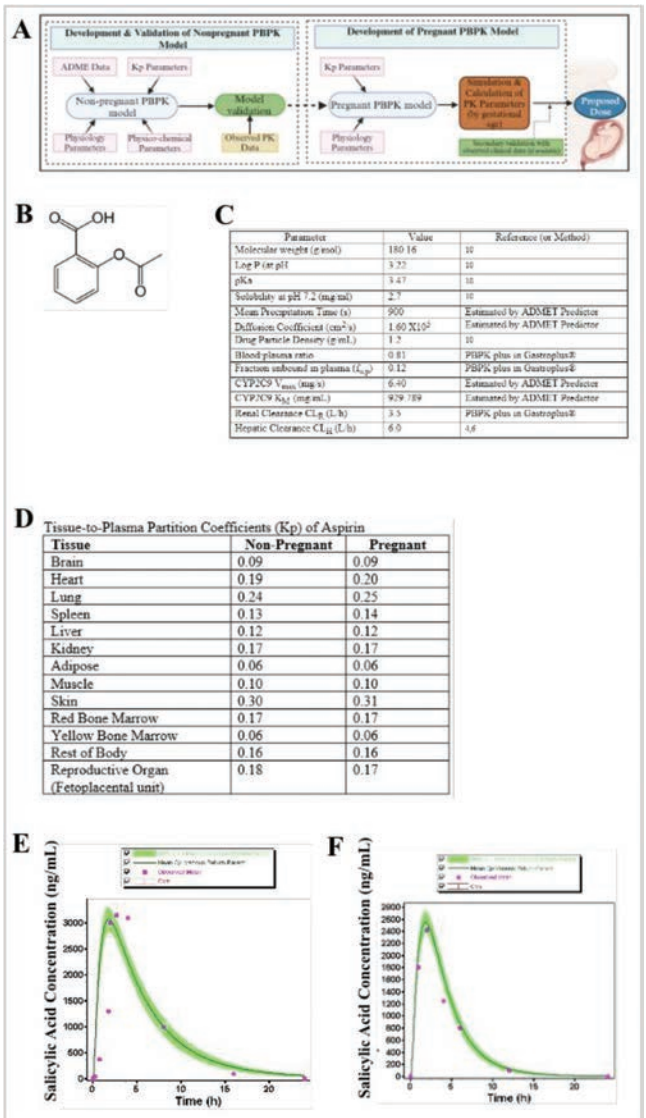
10:30 AM - 12:30 PM

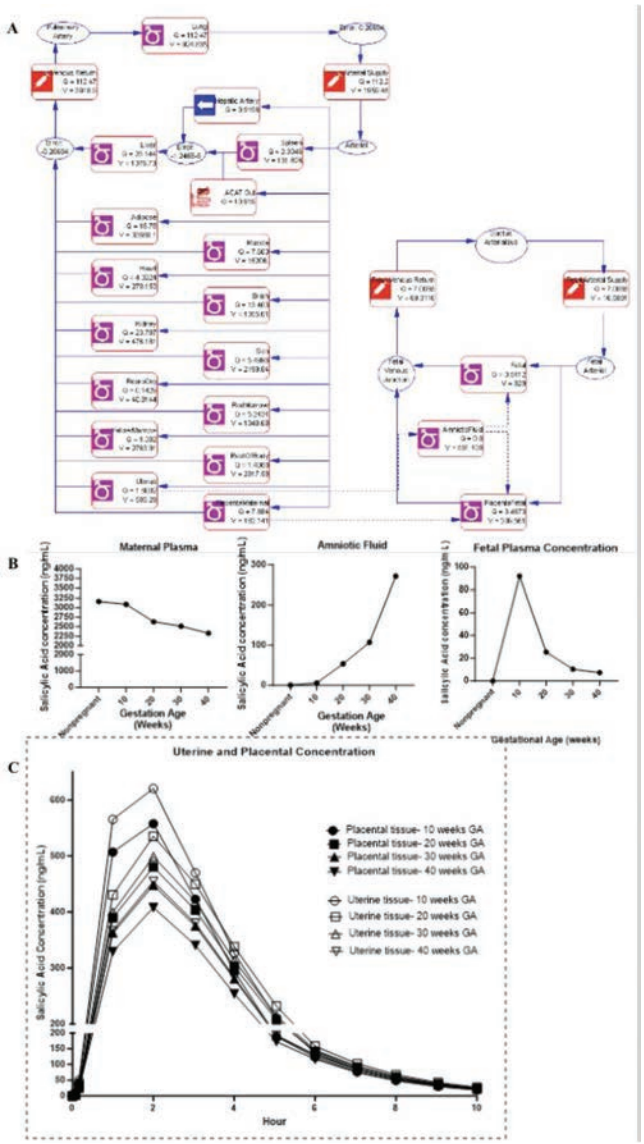
Objective: Aspirin is one of the most commonly used over-the-counter medications in pregnancy, particularly for the prevention of hypertensive disorders. However, there are limited studies on aspirin's pharmacokinetics (PK) in pregnant women. This study aimed to develop a pregnancy-specific physiologically based pharmacokinetic (PBPK) model for aspirin that could be individualized to patient specific parameters; illustrating differences in aspirin pharmacokinetics across the different trimesters of pregnancy.

Study Design: A PBPK model was developed using GastroPlus (a mechanistically based simulation software) for nonpregnant and pregnant subjects, including each trimester of pregnancy. The nonpregnant PBPK model was first established and validated against existing data from healthy adult volunteers. Once validated, the model was adapted for pregnant subjects and verified using observed pharmacokinetic profiles.

Results: The simulated PK parameters of aspirin in pregnant and nonpregnant women closely matched the clinical observations reported in the literature, with fold errors ≤1.04 (less than 1.5 is considered an acceptable simulation model). The predicted systemic exposure ($AUC_{0-24}h$) to aspirin decreased throughout gestation, showing a reduction of approximately 20% at 10 weeks and 30% at 40 weeks of gestation. An increase in clearance of approximately 3% was observed as gestation progressed.

Conclusion: A validated PBPK model using GastroPlus was developed to describe the pharmacokinetics and pharmacodynamics of aspirin in both pregnant and nonpregnant healthy adults. The model predicted a modest decrease of 10% in systemic exposure in pregnant women and a 20% increase in fetal exposure to aspirin as pregnancy progresses. The increasing fetal exposure with advancing gestational age may pose potential safety risks to the fetus.





126 | Success of Vaginal Birth after Cesarean (VBAC) Following Induced Versus Spontaneous Labor

Andrew Storm[1]; Niraj R. Chavan[1]; Gilad A. Gross[2]; Samantha J. Mullan[2]; Elena M. Kraus[2]; William M. Perez[2]; Tracy M. Tomlinson[3]

[1]Saint Louis University School of Medicine, St. Louis, MO; [2]Saint Louis University School of Medicine, Division of Maternal Fetal Medicine, St. Louis, MO; [3]Saint Louis University, St. Louis, MO

10:30 AM - 12:30 PM

Objective: To evaluate characteristics associated with vaginal birth after cesarean (VBAC) success in women undergoing induction of labor (IOL).

Study Design: Passive prospective cohort of singleton pregnancies with a history of one or two prior Cesareans undergoing a trial of labor after Cesarean (TOLAC) following IOL and spontaneous labor ≥ 36 weeks at a tertiary care center (2011-2022), retrospectively analyzed. We assessed univariate associations between pregnancy characteristics and 1) form of TOLAC onset (spontaneous versus induced) & 2) VBAC outcome (success / failure). Factors with P < .2 on one or both univariate analyses were considered for incorporation into a multivariable model predictive of VBAC.

Results: Of 1434 individuals undergoing TOLAC, 919/1242 (74%) who met inclusion criteria had VBAC - 405/625 (65%) following induction vs 514/617 (83%) spontaneous labor, P < .0001. Some characteristics were similar between groups but the IOL group was slightly older and had a higher BMI, later gestational age, and lower modified Bishop scores at time of TOLAC (Table 1). Fewer undergoing IOL had a prior VBAC. More had gestational weight gain in excess of guidelines, hypertension, and diabetes. 13 factors were independently associated with odds of VBAC on multivariable analysis (Figure 1). IOL for preeclampsia was independently associated with lower odds of VBAC but IOL that was elective or for another indication was not (aOR0.78, 95% CI 0.53-1.14). The 15-covariate model (Figure 1) had an optimism-corrected bootstrapped (1000 replicates) AUROC of 0.78 (95% CI 0.74-0.80).

Conclusion: As compared to IOL, a higher proportion of pregnancies with spontaneous labor had VBAC. However, after adjustment of relevant clinical factors associated with VBAC success, only IOL for preeclampsia was found to be independently associated with failed TOLAC, while elective IOL and IOL for other indications was not.

Table 1. Demographic characteristics by labor method, induction or spontaneous (N=1242)

	Induction of labor (n = 625)	Spontaneous labor (n = 617)	P
Age (y)	29.0 ± 5.4	27.9 ± 5.2	<.001

127 | Provider Perspectives About Smoking Cessation Programming For Patients With Substance Use Disorder: Mixed Methods Approach

Andrew Storm[1]; Lauren Borato[2]; Katherine L. Chen[1]; Miriam Rivkin[3]; Jeremiah Weinstock[4]; Niraj R. Chavan[1]

[1]Saint Louis University School of Medicine, St. Louis, MO; [2]St. Louis University Dept. of Psychology–SLU College of Arts & Science, St. Louis, MO; [3]St. Louis University, Saint Louis University School of Medicine/ St. Louis, MO; [4]St Louis University Dept. of Psychology–SLU College of Arts & Science, Saint Louis, MO

10:30 AM - 12:30 PM

Objective: To examine provider-centric determinants of smoking cessation counseling among patients with perinatal substance use disorder (SUD).

Study Design: We undertook a convergent parallel mixed methods study that included semi-structured key informant interviews and a systematic survey administered to providers caring for pregnant women with SUD. Survey elements contained Likert scale, open and closed ended questions focused on provider knowledge, attitudes and practices around smoking cessation counseling specifically while managing perinatal SUD. Interview questions were guided by the Consolidated Framework for Implementation Research (CFIR) and focused on provider-level barriers and facilitators to smoking cessation counseling, provider perceptions about patient-level barriers and motivators as well as role of the provider-patient relationship in achieving cessation during pregnancy. Interviews were audio recorded, transcribed and analyzed using deductive and inductive content analysis.

Results: 25 prenatal care providers including physicians in obstetrics & gynecology (n = 20), family medicine (n = 1), addiction medicine (n = 1) and nurse practitioners (n = 3) completed the in-depth interviews and surveys. The majority of respondents had not received formal training in smoking cessation counseling (n = 21, 84%). Major interview themes identified were: 1) Provider-level barriers and facilitators to cessation counseling 2) Provider perceptions about patient-level barriers and motivators for cessation 3) Role of the provider-patient relationship and 4) Smoking cessation as a means to achieve healthy pregnancy outcomes. Participants also provided valuable insights into the design and implementation of interventions to address provider, hospital and system-level barriers to enhance smoking cessation among patients with SUD.

Conclusion: Our mixed methods approach grounded in an implementation science framework has identified several actionable provider-level determinants of tobacco cessation for patients with perinatal SUD, laying the groundwork for designing multi-level interventions in future endeavors.

Table 1: Key Insights from Provider Surveys (n = 25)

Survey Question	"Somewhat Agree" (n %)	"Strongly Agree" (n %)
Counseling pregnant patients to stop smoking is important.	0 (0%)	25 (100%)
Healthcare providers should be trained in tobacco cessation counseling or treatment.	4 (16%)	21 (84%)
Healthcare providers have a responsibility to help their patients quit smoking.	3 (12%)	22 (88%)
I am comfortable counseling my patients through the tobacco quit process.	19 (76%)	5 (20%)
Pregnant women are often able to quit using tobacco during pregnancy.	15 (60%)	1 (4%)
Most pregnant women who use tobacco will not give up smoking even if their physician tells them to.	4 (16%)	0 (0%)
Most pregnant women are not interested in quitting smoking.	3 (12%)	0 (0%)
Pregnant women who stop smoking during pregnancy will start again after delivery.	4 (16%)	0 (0%)
Physicians, rather than nurses or health educators, should provide tobacco cessation counseling to patients.	3 (12%)	0 (0%)
Physicians receive sufficient reimbursement for tobacco cessation services.	0 (0%)	1 (4%)

Table 2: Primary Themes and Subthemes from Provider Interviews (n=25)

Themes	Subthemes
Provider-level barriers and facilitators to smoking cessation counseling.	• Provider knowledge: opportunities for enhanced training and formal education • Need for integration into clinic workflow • Lack of time to adequately address social and structural determinants • Smoking cessation is not prioritized in the setting of other comorbidities or other SUDs • Opportunities for increased multidisciplinary care coordination
Provider perceptions about patient-level barriers and motivators for smoking cessation	• Prioritizing smoking cessation in prenatal care education • Difficulty with obtaining prescribed medications • Smoking is normalized behavior • Lack of social support systems for cessation • Cessation counseling is not routinely addressed in the postpartum/preconception period
Role of the provider-patient relationship to foster smoking cessation	• Maintaining a healthy therapeutic patient-provider relationship throughout prenatal care • Patient empowerment through knowledge and resources • Acknowledging difficulties with achieving cessation with ongoing SUDs
Smoking cessation as a means to achieve healthy pregnancy outcomes	• Pregnancy as a facilitator to enhance readiness to change • Understanding and channeling inherent motivators to embrace healthy behaviors • Link between smoking cessation and achieving sobriety from substance use • Linking cessation with the maternal and neonatal outcomes during counseling

128 | "CODE OB": The Impact of Hospital-Wide Announcements on Decision-to-Incision Interval, Neonatal Outcomes in Emergency C-Sections

Andy Chen[1]; David Roth[1]; Yisrael Lipener[2]

[1]Rutgers Health/Jersey City Medical Center: Department of Obstetrics, Gynecology and Women's Health, Jersey City, NJ; [2]Robert Wood Johnson Barnabas Health/Jersey City Medical Center: Department of Neonatology, Neonatal Intensive Care Unit, and Neonatal Services, Jersey City, NJ

10:30 AM - 12:30 PM

Objective: This study evaluates the effect of calling a hospital-wide obstetrical code on decision-to-incision (D-I) interval and neonatal outcomes for different emergency C-section indications. D-I intervals, arterial cord pH, arterial base deficit, and five-minute APGARs were assessed in relation to whether or not a code was called for bleeding placenta previa, placental abruption, category 2 tracing, category 3 tracing, cord prolapse, uterine rupture, and other indications (active herpes, detectable HIV, or malpresentation in active labor; uncontrolled pre-eclampsia/HELLP, etc.)

Study Design: A retrospective cohort study analyzing all emergency C-sections (689) between August 2017 and April 2023 was performed. Two-sample t-tests assessed for potential statistical significance in D-I interval and neonatal outcomes between code and non-code emergency deliveries for each hysterotomy indication.

Results: D-I time appeared to improve when a code was called for every indication except for bleeding placenta previa (insufficient sample size) and cord prolapse (9.91 minutes vs. non-code: 24.25 minutes, $p = 0.07$). For placental abruptions, there was a statistically significant difference in cord pH (7.12 vs. 7.24, $p = 0.007$) and base excess (-9.44 vs. -5.83, $p = 0.05$) between code and non-code c-sections. Calling a code appeared to have no effect on five-minute APGARs for any indication. When all indications were combined, there was a statistically significant difference in D-I interval (11.50 vs. 49.06 minutes, $p = 1.86E-69$), cord pH (7.13 vs. 7.22, $p = 5.37E-9$) and base excess (-8.79 vs. -5.79, $p = 1.62E-7$) between code and non-code c-sections.

Conclusion: It appears that calling a code in emergency c-sections shortens D-I interval but does not improve neonatal outcomes.

129 | Examining Maternity Care Workers' Antiracist Attitudes in the Southeast US

Angelina A. Toluhi[1]; Kevin O. Owuor[1]; Rachel G. Sinkey[1]; Jeff M. Szychowski[2]; Waldemar A. Carlo[1]; Alan T. Tita[1]; Martha S. Wingate[1]; Janet M. Turan[1]

[1]University of Alabama at Birmingham, Birmingham, AL; [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL

10:30 AM - 12:30 PM

Objective: Racism contributes significantly to persistent racial disparities in maternal health outcomes in the Southeast United States (US). We aimed to identify key predictors of antiracist attitudes in maternity healthcare (MCH) staff.

Study Design: MCH staff completed a cross-sectional online survey adapted from a validated Anti-RaCist (ARC) Survey tool with 5-point Likert scale items. Outcome variables were antiracist attitudes including acknowledging the impact of racism, the likelihood of actually or hypothetically acting on a racist incident, and support for bias training. Predictor variables included job role, age, race, gender identity, and place of highest education. We performed ordinal logistic regression to model the associations between outcome quartile and predictor variables.

Results: Respondents (n = 93) included physicians, nurses, patient encounter specialists, administrative and other staff working in a major maternity care system in the US South. We found that some characteristics were associated with higher antiracist attitudes (Table 1). Compared to physicians, all other MCH staff had significantly lower odds of endorsing the impact of racism in healthcare. One or no bias trainings over the last 36 months was associated with 0.34 lower odds of acknowledging the impact of racism. Not witnessing a racist encounter at work was associated with 0.19 lower odds of endorsing the impact of racism in healthcare. Older aged (≥35 years) MCH staff had 0.21 lower odds of reporting that they would act ***if*** they witnessed a racist incident. Cis-male MCH staff had higher odds of acting ***when*** they actually witnessed a racist incident in their workplace, compared to cis-female MCH staff.

Conclusion: Our results indicate that endorsing antiracist attitudes varied by specific characteristics of MCH staff in this maternity care setting in the US South. Some types of staff were less likely than others to exhibit attitudes showing antiracism. Efforts to improve the quality of maternity care for racial minorities should address factors that promote antiracist attitudes in all maternity care workers.

Table 1: Maternity Healthcare Workers Antiracist Attitudes

130 | Fear of Insulin and Other Experiences with Gestational Diabetes Mellitus Management–a Qualitative Study

Idayat Akinola[1]; Kathryn E. Flynn[1]; Lynn M. Yee[2]; Eleanor Saffian[1]; Zaira Peterson[1]; Anna Palatnik[1]

[1]Medical College of Wisconsin, Milwaukee, WI; [2]Northwestern University Feinberg School of Medicine, Chicago, IL

10:30 AM - 12:30 PM

Objective: To understand the experiences of patients with gestational diabetes mellitus (GDM) using qualitative methods to explore barriers and facilitators to GDM self-management and insulin use, aiming to inform future interventions.

Study Design: In this ancillary study of an ongoing randomized controlled trial of thresholds for insulin initiation and titration for GDM, participants were recruited from 2/2023 to 1/2024 using purposive sampling, aiming for diversity with respect to age, race, ethnicity, insurance status, parity, and insulin use. In-depth

semi-structured interviews were conducted after 34 weeks' gestation and again postpartum within a week of childbirth. Interview guides covered 1) experience with and knowledge about GDM, 2) self-efficacy and social support, 3) experience with insulin, 4) adherence and persistence to their treatment plan, and 5) birth experience. Transcripts were analyzed using a reflexive thematic analysis approach to develop themes.

Results: Of 20 participants, 80% had GDM for the first time and 50% required insulin treatment (Table 1). Initial coding of transcripts identified key barriers and facilitators to treatment plan adherence (Table 2). Barriers included: 1) fear of insulin ("When I was first told about it, I threw a tantrum… I do not like needles, and that's all I could think about."), 2) the time and cognitive effort to learn self-management, 3) managing emotions related to GDM diagnosis and self-management, and both 4) jobs and 5) family/friends unawareness made it difficult to manage GDM as recommended. Facilitators included 1) training from the medical team ("once I saw my insulin pen, it wasn't that bad."), 2) support from family/friends, and 3) concern for the well-being of the baby.

Conclusion: Self-management of GDM requires substantial social and institutional support, learning, and adjusting to a new lifestyle in a short period of time. For some, the initial recommendation to use insulin caused a strong negative reaction, but hands-on education provided by the medical team helped to alleviate that fear.

Table 1 - characteristics of study participants

Characteristic		N=20 n (%) or mean ± SD
Age		32.6 ± 5.6
Race	American Indian or Alaskan Native	1 (5%)
	Asian	4 (20%)

Use of medications for GDMA2 in prior pregnancy	Insulin	1 (5%)
	Oral antidiabetic medication	1 (5%)
Insulin use in this pregnancy		10 (50%)

Table 2. Exemplary quotation of barriers and facilitators to treatment plan adherence

Theme	Exemplary quotation
Barriers to treatment plan adherence	
Fear of Insulin	This pregnancy has been very smooth so far. My only additional experience is with the gestational diabetes and having to take insulin. So that was something new for me. Now, when I was first told about it, I threw a tantrum. I threw a tantrum for the simple fact that I do not like needles. And that's all I could think about is when I thought about the insulin. "I have to poke myself. Am I going to be able to do it? Will I need a family member to poke for me?" That's all I could think about, was the needles part. (GAP-0208)
The time and cognitive effort to learn self-management	It was scary at first. I've never had to inject myself with anything before. And I knew that taking the exact same dosage or units at the same periods every day doesn't really match up with my eating patterns, just because I have different things every day at different times. So I thought it could be more of a roller coaster. And it was at first, but after I got-- it took a long time to get the hang of it...It was very challenging for me…and it just took a while to get used to. It was really hard to do in a short period of time, especially. (GAP-0119)
Managing emotions related to GDM diagnosis and self-management, and both	It was a little overwhelming for me. And I was a little scared, too, googling it, what it is, how it will affect my pregnancy and my baby. I was scared in the beginning, but as time passed, I talked with my doctors and everyone. They helped me a lot. And yeah, yeah, it was overwhelming in the beginning, but now I'm just used to it. (GAP-0209)
Jobs	But the hardest part with work is if I'm in the middle of doing something, I can't always test right at that two-hour mark. I mean, I can't be like, "I'm sorry. Sorry. I'm in the middle of doing whatever. Let me just step out." So sometimes, I would test a little before or a little after. That makes it a little difficult. (GAP-0160)
Family/friends unawareness made it difficult to manage GDM as recommended	It was very challenging for me. A few months ago, I felt a lot more tired, so I didn't want to exercise like I should have. And I was just more spoiled by friends and family, so they love feeding me sugary treats. And if we had-- I just had a few baby showers. We had lots of snacks with carbs and sugary treats. But I feel like it was a lot easier without outside influences. (GAP-0119)
Facilitators to treatment plan adherence	
Training from the medical team	And once I saw my insulin pen, it wasn't that bad. I'm not going to say that I am used to it now, but I know that I have to do it to try to keep me and the baby together. So, I just basically do it because I know that I need the medicine to stay afloat. (GAP-0208)
Support from family	My husband, my mother, I mean, even my entire family. Like I said before, even if it's just calling to ask me, if we have a gathering, just what I can eat. My husband has found me keto cupcakes that I can have every now and then, so I'm not missing the pastry part of anything. And he's been really good because when I eat a healthy dinner, he'll also eat it with me. So, it's just having somebody there or even like your family that just listens to what you can and can't have and then kind of moving their views a little bit and what they can eat makes it really nice. (GAP-0143)
Concern for the well-being of the baby.	I feel like it was very easy to be motivated once you think, "I'm doing this for my baby. It's not for me. It's for my baby." And I think everyone just wants to do what's best for their baby. So, it makes it very easy to make those changes quickly. (GAP-0143)

131 | Mid-Pregnancy Cervical Length and Pregnancy Outcomes in Low-Risk Singletons: A Prospective Cohort (QP screening study)

Annabelle L. van Gils[1]; Charlotte E. van Dijk[1]; Anita C. Ravelli[1]; Maud D. van Zijl[1]; Bouchra Koullali[1]; Brenda M. M. Kazemier[1]; Martijn A. Oudijk[2]; Eva Pajkrt[1]

[1]Amsterdam UMC, Amsterdam, Noord-Holland; [2]Amsterdam UMC, location University of Amsterdam, Amsterdam, Noord-Holland

10:30 AM - 12:30 PM

Objective: Short midtrimester cervical length (CL) increases the risk for spontaneous preterm birth (sPTB), but sensitivity of this screening tool is low. This study aims to improve sPTB prediction by identifying which factors, combined with CL most accurately predict sPTB.

Study Design: This multicenter prospective cohort study included singletons with no prior sPTB < 34 weeks of whom CL was measured at 18-22 weeks gestation. Primary outcome was sPTB < 37 weeks. Secondary outcomes were (s)PTB < 28, 32, 34 and 37 weeks. CL predictive capacity was assessed with likelihood ratios (LR). Multivariable cox regression (MCR) combined CL with other risk factors (e.g. smoking, cervical surgery, interpregnancy interval (IPI) and was expressed as Hazard Ratios (HR) and 95% confidence intervals (CI)). For PTB risk factors, we calculated population-attributive risk (PAR) for sPTB < 37 and < 32 weeks. Nulliparous and multiparous women were assessed separately.

Results: We included 14,718 singletons between 2015–2021. Nulliparous women (N = 7532) with a CL ≤ 25, 26-30, 31-35 and > 35mm had sPTB < 37 rates of 28.6%, 9.0%, 9.4% and 3.4%, respectively. In multiparous (N = 7186) women, rates were 17.5%, 7.9%, 4.9% and 2.2%. Rates of sPTB < 32 weeks for CL ≤ 25 mm were 20.9% in nulliparous and 12.7% in multiparous women. MCR in nulliparous women showed that CL ≤ 25, 26-30 and 31-35 mm remained significantly associated with increased sPTB hazard (all $p < 0.001$). In multiparous women, CL ≤ 25mm ($p < 0.001$), smoking ($p = 0.049$) and IPI < 6 months ($p = 0.002$) increased

sPTB hazard. In total, 1.0% of women had a CL ≤25mm, yet the PAR of short cervix for sPTB < 37 and < 32 weeks was 7.0% and 29.3% in nulliparous vs 5.1% and 25.1% in multiparous women.

Conclusion: Asymptomatic short midtrimester CL is a significant predictor of sPTB, highlighting the need for implementation of measurement in routine care. A multifactorial approach may enhance sPTB prediction, yet the impact of these additional factors seems limited. CL measurement remains the most effective tool available, especially for identifying those at high risk for very sPTB.

Table 1: Rates and likelihood ratios of (s)PTB and other outcomes in low-risk nulliparous and multiparous singletons

Nulliparous singletons	Total N=7532	CL ≤ 25mm N=91			CL 26-30mm N=221			CL 31-35mm N=466			CL >35 mm N=6754

132 | Whole Blood in the Management of Postpartum Hemorrhage

Anne M. Ambia[1]; April R. Gorman[2]; Jessica E. Pruszynski[1]; Kristen Warncke[2]; Elaine L. Duryea[2]; David B. Nelson[2]
[1]University of Texas Southwestern, Dallas, TX; [2]University of Texas Southwestern Medical Center, Dallas, TX

10:30 AM - 12:30 PM

Objective: Although whole blood (WB) has been shown to improve outcomes in acute trauma patients, it is not widely available in many institutions. The objective of this study was to examine maternal outcomes in those receiving WB versus packed red blood cells with multiple blood products to reconstitute whole blood for postpartum hemorrhage (PPH).

Study Design: This was a prospective cohort study of patients undergoing vaginal delivery complicated by uterine atony who received transfusion within the first 2 hours after delivery at a large, academic facility. As an institutional practice, WB is preferentially ordered for PPH, however, when unavailable, a combination of packed red blood cells (PRBC) and fresh frozen plasma (FFP) is provided by transfusion services as a substitute. Data was collected by dedicated, trained research nurses in coordination with transfusion services. Statistical analysis included chi-square with P< 0.05 considered significant.

Results: Between Jan 2019 and Nov 2023, there were 119 patients meeting inclusion criteria. As shown in the Table, there were no significant differences in demographics or time from order to transfusion (P = 0.26) among the study cohort. Estimated blood loss was lower in the WB group: (1875 [1250,2500] mL vs 1250 [1000,1750] mL, P = 0.01). Compared to patients receiving multi-component therapy without WB, those who received WB required significantly fewer total blood products (2 [2,2] vs 6 [4,7], P< 0.001) and required an operative procedure less frequently (15.8% vs 42.9%, P = 0.04). There was a trend for less febrile morbidity and acute renal insufficiency with use of WB compared to use of multi-component therapy.

Conclusion: The Alliance for Innovation on Maternal Health advocates for early recognition and treatment of PPH. Compared to the use of PRBC and FFP, the use of WB reduces the need for large-volume (>4 units) blood product transfusion and need for operative intervention, in the setting of PPH due to uterine atony within the first 2 hours following delivery. Whole blood, if available, should be the preference for resuscitation in such cases.

133 | Trends in Perinatal Outcomes Following Publication of the Chap Trial: An Interrupted Time Series

Anthony E. Melendez Torres[1]; Sarah E. Little[2]; Sarah K. Dotters-Katz[1]; Sarahn M. Wheeler[1]; Rachel L. Wood[3]
[1]Duke University School of Medicine, Durham, NC; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]Duke University, Durham, NC

10:30 AM - 12:30 PM

Objective: The April 2022 CHAP trial showed that tight chronic hypertension (cHTN) control decreased preterm birth (PTB) and low birthweight (BW) < 2500g. We assessed national trends in PTB and low BW in pregnant patients with cHTN after publication and dissemination of the CHAP trial.

Study Design: Population level interrupted time series (ITS) analysis from February 2021 to August 2023 using US Natality data including patients with a singleton, non-anomalous gestation, cHTN, and who initiated prenatal care at ≤ 6 months gestation. Pre- and post-CHAP periods were defined *a priori* as February 2021-January 2022 and September 2022-August 2023 respectively with a washout period from February 2022-August 2022. Primary outcomes were PTB< 35 weeks, PTB< 37 weeks, and BW< 2500g. Poisson regression was used allowing for both a one-time level change and ongoing changes in trends following the CHAP trial. Incidence rate ratios (IRR) were adjusted for seasonality and the proportion of individuals with age >35 and BMI >30. A sensitivity analysis excluding patients with history of PTB to check for robustness was also performed. Analyses conducted with Stata18 SE.

Results: There were 3,681,963 total births in the pre-CHAP period, 81,881 affected by cHTN (2.2%) and 3,625,611 total births in the post-CHAP period, 90,983 affected by cHTN (2.5%) (X^2, $p < 0.00001$). Baseline demographics were similar in the pre- and post-CHAP periods (Table 1). Though observed rates of primary outcomes were lower than expected immediately after the dissemination period, these one-time level changes were not significant (PTB< 35 weeks 8.6 v 8.8%, PTB< 37 weeks 18.6 v 19.1%, BW< 2500g 15.5 v 16.3%). There were significant ongoing temporal decreases in rates of PTB< 35 weeks (aIRR 0.977, 95% CI 0.965–0.990, p = 0.001), PTB< 37 weeks (aIRR 0.992, 95% CI 0.987–0.997, p = 0.001), and BW< 2500g (aIRR 0.981, 95% CI 0.970–0.993, p = 0.002) (Figure 1). Sensitivity analysis did not affect results.

Conclusion: These findings suggest a population-level impact of the CHAP trial. Further research is warranted to assess if these trends are found in all sub-groups.

134 | Experiences of Black and Latin-X Pregnant People Undergoing Prenatal Diagnosis for Ultrasound Identified Fetal Anomalies

Asha N. Talati; Karen Sheffield-Abdullah; Catalina Montiel; Aryana Daye; Maria Reyes-Montilla; Kelly L. Gilmore; Neeta L. Vora
University of North Carolina at Chapel Hill, Chapel Hill, NC

10:30 AM - 12:30 PM

Objective: To describe experiences of prenatal genetic diagnosis (PGD) among pregnant people (PP) that self-identify as Black or Latin-X with ultrasound detected fetal anomalies.

Study Design: Qualitative study of PP that self-identify as Black or Latin-X with ultrasound detected fetal anomalies offered genetic counseling and PGD care between 11/22–01/24 at a tertiary care center. Interviews were conducted by team members that had ethnic and language concordance with participants. Interviews were one-on-one, semi structured, recorded and transcribed. Interviews with Spanish-speaking participants were translated to English for analysis. Interview domains included the following: respect, trust and genetic privacy, quality of care, and support. Interviews were coded and analyzed using thematic analysis and sampling was completed after theme saturation was achieved. All participants completed a demographic survey and the Everyday Discrimination Scale (EDS), a validated tool to assess the experiences of racial and ethnic minority groups.

Results: 24 interviews were completed (Table 1). All participants had complex, multi-anomaly fetal phenotypes. Six (25%) participants had an amniocentesis. Several key themes were identified across the cohort, including: (1) definitions of respectful care; (2) a need for self-advocacy; (3) the value of racial, ethnic, and linguistic concordance in care, and (4) navigation of healthcare policies (e.g. abortion restrictions, insurance). For Spanish speaking PP, Theme 3 included a discussion of translation services and Theme 4 included discussion of healthcare costs, particularly for those that recently immigrated (Figure 1). Zero interviewees expressed concern regarding genetic privacy for the fetus, self, other family members, now or in the future. Mean EDS score was 21.1 (SD 9.2); EDS scores were not associated with preferences for amniocentesis (r = 0.09).

Conclusion: Black and Latin-X PPs' reflections define respectful care and identify unique considerations and areas for improving quality of PGD care for these racial/ethnic groups.

Table 1. Demographic Characteristics

Characteristic	N=24
Age (mean, SD)	29 (5.4)
Race/Ethnicity[a]	
Black	12 (50)
Latin-X	12 (50)
Gravidity (median, IQR)	2 [1, 2.7]
Parity (median, IQR)	1 [0, 1.7]
Married or In a Relationship	19 (79)
Employed	11 (46)
High School Graduate or Above	22 (92)
Spanish (Primary Language)	7 (29)
Amniocentesis Performed	6 (25)
Termination of Pregnancy	5 (21)

[a]Note two participants in the group identified as biracial: Latin-X/White and Black/White.
[b]Data displayed as n (%) unless noted otherwise

Figure 1. Key Themes and Exemplary Quotations

Definitions of Respectful Care

Multiple participants described respectful care using the following or similar language:

- *"They listened to me"*
- *"They taught me, using pictures and images" "not using medical terms"*
- *"They provided resources and follow up"*
- *"They gave me time to ask questions"*
- *"They gave us contact information"*
- *"She made it her business to check on me..." "became my village"*

By contrast, less respectful care had the following or similar phrases attached:

- *"It wasn't explained"*
- *"In a rush"*
- *"I was shuffled from room to room"*

Self-Advocacy

Participants across the cohort described needing to find information for themselves, online, through community, or other trusted advisors:

- Participant 16 (27 yo, Latin-X PP) describes going online to find data from Facebook groups: *"I needed more information; when you receive that news, it's shocking.... Reading the stories from the groups [was most helpful]."*
- Participant 8 (37 yo, Black PP) describes calling a former primary care provider to verify recommendations: *"I did message her. I talk to her a lot. She's also African American... she helps me have a little resource."*

Value of Racial, Ethnic, and Linguistic Concordance

Black participants noted the lack of racial and ethnic concordance with members of their team, particularly in PGD care:

- Participant 12 (27 yo Black PP) reflects broadly on disparities in care and then on her own care team: *"I know for a fact that non-white women have different care whether it's conscious or unconscious and unfortunately pretty much all of the providers there are White."*

LatinX patients reflected on lack of language concordance; those speaking Spanish as a primary language discussed challenges with translation.

- Participant 21 (29 yo LatinX PP) describes challenges with interpretation and how language concordance adds value to her care: *"Doctors who speak your language, you feel like more confident to ask questions. Because when they were going to operate on the baby there was a doctor who spoke Spanish, so I felt more confident to ask him than to the others, even though there was an interpreter."*

Navigation of Healthcare Policies

Participants allude to the impact of policies such as abortion legislation, health insurance, and immigration as unique considerations for their PGD care.

- Participant 19 (22 yo LatinX PP) discussing testing decisions and cost: *"I wasn't born here so I don't have health insurance."*
- Participant 14 (29 yo Black PP) discussing decision for TOP and state regulations: *"I wasn't sure where I'd go with everything going on in the world, Roe v. Wade... I was stuck."*

[a]yo = year old

135 | Impact of Prenatal Trio-Exome Sequencing on Future Reproductive Decisions: A Qualitative Study

Asha N. Talati[1]; Kelly L. Gilmore[1]; Anne Lyerly[1]; Marsha Michie[2]; Neeta L. Vora[1]
[1]*University of North Carolina at Chapel Hill, Chapel Hill, NC;*
[2]*Case Western Reserve University, Cleveland, OH*

10:30 AM - 12:30 PM

Objective: o determine how trio-exome sequencing (t-ES) in an incident pregnancy (IP) impacts reproductive decision making.

Study Design: Qualitative study of individuals from a t-ES cohort that had a pregnancy with ultrasound-detected fetal anomalies (fetal brain anomalies and/or multiple anomalies) and negative karyotype (K) and microarray (CMA) in an IP. Participants had t-ES 12-30 months prior to interview. Interviewer was blinded to IP history and t-ES results. One-on-one semi-structured interviews were completed, recorded and transcribed. Interview domains included adaptation of t-ES results, perceived value of testing at current time point, and future pregnancy decisions. Interviews were analyzed using grounded theory methods and sampling was completed after theme saturation was achieved.

Results: 15 interviews were completed. Mean age was 31. Eleven (73%) self-identified as non-Hispanic, White. Fourteen (93%) had at least a college education and all were employed. One had diagnostic findings that explain the fetal phenotype. Eight (53%) had subsequent pregnancies; of those, 100% used some form of genetic screening or testing (3 used cell free DNA (cfDNA), 2 used preimplantation genetic testing (PGT-A, PGT-M), 3 had amniocentesis for K and CMA) (Table 1). Key themes identified include: (1) "Knowledge is power"–participants valued genetic testing to guide future pregnancy decisions; (2) "Whiplash"–participants described how medical and psychological complexity of the IP felt incongruent with receiving negative t-ES results; (3) "Confidence moving forward"–participants described how t-ES results, even if negative, provided confidence with future pregnancy; (4) "value of genetic counseling"–participants describe the importance of genetic counseling to interpret results and guide subsequent pregnancies and prospective testing decisions.

Conclusion: Participants using t-ES expressed value in this testing strategy paired with genetic counseling and used results for future pregnancy decisions despite majority negative results.

Table 1. Interview Participants, t-ES results, and Subsequent Pregnancy

Number	Age	Pregnancy Disposition	t-ES DNA source	Results	Subsequent Pregnancy	Type of Genetic Testing
1	36	TOP	AF	Negative	No	
2	38	TOP	AF	Negative	Yes	IVF, PGT-A
3	23	IUFD	AF	Negative	No	
4	33	TOP	AF	Negative	No	
5	28	ND	CB	Negative	Yes	K, CMA
6	27	TOP	AF	Positive[c]	Yes	IVF, PGT-M
7	38	Living child	AF	Negative	Yes	cfDNA
8	26	TOP	AF	Negative	No	
9	25	TOP	AF	Negative	Yes	cfDNA
10	31	TOP	AF	Negative	No	
11	34	TOP	AF	Negative	No	
12	26	ND	AF	Negative	Yes	K, CMA
13	33	ND	AF	Negative	Yes	cfDNA
14	36	TOP	AF	Negative	Yes	K, CMA
15	34	TOP	AF	Negative	No	

[a]All included participants had incident pregnancy with fetal brain anomalies and/or multiple fetal anomalies.
[b]TOP= termination of pregnancy, AF = amniotic fluid, IUFD = intrauterine fetal demise, ND = neonatal demise, CB = cord blood
[c]Positive results included biallelic pathogenic variants in *ROBO1* that explained the fetal phenotype, maternally and paternally inherited

Figure 1. Key Themes and Exemplary Quotations

"Knowledge is Power"
"We really were searching for answers to what happened with our son…. also, you know, if we were going to try again…. this was kind of a cornerstone of whether we were going to try again, because if it came back with anything, we both said we're not going to do this again. We're not trying again. ***Participant 8***
"[talking about t-ES]…we just jumped in and said, "Okay, if you can find a risk for something, it's better to know than not know." ***Participant 6***
"Whiplash"
"It was such a weird feeling because I was so relieved for [living child], but then I was so mad that I had no answers why that happened to [incident pregnancy]. I wanted it to be something like that we could look at and point to and be like, This is what happened in his genetic sequencing, or in his DNA, or like, whatever that caused this, but there was none of that…It was very weird, because I was, obviously, really happy because I wouldn't have to worry about it with [living child]….But I was angry that we didn't have answers. ***Participant 9***
"I was also surprised, because I don't know, that was such a major diagnosis for him. And I just felt it, you know, the results. And what we went through did not match in my head." ***Participant 8***
"Confidence Moving Forward"
"[t-ES] was positive…I wanted that information. It ended up being good information. And I don't feel like I'd be confident going forward without that information." ***Participant 10***
"I remember getting the results saying that there was nothing that was found…And I remember feeling almost relieved knowing that this probably will not happen to me again…I was ten weeks pregnant with my son at the time." ***Participant 13***
"Value of Genetic Counseling"
"we sat down with the genetic counselor… and they took their time and explained it [t-ES results] to us… and based on that we decided to do the initial testing of the embryo and the NIPT [in subsequent pregnancy]. ***Participant 2***
"with genetic counseling, like…I really felt very well taken care of …[the genetic counselor] reached out a couple times through the portal…" ***Participant 1, discussing adapting testing results and future pregnancy decisions***

136 | Effect of Gestational Diabetes on Neonatal and Delivery Outcomes Across Race and Ethnicity

Ashley Zimmermann[1]; Natalie Suder[2]; Rachel Kim[3]; Karen Huang[3]; Maria Teresa Benedetto[2]; Mio Sawai[2]; Teresa Cheon[2]; Yuzuru Anzai[2]
[1]Northwell Lenox Hill Hospital, New York, NY; [2]Lenox Hill Hospital, NY; [3]University of Chicago, Chicago, IL

10:30 AM - 12:30 PM

Objective: This study aims to evaluate the impact of gestational diabetes mellitus (GDM) on neonatal and delivery outcomes across different races and ethnicities, providing a comprehensive understanding of GDM and the influences it has on neonatal health across diverse populations.

Study Design: A retrospective analysis was conducted using CDC natality data from 2016 to 2022. The study group comprised pregnant individuals with gestational diabetes across Non-Hispanic (NH) White, NH Black, NH Asian, and Hispanic mothers with gestational age range of 37 to 42 weeks and infant birth weight (BW) range of < 5,000 grams (n = 1,535,308). GDM prevalence was measured in each race and ethnicity. Primary outcome measures included neonatal intensive care unit (NICU) admission rates, assisted ventilation (AV) usage, large for gestational age (LGA) (> = 4000 g), average infant BW, low five-minute APGAR scores (< = 6), and C-section rate. Descriptive analysis and multinomial logistic regression analysis were done using SPSS to calculate adjusted odds ratios (aOR) and 95% confidence intervals.

Results: NH Asian individuals have the highest prevalence of GDM, whereas NH Black individuals have the lowest (Table 1). Unlike other groups, NH Asians with GDM have lower average infant BW than those without GDM. GDM has the greatest impact on NICU admission, AV usage, C-section rate, and LGA rate in the NH Black population.

Conclusion: While GDM significantly increases the risk of various neonatal and delivery outcomes across all races and ethnicities, the extent to which it affects each population differs. NH Black individuals, who have the lowest overall prevalence of GDM and baseline birth weight compared to other populations, face the highest risk of adverse outcomes, particularly for LGA infants. On the contrary, despite the high prevalence of GDM, outcomes among Asian mothers were comparable to White race. Physicians should consider these racial and ethnic differences when managing GDM and the associated risks. Limitations of this study include potential error biases from using CDC birth certificate data.

137 | Construction of a Predictive Model to Determine Probability of Low Birth Weight Using Machine Learning

Rachel Kim[1]; Karen Huang[1]; Ashley Zimmermann[2]; Natalie Suder[3]; Maria Teresa Benedetto[3]; Mio Sawai[3]; Teresa Cheon[3]; Yuzuru Anzai[3]
[1]University of Chicago, Chicago, IL; [2]Northwell Lenox Hill Hospital, New York, NY; [3]Lenox Hill Hospital, NY

10:30 AM - 12:30 PM

Objective: Low birth weight (LBW) is classified as weight of less than 2,500 grams after birth. Identifying LBW is crucial due to its association with high-risk neonatal outcomes. This study aims to predict the probability of LBW for full term (37 week) neonates using maternal and pregnancy characteristics as well as the expected fetal weight (EFW) at 30 weeks.

Study Design: CDC natality data from 2022 was used to select maternal, neonatal, and pregnancy factors associated with infant birth weight. Maternal factors included: BMI, age, height, race, weight gain during pregnancy, gestational diabetes, gestational hypertension, plurality, cigarette use, and pre-pregnancy diabetes. Pregnancy and neonate-related characteristics included: infant sex, gestational age, and total birth order. The birth weights for infants delivered at 37 weeks of gestational age from this database were used and unknown parameters were excluded (n = 439,251). The EFWs at 30 weeks for these neonates were computed using Hadlock's EFW curves at the 10th and 90th percentiles. A least squares logistic regression model was generated using

Google Colab to predict the probability of LBW given all the characteristics and EFW at 30 weeks. The model used an 80:20 split for testing and training, respectively, for validation purposes.
Results: The model performed with an accuracy of 94.3%. The positive predictive value (PPV) was 93.4% and the negative predictive value (NPV) was 95.2%. Sensitivity was 95.3% and specificity was 93.3%. The area under the curve (AUC) score was 98.7% (Graph 1).
Conclusion: The high accuracy, NPV, PPV, sensitivity, specificity, and AUC score of the model attest to its predictive strength. Moreover, the model was trained using a large, national dataset, demonstrating its applicability. Physicians can incorporate machine-based learning models in quantifying the risk of LBW during the earlier stages of the third trimester. Further model developments can include modeling based on earlier EFWs (< 30 weeks) to provide specialized prenatal care for those who are at higher risk for LBW.

138 | Impact of Interpregnancy Interval on Adverse Pregnancy Outcomes in Individuals with Prior Gestational Diabetes Mellitus

Ava D. Mandelbaum; Bharti Garg; Megha Arora; Aaron B. Caughey
Oregon Health & Science University, Portland, OR

10:30 AM - 12:30 PM

Objective: Interpregnancy interval (IPI) has been shown to influence perinatal outcomes, yet its impact on individuals with prior gestational diabetes mellitus (GDM) remains under-explored. This study aims to evaluate the impact of IPI on pregnancy outcomes in patients with a history of GDM.
Study Design: This retrospective cohort study analyzed singleton, non-anomalous births in two consecutive deliveries among patients with a history of GDM in the index pregnancy in California (2008-2020). IPI was categorized into five groups: < 12, 12-23, 24-35, 36-59, and ≥ 60 months. Outcomes for the subsequent pregnancy included GDM, gestational hypertension, preeclampsia, preterm delivery < 37 weeks, cesarean delivery, severe maternal morbidity (SMM), macrosomia, and NICU admission. Chi-squared and multivariable logistic regressions were used for statistical analyses.
Results: Among 63,746 patients in our final sample, 20.7%, 31.8%, 19.3%, 18.4%, and 9.9% were classified in the < 12, 12-23, 24-35, 36-59, and ≥ 60-month IPI groups, respectively. Relative to the 12-23-month group, patients with IPI < 12 months had significantly higher proportions of preeclampsia (4.7% vs 4.3%), preterm delivery (8.5% vs 7.4%), macrosomia (16.2% vs 15.2%), and NICU admission (10.2% vs 9.3%) (Table 1). After adjustment, pregnancies with an IPI < 12 months remained associated only with preterm delivery (aOR 1.12, 95% CI 1.03-1.21) relative to an IPI of 12-23 months (Table 2). Conversely, compared to 12-23 months, an IPI ≥ 60 months was associated with higher rates and odds of gestational hypertension (aOR 1.46, 95% CI 1.30-1.65), preeclampsia (aOR 1.65, 95% CI 1.47-1.86), preterm delivery (aOR 1.63, 95% CI 1.48-1.79), cesarean delivery (aOR 1.58, 95% CI 1.42-1.75), and NICU admission (aOR 1.26, 95% CI 1.15-1.38).
Conclusion: Both short (< 12 months) and long (≥ 60 months) IPIs are associated with adverse perinatal outcomes among patients with GDM. These findings highlight the importance of counseling individuals with GDM on optimal pregnancy timing to mitigate risks in subsequent pregnancies.

139 | Association of Interpregnancy Interval on Obstetric Outcomes Among Patients with a History of Preeclampsia

Ava D. Mandelbaum; Bharti Garg; Megha Arora; Aaron B. Caughey
Oregon Health & Science University, Portland, OR

10:30 AM - 12:30 PM

Objective: Preeclampsia is associated with significant maternal morbidity, yet the impact of interpregnancy interval (IPI) on perinatal outcomes for subsequent pregnancies in these patients remains unclear. We aimed to evaluate the association of IPI with pregnancy outcomes in patients with a history of preeclampsia.

Study Design: This retrospective cohort study analyzed singleton, non-anomalous births in two consecutive deliveries among individuals with a history of preeclampsia in the index pregnancy in California (2008-2020). IPI was categorized into five groups: < 12, 12-23, 24-35, 36-59, and ≥ 60 months. Outcomes for the subsequent pregnancy included gestational hypertension, preeclampsia, preterm delivery, cesarean delivery, and severe maternal morbidity (SMM). Chi-squared and multivariable logistic regressions were used for statistical analyses.

Results: Our final sample included 36,435 patients with a history of preeclampsia in an index pregnancy. Among this group, 7,494 (20.6%), 10,827 (29.7%), 6,761 (18.6%), 6,918 (19.0%), and 4,435 (12.2%) individuals were classified in the < 12, 12-23, 24-35, 36-59, and ≥ 60-month IPI groups, respectively. Relative to the 12-23-month group, an IPI of < 12 months was significantly associated with gestational hypertension (10.5% vs 10.0%; aOR = 1.12, 95% CI 1.02-1.24) and preterm delivery (10.9% vs 9.1%; aOR = 1.16, 95% CI 1.05-1.28) (Table 1-2). Compared to 12-23 months, an IPI ≥ 60 months was linked to gestational hypertension (11.2% vs 10.0%; aOR = 1.17, 95% CI 1.04-1.31), preterm delivery (15.8% vs 9.1%; aOR = 1.72, 95% CI 1.54-1.91), cesarean delivery (17.3% vs 10.2%; aOR = 1.73, 95% CI 1.51-1.99), and SMM (2.3% vs 1.5%; aOR = 1.43, 95% CI 1.10-1.86).

Conclusion: This study demonstrates that short (< 12 months) and long (≥ 60 months) IPIs are associated with increased risks of adverse perinatal outcomes in patients with a history of preeclampsia. These findings may inform preconception counseling and tailored care plans to optimize maternal outcomes in this high-risk population.

140 | Continuous Glucose Monitoring (CGM) with Poor Glycemic Control Correlates to Increased Risk of Preterm Birth/Preeclampsia

Ayesha Hasan[1]; Lauren LaRocca[1]; William E. Ackerman, IV[2]
[1]University of Illinois at Chicago, Chicago, IL; [2]University of Illinois at Chicago, College of Medicine, Chicago, IL

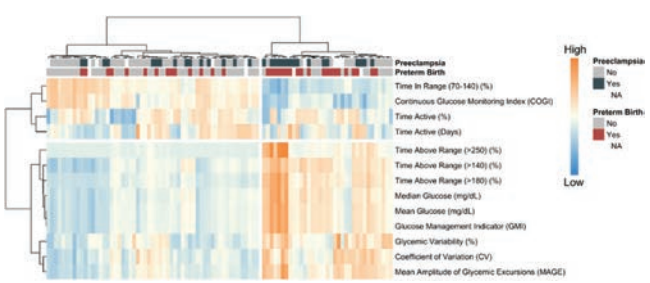
10:30 AM - 12:30 PM

Objective: We evaluated the association between glycemic control derived from CGM in patients with diabetes and the risk of adverse maternal/neonatal outcomes.

Study Design: We performed a retrospective cohort study of pregnant people with gestational and pregestational diabetes using CGM, who received care in a university-based MFM practice and delivered between July 2020 to December 2022, to evaluate the association between glycemic control and maternal/neonatal outcomes. CGM data was downloaded from the proprietary website and analyzed using a modified version of the iglu package using R. Maternal and neonatal demographic and pregnancy outcomes were abstracted from the EMR. Multivariable logistic regression was used to evaluate the relationship between glycemic control with maternal/neonatal outcomes.

Results: We evaluated 92 pregnancy episodes. HgbA1c was negatively correlated with time in range, composite glucose index and gestational age at delivery. HgbA1c was positively correlated with time above range, median glucose, GMI (vector of glucose measurement) and mean amplitude of glycemic excursion. Given high multicollinearity among CGM indices (VIF >24), we focused on GMI as a predictor. In simple logistic regression models, GMI was not significantly associated with: NICU admission (p = 0.23), LGA infants (p = 0.54), or SGA infants (p = 0.29). However, GMI was associated with PTB< 37w (OR 5.67, p < 0.002) and preeclampsia (OR 4.07, p < 0.005). In multivariable logistic regression models, GMI remained a significant predictor of PTB< 37w (aOR 5.50, 95% CI, 1.47-20.59, p < 0.02) and preeclampsia (aOR 3.56, 95% CI, 1.20-10.58, p < 0.03). Among the 34 preterm births noted in our cohort, 58.8% were noted to be iatrogenic and 41.2% were spontaneous.

Conclusion: We found that worsening glycemia in pregnancy was correlated with an increased risk of spontaneous and iatrogenic PTB and preeclampsia. Use of CGM in pregnancy has the potential to revolutionize diabetes care to provide a unique tool for patient education and targeted adjustments in medication therapy but more research is required to guide clinicians in its use.



141 | Preeclampsia-Like Features Induced by Reduced Uteroplacental Perfusion in a Transgenic Mouse Model of Alzheimer's Disease

Bani Medegan Fagla; Cielo Dela Rosa; Savita Sundar; Erykah Walton; Jason York; Guomao Zhao; Aswathi Jayaram; Leon M. Tai; Irina A. Buhimschi
University of Illinois at Chicago, College of Medicine, Chicago, IL

10:30 AM - 12:30 PM

Objective: Animal models that recapitulate preeclampsia (PE)-like features can greatly facilitate studies of PE mechanism. One such model, the reduced uteroplacental perfusion pressure (RUPP), was originally optimized in Sprague-Dawley rats. However, the advancement of genetically modified mice has led researchers to search for murine models where relationships between genes and disease phenotypes can be specifically studied. We aimed to optimize the RUPP procedure in *5xFAD*$^{+/-}$*/APOE*-TR$^{+/+}$ (EFAD) mice, a humanized transgenic mouse model of Alzheimer's disease and to compare the presence and severity of PE-like features to wild-type (WT) mice.

Study Design: 2-4 month old timed pregnant WT and EFAD C57/BL6J mice underwent RUPP on (GD)13.5 by bilateral ligation of ovarian vessels. Animals were sacrificed on GD17.5, for tissue harvest and assessment of PE endpoints: mean arterial pressure (MAP), albumin/creatinine ratio, serum sFlt-1/PlGF-2 ratio, kidney and placental morphology, fetal weights and placental efficiency (placental/fetal weight ratio). Pilot experiments assessing PE endpoints on GD18.5 resulted in fetal death of ~60% of RUPP mice. Control mice underwent sham procedures where ovarian vessels were not ligated. Data from n = 6-13 mice per group was tested for normality and analyzed by parametric statistics.

Results: **1)** RUPP resulted in a significant increase in MAP in WT ($p = 0.006$) but not in EFAD mice; **2)** RUPP did not increase the albumin/creatinine or sFlt-1/PlGF-2 ratios in either WT or EFAD mice; **3)** RUPP mice had discernable changes in kidney morphology consistent with kidney injury independent of genotype; **4)** RUPP decreased placental efficiency in EFAD ($p = 0.003$) but not in WT mice.

Conclusion: The extent to which RUPP mimics different PE-endpoints varies with mouse genetic background. Unlike WT mice, EFAD mice remain normotensive following RUPP, yet they have increased susceptibility to placental insufficiency; an observation with relevance to the heterogeneity of clinical manifestations comprising the PE syndrome.

142 | Outpatient Mangement Protocol for Preterm Premature Rupture of Membranes Before 34 Weeks

BARROIS Mathilde[1]; Seyral Antonin[1]; Aude Girault[2]; Francois Goffinet[3]; Camille Le Ray[4]
[1]*Port Royal Maternity Unit Cochin Hospital, Paris, Ile-de-France;* [2]*FHU PREMA, Paris, France. FHU PREMA, Paris, France; Université Paris Cité, Inserm, Centre for Research in Epidemiology and StatisticS (CRESS), Obstetrical Perinatal and Pediatric Epidemiology Research Team (EPOPé), Paris, France., Paris, Ile-de-France;* [3]*Université Paris Cité, Inserm, Centre for Research in Epidemiology and StatisticS (CRESS), Obstetrical Perinatal and Pediatric Epidemiology Research Team (EPOPé), Paris, Ile-de-France;* [4]*INSERM UMR 1153, Obstetrical, Perinatal and Pediatric Epidemiology Research Team (Epopé), Center for Epidemiology and Statistics, FHU PREMA, Université de Paris, Paris, Ile-de-France*

10:30 AM - 12:30 PM

Objective: In cases of preterm premature rupture of membranes (PPROM), expectant management is preferred to reduce neonatal morbidity when no infection is present. While monitoring has traditionally been done through hospitalization, outpatient management (OM) is now an option, though selection criteria remain unclear. This study aims to compare obstetric and neonatal outcomes before and after the implementation and modification of a OM protocol for PPROM patients introduced in April 2013.

Study Design: We included all patients with PPROM before 34 weeks, admitted from January 1, 2011, to December 31, 2021. Patients were divided into two groups: Period A, where all were hospitalized until delivery, and Period B, where eligible patients were monitored at home (OM). Periods B1 to B3 reflect successive modifications of the OM protocol (Figure 1).

The primary outcome was the latency period, defined as the duration in days between PPROM and delivery. Secondary outcomes included obstetric and neonatal outcomes. Obstetric and neonatal outcomes were compared between periods A and B, and further analyzed among OM patients across periods B1 to B3

Results: During Period A, 145 patients were included, and 394 in Period B, of whom 126 (32%) received OM. Gestational age at PPROM was comparable between the periods (28.9 weeks ±3.1 vs. 28.9 weeks ±3.32, $p = 0.94$), as were the latency period (13.9 ±19.9 days vs. 14.5 ± 16.8, $p = 0.77$) and gestational age at delivery (30.8 ±3.26 weeks vs. 30.9 ±3.77, $p = 0.62$). Early neonatal bacterial infections were significantly lower in Period B (42% vs. 31%; $p = 0.018$), as was the rate of intraventricular hemorrhage (24% vs. 6.2%; $p < 0.01$). OM use increased from B1 to B3 due to relaxed eligibility criteria, with no significant change in the latency period (Table).

Conclusion: After the OM protocol was implemented, one-third of patients benefited from home monitoring, with usage increasing over time. In PPROM cases, HCM, even with broad eligibility criteria, does not appear to extend the latency period but may reduce neonatal morbidity.

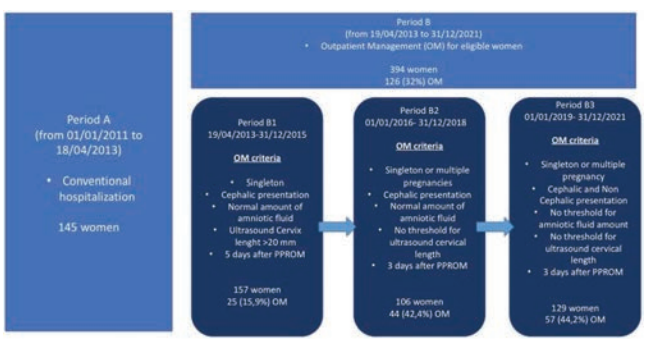


Table : OM patients issues

OM patients issue	Period B1 n = 25 n (%) Moy +/- SD	Period B2 n = 44 n (%) Moy +/- SD	Period B3 n = 57 n (%) Moy +/- SD	p
Initial hospitalization duration	8,44 +/- 7,43	7,29 +/- 4,91	6,60 +/- 2,83	0,88
Gestational age of HCM (weeks)	29.9 +/- 2.29	29.1 +/- 3.00	29.3 +/- 3.19	0,56
Latency period duration (days)	29,2 +/- 19,4	30,5 +/- 20,8	28,6 +/- 16,7	0,99
Term of delivery (weeks)	33.2 +/- 3.13	32.9 +/- 3.40	32.2 +/- 3.45	0,39

143 | Normal Blood Pressure Standard Across Gestation in Low-Risk Pregnant Individuals and Comparisons by Pregnancy Outcome

Beth L. Pineles[1]; Lisa D. Levine[2]; Jennifer Lewey[2]; Katherine L. Grantz[3]; Nehemiah Weldeab[4]; Jesse Chittams[4]; Markolline Forkpa[5]; Stefanie N. Hinkle[2]
[1]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [3]Epidemiology Branch, NICHD-NIH, Bethesda, MD; [4]University of Pennsylvania School of Nursing, Philadelphia, PA; [5]Pennsylvania Medicine Women's Health Clinical Research Center, Philadelphia, PA

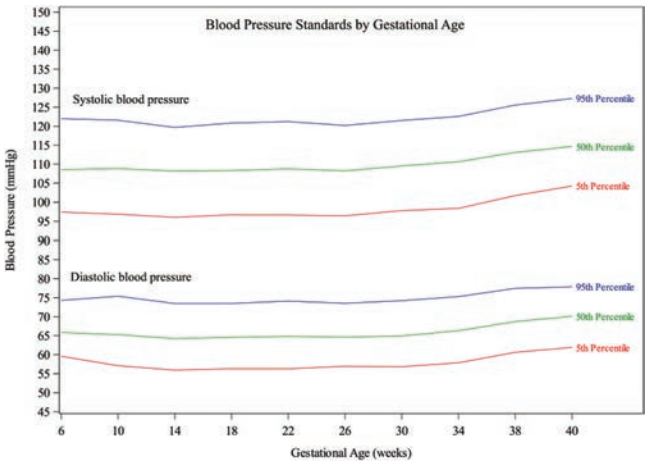
10:30 AM - 12:30 PM

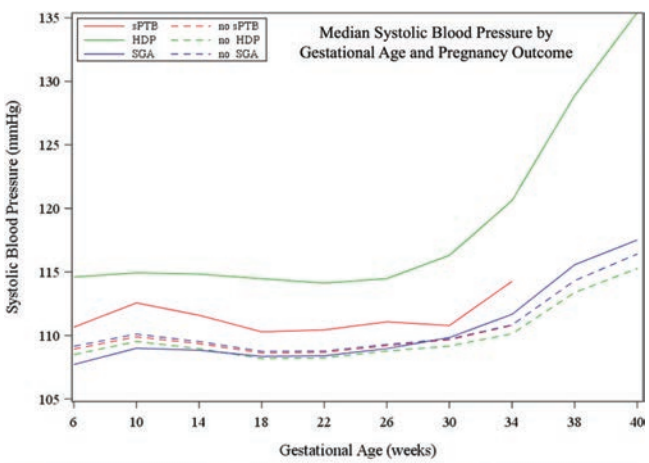
Objective: Nearly 50 years ago, mean blood pressure (BP) in 6,662 white pregnant women was reported to vary by gestational age, but the upper and lower limits of normal across gestation have not been defined. Our objectives were to create a BP standard based on the gestational age-specific BP in low-risk pregnant people, and to compare BP trajectories between those with and without hypertensive disorders of pregnancy (HDP; gestational hypertension or preeclampsia), spontaneous preterm delivery (sPTD), or small-for-gestational age neonates (SGA).

Study Design: This was a secondary analysis of 2334 low-risk, singleton pregnancies from 2009-2013 that were a part of a prospective NICHD cohort of individuals 18-40 years without medical conditions or prior pregnancy complications; BMI 19.0-29.9 kg/m2. Linear mixed models with cubic splines were used to estimate systolic and diastolic BP curves, based on BP abstracted from prenatal records. Likelihood ratio tests compared curves between pregnancies with HDP, sPTD, or SGA (< 10%ile based on Duryea reference) vs. those without these outcomes, adjusting for confounders.

Results: There were 2278 pregnancies included in the standard with a mean of 11 measurements (standard deviation [SD] 3). The mean maternal age was 28.2y (SD 5.5), gestational age at delivery 38.8wk (SD 1.7), and 49% were nulliparous. Participants were 28% Hispanic, 26% non-Hispanic (NH) Black, 26% NH white, and 20% NH Asian. HDP occurred in 123 (6%), sPTD in 90 (4%), and SGA in 191 (9%). BPs were lower and varied less with gestation than reported in the prior study, with standard curves shown in Figure 1. As early as at 6-8 weeks, BPs were significantly higher in those who ultimately developed HDP and sPTB compared to those who did not (p values < 0.05, Figure 2).

Conclusion: In a diverse, contemporary cohort, we established normative BP curves and trends for pregnancy. Additionally, early first-trimester BPs are higher for those destined to have HDP or sPTB. Future studies should evaluate whether deviation of BP trajectories is an opportunity for early intervention to decrease risks of HDP and sPTB.





sPTB, spontaneous preterm birth; HDP, hypertensive disease of pregnancy; SGA, small-for-gestational age

144 | Influence of the Solomon Technique in TTTS on Survival and Abruption–Temporal Or Causal?

Bettina Paek; Melissa Dorn; Martin Walker
Seattle Children's Hospital, Seattle, WA

10:30 AM - 12:30 PM

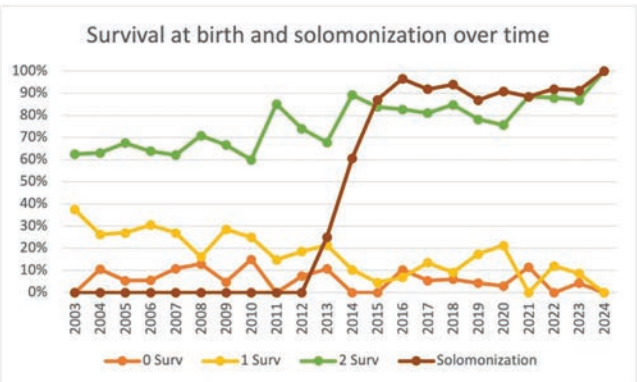
Objective: The fetoscopic laser Solomon technique (FLS) for treatment of Twin-Twin Transfusion Syndrome (TTTS) has been associated with an increased risk of placental abruption while also improving neonatal survival when compared to standard fetoscopic laser (FL). We aimed to determine the impact of implementation of FLS on neonatal survival and placental abruption.

Study Design: We conducted a single center retrospective study of patients with mo-di twins undergoing Fl or FLS from 2003-2024. We used logistic regression, interrupted time series, and non-parametric analysis to determine the impact of adoption of FLS on neonatal survival and placental abruption.

Results: Between 2003-2024, 584 mo-di twins underwent laser for the treatment of TTTS and had information on abruption status and neonatal outcomes available. FLS was adopted between 2013-2014. Patients undergoing FLS had improved chances of dual

survival (84% vs 69%, p < 0.001) and an increased risk of abruption (15% vs 5%, p = 0.027). There was no association between gestational age at surgery, placental position, number of anastomoses ablated or total fetoscopy time and risk of subsequent abruption. However, survival showed a significant incremental improvement throughout the study period with dual survival (annual means) increasing from 63% to 88% for the last year that full data were available (p = 0.02) and single survival decreasing from 38% to 9% (P = 0.01). The frequency of no survivors ranged from 0-12% and did not change significantly over time. The rate of TAPS requiring treatment was low (< 2%) pre and post adoption of FLS. Similarly, the rate of abruption increased starting early in the study period with a marginally significant decrease of the slope after adoption of FLS.

Conclusion: While both survival and abruption increased during the study period, this increase predated the adoption of FLS. This raises the question of causal attribution to FLS versus other factors, such as operator experience or more extensive use of laser. A randomized trial may be required to assess the true impact of FLS on obstetric and neonatal outcomes.



145 | Maternal Laparotomy to Fetoscopic MMC Repair in the Morbidly Obese is Safe and Feasible

Braxton Forde[1]; K. Schuyler Nissen[1]; Charles Stevenson[2]; Foong-Yen Lim[3]; Mounira Habli[2]; David McKinney[1]; Erinn Goetz[2]; Jose L. Peiro[4]

[1]University of Cincinnati College of Medicine, Cincinnati, OH; [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [3]Cincinnati Children's Hospital, Cincinatti, OH; [4]Cincinnati Children's Fetal Care Center, Cincinnati, OH

10:30 AM - 12:30 PM

Objective: The Management of Myelomeningocele Study (MOMS) delineated inclusion and exclusion criteria for in utero myelomeningocele (MMC) repair. One exclusion was maternal BMI > 35 kg/m. Our institution expanded the criteria to include body mass index (BMI) up to 39.99. Concerns have been raised regarding fetoscopic MMC repair and the prolonged operative time in the morbidly obese, therefore, we sought to evaluate the outcomes of fetoscopic MMC repair in the setting of BMI ≥ 35 at the time of surgery.

Study Design: This was an IRB-approved, single institution study from 2016-2024. Inclusion criteria were any patients that underwent fetoscopic repair at our institution that had a BMI of at least 35.0 on the date of surgery. These patients all had a midline laparotomy to 3 port fetoscopic MMC repair (Figure 1). All patients underwent 3-layer closure, with 2 overlapping human umbilical cord matrix patches and either primary skin closure or skin patch placement. Outcomes assessed were operative time, gestational age at delivery, route of delivery, need for cerebrospinal fluid (CSF) diversion at 12 months, and postoperative complications.

Results: During study window, 92 patients underwent maternal laparotomy to fetoscopic MMC repair. Of those 92, 19 had a BMI ≥ 35 as documented in the medical record at the date of surgery. The median gestational age at surgery was 25 2/7 weeks (IQR 24 6/7, 25 5/7), median gestational age at delivery was 35 3/7 weeks (IQR 34 1/7, 36 5/7), and CSF diversion rate at 12 months was 31.3%, which were similar to better than outcomes with BMI < 35 (Table 1). The rate of vaginal delivery was 42%, also similar to those with BMI < 35. Interestingly, total OR time was no different with respect to BMI (OR time 255 min, IQR 235.5, 294 in BMI ≥ 35 vs 251, IQR 230, 297 in BMI < 35, p = 0.707).

Conclusion: Maternal BMI 35-< 40 did not negatively affect the pregnancy or postoperative outcomes in the setting of fetoscopic MMC repair. Further evaluation of fetoscopic MMC outcomes in the setting of maternal BMI of 40-45 may be warranted.

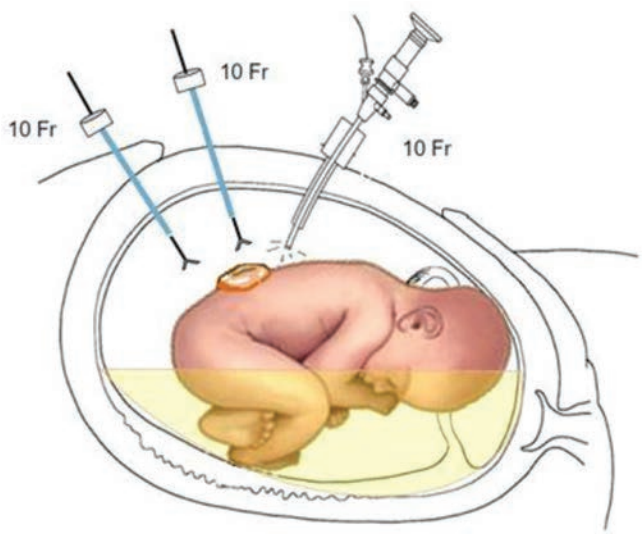


Table 1. Comparison between Fetoscopic MMC repair in the setting of BMI ≥ 35 and < 35.

	BMI ≥ 35 kg/m N = 19	BMI < 35 kg/m N = 73	p

146 | TTTS + sFGR + TAPS: Does "Triple Disease" Lead to Worse Outcomes in TTTS?

Braxton Forde[1]; Mounira Habli[2]; David McKinney[1]; Kara B. Markham[1]; Mallory Hoffman[3]; Jose L. Peiro[4]; Beth Rymeski[2]; Laura Galganski[2]; Foong-Yen Lim[5]
[1]University of Cincinnati College of Medicine, Cincinnati, OH; [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [3]Trihealth, Cincinnati, OH; [4]Cincinnati Children's Fetal Care Center, Cincinnati, OH; [5]Cincinnati Children's Hospital, Cincinatti, OH

10:30 AM - 12:30 PM

Objective: Twin-twin transfusion syndrome (TTTS) is often diagnosed with selective fetal growth restriction (sFGR). Concomitant TTTS + sFGR is believed to worsen outcomes, but the impact of TAPS upon TTTS + sFGR, i.e. "triple disease," is unknown. Thus we sought to evaluate these patients' outcomes relative to the TTTS and TTTS + sFGR populations.

Study Design: IRB-approved retrospective cohort at a single institution from 2011-2024. Inclusion criteria were patients who underwent fetoscopic laser photocoagulation (FLP) for monochorionic twins and had both middle cerebral artery peak systolic velocity (MCA-PSV) and estimated fetal weight (EFW) calculated by ultrasound. Three groups were analyzed: TTTS alone, TTTS + sFGR, and TTTS + sFGR + TAPS. sFGR was defined by ≥2 of the following: EFW or abdominal circumference (AC) of one twin < 10th percentile, EFW discordance of ≥25%, or umbilical artery pulsatility index of the smaller twin >95th percentile. TAPS was defined by an MCA-PSV delta >0.5 between the twins. Preoperative, operative, and postoperative characteristics were compared, with primary outcomes being fetal survivorship and gestational age at delivery.

Results: Out of 942 patients who underwent FLP, 780 met study criteria: 392 with TTTS, 296 with TTTS + sFGR, and 92 with TTTS + sFGR + TAPS. The TTTS + sFGR + TAPS group had a later gestational age at surgery and higher rates of Stage IV disease (Table 1). Outcomes varied significantly between groups. Fetal survival (i.e. live birth) of 2 infants was 88% for TTTS, 76% for TTTS + sFGR, and 68% for TTTS + sFGR + TAPS (p < 0.001). The gestational age at delivery was latest in the TTTS + sFGR + TAPS group (mean 33.1 weeks, 95% CI 32.4-33.8) compared to TTTS alone (30.1 weeks, 95% CI 29.8-30.4, p < 0.001). This later age correlated with higher birthweights for both donors and recipients (Figure 1). Donor birthweight was lowest in the TTTS + sFGR group (Table 1).

Conclusion: TTTS + sFGR + TAPS is associated with worse survival but longer pregnancy duration compared to TTTS + sFGR and TTTS alone. This information is valuable for preoperative counseling.

*Delivery information only available for 375, 284, and 91 patients, respectively amongst groups.
Fetal survival is defined as a livebirth of a vigorous infant.
Data is presented as mean (95% CI) or N (%) unless noted otherwise. GA = gestational age, PPROM = preterm prelabor rupture of membranes

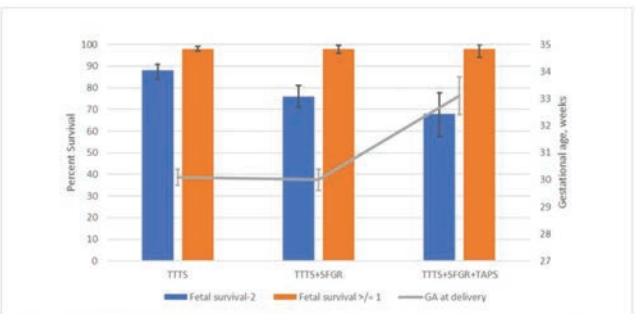

Figure 1. Fetal survival and gestational age at delivery stratified by diagnoses.
The left Y axis is the percent survival of either 2, or at least 1 fetuses, represented by the bar graph, and the right Y axis is the gestational age at delivery in weeks, represented by the line graph. Data is presented as Percent +/- 95th CI, or Mean +/- 95th CI.

147 | Outcomes of Maternal Alloimmunization with Multiple Antibodies Compared to a Single Antibody

Brittany J. Arkerson[1]; Faezeh Aghajani[2]; Evelyn McGuire[3]; Katherine Modrall[3]; Lucy Salter[3]; Anthony L. Shanks[3]; Hiba J. Mustafa[4]
[1]Indiana University, Indianapolis, IN; [2]Maternal Fetal Care Center, Division of Fetal Medicine and Surgery, Boston Children's Hospital and Harvard School of Medicine, Boston, MA; [3]Indiana University School of Medicine, Indianapolis, IN; [4]Indiana University and Riley Children's Hospital, Indianapolis, IN

10:30 AM - 12:30 PM

Objective: To investigate outcomes related to the presence of multiple alloantibodies compared to a single antibody.

Study Design: A single-center retrospective cohort study of alloimmunized singleton gestations with antibodies known to be associated with hemolytic disease of the fetus and newborn (HDFN) from 2018 to 2023. We excluded pregnancies if the fetus was determined to be not at risk for HDFN either by negative paternal genotyping or negative invasive diagnostic testing. Multiple gestations were excluded as well. Univariate and multivariate analyses were performed. P-value < 0.05 was considered statistically significant.

Results: 166 alloimmunized pregnancies were identified during the study period. Patients with multiple antibodies were more likely to have had an intrauterine transfusion (IUT) in a previous pregnancy (20% vs. 0.8%, $p < 0.001$) and were more likely to be with anti-D. 64% of patients had antibody titers drawn early in pregnancy. This titer was higher in patients with multiple antibodies (254.5 ± 325.8 vs. 19.48 ± 51.1, $p = 0.007$) despite being collected at around the same gestational age (10.97 ± 3.3 vs. 10.35 ± 2.7, $p = 0.39$). Patients with multiple antibodies reached a higher maximum titer during pregnancy (381.6 ± 431.4 vs. 40.56 ± 92.2, $p = 0.004$) and were more likely to undergo middle cerebral artery (MCA) Dopplers (93.3% vs. 59.8%) that was started at an earlier gestational age (25.6 ± 4.6 vs. 29.8 ± 6.3, $p = 0.02$). They were also more likely to need IUT (80% vs. 34.3%, $p = 0.005$) that was both earlier and more frequent(3.6 ± 1.3 vs. 1.9 ± 1, $p = 0.003$) and to deliver at an earlier gestational age (34.7 ± 5.4 vs. 36.7 ± 2.6, $p = 0.01$).

Conclusion: Patients with alloimmunization involving multiple antibodies rather than a single antibody are more likely to have critical antibody titers, require early MCA Dopplers, develop HDFN requiring IUT procedures that were more commonly early and multiple, and deliver at an earlier gestational age.

Table 1: Alloimmunization diagnostic and antenatal monitoring characteristics

		1 antibody (n=136)	≥2 antibodies (n=30)	P-Value

148 | Differences in Risk Factors for Postpartum Hemorrhage in Obese and Non-Obese Patients

Bryce T. Munter[1]; Margaret T. Klausmeyer[2]; CeCe Cheng[3]; Claire D. Sundjaja[4]; Michaela Y. Lee[2]; Natasha Paul[2]; Nastassia Anna Yammine[2]; Patrick S. Ramsey[1]; John J. Byrne[4]
[1]University of Texas Health Science Center San Antonio, San Antonio, TX; [2]UTHSCSA, San Antonio, TX; [3]University of Washington, Seattle, WA; [4]University of Texas Health San Antonio, San Antonio, TX

10:30 AM - 12:30 PM

Objective: Several studies have noted an association between obesity and increased rates of postpartum hemorrhage. However, it is still unclear why this correlation exists. Our objective is to evaluate if there are differences in risk factors for postpartum hemorrhage between obese and non-obese pregnant patients.

Study Design: We conducted a retrospective cohort study of all patients who delivered at our level 4 maternal care hospital between August 1, 2020 and July 31, 2021. Records were reviewed for sociodemographic characteristics, pre-existing medical conditions, and whether they had a postpartum hemorrhage, defined as a quantitative blood loss (QBL) of > = 1000ml within the first 24 hours after delivery, based on ReVITALize criteria. Univariate logistic regression was then used to analyze known risk factors for postpartum hemorrhage in patients with BMI < $30 kg/m^2$ and BMI ≥ $30 kg/m^2$.

Results: A total of 693 patients delivered during the study period, of which 225 (32%) had BMI < 30 and 468 (68%) had BMI >30. Of note, 76% of our study population identified as Hispanic or LatinX. Risk factors differed between the two BMI groups.

Regardless of BMI, having a placental abnormality including placenta accreta spectrum was a risk factor for postpartum hemorrhage. Having vaginal bleeding or anemia on admission were only risk factors in the BMI < 30 group. Intraamniotic infection was only a risk factor in the BMI ≥ 30 group. All other variables listed here were not risk factors for postpartum hemorrhage in this cohort of patients.

Conclusion: In our primarily Hispanic cohort of pregnant patients, there are differences in risk factors for postpartum hemorrhage between obese and non-obese patients. This study may have been limited due to sample size. Further studies should utilize this information to create better models to predict postpartum hemorrhage.

149 | Associations Between H48/H0 β-HCG Ratio in the Fourth Gestation Week and Pregnancy Outcomes:A Retrospective Analysis

Cai Liu[1]; Kexin Wang[2]; Hui Yao[2]; Fang Wang[2]
[1]Lanzhou University Second Hospital, Lanzhou, Gansu; [2]Lanzhou University Second Hospital, Lanzhou University Second Hospital, Gansu

10:30 AM - 12:30 PM

Objective: Does an H48/H0 hCG ratio of pregnancy in the fourth gestation week associate with pregnancy outcomes in pregnancy loss patients? we aimed to investigate the correlations between hCG ratio and pregnancy outcomes in patients with a history of pregnancy loss.

Study Design: This is a retrospective cohort study, the receiver operator curves were plotted to determine the optimal cut-off for the pregnancy outcomes. The odds ratio was also calculated through univariable and multivariable analyses, with continuous variables categorized into binary categories based on the cut-off value.

Results: In total, 279 women ended with live birth and 79 with no live birth. A lower H48/H0 ratio of hCG in the fourth gestation week was an independent risk factor for no live birth ($p < 0.01$) and preterm birth ($p = 0.03$). The optimal value for predicting no live birth of H48/H0 is 1.85 (AUC = 0.717). For early pregnancy loss, the optimal value of H48/H0 is 1.85 (AUC = 0.711), and for biochemical pregnancy loss, it is 1.55 (AUC = 0.953). Compared to the live birth group, patients with a H48/H0 ratio < 1.85 exhibited a significantly higher risk of no live birth (OR: 9.54, 95% CI: 5.16-17.63). Similarly, individuals with a H48/H0 ratio < 1.55 faced an elevated risk of biochemical pregnancy loss (OR:603.0, 95% CI: 61.08-5953.14). A H48/H0 ratio (< 2.56) was associated with a tendency towards an increased risk of preterm birth (OR: 1.85, 95%CI:0.74-4.65).These odds ratio remained consistent even after adjusted by age, BMI, previous losses, initial hCG(H0), E2 and P.

Conclusion: Our study revealed that the H48/H0 ratio of hCG in the fourth gestation week of pregnancy might be correlated with both no live birth and preterm birth. Further prospective large studies are needed to confirm our findings.

150 | Subdividing Early Fetal Growth Restriction Based on Gestational Age at Diagnosis: Implications for Perinatal Management

Cammy Tang[1]; Diya Yang[1]; Katie Fioritto[2]; Giancarlo Mari[2]
[1]Case Western Reserve University, School of Medicine, Cleveland, OH; [2]University Hospitals, Cleveland, OH

10:30 AM - 12:30 PM

Objective: Two distinct phenotypes of fetal growth restriction (FGR) have been identified based on gestational age at diagnosis: early (< 32 weeks) and late (≥32 weeks), with different outcomes observed between these two categories, though this cutoff is debated. We hypothesized differences in early FGR outcomes based on the gestational age at diagnosis.

Study Design: To test our hypothesis, we conducted a retrospective cohort study on data extracted from our database on 334 women with singleton pregnancies diagnosed with FGR (fetal weight/AC below the 10th percentile). The 1st ultrasound was at less than 20 weeks' gestation. Patients were divided into four groups based on the gestational age at diagnosis: Group A (20.0-23.6 weeks), Group B (24.0-27.6 weeks), Group C (28.0-31.6 weeks), and Group D (≥32 weeks).

Outcome measures included:

1. Composite adverse perinatal outcomes (neonatal acidosis, Apgar score < 7 at 5 minutes, perinatal death, severe intraventricular hemorrhage, necrotizing enterocolitis, and respiratory distress requiring intubation)
2. Gestational age at delivery < 37 weeks
3. Mode of delivery

Chi-square, Fisher's exact test, and pairwise comparisons were used when appropriate, with a p-value < 0.05 indicating statistical significance.

Results: Group A had the highest number of deliveries at < 37 weeks (see Table); however, the difference was significant only when compared to Group D. Composite adverse perinatal outcomes decreased from Group A to Group D, with significant differences between Group A and Group C, and between Group A and Group D (see Figure). Although the cesarean delivery rate declined from Group A to Group D, this change was statistically significant only between Group A and Group D (see Figure).

Conclusion: Our results highlight the importance of subdividing early FGR by gestational age at diagnosis. This stratification aims to improve perinatal management and outcomes. Further research should focus on optimizing protocols for each FGR subgroup.

Table 1. Gestational age at delivery of the four FGR groups

	Group A GA at Diagnosis 20-23.6 weeks (n=40)	Group B GA at Diagnosis 24-27.6 weeks (n=45)	Group C GA at Diagnosis 28-31.6 weeks (n=92)	Group D GA at Diagnosis ≥32 weeks (n=157)	P-Value
Gestational Age at Delivery					
< 37 weeks	14 (35.0)	8 (17.8)	19 (20.7)	16 (10.2)	0.018

151 | Association Between Rural-to-Urban Obstetric Transport and Severe Maternal Morbidity and Neonatal Complications

Carly M. Dahl[1]; Lisa Pappas[1]; Marcela C. Smid[2]; Torri D. Metz[1]; Kaitlyn P. Casper[1]; Michelle P. Debbink[1]
[1]University of Utah, Salt Lake City, UT; [2]University of Utah Health, Salt Lake City, UT

10:30 AM - 12:30 PM

Objective: To compare the frequency of severe maternal morbidity (SMM) between obstetric transports from rural-to-urban counties (RTU) versus urban-to-urban (UTU) counties.

Study Design: Retrospective cohort study of pregnant individuals undergoing transport for delivery for maternal medical or fetal indications using National Vital Statistics System birth records from 2016-2021. Inclusion criteria were all individuals who underwent transport with available county level data. The primary exposure was maternal residence in a rural county (< 99 individuals per square mile). The primary outcome was SMM (ICU admission, uterine rupture, hysterectomy, and blood transfusion). The secondary outcome was a composite of neonatal complications. Maternal demographic, obstetric, and medical factors were assessed as potential covariates. We performed univariate and bivariate analyses using Chi-squared and Wilcoxon tests as appropriate. A multivariable generalized linear model was used to assess the association between rurality and outcomes.

Results: 117,050 obstetric transports occurred between 2016-2021 (0.52% of all births). Among people undergoing RTU transports, SMM was lower than UTU transports (3.4% versus 3.7%, p = 0.012). Neonatal complications were higher among RTU versus UTU transports (71.3% versus 63.6%, p = < 0.001). After adjusting for covariates, people undergoing RTU transports had 12% lower odds of SMM than UTU transports [aOR 0.88, 95% CI (0.81-0.95, p = 0.001)]. However, neonates born after RTU transports had 7% higher odds of neonatal morbidity [aOR 1.07, 95% CI (1.03-1.11, p < 0.001)] (Figure).

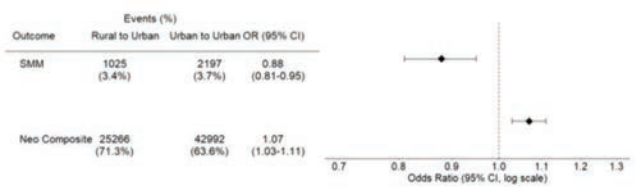
Conclusion: Pregnant people undergoing UTU obstetric transportation experience higher rates of SMM than RTU transports, which may reflect differences in threshold to transfer based on hospital capabilities. Neonatal complications are higher amongst RTU transports compared to UTU transports, indicating that RTU transports may be more likely to involve complications that affect neonatal safety.

Table: Maternal and Neonatal Outcomes Associated with RTU versus UTU Obstetric Transportation

Primary Outcome: Severe Maternal Morbidity (SMM)			
	Rural to Urban (RTU)	**Urban to Urban (UTU)**	**P value**
Singleton births	30092	58726	
SMM (%)	1025 (3.4)	2197 (3.7)	0.012
Maternal Transfusion (%)	549 (1.8)	1117 (1.9)	0.033
Ruptured Uterus (%)	36 (0.1)	62 (0.1)	0.039
Unplanned Hysterectomy (%)	110 (0.4)	176 (0.3)	0.012
Admission to Intensive Care Unit (%)	513 (1.7)	1287 (2.2)	<0.001
Secondary Outcome: Composite Neonatal Outcome			
	Rural to Urban (RTU)	**Urban to Urban (UTU)**	**P value**
All births	35447	67603	
Composite Neonatal Complications (%)	25266 (71.3)	42992 (63.6)	<0.001
Assisted Ventilation (>6 hrs) (%)	9055 (25.5)	15232 (22.5)	<0.001
Admission to NICU (%)	24493 (69.1)	41124 (60.8)	<0.001
Surfactant (%)	3911 (11.0)	6777 (10.0)	<0.001
Antibiotics (%)	7721 (21.8)	13848 (20.5)	<0.001
Seizures (%)	59 (0.2)	120 (0.2)	0.147
Infant Alive (%)	34487 (97.3)	65145 (96.4)	<0.001

NICU – neonatal intensive care unit; hrs – hours; Analyses assessing SMM were limited to singleton pregnancies to avoid double-counting; analyses assessing neonatal complications included all births and multifetal gestation as a covariate.

Figure: Maternal and Neonatal Outcomes of RTU versus UTU Obstetric Transports



OR – Odds Ratio, CI – Confidence Interval, Neo Composite – Neonatal Composite Outcome, SMM – Severe Maternal Morbidity; RTU – Rural to Urban; UTU – Urban to Urban; After adjusting for weekend birth, maternal age, marital status, maternal education level, parity, month prenatal care began, WIC, cigarette usage, BMI, prenatal diabetes, chorioamnionitis, trial of labor attempted (if cesarean), gestational age and type of insurance, the observed associations with rurality were significant. Delivery method, previous cesarean delivery, and gestational diabetes were dropped from the model due to collinearity.

152 | Obstetric Air Transportation in the Intermountain West: An Assessment of Quality Metrics

Carly M. Dahl[1]; Michelle P. Debbink[1]; Krista Haberstock[1]; Lisa Pappas[1]; Sunaya Wahi[1]; Torri D. Metz[1]; Marcela C. Smid[2]

[1]University of Utah, Salt Lake City, UT; [2]University of Utah Health, Salt Lake City, UT

10:30 AM - 12:30 PM

Objective: Obstetric transport is a critical service for high risk and rural patients and is largely understudied, especially with respect to quality metrics (QM) for common transport indications. We aimed to 1) describe obstetric transportation in the Intermountain West and 2) define and assess QM adequacy among individuals transported for the most common obstetric indications - preterm prelabor rupture of membranes (PPROM), preterm labor (PTL), and preeclampsia.

Study Design: This was a prospective cohort study of obstetric transports within a single tertiary institution with a perinatal transport service. Demographic, transport, and clinical factors were collected for all obstetric transports. Based on the Society of Maternal Fetal Medicine transport checklist, we defined QMs as recommended interventions during obstetric transport specific to PPROM, PTL, and preeclampsia. A priori, we defined QM adequacy as receipt of ≥ 75% of recommended interventions per indication. We compared QM adequacy across transport indications using Chi-squared analysis.

Results: Between July 2023-June 2024, 125 obstetric transports were performed, most frequently by rotor wing (70.4%), fixed wing (26.4%), and ambulance (3.2%). Transport distance on average was 226.1 miles (SD 186.5) (Figure 1). Mean gestational age at time of transportation was 31.1 weeks (SD 5.91). Most frequent indications for transport were preeclampsia (33.6%), PTL (27.2%), PPROM (15.2%), and fetal anomalies (13.6%). Most transported patients (88%) received medications peri-transport; 76.8% of patients received either antenatal corticosteroids, magnesium, a tocolytic, or antibiotics. QM adequacy did not differ by indication for transport (p = 0.265), and was most frequently met within transports for preterm labor (73.5%), followed by preeclampsia (71.4%), and PPROM (63.2%) (Figure 2).

Conclusion: Obstetric transport in the Intermountain West relies primarily on air given the large geographic catchment. QMs specific to obstetric transport were not always met, and may provide valuable quality benchmarks to identify areas for improvement.

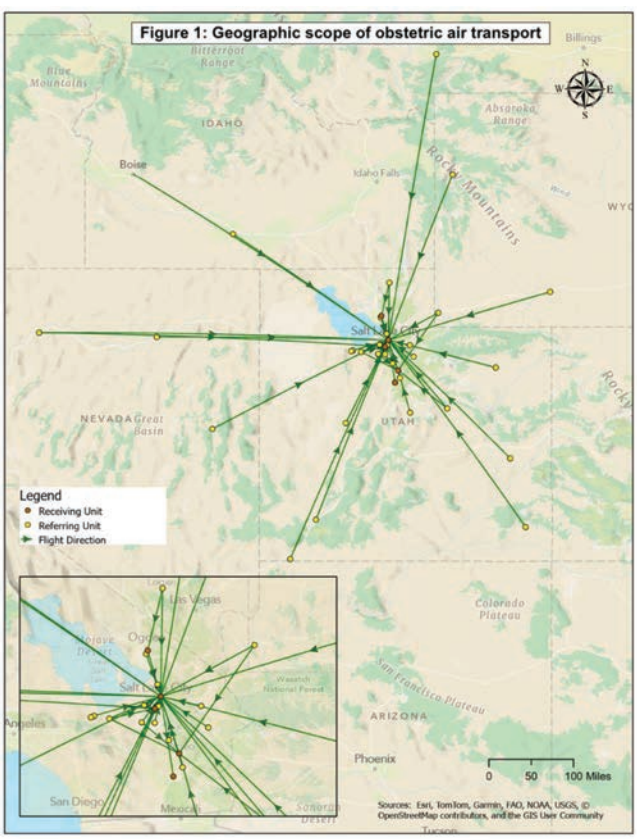


Figure 2: Quality Metrics by Transport Indication

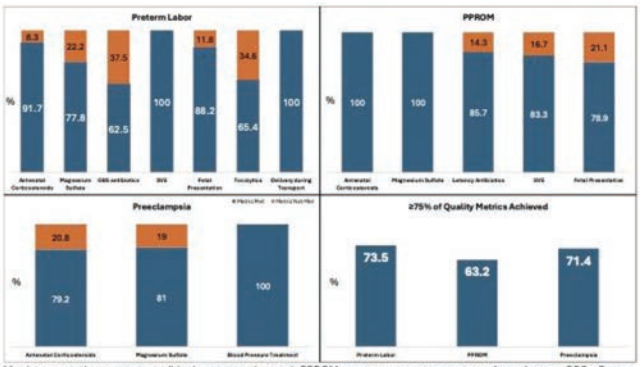


Metrics reported as percent met (blue) or not met (orange). PPROM – preterm premature rupture of membranes. GBS – Group B streptococcus. SVE – sterile vaginal exam or evaluation of cervical dilation via speculum exam. Preterm labor metrics include receipt of antenatal corticosteroids if <34 weeks, magnesium sulfate if <32 weeks, GBS antibiotics if GBS unknown and <37 weeks, tocolytics if <34 weeks, evaluation of cervical dilation (SVE) and fetal presentation and if delivery during transport occurred. PPROM metrics include receipt of antenatal corticosteroids if <34 weeks, magnesium sulfate <32 weeks, latency antibiotics, and evaluation of cervical dilation (SVE) and fetal presentation. Preeclampsia metrics include receipt of antenatal corticosteroids if <34 weeks and magnesium sulfate as well as if severe range blood pressures were treated in the peri-transport period. Metrics met/Metrics not met exclude individuals that were not eligible for the intervention based on clinical factors (i.e., magnesium sulfate for cerebral palsy prophylaxis >32 weeks). Percentage of quality metrics met is the % of individuals who received ≥75% of the interventions in the peri-transport period (pre-transport patient stabilization and in transit).

153 | Oral Probiotic Versus Placebo and the Maternal Metabolome During Pregnancy: a Randomized Controlled Trial

Charlotte L. Conturie[1]; Kelly Weldon[2]; Lindsey A. Burnett[3]; Grant Norton[2]; Celeste Allaband[2]; Peter DeHoff[2]; Gregory Humphrey[2]; Shalisa Hansen[2]; Pieter Dorrestein[2]; Rob Knight[2]; Se Jin Song[2]; Austin Swafford[2]; Louise C. Laurent[4]

[1]Keck Medicine of USC, Los Angeles, CA; [2]University of California San Diego, La Jolla, CA; [3]UC San Diego Medical Center, La Jolla, CA; [4]University of California, San Diego Medical Center, La Jolla, CA

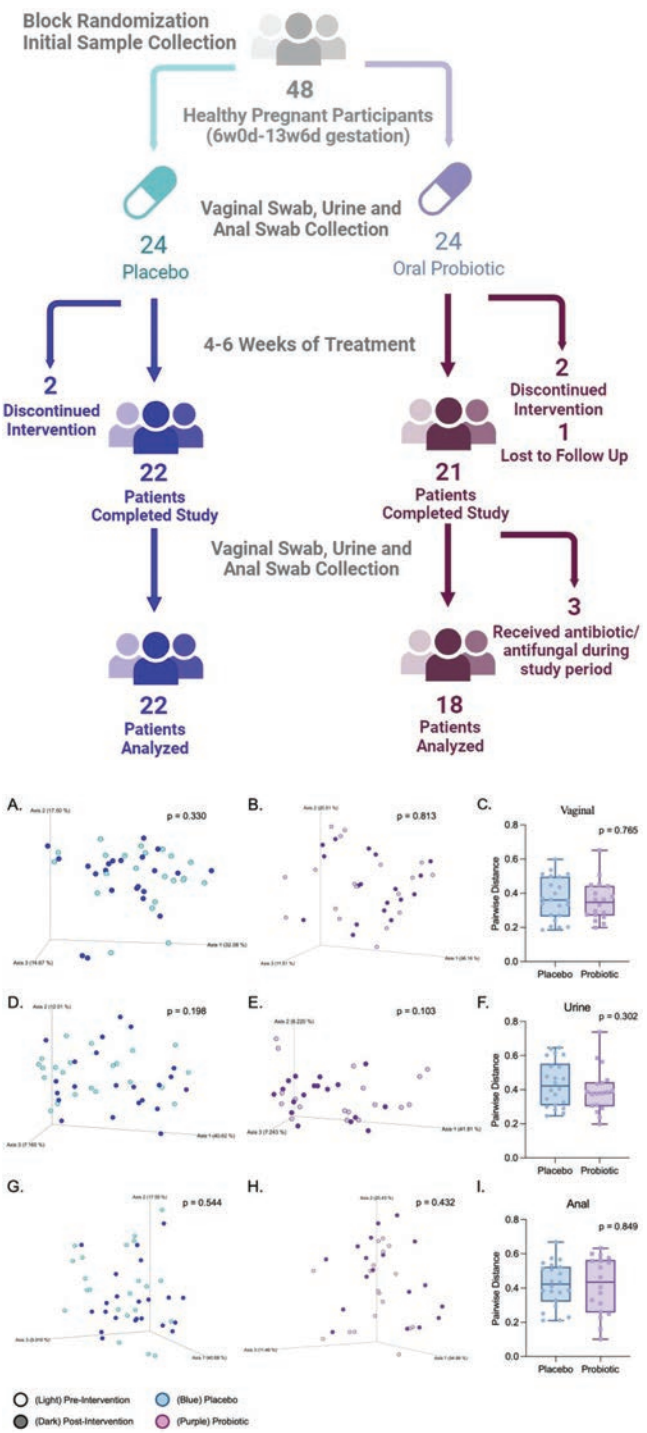
10:30 AM - 12:30 PM

Objective: The original aim of this study was to investigate whether an oral probiotic with a mixture of Lactobacillus and Bifidobacterium species could change the vaginal microbiome during pregnancy, and the results showed overall no change. Studies suggest a complex interplay between the microbiome and metabolome during pregnancy, which can have an impact on perinatal outcomes. Therefore, a secondary aim was to examine the influence of the oral probiotic on the maternal metabolome.

Study Design: This was a pilot randomized double-blinded placebo-controlled trial at a university hospital. Healthy singleton pregnancies were enrolled between 6w0d and 13w6d and randomized to an oral probiotic or placebo. Samples from the vagina, urine, and anus were obtained prior to randomization and 4-6 weeks after intervention. Samples were extracted using ideal conditions for small molecule reverse phase positive mode untargeted metabolomics and run using a high-performance mass spectrometer coupled to a liquid chromatography system. Data was analyzed using GNPS and QIIME2.

Results: 48 patients were enrolled, and 43 completed the study, with 22 randomized to the placebo, and 21 to the probiotic. 3 patients in the probiotic group developed vaginal infections requiring treatment during the study period and were excluded from the analysis (Figure 1). The groups were similar in baseline characteristics and metabolomic profiles for all sample sites. Post-intervention, the groups remained similar. Comparing pre versus post intervention with Bray Curtis distance metric PCoA, there was no significant difference in the metabolome for the placebo group (Figure 2; A, D, G) or the probiotic group (B, E, H). Comparing the placebo versus probiotic groups with paired longitudinal distance boxplots, there was no significant shift in the metabolome for participants (C, F, I).

Conclusion: The overall vaginal, urine, and anal metabolomes did not change significantly after the introduction of an oral probiotic into the maternal diet, and the metabolomes appeared relatively stable over the course of 4-6 weeks during the first half of pregnancy.



154 | Participation in a Comprehensive Addiction In Pregnancy Program and Maternal Outcomes

Charlotte B. McCarley[1]; Yumo Xue[2]; Victoria C. Jauk[1]; Lynda Ugwu[1]; Lorie M. Harper[3]; Casey Brian[4]; Brian E. Brocato[1]; Carolyn Webster[1]; Rachel G. Sinkey[1]; Ayodeji Sanusi[2]
[1]University of Alabama at Birmingham, Birmingham, AL; [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL; [3]Dell Medical School, Austin, TX; [4]West Virginia University, Morgantown, WV

10:30 AM - 12:30 PM

Objective: The Society for Maternal-Fetal Medicine issued a special report on substance use disorder (SUD) in pregnancy recommending research "to determine the care model that results in the best outcomes for women…" Our objective was to evaluate the effect of a comprehensive addiction in pregnancy program (CAPP) on maternal outcomes among pregnant persons with SUD.

Study Design: Retrospective cohort of pregnant patients with SUD who delivered a live neonate at ≥22 weeks gestational age (WGA) at a referral center in the southeast US (4/9/2018-8/5/2022). Patients with SUD were divided into 2 groups: those who attended CAPP and those who did not (non-CAPP). CAPP combines perinatal care with social services, case management, peer support, ±pharmacotherapy. Participation in CAPP required prenatal care (PNC) < 32 WGA and score ≥4 on the National Institute on Drug Abuse–Modified Assist Tool. The primary outcome was number of PNC visits. Secondary outcomes included pharmacotherapy, non-prescription substance use at delivery, SUD treatment program graduation, and depressive symptoms as determined by Center for Epidemiologic Studies Depression Scale (CES-D). Outcomes were compared between groups; multivariable logistic regression was used to adjust for covariates.

Results: Overall, 431 patients were included: 153 CAPP, 278 non-CAPP. CAPP participants initiated PNC earlier (16±7 vs 21±10 WGA, p< .001) and delivered later (39 vs 38 WGA, p = .047, Table 1) than non-CAPP. CAPP participants attended a median of 10 PNC visits while non-CAPP attended 6 (mean difference 3.48 [2.48-4.48], Table 2). There was no difference in pharmacotherapy, however, CAPP participants were less likely to have a positive urine drug screen for a non-prescribed substance at delivery (OR 0.37, 95%CI 0.21-.067). Among those who participated in CAPP, 30% completed a SUD treatment program and had a 4.5 point decrease in the CES-D score from intake to 6 weeks postpartum.

Conclusion: CAPP participation is associated with increased utilization of PNC and decrease use of non-prescribed substances. Additional follow up is needed to assess long-term outcomes.

Table 1. Baseline Demographics

Characteristic	CAPP (n=153)	Non-CAPP Group (n=278)	p-value

155 | The Association Between Participation in a Comprehensive Addiction Medicine Prenatal Care Program and Child Custody

Charlotte B. McCarley[1]; Yumo Xue[2]; Ayodeji Sanusi[2]; Victoria C. Jauk[1]; Lynda Ugwu[1]; Casey Brian[3]; Brian E. Brocato[1]; Samuel Gentle[1]; Rachel G. Sinkey[1]
[1]University of Alabama at Birmingham, Birmingham, AL; [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL; [3]West Virginia University, Morgantown, WV

10:30 AM - 12:30 PM

Objective: Patients with substance use disorder (SUD) are more likely to lose custodial rights than those who do not have SUD. We evaluated the effect of a comprehensive addiction in pregnancy program (CAPP) on parental custody.

Study Design: Retrospective cohort of pregnant patients with SUD who delivered a liveborn neonate at ≥22 weeks gestational age (GA) at a referral center in the southeast US (4/9/2018-8/5/2022). Patients with SUD were divided into 2 groups: those who attended CAPP and those who did not (non-CAPP). CAPP combines perinatal care with social services, case management, peer support, ±pharmacotherapy. CAPP participation requires entry to care < 32 weeks GA and score ≥4 on the National Institute on Drug Abuse–Modified Assist Tool. The primary outcome was proportion of neonates discharged with the birthing parent. Secondary outcomes included neonatal opioid withdrawal syndrome (NOWS), neonatal urine drug screen (UDS) at delivery, and neonatal length of stay (LOS). Outcomes were compared between groups.

Results: Overall, 431 patients were included: 153 CAPP, 278 non-CAPP. CAPP patients initiated prenatal care earlier than non-CAPP (p< .001) and delivered at a greater mean GA (38.9 vs 37.9 weeks, p = .047, Table 1). CAPP neonates were more likely to be discharged home in parental custody (77% vs 58%, OR 2.49 [1.55-4.01], Table 2). There was no difference in diagnosis of NOWS (OR 1.20 [0.78-1.86]) or neonatal LOS (OR -0.61 [-5.19-3.97]). Neonatal UDS was less likely to be positive (OR 0.45 [0.29-0.72]) among CAPP neonates compared to non-CAPP neonates.

Conclusion: Participation in CAPP was associated with parental custody, though nearly one-quarter of participating individuals were not granted custody. Further research is needed to understand how to safely support custodial rights for all birthing persons with SUD interested in parenting.

Table 1. Baseline Demographics

156 | The Philadelphia Urban ACE is associated with Spontaneous Preterm Birth Among Black Pregnant Individuals

Chelsea A. DeBolt[1]; Valerie Riis[1]; Kimberly B. Glazer[2]; Liqhwa Ncube[1]; Michal A. Elovitz[1]
[1]Icahn School of Medicine at Mount Sinai, New York, NY;
[2]Department of Population Health Science and Policy; Department of Obstetrics, Gynecology and Reproductive Science, Blavatnik Family Women's Health Research Institute, Icahn School of Medicine at Mount Sinai, New York, NY

10:30 AM - 12:30 PM

Objective: Adverse childhood experiences (ACE), including physical, sexual, and verbal abuse and household dysfunction associate with poor health across an individual's life course. Evidence of associations with these exposure and adverse pregnancy outcomes has been based on the traditional Kaiser ACE survey (KACE), which quantifies childhood adversity within the home. The Philadelphia Urban ACE survey (PHLACE) expands on KACE by incorporating community-level stressors derived from a more socioeconomically and racially diverse urban population. We sought to assess associations between these surveys and spontaneous preterm birth (sPTB) among Black individuals.

Study Design: From a prospective cohort of Black pregnant persons (N = 638), those who completed both KACE and PHLACE and had an adjudicated birth outcome were included for this analysis (N = 336). A high score was defined as ≥4 for both surveys. We used multivariable logistic regression to estimate odds ratios for sPTB among participants with high vs. low KACE and high vs. low PHLACE, controlling for maternal education and insurance.

Results: Overall, 5.2% of participants experienced sPTB, 68.4% reported high PHLACE while only 15.8% reported high KACE (Table 1). In bivariate analysis, high PHLACE (p = 0.015), but not high KACE (p = 0.774) was associated with sPTB. In adjusted models, those with high PHLACE had 3.9 times (95% CI 1.46, 11.49) higher odds of sPTB compared to those with low PHLACE. Removing those with prior sPTB, the association persisted (aOR 4.55 95% CI 1.21, 21.74). Among the same single childhood adversities, the PHLACE appears to capture higher rates of positive responses compared to the KACE (Table 2).

Conclusion: PHLACE may capture childhood adversity more comprehensively than KACE and may more accurately reflect the impact of early lived experiences on adverse pregnancy outcomes in Black, urban populations. Understanding how these experiences perturb biological pathways leading to sPTB is imperative for the optimization of therapeutic strategies. Importantly, policies that help to mitigate these experiences can also improve pregnancy health.

157 | Accuracy of Fetal Anatomy Survey in Diagnosis of Marginal Cord Insertion: A Retrospective Case Study

Lauren Cue[1]; Paul Bobby[2]
[1]Rutgers University and the Jersey City Medical Center, Jersey City, NJ; [2]Jersey City Medical Center, Jersey Medical Center, NJ

10:30 PM - 12:30 PM

Objective: Marginal cord insertion (MCI) is defined as the umbilical cord insertion within 2cm of the placental edge. Preeclampsia, placental abruption and low birth weight have historically been associated with MCI. While assessment of placental cord insertion is recommended during formal fetal anatomy survey, the accuracy of ultrasound detection in the second trimester has not been studied. This study was designed to assess the accuracy of ultrasound diagnosis of MCI at the time of midtrimester fetal anatomical survey, as compared to postnatal histological evaluation.

Study Design: We conducted a retrospective study of all deliveries at our hospital from January 2021 to June 2024 in which MCI was diagnosed on fetal anatomy survey and examined the corresponding placental pathology reports. All anatomical surveys were performed in the second trimester. Maternal variables such as age, presence of prior Cesarean scar, and severe obesity (BMI >35) were collected, as well as fetal variables such as presence of multi-fetal gestation and placental location.

Results: Among the 210 patients diagnosed with MCI on anatomy scan, only 45.2% were confirmed to have MCI on review of placental pathology. A false positive finding of MCI was more common in obese (BMI >35) patients and in multiple gestations. Only placental location correlated significantly with sonographic accuracy of detection- with anterior placentation favoring correct diagnosis.

Conclusion: MCI found at the time of midtrimester fetal anatomical survey is often not confirmed at postnatal histology. Placental location at the time of exam modestly impacts accuracy of midtrimester MCI diagnosis.

158 | Does Fetal Sex Impact the Risk of Maternal Diabetes 10-14 Years After Delivery?

Christine P. Field[1]; Patrick Catalano[2]; Jiqiang Wu[1]; Mark B. Landon[1]; Denise Scholtens[3]; William Lowe[3]; Jami Josefson[3]; William A. Grobman[1]; Kartik K. Venkatesh[1]
[1]The Ohio State University, Columbus, OH; [2]Tufts University, Tufts University/Boston, MA; [3]Northwestern University, Northwestern University/Chicago, IL

10:30 AM - 12:30 PM

Objective: Limited data suggest that male fetal sex is associated with worse maternal Beta-cell function in pregnancy and a possible increased risk of maternal diabetes after delivery. We examined the association between fetal sex and the risk of prediabetes or diabetes 10-14 years after delivery.

Study Design: This is a secondary analysis of data from the prospective Hyperglycemia and Adverse Pregnancy Outcome Follow-Up Study (HAPO FUS). The exposure was assigned fetal sex at birth (female as the reference). The primary outcome was having either prediabetes or diabetes assessed 10-14 years after the index pregnancy; secondarily, prediabetes and diabetes were assessed separately. Modified Poisson regression models were used and adjusted for baseline covariates at enrollment (study field center, maternal age, parity, family history of diabetes) as well as time from enrollment to follow-up. We secondarily assessed whether the association between fetal sex and diabetes or prediabetes varied by gestational diabetes (GDM) status (effect modification), and whether maternal insulin sensitivity at pregnancy enrollment and insulin resistance at 10-14 year follow-up differed by fetal sex.

Results: Of 3,976 individuals in the analytic sample, 16.7% developed GDM and 48.7% of infants were assigned female sex. At 10-14 years after delivery (median 11.6 years), 3.1% of individuals developed diabetes and 22.9% developed prediabetes. In adjusted analyses, the risk of diabetes or prediabetes did not differ by fetal sex (female vs. male: 24.9 vs. 25.5%; aRR: 1.02, 95% CI 0.90, 1.15) (TABLE). This association was similar regardless of GDM status (interaction p = 0.59). There was also no association between fetal sex and maternal insulin sensitivity at enrollment or insulin resistance at 10-14 year follow-up.

Conclusion: There was no association between fetal sex and the risk of maternal diabetes or prediabetes 10-14 years after delivery. Further research is needed to better understand the possible impact of fetal sex on maternal Beta-cell function.

Table. Risk of maternal diabetes and prediabetes at 10-14 years by fetal sex in index pregnancy

	Overall N=3,976	Female N=1,940	Male N=2,036	Unadjusted analysis	Adjusted analysis

159 | Primipara with Cesarean History: Impact of Gestational Age at Term on Mode of Delivery

Claire THUILLIER[1]; Anne-Sophie BOUCHERIE[2]; JULIETTE FRANCOIS[3]; ANNE ROUSSEAU[3]; PATRICK ROZENBERG[4]; THIBAUD QUIBEL[3]
[1]UVSQ, Neuilly, Ile-de-France; [2]UVSQ, POISSY, Ile-de-France; [3]UVSQ, Poissy, Ile-de-France; [4]UVSQ, Neuilly sur seine, Ile-de-France

10:30 AM - 12:30 PM

Objective: To assess the risk of cesarean delivery (CD) for each week of gestation (WG) of ongoing pregnancy (OP) in primipara at term with a prior CD.

Study Design: Secondary analysis of the randomized Lower Uterine Segment Trial. All included women were eligible for a trial of labor. From the start of term and at the start of each subsequent week of completed gestation, OP was defined as that of a woman who was still pregnant and who gave birth at any time after that date. For each WG for these OP, the CD rate was defined as the number of CDs performed in each OP group divided by the number of women in this group. Separate models for each WG, adjusted by maternal characteristics and hospital status, were used to compare the CD risk between OP and those delivered in the preceding week. The same methodology was applied in a subgroup of women with induction of labor (IoL). Odds ratios were calculated after adjusting for center, BMI, diabetes, hypertensive disorders, and macrosomia.

Results: Among the 2,339 included primipara at term, 1834 (78.4%) finally had a trial of labor including 390 (16.6%) IoL. The overall CD rate was 44.2% (n = 1,034). This rate was 44.3% (n = 173) in the 390 women with IoL. These rates remained stable for OP from 370/7 to 400/7 WG and increased at 410/7 WG (Table 1). In both univariate and multivariate analyses, OP at or beyond 410/7 WG was associated with a higher risk of CD than pregnancy delivered the previous week (ORa = 2.13 (95% CI [1.65-2.75]). In contrast, at each gestational week, the CD rate after IoL was not significantly different between OP and pregnancy delivered the previous week, even at or beyond 41 0/7 WG (Table 2).

Conclusion: The overall CD rate for OP in primipara with a previous CD only increases from 41 0/7 weeks. Among women delivered after IoL, there was no significant difference in CD rates for OPs compared with those for women who gave birth in the preceding WG.

Table 1. Risk of caesarean delivery (CD) per week of gestation

Gestational Age	Overall number of deliveries N=2339	Overall number of CDs N=1034	CD Rate, %, (95% CI)
OPs at 37 0/7 WG	2339	1034	44.2 (42.2-46.2)
OPs at 38 0/7 WG	2267	1002	44.2 (42.2-46.3)
OPs at 39 0/7 WG	1974	877	44.4 (42.1-46.6)
OPs at 40 0/7 WG	1333	600	45.0 (42.3-47.7)
OPs at 41 0/7 WG	604	341	56.4 (42.3-60.4)

** In the mixed model, the associations between CD rates and gestational age were adjusted for maternal BMI, diabete, hypertensive disorders, macrosomia, and center.*

160 | Outcomes Associated with Prolonged Rupture of Membranes

Claudia J. Ibarra[1]; Baha M. Sibai[2]; Hector M. Mendez-Figueroa[1]; On behalf of the Maternal-Fetal Medicine Units (MFMU) Network
[1]McGovern Medical School at UTHealth, Houston, TX; [2]McGovern Medical School at UTHealth Houston, Houston, TX

10:30 AM - 12:30 PM

Objective: Prolonged rupture of membranes (ROM) can be associated with worse maternal and neonatal outcomes. However, there is no clear understanding of the linear relationship between duration of ROM during labor and adverse outcomes. We aimed to evaluate how length of ROM can affect maternal and neonatal outcomes.

Study Design: This was a secondary analysis of the MFMU network ARRIVE trial. Low-risk nulliparous were randomized to labor induction at 39 weeks versus expectant management until 42 weeks 2 days. We compared women with ROM between 6-11.9 hours (baseline) versus those who had prolonged ROM between 12-17.9 hours (group I) and 18+ hours (group II). The primary outcome was a composite maternal adverse outcome (CMAO) defined as postpartum infection, postpartum hemorrhage, chorioamnionitis, ICU admission, or uterine rupture. Our secondary outcome was the composite neonatal adverse outcome (CNAO) defined as APGAR < 3 at 5 minutes, NICU admission, seizures, sepsis, hypoxic-ischemic encephalopathy, birth injury, and neonatal death. Adjusted relative risk (aRR) with 95% confidence interval (CI) was calculated.

Results: Overall, 2199 were in the baseline group, 1117 in group I, and 743 in group II. BMI on admission, and delivery type varied among the groups. The primary outcome was significantly different between the groups when compared with the baseline group; there was a higher CMAO in Group I (aRR 1.74 CI 1.5-2.0)

and group II (aRR 2.0 CI 1.7-2.4). The CNAO was also higher in Group I (aRR 1.53 CI 1.3-1.8) and Group II (aRR 2.1 CI 1.8-2.6). Length of ROM was not a predictor of CMAO or CNAO based on the area under the receiver operating characteristic curve for prolonged ROM. A logistic regression curve demonstrated for every hour of prolonged ROM increased the risk of CD by 7% ($p < 0.01$ CI 6.0-8.0).

Conclusion: Our secondary analysis suggests that prolonged ROM during labor, regardless of the mode of delivery, is associated with increased likelihood of CMAO and CNAO. This risk is highest among those with 18+ hours of ROM during labor.

161 | Twins Exposed to Late Preterm Steroids May Be at Increased Risk for Neonatal Respiratory Morbidity

Dana S. Berger[1]; Diana S. Abbas[1]; Lindsay N. Marty[1]; Kate Tolleson[1]; Cole Turner[1]; Steven Friedman[1]; Erinn M. Hade[1]; Justin S. Brandt[2]; Meghana A. Limaye[2]
[1]NYU Grossman School of Medicine, New York, NY; [2]NYU Langone Health, New York, NY

10:30 AM - 12:30 PM

Objective: To determine if administration of antenatal corticosteroids (ACS) to patients with twin gestations at risk of late preterm delivery is associated with reduced risk of neonatal respiratory morbidity.

Study Design: This was a retrospective cohort study in a large tertiary care health system (2013–2022) of non-anomalous twin gestations at risk of preterm delivery between 34 0/7- 36 6/7 weeks. Patients were excluded if they previously received ACS or had pregestational diabetes. The exposed group included twin gestations that received 1 or 2 doses of betamethasone in the late preterm period. The primary outcome was a respiratory morbidity composite including need for any of the following in the first 72 hours: continuous positive airway pressure (CPAP) or high flow nasal cannula (HFNC) for 2 or more hours, supplemental oxygen of 30+% for 2 or more hours, ECMO, mechanical ventilation, fetal or neonatal death. Secondary outcomes included surfactant use, RDS, and TTN. Adjusted and unadjusted relative risks (RR) with 95% confidence intervals (CI) were calculated.

Results: During the study period, 366 twin gestations, corresponding to 733 patient-infant dyads, were included, with 162 gestations (321 infants) in the exposed group and 204 gestations (401 infants) in the unexposed group. The mean gestational age of ACS administration was 35 2/7 weeks in the exposed group and 35 6/7 weeks in the unexposed group. Timing and indications for administration are described in Table 1. Exposed fetuses had 16% higher risk of composite respiratory morbidity (95% CI 0.83–1.61), which was driven by higher rates of CPAP and HFNC. Exposed fetuses had lower risk of needing supplemental oxygen of 30+% for 2 or more hours (aRR 0.16, 95% CI 0.02–0.75) and mechanical ventilation (aRR 0.19, 95% CI 0.04 - 0.86) (Table 2).

Conclusion: In a large cohort of twins at risk for late preterm delivery, exposure to ACS was associated with increased risk of composite neonatal respiratory morbidity. The results of our study add to the literature questioning the benefits of late preterm ACS in twins.

Bronchopulmonary dysplasia	0	0	—	—

Data is n (percent) unless otherwise specified.
[a]Adjusted for age, chorionicity, ethnicity, and gestational diabetes
ACS: antenatal corticosteroids; CI: confidence interval; CPAP: continuous positive airway pressure; HFNC: high flow nasal cannula; O2: oxygen; ECMO: extra corporeal membrane oxygenation; RDS: respiratory distress syndrome; and TTN: transient tachypnea of the newborn
Note: RDS was defined as respiratory distress requiring some form of supplemental oxygen and/or respiratory support, along with a chest radiograph consistent with RDS or surfactant deficiency; TTN was defined as clinical signs of respiratory distress that resolved within 72 hours of life and with radiographic findings of increased perihilar interstitial markings and pulmonary fissure edema (or in the absence of a chest x-ray).

162 | Twins Exposed to Late Preterm Steroids and the Risk of Neonatal Hypoglycemia

Dana S. Berger[1]; Diana S. Abbas[1]; Lindsay N. Marty[1]; Kate Tolleson[1]; Cole Turner[1]; Steven Friedman[1]; Erinn M. Hade[1]; Justin S. Brandt[2]; Meghana A. Limaye[2]
[1]NYU Grossman School of Medicine, New York, NY; [2]NYU Langone Health, New York, NY

10:30 AM - 12:30 PM

Objective: Singletons exposed to late preterm antenatal corticosteroids (ACS) are at higher risk of hypoglycemia. We sought to determine if twins exposed to late preterm ACS are also at increased risk for neonatal hypoglycemia.

Study Design: This was a retrospective cohort study in a large tertiary care health system (2013–2022) of non-anomalous twin gestations at risk of preterm delivery between 34 0/7- 36 6/7 weeks. Patients were excluded if they previously received ACS or had pregestational diabetes. The exposed group included gestations who received 1 or 2 doses of betamethasone (BMZ) in the late preterm period. The primary outcome was risk of neonatal hypoglycemia (blood glucose < 40 mg/dL). Secondary outcomes were lowest average blood glucose, need for hypoglycemia treatment and NICU admission for hypoglycemia. Descriptive statistics and adjusted and unadjusted risk ratios (RR) with 95% confidence intervals (CI) were calculated.

Results: During the study period, 366 twin gestations, corresponding to 733 patient-infant dyads, were included with 162 gestations (321 infants) in the exposed group and 204 gestations (401 infants) in the unexposed group. The mean gestational age of ACS administration was 35 2/7 weeks in the exposed group and 35 6/7 weeks in the unexposed group. In the exposed group, 72 (44%) received 2 doses of BMZ. Ten percent had gestational diabetes in both groups. Other group demographics are listed in Table 1. Compared to unexposed twins, exposed twins had a modest increase in risk of hypoglycemia (RR 1.06, 95% CI 0.88 - 1.28). Exposed twins had lower mean blood glucose and higher risk of need for hypoglycemia treatment (Table 2). Exposed twins were more likely to be admitted to NICU for hypoglycemia and to have hypoglycemia as the only indication for NICU admission.

Conclusion: In a large cohort of twins at risk for late preterm delivery, exposure to ACS was associated with a modest increase in risk for hypoglycemia. These data add to the body of literature on potential risks associated with late preterm ACS administration for twins.

163 | Examining Psychometric Screening Scores for Depression, Anxiety, and Post-Traumatic Stress After Fetal KCL Injection

Daniel L. Kuhr[1]; Nicola F. Tavella[2]; Alexandra N. Mills[1]; Henri M. Rosenberg[3]; Camila Cabrera[2]; Elizabeth Cochrane[1]; Sara E. Edwards[1]; Allison Perelman[2]; Sara M. Hachey[2]; Victoria Ly[2]; Leslie J. Warren[2]; Angela T. Bianco[2]
[1]Division of Maternal-Fetal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Icahn School of Medicine at Mount Sinai, Division of Maternal-Fetal Medicine, Icahn School of Medicine at Mount Sinai, NY

10:30 AM - 12:30 PM

Objective: To examine the incidence of positive screens for depression, anxiety, and post-traumatic stress among patients undergoing therapeutic abortion at ≥ 22 weeks' gestation.

Study Design: This was a prospective, observational cohort study of patients undergoing fetal potassium chloride (KCL) injection for therapeutic abortion at ≥ 22 weeks' gestation. All patients scheduled for said procedure were approached within 48 hours of the scheduled termination. After obtaining informed consent, basic demographic information was collected. Patients completed the Edinburgh Postnatal Depression Scale (EPDS), General Anxiety Disorder-7 (GAD-7), and Primary Care Post-Traumatic Stress Disorder-5 (PC-PTSD-5) questionnaires twice, first prior to their KCL procedure and then again two weeks later. Consents and questionnaires were provided in both English and Spanish. Patients who scored positive on any tool were referred to an in-house social worker and connected to ongoing mental health care as appropriate.

Results: 41 patients were screened for this study, of whom 24 enrolled. The mean gestational age in weeks was 24.8 (Table 1). Fetal anomaly was the indication for termination in 70.8% of patients. 14 patients (58.3%) completed the two-week follow-up surveys. The median baseline and two-week follow up scores for the EPDS, GAD-7, and PC-PTSD-5 were, respectively, 13.5 and 10, 7 and 4.5, and 1 and 2 (Table 2). There was no difference in the proportion who screened positive on any measures between those patients who completed the follow up surveys and those who did not. There were also no differences in the proportion of positive screens by evacuation method or termination indication.

Conclusion: Most patients undergoing termination at ≥ 22 weeks' gestation at our institution during the study period did so for fetal anomalies. Patients undergoing these terminations should be screened for depression, anxiety, and PTSD, and those who screen positive should be connected to resources for further care. More research is needed on the long-term mental health outcomes of patients undergoing termination after 22 weeks.

164 | Examining the Role of Neighborhood Level Indices in Predicting Spontaneous Preterm Birth

Daniel L. Kuhr[1]; Nicola F. Tavella[2]; Zahava P. Michaelson[1]; Raina Kishan[2]; Nicole Parkas[1]; Helen Feltovich[1]; Kimberly B. Glazer[3]
[1]Division of Maternal-Fetal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Department of Population Health Science and Policy; Department of Obstetrics, Gynecology and Reproductive Science, Blavatnik Family Women's Health Research Institute, Icahn School of Medicine at Mount Sinai, New York, NY

10:30 AM - 12:30 PM

Objective: Cervical length is an established but limited predictor of spontaneous preterm birth (sPTB). We examined whether measures of the neighborhood environment, which reflect structural determinants of pregnancy outcomes, improve prediction of sPTB as compared to CL alone.

Study Design: This was a retrospective cohort study of 1000 patients and each of their gestations with: 1) delivery at a tertiary, urban academic hospital between January 2013-August 2023 and

2) at least one transvaginal CL at 16w0d-24w6d gestational age (GA). The primary outcome was sPTB, defined from chart review as delivery prior to 37w0d GA. CL was abstracted from ultrasound images. Medical history, GA at delivery, progesterone therapy, and cerclage placement were abstracted from the electronic medical record. We ascertained neighborhood structural and social determinants of health (SDOH) from the Index of Concentration at the Extremes (indicator of racial-economic segregation) and Child Opportunity Index (neighborhood resources), based on patient address and 2020 census tract. We used logistic regression to predict the probability of sPTB in models with (1) CL only, (2) CL plus neighborhood indices, and (3) CL, neighborhood, and individual-level characteristics We compared model discrimination using the area under the receiver operating characteristics curve (AUC). Analyses were performed in R version 4.4 (24 April 2024).

Results: The 1000 patients yielded 1038 pregnancies that met inclusion criteria. 21.4% of pregnancies had a prior sPTB (Table 1). 13.3% of index pregnancies ended in sPTB. Decreased CL was associated with increased odds of sPTB in all models. A model with CL only achieved an AUC of 0.56 and 0.57 with addition of neighborhood indices (Table 2). Including other individual covariates increased performance to an AUC of 0.72.

Conclusion: Inclusion of the ICE and COI neighborhood indices did not improve sPTB prediction among individuals who underwent CL screening. Research should explore additional, diverse SDOH indicators alongside individual clinical characteristics to identify those at highest risk of sPTB.

165 | Antibiotic Prophylaxis with Balloon and Vacuum-induced Tamponade Devices for Vaginal Deliveries Complicated by Postpartum Hemorrhage

Daniel J. Martingano[1]; Amanda F. Francis Oladipo[2]; Marwah Al-Dulaimi[3]; Sandra Kumwong[4]; Andrea Ouyang[5]; Lauren Cue[6]; Ashley Nguyen[3]; Francis X. Martingano[7]; Shailini Singh[8]; Mark Rebolos[3]; Alexander Ulfers[9]; Kristin Cohen[10]; Donald Morrish[3]; Iffath A. Hoskins[11]

[1]St. John's Episcopal Hospital-South Shore and William Carey University College of Osteopathic Medicine, Far Rockaway, NY; [2]Hackensack University Medical Center, Hackensack, NJ; [3]St. John's Episcopal Hospital-South Shore, Far Rockaway, NY; [4]Touro College of Osteopathic Medicine-Harlem Campus, New York, NY; [5]William Carey University, Hattiesburg, MS; [6]Rutgers University and the Jersey City Medical Center, Jersey City, NJ; [7]NYU Grossman School of Medicine - NYU Brooklyn, New York, NY; [8]AtlantiCare Regional Medical Center, Pamona, NJ; [9]Walter Reed National Military Medical Center, Bethesda, MD; [10]RWJBarnabas Health - Trinitas Regional Medical Center, Elizabeth, NJ; [11]Albert Einstein College of Medicine - Montefiore Medical Center, New York, NY

10:30 AM - 12:30 PM

Objective: Balloon and vacuum-induced tamponade devices provide alternative treatment options in cases of postpartum hemorrhage when first-line uterotonic agents either fail or are contraindicated. This study sought to determine if antibiotic prophylaxis at time of intrauterine balloon tamponade (IBT) or vacuum-induced tamponade (VID) insertion in vaginal deliveries complicated by postpartum hemorrhage effects subsequent rates of postpartum endometritis.

Study Design: We conducted a prospective observation cohort study comparing all patients who received an IBT following vaginal delivery to those who did not from dates 7/2022 through 7/2024. Patients were excluded if additional antibiotics apart

from penicillin for GBS prophylaxis were administered, were gestational age < 34 weeks, or had an allergy to antibiotic therapy. Patients receiving antibiotics specifically were given cefazolin 1g every 8 hours until removal of IBT or VID.

Results: The study included 415 patients, where 313 patients received IBT and 102 received VID. In the IBT group, 160 received antibiotics and 153 did not. In the VID group 55 received antibiotics and 47 did not. Demographic factors were not significantly different. Rates of postpartum endometritis were less in the IBT antibiotic group (5.6% versus 13.7%, p = 0.003) in addition to a 37% decreased risk in confounder adjusted models (RR = 0.63, 95% CI 0.47-0.75, p = 0.041). Rates of postpartum endometritis were not significantly different in the unstratified VID group. In stratified analysis, rates of postpartum endometritis were less in the VID antibiotic groups for nulliparous patients (0.55% v. 2.35%, p = 0.001), with a 11% decreased risk in adjusted models (RR = 0.89, 95% CI 0.72-0.97, p = 0.034).

Conclusion: Antibiotic prophylaxis at time of IBT for vaginal deliveries complicated by postpartum hemorrhage is reasonable for endometritis prevention with potential benefits for VID use in nulliparous patients.

166 | Intrapartum Cesarean Delivery in PPROM: Identifying Key Risk Factors and Developing a Predictive Model

Daniel Gabbai[1]; Emmanuel Attali[1]; Itamar Gilboa[1]; Yariv Yogev[2]; Anat Lavie[3]

[1]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel-Aviv, Tel Aviv; [2]Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv University, Tel Aviv Sourasky Medical Center, Tel Aviv; [3]Tel Aviv Sourasky Medical Center, Tel Aviv Sourasky Medical Center, Tel Aviv

10:30 AM - 12:30 PM

Objective: To identify risk factors for intrapartum cesarean delivery (CD) in women with preterm premature rupture of membranes (P-PROM) and to develop a risk prediction score for this outcome.

Study Design: We conducted a retrospective cohort study at a university-affiliated tertiary medical center with approximately 12,500 deliveries annually (2012-2023). The study included women with P-PROM who planned a trial of labor, excluding those opting for elective CD or with non-viable fetuses. We compared maternal and neonatal characteristics between those who delivered vaginally and those who underwent intrapartum CD. Risk factors were identified using univariate and multivariate logistic regression analyses. A predictive risk score was developed based on the relative risk of each factor, with model performance assessed using the ROC curve.

Results:

1. During the study period, 145,833 women delivered at our center. Of these, 1,494 (1%) were admitted with P-PROM and were eligible for analysis.
2. Among these, 470 (31.5%) underwent intrapartum CD, with a median gestational age of 34.5 weeks (IQR 32.3, 36.0) compared to 35.4 weeks (IQR 33.5, 36.4) in women who delivered vaginally.
3. Multivariate analysis revealed that maternal age > 40 years, multiple gestations, and previous CD are independent risk factors for intrapartum CD. Conversely, BMI > 30, use of oxytocin or antibiotics during labor, and spontaneous onset of labor were protective factors. We assigned risk scores to each factor and incorporated them into our model. [Table 2].
4. The developed risk score model, with a cut-off of 7, predicted intrapartum CD with an area under the curve of 0.85 (95% CI [0.80-0.88], p < 0.001), demonstrating 70% sensitivity and 80% specificity.

Conclusion: Utilizing our risk score to assess factors before and during labor can aid clinicians in making more informed decisions regarding the risk for intrapartum CS in women with P-PROM.

Table 1: Clinical and Demographic Characteristics

	Vaginal birth N = 1024	CS N = 470	p- value
Maternal age, (mean, SD)	33.2 (4.69)	35.1 (5.59)	<0.001
Pre-gestational BMI (median, IQR)	22.1 (20.08, 24.6)	22.8 (20.3, 25.4)	0.005

167 | Comparison of Antibiotic Regimens for Preventing Infectious Complications Following Elective Cesarean Delivery

Daniel Gabbai[1]; Itamar Gilboa[1]; Anat Lavie[2]; Yariv Yogev[3]; Emmanuel Attali[1]
[1]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel-Aviv, Tel Aviv; [2]Tel Aviv Sourasky Medical Center, Tel Aviv Sourasky Medical Center, Tel Aviv; [3]Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv University, Tel Aviv Sourasky Medical Center, Tel Aviv

10:30 AM - 12:30 PM

Objective: To compare the efficacy of two antibiotic regimens (Cefazolin versus Clindamycin + Gentamicin) for preventing infectious complications following elective cesarean delivery.

Study Design: A retrospective cohort study was conducted at a single tertiary university-affiliated medical center (2012 and 2023). All women who underwent an elective cesarean delivery were included and divided into two groups: the standard regimen group (control) were treated by Cefazolin (2 grams) and the study group, comprising of women with cephalosporin allergy were treated by a Clindamycin (900 mg) + Gentamicin (5 mg/kg) regimen. Maternal and neonatal outcomes were collected and analyzed.

The primary outcome was the need for antibiotics admission for the mother during hospitalization and the secondary outcome was the need for readmission due to obstetric or gynecological complications.

Results:

1. Out of 145,883 deliveries, 19,977 (13.5%) were elective cesarean deliveries.
2. Cefazolin was administered to 11,586 women (92%), while 1,010 women (8%) received Clindamycin + Gentamicin.
3. The control group (Cefazolin only) had a lower incidence of infectious complications compared to the study group. [Table 1].
4. Primary outcome (the need for antibiotic treatment during hospitalization) was 35.4% vs. 5.7% in the control group ($p < 0.001$) and rate of re-admission was 3.2% vs. 1.9% in the control group ($p = 0.008$)
5. Multivariate logistic regression analysis revealed that women in the alternative regimen group (Clindamycin + Gentamicin) had higher odds for antibiotic treatment during hospitalization (aOR 13.04, 95% CI 5.3-31.6, $p < 0.001$), and readmission (aOR 1.92, 95% CI 1.27-2.94, $p = 0.002$). [Table 2]

Conclusion: The antibiotic regimen of Cefazolin is more effective in preventing infectious complications following elective cesarean delivery compared to the combination of Clindamycin + Gentamicin regimen. The study highlights the need for careful assessment of beta-lactam allergies to ensure appropriate prophylactic choices.

Table 1: Comparison of Maternal and Neonatal Outcomes

	Standard Regimen (Cefazolin) N= 11,586	Alternative Regimen (Clindamycin + Gentamicin) N= 1010	p-value
Maternal age (mean SD)	35.1 (5.24)	35.6 (5.45)	0.003

10:30 AM - 12:30 PM

Objective: Long Covid (LC) is a collective term referring to the persistence of symptoms and complications related to those acquiring an acute SARS-CoV-2 infection. This study sought to evaluate the effects of medications often employed empirically in the management of LC for pregnant patients in the 3rd trimester and postpartum periods.

Study Design: We conducted a multi-center, prospective observational study from 7/2022 to 7/2024 comparing all pregnant women diagnosed with SARS-CoV-2 infection (CoV-2) in the 3rd trimester through 6 weeks postpartum. Patients with preexisting respiratory or neurological disorders or preterm delivery < 37 weeks-gestation, were excluded. Medications including enoxaparin, aspirin, inhaled corticosteroids with or without a long-acting beta blocker (CBB), theophylline, antidiabetic medications, and 1st generation antihistamines were included as covariates. The primary outcomes included the development of LC and improvement or worsening following treatment. Primary outcomes were determined by patient-reported symptoms confirmed by physician assessment in the immediate, 1-week (1P), and 6-week postpartum (6P) periods, as discrete events.

Results: The study included 369 patients diagnosed with LC. Patients who received enoxaparin were less likely to report LC at the 1P and 6P visits (39.7% v. 47.9%, p = 0.004). Patients receiving aspirin antepartum were also less likely to report LC at the same intervals (25.8% v. 51.2%, p = 0.001). Patients with LC were more likely to report improvement when taking aspirin at doses of at least 325mg (31.8% v. 11.9%, p = 0.022). In stratified analysis, patients with diabetes in pregnancy and received metformin were less likely to report LC at the 1P and 6P visits (22.7% v. 48.2%, p = 0.004). Patients with LC who received semaglutide were more likely to report worsening status at the 6P visit (45.2% v. 54.8%, p = 0.045).

Conclusion: These findings suggest that treatments targeting the circulatory system may prove more useful for LC in the 3rd trimester and postpartum period, with a possible extended benefit when using metformin in diabetic patients.

169 | Physical Activity in Pregnancy Moderates Short and Long-Term Associations Between Depressive Symptoms and Psychobiologic Markers

Danielle M. Panelli[1]; Jessica Buthmann[1]; Tan Kok Hian[2]; Helen Chen[3]; Ai Peng Tan[2]; Yap-Seng Chong[2]; Katherine Bianco[1]; Ian H. Gotlib[1]; On behalf of the GUSTO

[1]*Stanford University, Palo Alto, CA;* [2]*National University of Singapore, Queenstown;* [3]*KKH*

10:30 AM - 12:30 PM

Objective: Poor mental health is a leading cause of maternal morbidity and mortality, yet simple interventions that are effective on a biologic level are lacking. We evaluated whether physical activity is associated with improvements in psychobiologic markers in pregnant people with depressive symptoms.

Study Design: We analyzed pregnancies among people enrolled in a prospective cohort from 2009-2010 who had depressive symptoms (Edinburgh Postpartum Depression Scale [EPDS] score >8) at 26 weeks gestation. We examined: 1) the cross-sectional interaction of EPDS score and physical activity (PA) predicting maternal leukocyte telomere length (LTL), a biomarker of stress and aging when shortened; and 2) whether LTL and PA predict longitudinal change in EPDS scores from pregnancy to 2 years postpartum. PA was categorized as based on report of metabolic equivalent tasks (METs). LTL was reported as telomere/single gene (T/S) ratios from quantitative PCR. We used linear generalized estimating equation regression models, adjusting for confounders.

Results: 235 pregnancies were included. In pregnant people with no PA, higher EPDS scores were related to shorter LTL; this was reversed in people with mild or high PA, in whom LTL lengthening was seen (mild PA: ß = 0.02, 95% CI 0.002, 0.04, p = 0.03; high PA: ß = 0.03, 95% CI -0.001, 0.05, p = 0.06; Figure 1). Longitudinally, longer LTL and higher PA levels predicted significant decreases in EPDS scores by 2 years postpartum (mild PA: ß = -12.8, 95% CI -20.1, -5.4, p < 0.01; high PA: ß = -15.3, 95% CI -30.3, -0.19, p = 0.047, Figure 2).

Conclusion: In pregnant people with depressive symptoms, physical activity reversed the negative effects of higher EPDS scores on LTL shortening. This was also evident longitudinally: people with the longest LTL and highest PA had a 15-point reduction in EPDS scores by 2 years postpartum compared to people with no PA. Investigation into PA as a treatment for perinatal depressive symptoms is warranted.

Figure 1. Regression model fit (with 95% Confidence Intervals) demonstrating interaction between pregnancy physical activity level and maternal depressive symptoms on maternal leukocyte telomere length (N=235)

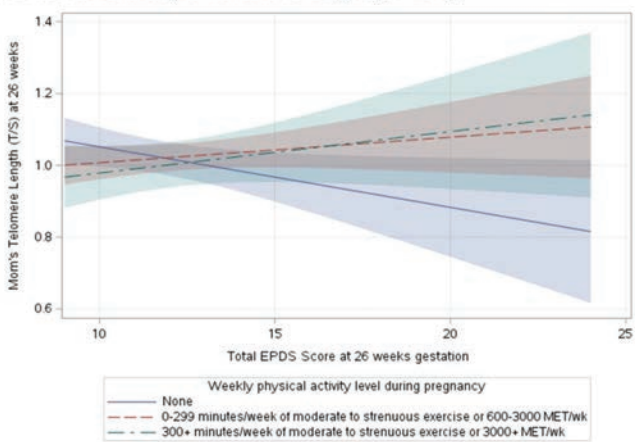

Figure 2. Longitudinal changes in Edinburgh Postpartum Depression (EPDS) scores by physical activity level

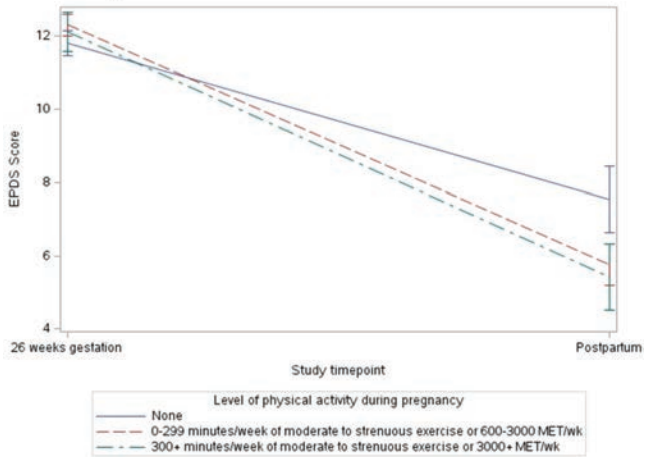

170 | Induction Versus Expectant Management in Nulliparous Low-Risk Women: Single Institution Impact of the Arrive Trial

Kathleen M. Pulice[1]; Shekinah Dosunmu[2]; Joanne N. Quiñones[2]; Meredith Rochon[2]; Amanda B. Flicker[2]; Travis Dayon[2]; George Angelakakis[3]; Ahsan Usmani[3]; Janae Cornwall[3]; Danielle Durie[2]
[1]Lehigh Valley Health Network, Macungie, PA; [2]Lehigh Valley Health Network, Allentown, PA; [3]University of South Florida Morsani College of Medicine, SELECT Program, Tampa, FL

10:30 AM - 12:30 PM

Objective: The ARRIVE trial found that elective induction of labor (eIOL) at 39 weeks in nulliparous persons compared to expectant management was associated with a lower rate of cesarean delivery (CD). Our goal was to see if this benefit persisted in a non-research setting.

Study Design: Retrospective cohort study of all nulliparous pregnant persons admitted for delivery ≥ 39w0d at a single academic community institution between 3/1/20-3/1/22, when we started offering eIOL. Those with singleton low risk pregnancies, without any clinical indication for delivery prior to 40w5d, were included. Maternal and neonatal outcomes of persons undergoing eIOL between 39w0d-39w4d were compared to women expectantly managed. The primary outcome was rate of CD. Secondary outcomes included select maternal outcomes and composite neonatal outcome (neonatal death and/or serious morbidity).

Results: 1009 nulliparous persons with low-risk singleton gestations admitted for delivery during the study period were identified, 149 (14.8%) undergoing eIOL and 860 (85.2%) expectantly managed. Those undergoing eIOL delivered earlier (39.2 vs 40.1 wks, $p < 0.001$), were more likely to be obese (38.8% vs 20.4%, $p < 0.001$) and were less likely to be of advanced maternal age (4.0% vs 9.3%, $p = 0.033$). There was no difference in CD rate (20.8% vs 17.8%, $p = 0.38$), maternal outcomes or composite neonatal outcome between the eIOL and expectant management groups (Table). eIOL was associated with longer maternal length of stay (LOS) but similar neonatal LOS. When evaluating only those undergoing induction, CD rate was significantly lower in the eIOL group (20.8% vs 32.9%, $p = 0.019$).

Conclusion: In our cohort of low-risk nulliparous pregnant persons in a non-research setting, eIOL at 39w0d-39w4d did not decrease CD rate, which differs from the ARRIVE trial results. Reassuringly, there was no increase in adverse outcomes, confirming that eIOL is safe. In low-risk patients, induction at 39w0d-39w4d may be associated with a lower CD rate than induction later in gestation.

Table 1: Nulliparous Patient Demographics, Perinatal and Neonatal Outcomes

	eIOL (n=149)	Exp. Mgt (n=860)	p-value

171 | Impact of Emergency Room Abortion Bans on Pregnancies with Previable Preeclampsia: a Cost-Effectiveness Analysis

David M. Monroe; Ava D. Mandelbaum; Aaron B. Caughey
Oregon Health & Science University, Portland, OR

10:30 AM - 12:30 PM

Objective: In August 2022, the federal government sued the state of Idaho, arguing that the federal Emergency Medical Treatment and Labor Act (EMTALA) required providers in the state to provide abortions in certain emergency situations. The suit cited severe preeclampsia as a condition that would require abortion as definitive treatment, particularly in the previable period. This cost-effectiveness model estimated the maternal health outcomes and costs associated with an inability to provide emergency abortion care for previable preeclampsia across the United States.

Study Design: A decision-analytic model was built using TreeAge software to evaluate a total ban on emergency abortion in a theoretical cohort of 5,428 women based on the incidence of previable preeclampsia and birth data from the 23 states with bans. Probabilities, utilities and costs were derived from the literature. National data were used to estimate the number of women who would travel out of state to obtain an abortion (27.2%). The threshold for cost-effectiveness was set at $100,000 per quality adjusted life year (QALY). Clinical outcomes included ICU admission, cases of HELLP syndrome or eclampsia, maternal death, NICU admission, and neonatal neurodevelopmental delay.

Results: Emergency abortion bans limiting care for previable severe preeclampsia resulted in 549 additional maternal and neonatal ICU admissions, 1,976 cases of HELLP syndrome, and 152 cases of eclampsia. The ban resulted in 1,476 individuals traveling out-of-state for termination. A policy restricting abortion was associated with higher costs ($374,350,596) and decreased quality of life (2,859 QALYs) annually.

Conclusion: Abortion bans that restrict emergency abortion care to treat previable severe preeclampsia result in increased maternal complications and costs and decreased quality of life. Policies addressing abortion access should consider these health and cost impacts for both individuals and society.

Table 1.
Additional cases of each outcome in a theoretical cohort of 5,428 women with previable severe preeclampsia at 20 weeks' gestation in states with abortion bans.

n=5,428	No Abortion Ban	Abortion Ban	Difference
Maternal Mortality	0	64	64
Maternal ICU Admission	0	439	439
HELLP Syndrome	0	1,976	1,976
Eclampsia	0	152	152
NICU Admission	0	110	110
Neonate with Neurodevelopmental Disability	0	31	31
Abortions	5,428	1,476	3,952
Cost	$43,913,823	$418,264,419	$374,350,596
Effectiveness (QALY)	134,352	131,493	2,859

172 | Reference Range for Elecsys Sflt-1/Plgf Ratio in a Diverse U.S Population

Antonio F. Saad[1]; David M. Haas[2]; Eugene Y. Chang[3]; Scott A. Shainker[4]; Michelle Silasi[5]; George R. Saade[6]; Sarosh Rana[7]; Tetsuya Kawakita[6]; Luis D. Pacheco[8]; Jennifer Powers Carson[9]; Angela Dietl[10]; Deirdre Allegranza[11]; Ge Guo[12]; David M. Stamilio[13]

10:30 AM - 12:30 PM

Objective: Preeclampsia (PE) is a major cause of maternal and neonatal mortality and morbidity. The imbalance of two proteins, soluble fms-like tyrosine kinase 1 (sFlt-1) and placental growth factor (PlGF), are known to contribute significantly to the development of PE.

The sFlt-1/PlGF ratio test is used for the clinical prediction of PE in many countries worldwide but has not been widely adopted in the US. This study aimed to determine the reference range for the Roche Elecsys® sFlt-1/PlGF ratio (electrochemiluminescent immunoassays) in a racially and ethnically diverse healthy US population of pregnant women at 23+0 - 34+6 gestational weeks.

Study Design: A non-interventional sample and data collection study performed from November 2022 to December 2023 at nine US hospitals. Consented apparently healthy pregnant individuals (≥18 years old) had one serum sample collected (frozen at -60 to -90°C) with postpartum maternal and neonatal clinical outcomes collected to confirm eligibility for analysis. To ensure a healthy study population subjects were excluded from analysis if they met any of the pre-defined exclusion criteria including diagnosis of specific health conditions or preterm delivery < 37 weeks. The sFlt-1/PlGF ratio was not known to the enrolling sites at any time. A nonparametric method per CLSI EP28-A3c was used to calculate the central 95% reference interval and the 90% confidence intervals (CIs) around the lower and upper reference limits (2.5th and 97.5th percentiles) for the overall cohort and three gestational age windows subgroups (23+6 - 26+6, 27+0 - 30+6, 31+0 - 34+6).

Results: Of 591 enrolled, 380 subjects met criteria for analysis in gestational weeks 23+0 - 34+6 days. Gestational hypertension was the main reason for exclusion followed by PE and preterm delivery. The cohort (n = 380) was representative of the US population in terms of self-reported race and ethnicity: 78.16% White, 14.21% Black/African American, 5.53% Asian and 18.95% Hispanic or Latina.

Conclusion: This study is the first to estimate sFlt-1/PlGF ratio reference ranges in a diverse US population using the Roche Elecsys assays.

Table 1: sFlt-1/PlGF reference range distribution

Gestational week	Total N	Mean	Median	2.5th percentile (90% CI)	97.5th percentile (90% CI)
23+0 - 34+6	380	4.31	3.21	0.857 (0.671, 1.01)	13.5 (11.6, 14.9)
Sub-divided reference range windows					
23+0 - 26+6	141	4.59	3.91	1.32 (0.848, 1.43)	11.9 (11.0, 14.1)
27+0 - 30+6	116	3.55	3.05	0.853 (0.290, 1.08)	10.4 (7.25, 13.5)
31+0 - 34+6	123	4.68	2.76	0.733 (0.395, 0.887)	16.4 (13.1, 43.9)

173 | Severe Maternal Morbidity from Peripartum Hysterectomy: Is there a Difference Between Accreta and Non-Accreta Cases?

Devesh Naidoo[1]; Vineet Shrivastava[2]; Megan C. Oakes[3]

[1]MemorialCare Miller Children's and Women's Hospital Long Beach, Long Beach, CA; [2]MemorialCare Miller's Children's and Women's Hospital, Long Beach, CA; [3]MemorialCare Miller Children's and Women's Hospital Long Beach, Miller Children's and Women's Hospital, Long Beach, CA

10:30 AM - 12:30 PM

Objective: Evaluate the difference in rates of severe maternal morbidity (SMM) among patients undergoing peripartum hysterectomy for placenta accreta spectrum (PAS) compared to non-PAS indications.

Study Design: This was a retrospective cohort study of all patients who had a peripartum hysterectomy performed at an urban, tertiary care hospital from 1/1/2010-6/30/2023. Patients with a preoperative diagnosis of suspected PAS were compared to those who underwent peripartum hysterectomy for non-PAS indications, such as uterine atony. The primary outcome was composite SMM. Secondary outcomes included individual

maternal morbidities and mortality. A planned subgroup analysis comparing unscheduled, peripartum hysterectomy for PAS compared to non-PAS peripartum hysterectomy was conducted. Chi-square and Fisher's exact were used as appropriate.

Results: 125 patients underwent peripartum hysterectomy during the specified period, 63 (50.4%) for suspected PAS and 62 (49.6%) for non-PAS indications. Those who underwent peripartum hysterectomy for non-PAS cases had a significantly higher SMM rate compared to suspected PAS cases (96.7% vs 85.7%, p = 0.03). This was largely driven by transfusion (96.7% vs 85.7%, p = 0.03), as non-transfusion SMM did not differ between the groups (67.7% vs 68.2%, p = 0.95). Only bowel and bladder injury were noted to be different between the groups, with more events in the suspected PAS group (26.9% vs 6.4%, p < 0.05). In a subgroup analysis comparing unscheduled, peripartum hysterectomy for PAS (n = 24) compared to non-PAS cases, there was no difference in composite SMM between the groups (100% vs 96.7%, p = 0.37).

Conclusion: Composite SMM was higher in cases of non-PAS peripartum hysterectomy compared to suspected PAS cases, driven exclusively by higher rates of blood transfusion. However, this difference disappears when comparing non-PAS hysterectomy to unscheduled, peripartum hysterectomy for suspected PAS. While both groups have high rates of SMM, this highlights the difference that preparation can have for planned peripartum hysterectomy for suspected PAS cases.

Table 1 Severe Maternal Morbidity (SMM) for peripartum hysterectomies between non-PAS and PAS indications

	Non-PAS n = 62		Suspected PAS n = 63		
	n	%	n	%	*p* -value

174 | Factors Associated with a Positive Tilburg Pregnancy Distress Scale Among Ghanaian Patients

Dhanalakshmi Thiyagarajan[1]; Sarah Compton[1]; Astrid Sarfo[2]; Elijah Amenuveve[3]; Alim Swarray-Deen[4]; Emma Lawrence[1]; Promise Sefogah[5]

[1]University of Michigan, Ann Arbor, MI; [2]UCLA, Los Angeles, CA; [3]Korle Bu Teaching Hospital, Korle Bu Teaching Hospital, Greater Accra; [4]University of Ghana Medical School, University of Ghana Medical School, Greater Accra; [5]University of Ghana, University of Ghana, Greater Accra

10:30 AM - 12:30 PM

Objective: To identify factors associated with a positive Tilburg Pregnancy Distress Scale (TPDS) among Ghanaian patients.

Study Design: We performed a prospective cohort study of obstetric patients who were admitted at an urban, teaching hospital in Ghana between November to December 2023. Patients below the age of 18 or critically ill were excluded. Demographic and medical history were collected, and the TPDS was administered. We performed descriptive and inferential statistics including cross tabs with chi-square analysis and logistic regression models.

Results: Out of the 440 patients eligible for participation, 420 patients enrolled in our study. A total of 166 (40%) patients were admitted antepartum, and 254 (60%) patients were admitted postpartum. Overall, 157 (37%) patients screened positive for pregnancy distress; 60 (36%) antepartum patients, and 97 (38%) postpartum patients screened positive for pregnancy distress.

For those in the antepartum period, the factors associated with a positive screen included low income (p = 0.042), younger age (p < 0.001), and lower parity (p-0.049) while those with more education and older age were less likely to have a positive TPDS.

For those in the postpartum period, less education (p = 0.048), cohabitation compared to other relationships (p = 0.01), having an emergency compared to elective cesarean delivery (p = 0.036), and having at least one antepartum admission (p = 0.025) were associated with having a positive TPDS.

Conclusion: Our study is the first to identify risk factors contributing to Ghanaian patients' pregnancy distress, which can contribute to depression with peripartum onset. We believe utilizing these risk factors among Ghanaian pregnant patients for increased screening and monitoring can improve the prevention and treatment of mental health disorders, which is aligned with Sustainable Development Goal 3.4.

175 | Implementation of External Cephalic Version at Korle Bu Teaching Hospital, Ghana: A Quasi-Experimental Design

Dhanalakshmi Thiyagarajan[1]; Jessica McCoy[1]; Mackenzie Woock[1]; Promise Sefogah[2]; Samuel Oppong[2]; Nana Essuman Oduro[2]; Alim Swarray-Deen[3]
[1]University of Michigan, Ann Arbor, MI; [2]University of Ghana, University of Ghana, Greater Accra; [3]University of Ghana Medical School, University of Ghana Medical School, Greater Accra

10:30 AM - 12:30 PM

Objective: To understand outcomes after the implementation of external cephalic version (ECV).

Study Design: We conducted a quasi-experimental study of patients with malpresentation at an urban teaching hospital in Ghana. Patients with multiple gestation or presenting with intrauterine fetal demise were excluded. Demographics and medical history of those presenting for delivery complicated by malpresentation between January 2012 to December 2015 were collected. The practice of ECV was implemented by the Obstetrics and Gynecology Department between 2016-2018. Demographics and medical history of those receiving ECVs between January 2019 to December 2022 were collected. We performed descriptive statistics.

Results: From 2012 to 2015, data was available for 1,789 patients who presented for delivery with malpresentation. Our study included 1,739 patients after excluding incomplete data entries. From 2019 to 2022, data was available for 133 patients who underwent ECV. Our study included 72 patients after excluding incomplete data entries.

Prior to implementation of ECV, 438 (25%) and 1,301 (75%) had vaginal breech and cesarean deliveries, respectively. Overall, 122 (7%) of malpresentations resulted in intrapartum fetal demise. Ninety-five (22%) of the vaginal deliveries, and 27 (2.1%) of the cesarean deliveries were complicated by intrapartum fetal demise.

After implementation of ECV, 39 (54%) had spontaneous, breech, or operative vaginal deliveries, and 33 (46%) had cesarean deliveries. There was no intrapartum fetal demise.

Of the 72 ECVs, 53 (74%) were successful. When presenting for delivery, 48 (91%) remained in the cephalic presentation. Of those with successful ECV and remaining in the cephalic presentation, 35 (73%) had a spontaneous or operative vaginal delivery, and 13 (27%) had a cesarean delivery.

Conclusion: The implementation of ECV resulted in the reduction of intrapartum fetal demises and cesarean deliveries. Our research suggests external cephalic version is a practical, feasible, and implementable intervention that can be integrated into low- and middle-income countries' hospitals.

176 | Clinical Outcomes with the use of Thromboelastography in Postpartum Hemorrhage

Aarti Kumar[1]; Dominique Noriega[1]; Claudia G. Durbin[1]; Madison S. House[2]; Ashley S. Roman[3]; Meghana A. Limaye[3]
[1]New York University, New York, NY; [2]New York University Grossman, School of Medicine, New York, NY; [3]NYU Langone Health, New York, NY

10:30 AM - 12:30 PM

Objective: Thromboelastography (TEG) is a viscoelastic test which has been shown to improve outcomes in postpartum hemorrhage (PPH) by rapidly guiding resuscitation. We incorporated TEG into our hemorrhage response protocol (HRP), an algorithm facilitating swift response to PPH, in a pilot study at our high-volume academic medical center. We evaluated the impact of TEG utilization on maternal outcomes and transfusion rate.

Study Design: We conducted a retrospective study of patients with PPH, defined as quantitative blood loss (QBL) >900cc for vaginal delivery or QBL >1500cc for cesarean delivery. The composite (primary) outcome of maternal morbidity included ICU admission, DIC, UAE, surgical intervention including hysterectomy, and/or administration of >3 units of any blood products. Secondary outcomes included number and type of products transfused. Outcomes were compared before (pre-TEG) and after (post-TEG) incorporation of TEG. Analysis was performed with Chi Square, Fisher's Exact, Mann Whitney U, T-tests, and relative risk. Outcomes were also analyzed by QBL category, mode of delivery, and stages of PPH.

Results: 271 post-TEG and 131 pre-TEG cases were analyzed. Demographics were similar in pre and post TEG groups (Table 1). 5.3% of pre-TEG and 7.4% of post-TEG cases met the composite outcome (p = 0.44). Overall more pRBCs were transfused post-TEG (p = 0.05) with no significant difference in non-RBC transfusion (p = 0.29). Subgroup analyses are shown in Table 2. Cases with stage 3 hemorrhage received more pRBCs post-TEG (p = 0.03) with no significant difference in non-RBC transfusion. Of cases with QBL >3L, significantly more non-RBC products were given post-TEG (p = 0.01).

Conclusion: Overall, inclusion of TEG in an HRP protocol was associated with unchanged rates of composite maternal morbidity. Future studies should investigate TEG as well as the optimal cohort of patients who could benefit from TEG for guided resuscitation of PPH.

	Pre-TEG (N = 131)	Post-TEG (N = 271)	p-value

177 | Preeclampsia and the Risk for Celiac Disease of the Offspring

Dora Davidov[1]; Eyal Sheiner[2]; Tamar Wainstock[2]; Gali Pariente[2]
[1]Soroka University Medical Center, Soroka University Medical Center, HaDarom; [2]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom

10:30 AM - 12:30 PM

Objective: While the pathophysiology of preeclampsia is multifactorial, the immune system plays a major role in the pathogenesis of the disease. As celiac is an immune mediated inflammatory disease, we opted to investigate the association between maternal preeclampsia and celiac disease of the offspring.

Study Design: A population-based cohort study was conducted to evaluate the risk of celiac disease in offspring (up to the age of 18 years) born to mothers with and without preeclampsia. Deliveries occurred between the years 1991-2021 in a tertiary medical center. Data for the diagnosis of celiac disease of the offspring was extracted from community-based clinics and hospitalization records. Kaplan-Meier survival curve was used to compare the cumulative incidence of celiac disease between the study groups. A cox proportional hazards model was used to control for confounders.

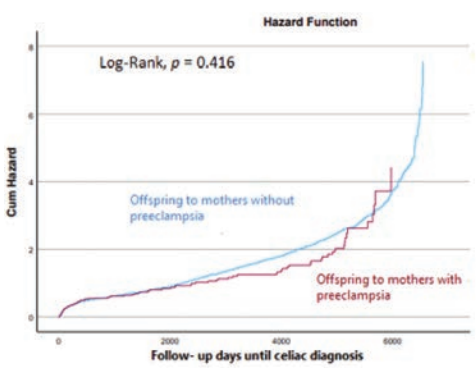
Results: During the study period, 356,356 singleton deliveries were included in the study of which 13,721 deliveries (4.2%) were in women with preeclampsia. Being born to a woman with preeclampsia was not significantly associated with higher risk for childhood celiac disease of the offspring (0.6% vs. 0.5%, p = 0.378, Table). Likewise, the Kaplan-Meier survival curve did not demonstrate a significantly higher cumulative incidence of celiac disease in offspring born to women with preeclampsia (Log- Rank p = 0.416, Figure). Using a Cox proportional hazards model, adjusted for maternal celiac disease, maternal age and gestational age at birth, maternal preeclampsia was not independently associated with childhood celiac disease of the offspring (Adjusted HR 0.89, 95% CI 0.71-1.11, p = 0.316, Table).

Conclusion: Despite the shared possible pathophysiology of preeclampsia and celiac disease, no significant association was found between maternal preeclampsia and childhood celiac disease of the offspring.

Figure: The association between maternal preeclampsia and celiac disease; univariable analysis, Kaplan-Meier survival curve, and a Cox proportional hazards model

	Preeclampsia (n=13,721) n (%)	No preeclampsia (n=342,635) n (%)	OR (95% CI)	P value	Adjusted HR* (95% CI)	P* value
Childhood celiac disease	83 (0.6)	1878 (0.5)	1.10 (0.88-1.37)	0.378	0.89 (0.71-1.11)	0.316

*Adjusted for gestational age, maternal age and maternal celiac



178 | Let's Talk About Race: Clinician Perspectives on Navigating Conversations Around Racial Disparities in Obstetrics

Eileen Wang-Koehler; Sindhu K. Srinivas; Abike T. James; Rebecca F. Hamm
University of Pennsylvania Perelman School of Medicine, Philadelphia, PA

10:30 AM - 12:30 PM

Objective: Discussions around racial disparities in obstetrics occur in varied silos including the media, communities, and medical institutions. Yet, whether and how these discussions occur in the context of the clinician-patient relationship is unknown. We sought to explore clinician perspectives on conversations with patients regarding racial disparities in maternal health using a qualitative approach.

Study Design: We enrolled perinatal clinicians (n = 14) across two hospitals within one academic health system from 8/2023-3/2024, purposively sampled by self-identified race/ethnicity and role until thematic saturation was achieved. Semi-structured interviews utilizing the Health Equity Implementation Framework evaluated (a) prior experience with, and (b) optimization of disparities counseling, focusing on clinician-patient race concordance, comfort levels, barriers, ideal circumstances, and recommended content for conversations around racial disparities in maternal health. Interviews were coded using a content analysis approach by two coders with high inter-rater reliability (k >0.8).

Results: Clinicians universally recognized the impact of race, specifically racism, on US maternal outcomes. Conversations around racial disparities most frequently arose (1) when Black patients voiced fears of dying or concerns about bias in their care, or (2) in the context of recommending aspirin for preeclampsia risk reduction. Black clinicians felt more comfortable with these discussions, attributed to lived experience and practice. While most clinicians agreed that conversations with patients about racial disparities are important, they identified barriers such as fear of patient reactions (particularly with discordant race), time constraints, and unclear actionable response (Table 1). Participant suggestions for facilitating these conversations are shown in Table 2.

Conclusion: These data, alongside ongoing work on the patient perspective, provide the groundwork for guiding clinician-patient conversations on maternal health disparities.

Table 1: Examples of Comfort Level and Barriers to Discussing Race with Obstetric Patients

	Participant Quotes
Factors underlying clinician comfort or discomfort	*Worry about patient perception* "I wouldn't want my intention to have the wrong impact, especially being a White person and in a relative position of power…**if it came across as me discriminating against them.**" (Non-BIPOC) *Unclear actionable response* "I think what makes me uncomfortable is that **I can't promise to keep someone as safe based on their race.**" (Non-BIPOC) *Overcoming discomfort through shared identity* "**I was black before I became a doctor.** I feel very comfortable talking about racial issues." (BIPOC) *Overcoming discomfort through practice* "There are many things in medicine that may have been uncomfortable [like taking a sexual history] **that if you keep doing them and if it becomes part of your workflow, it'll get easier.** You'll figure out your way to navigate around it." (BIPOC)
Concerns and barriers	*Lack of training* "I don't think **I've ever received true training in how to talk to patients** about it. I feel like I know how to talk to colleagues about it, but to actually talk to a patient who has a very real fear that they are going to be within that percentage of bad outcomes is very different." (BIPOC) *Finding the right phrasing and context* "Sometimes I would say, Black patients we know get preeclampsia at a higher rate. **I found it hard to explain the racism.**" (Non-BIPOC) *Time constraints* "I feel we only have time to get through so much. And a conversation about race and disparity is like an hours long conversation. **So, how do you do it justice, is my concern.**" (BIPOC) *Burden on Black providers* "There's an immense pressure on us to see black patients by black patients, because patients want racial concordance, especially if they've already had a bad outcome, and **we need to empower [our colleagues] to feel comfortable talking about race.**" (BIPOC)

BIPOC – those who self-identify as Black, indigenous, or other people of color

Table 2: Participant Suggestions for Facilitating Conversations about Race with Patients

	Examples:
Build Knowledge and Comfort with the Topic	• Engage in relevant book clubs, movie discussions, social media content • Participate in community work • Standardize implicit bias training • Hold Grand Rounds discussions
Practice	• Organize communication exercises or simulations with standardized patients • Practice with patients through trial and error
Enhance the System	• Lead guided patient group discussions, e.g. during group prenatal care • Use intake questionnaires to ask about experiences of racism and trauma • Incorporate doulas into obstetric care as a mediators

Use Example Strategies	• Frame conversations to make patients feel safe and that you are their advocate
	• Link a disparity with a medical or institutional action
	  • E.g. programs for free iron tablets or blood pressure cuffs
	• Acknowledge racism as the risk factor, not race
	  • E.g. discuss racism as a risk factor for preeclampsia, and the use of aspirin to reduce that risk

179 | Postpartum Contraceptive Use Among South Asians: A Retrospective Cohort Study from Kaiser Northern California

Ekta Partani[1]; Elijah Wade[2]; Cynthia Triplett[3]; Eisha B. Zaid[3]
[1]Kaiser Permanente Santa Clara, Santa Clara, CA; [2]Kaiser Permanente Division of Research, Kaiser Permanente Division of Research, CA; [3]Kaiser Permanente, Santa Clara, CA

10:30 AM - 12:30 PM

Objective: Health outcomes data among South Asian subgroups are scarce due to outdated federal reporting standards that merge various racial and ethnic groups into a single 'Asian or Pacific Islander' category, potentially obscuring disparities. As a result, obstetric and gynecologic outcomes, including contraception use and abortion trends, are poorly understood in this population. This study aimed to characterize postpartum contraceptive use among South Asian patients, factors associated with usage, and to determine the proportion of short interval pregnancies based on postpartum contraceptive use.

Study Design: This retrospective cohort study included all South Asian patients who delivered at Kaiser Northern California hospitals between 1/1/2018-1/1/2021 and had documentation of contraceptive use or declination within 12 weeks postpartum. Adjusted odds ratios for each outcome were calculated using multivariate logistic regression adjusting for variables found to be significant in bivariate comparisons.

Results: 11,264 patients met study inclusion criteria (91% Indian, 3% Pakistani, 2% Nepali, and 4% other South Asian or mixed race). 64.6% reported no postpartum birth control use. Only 7.37% of the total cohort selected a LARC (Nexplanon, Mirena or Copper IUD). Multiparity was associated with increased likelihood of birth control use ($p < 0.05$); while increasing age, higher socioeconomic status, marriage, and Indian descent ($p < 0.05$) were associated with lower likelihood of birth control and LARC use. Postpartum LARC users had the lowest incidence of short interval pregnancies ($p < 0.05$) and the use of any postpartum birth control was associated with a 14% lower incidence of short interval pregnancies ($p < 0.05$).

Conclusion: Use of postpartum birth control reduces the likelihood of short interval pregnancies. The majority of South Asians in our cohort reported no postpartum birth control use, and the rate of postpartum LARC use was lower than the US average of 9-15%. These findings suggest that targeted counseling and interventions are needed to improve postpartum contraception uptake among South Asian patients.

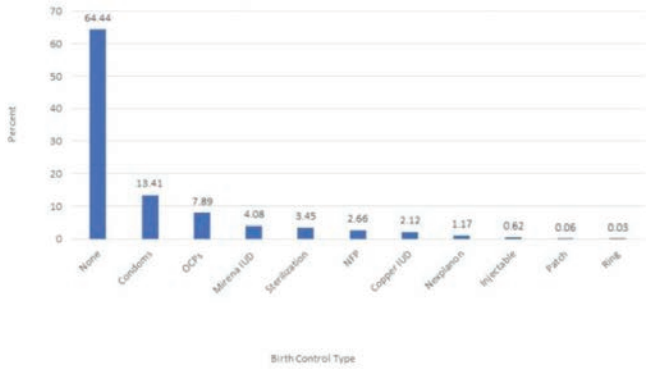


Table 1: Types of postpartum birth control within 12 weeks of delivery

10:30 AM - 12:30 PM

Objective: To uncover the hidden challenges and unmet needs of cardiac patients during the postpartum period.

Study Design: This was a parallel mixed-methods study of participants with cardiac disease who had delivered at a single tertiary hospital from 2013 to 2023. An electronic survey was sent to 330 participants with congenital heart disease (CHD) and acquired cardiac disease. Additionally, 20 participants with CHD were interviewed by phone in English or Spanish. Grounded theory methodology was employed to code and analyze the interviews, revealing key themes, which were then compared with survey findings.

Results: Interview participants highlighted five key themes: the necessity of taking time away from newborn for hospitalizations and surgeries due to cardiac complications, coping with cardiac symptoms that could be incapacitating, relying on support from family members or caregivers, desiring more medical follow-up appointments and in-person counseling about postpartum health expectations, and grappling with uncertainty regarding the appropriate healthcare professional to address their postpartum healthcare needs. Among the 128 survey participants, 83% preferred more than one postpartum visit and 61% preferred their first postpartum visit to take place within the first two weeks after delivery. When asked about their preferred alternatives to the standard postpartum clinic visit, 59% of respondents chose a telehealth visit with their obstetrician and 41% chose a home visit with a nurse or midwife.

Conclusion: Qualitative themes emphasize the physical and mental challenges patients with cardiac disease encounter following pregnancy. Interview participants also articulated the healthcare gaps they encountered during the postpartum period, resulting in unmet health concerns and visits to the emergency department. Survey findings highlight patient preference for earlier and more frequent postpartum visits with their obstetrician. These findings underscore the urgent need for more comprehensive postpartum care, particularly for patients with high-risk pregnancies.

Fig 1. Demographic and delivery information of phone interviewees and survey respondents.

Key Theme	Quotes
Taking time away from newborn for hospitalizations and surgeries due to cardiac complications	"…my second child I went into heart failure, I think four months or five months after that. So that was fun. So I had to deal with all this other stuff." "So I went to (hospital name). They took my blood pressure immediately…I have like a brand new baby in the hospital room with me for like, you know, over 24 hours you know, trying to like care for her..."
Coping with cardiac symptoms that could be incapacitating	"I'd say the only thing with the second one was I'd say some of the cardiac symptoms certainly remained after delivering and they have not…even five years almost six years later, I have not fully resolved at this point" "Going to my doctor's appointment like for me it was hard but I had to go especially with my condition. You know, I can't miss an appointment… I mean it was hard for me to get out of the bed sometimes"
Relying on support from family members or caregivers	"After a C section…you're told not to drive. So imagine somebody who has to take his or her child like my son was in the ICN… And he [husband] was able to drive us but like how do I even see my son or even send my milk?" "I didn't want to hold him. I didn't want to, like I knew in my heart that I loved him. I just didn't feel that connection with him right away. Like my husband pretty much took care of him for the first month of his life because I just couldn't do it."
Desiring more medical follow-up appointments and in-person counseling about postpartum health expectations	"Yeah, I feel like thing they would be better if they could offer a little more postpartum support. So basically all I have is one postpartum checkup at six week mark."
Uncertainty regarding the appropriate healthcare professional to address their postpartum healthcare needs	"I was okay with my primary care because…I trusted him but it did feel to me at the time that it should have been my OB just because I gave birth two weeks ago, and now I'm having blood pressure issues since." "You have a baby and then like for nine months or so you're under the care of somebody else. By the time you're out of that…I had to figure it out and I had to get a new family care provider."

181 | Fetal MRI Versus Ultrasound Ratios for Predicting Perinatal Outcomes in Prenatally Diagnosed Omphalocele

Simon E. Dadoun; Matthew Shanahan; Christian M. Parobek; Brian Burnett; Pamela Ketwaroo; April D. Adams
Baylor College of Medicine, Houston, TX

10:30 AM - 12:30 PM

Objective: Complications associated with pulmonary hypoplasia are the primary cause of morbidity and mortality in neonates with omphalocele. Various prognostic indicators have been employed to identify neonates at greatest risk. Recently, fetal MRI lung volumetric analysis has become more commonplace, despite being costly and requiring access to specialized centers. This study compares fetal MRI-derived fetal lung volumes and ultrasound-derived ratios as prognostic tools in fetuses with prenatally detected omphalocele (PDO).

Study Design: This retrospective cohort study included all pregnancies with PDO who underwent evaluation at our fetal center from 2007-2023. Pregnancies with fetal aneuploidy or concurrent life-limiting fetal anomaly were excluded. MRI-derived fetal lung volume analysis calculated the observed-to-expected total fetal lung volume (O/E TLV) ratio. Omphalocele diameter (OD), abdominal circumference (AC), and head circumference (HC) were recorded, and OD/HC and OD/AC ratios were calculated. The primary outcome was neonatal death. Secondary outcomes included the need for intubation, prolonged intubation >30 days, pulmonary hypertension, and time to full feeds. Cutoffs for the prediction of neonatal outcomes were determined by receiver operating characteristic curve (ROC) analysis.

Results: 53 pregnancies met the inclusion criteria. Omphaloceles ranged in size from 0.9-20cm in diameter. 8 neonates (15%) experienced neonatal death (Table 1). The most frequent secondary outcome was the need for intubation, occurring in 22 (42%) neonates. Using an optimal cutoff of >0.58, MRI-based O/E TLV outperformed ultrasound-based ratios in predicting neonatal death (sensitivity 0.75; specificity 1.0; AUC 0.92), as well as most of the secondary outcomes (Table 2). Among ultrasound-based ratios, OD/AC consistently outperformed OD/HC.

Conclusion: Fetal MRI O/E TLV outperforms ultrasound-based ratios in predicting perinatal severe morbidity and neonatal mortality in PDO. These findings underscore the need for more advanced ultrasound-based measures to increase accessibility to high-quality care.

182 | Electronic Health Record Smart-Phrase Intervention to Improve Rates of Low-Dose Aspirin Prescription for Preeclampsia Prevention

Elisha Jaeke[1]; Sara Abuzahra[1]; Ihuoma (Yvette) Igbokwe[1]; Amarpreet Mahil[2]; Emily Davidson[1]; Jacqueline Peebles[1]; Anna Palatnik[1]
[1]Medical College of Wisconsin, Milwaukee, WI; [2]MCW, Wauwatosa, WI

10:30 AM - 12:30 PM

Objective: While low-dose aspirin (LDA) is recommended for preeclampsia prevention in at-risk patients, studies show suboptimal screening and prescription in routine obstetric care. The goal of this quality improvement initiative was to create, implement and test an electronic health record (EHR) smart-phrase to increase LDA prescription rates.

Study Design: After a retrospective analysis in 2021 revealed low baseline rates of LDA prescription for eligible patients within our academic hospital system (Table), an LDA eligibility screening smart-phrase was created and launched for use in First OB note templates through a departmental quality initiative from January 2023-May 2024 (Figure). Low baseline LDA prescription rates

were shared at Hospital-Wide OB, OBGYN Generalist, and MFM Division meetings, with serial reminders to use the smart-phrase throughout the study period. Rates of smart-phrase utilization by obstetricians and LDA prescription for eligible patients were collected at three quality assessment cycles 3-, 9-, and 13-months post-intervention launch.

Results: A total of 721 LDA eligible First OB notes were evaluated. Rates of LDA prescription for patients with at least one high-risk factor improved from 72% pre-intervention to 92% at 13-months post-intervention (Table). LDA prescription for patients with at least two moderate-risk factors and no high-risk factors improved from 21% pre-intervention to 61% at 13-months post-intervention. The use of the LDA eligibility screening smart-phrase during First OB visits increased during each quality assessment cycle from 42% to 53% and to 56% at 3-, 9-, and 13-months post-intervention, respectively. Of patients eligible for LDA, there was a statistically significant increase in prescription rates across the evaluation periods for patients whose provider used a smart-phrase ($p = 0.02$, < 0.01, and 0.04 at 3-, 9-, and 13-months, respectively).

Conclusion: Incorporating a risk-identifying smart-phrase into First OB EHR notes led to two synergistic improvements: increased identification of at-risk patients who are LDA eligible and increased rates of LDA prescription.

Table. Baseline and post-intervention LDA eligibility and prescription rates, and associated smart-phrase utilization over three post-intervention study periods

	Baseline Cohort Patients who delivered between 9/1/2021 and 12/31/2021	3 Months Post-Intervention First OB Visit during July 2023	9 Months Post-Intervention First OB Visit during January 2024	13 Months Post-Intervention First OB Visit during May 2024
Total number of patients in each cycle	755	207	301	213
Number of LDA eligible in each cycle	398	121	173	132
Number of patients with at least one high-risk factor for preeclampsia	120	42	43	39
Number of patients with at least two moderate-risk factors and no high-risk factors for preeclampsia	278	79	130	93
Percent of eligible patients prescribed LDA for at least one high-risk factor	71.7%	83.3%	83.7%	92.3%
Percent of eligible patients prescribed LDA for no high-risk factors and at least two moderate-risk factors	20.5%	57.0%	61.5%	61.3%
Percent of patients in each cycle with an obstetrician note utilizing an LDA-identifying smart-phrase	N/A	42.0%	52.8%	56.3%
Percent of eligible patients whose obstetricians successfully identified their LDA eligibility with a smart-phrase	N/A	76.8%	87.6%	77.2%
Percent of eligible patients whose obstetricians successfully identified their LDA eligibility without using a smart-phrase	N/A	56.9%	47.4%	60.4%

LDA = low-dose aspirin

183 | Physical Activity Among Pregnant Individuals by BMI Category: a Specific Focus on Class III Obesity

Eliza M. Nguyen; Megan E. Branda; Linda M. Szymanski
Mayo Clinic, Rochester, MN

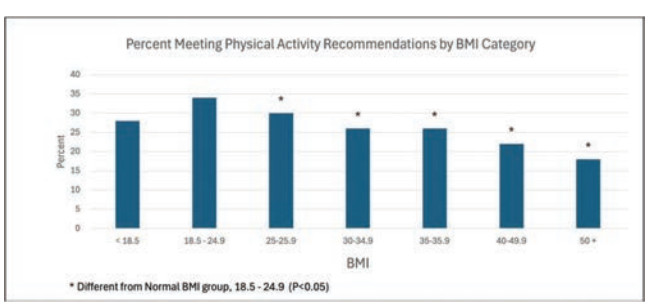
10:30 AM - 12:30 PM

Objective: The prevalence of pre-pregnancy obesity, including pre-pregnancy class III obesity has increased over time, with significant implications for maternal and neonatal well-being. Regular physical activity may mitigate these risks. Data also suggest that a majority of pregnant individuals do not meet the recommended physical activity guidelines of accumulating at least 150 minutes of moderate-intensity exercise per week; however physical activity data are limited for individuals in higher BMI categories, particularly for those with class III obesity (BMI > 40). The aim of this study was to evaluate whether pregnant individuals are meeting physical activity guidelines. We assessed self-reported physical activity across BMI categories including those with class III obesity, subdivided into BMI 40-49.9 and ≥ 50.

Study Design: This is a retrospective cohort study of individuals at an academic hospital system who delivered between May 1, 2018 and May 1, 2023. To be included, individuals had a documented pre-pregnancy BMI and responded to the following two-item physical activity questionnaire during or just prior to pregnancy: 1) On average, how many days per week do you engage in moderate to strenuous exercise? And 2) On average, "how many minutes do you engage in exercise at this level?" Individuals met physical activity guidelines if they engaged in greater than or equal to 150 minutes of physical activity per week. Data were analyzed using Kruskal Wallis and Chi-Square tests.

Results: A total of 6,884 individuals were included in the cohort. See table for descriptive data. Physical activity data are shown in the figure.

Conclusion: Our results are consistent with existing data showing that pregnant individuals are not meeting physical activity goals. Overweight and obese pregnant individuals participate in significantly less activity than normal weight counterparts with even less activity reported in those with Class III obesity. More data is needed on physical activity among pregnant individuals with class III obesity, as this may have implications for both maternal and neonatal health.



BMI: Category:	<18.5 (Underweight)	18.5 - 24.9 (Normal)	25-29.9 (Overweight)	30-34.9 (Class I)	35-39.9 (Class II)	40-49.9 (Class III)	50 + (Class III)	P-value

184 | Histologic Chorioamnionitis as a Marker for Surgical Site Infection

Elizabeth L. Lucarelli Baldwin[1]; Serdar Ural[2]; Christina Stetter[3]; Kendall M. Cunningham[2]; Ravi Chokshi[2]; William Hayes[2]; William M. Curtin[3]
[1]Penn State Health/Hershey Medical Center, Mendham, NJ; [2]Penn State/Hershey Medical Center, Hershey, PA; [3]Penn State College of Medicine, Hershey, PA

10:30 AM - 12:30 PM

Objective: Clinical chorioamnionitis is a known risk factor for c-section surgical site infection (SSI). As histologic chorioamnionitis (HCA) is a marker for intraamniotic infection, we hypothesized that the frequency of HCA would be increased in SSI.

Study Design: This was a case-control study of singleton pregnancies having had c-sections from 2002-2022, in which the placenta was submitted to pathology. Subjects were identified via electronic information management system query. Univariate comparisons of SSI and non-SSI groups were made using Student's t-test and chi-square test. We calculated that 189 patients (126 controls and 63 cases) would be needed to detect a two-fold increased rate of HCA, using a two-sided test, with 80% power and significance level of 0.05. Logistic regression analysis tested whether or not HCA was an independent predictor of SSI.

Results: The estimated incidence of SSI was 6.95%. 63 cases of SSI were compared to 127 randomly selected controls (see Figure); about 32% of subjects labored. Presence of HCA was higher in cases (20.6%) than in controls (9.4%), (OR 2.49, 95% CI [1.06, 5.84]). After adjusting for the independent variables of labor, ruptured membranes, pre-pregnancy BMI, nonreassuring fetal heart status, and preoperative vaginal preparation HCA was no longer significantly associated with SSI. Independent positive predictors for SSI included increasing BMI and c-section for nonreassuring fetal status, while having had a vaginal prep reduced the odds of SSI (see Table).

Conclusion: HCA was increased in cases but was not an independent predictor of SSI. The strength of this study was using a standardized definition for SSI and individual patient chart review. The study was limited by the sample size, and that the majority of cases didn't labor. As intraamniotic infection and HCA are relatively rare in nonlaboring patients, future studies should include only SSI in cesarean section after labor. If HCA were found to be an independent risk factor for SSI, this could be a group to target for further studies on the efficacy of postpartum antibiotic prophylaxis in reducing SSI.

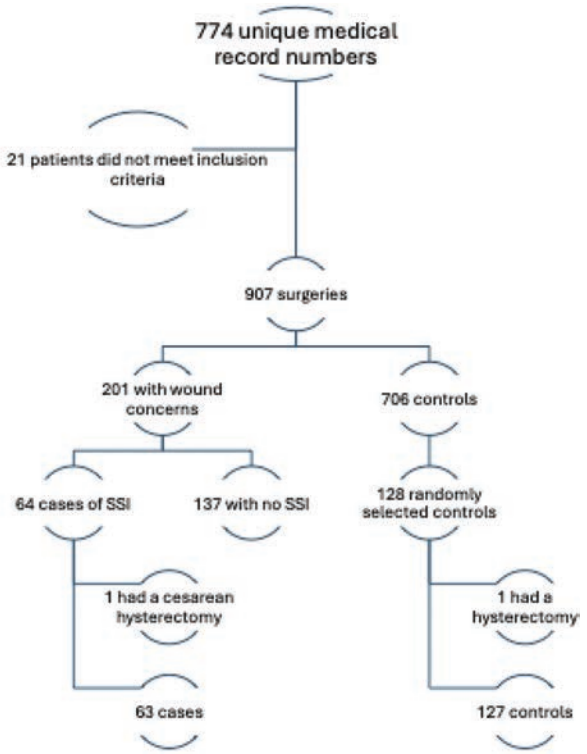

Figure: Flow diagram case (SSI) and control (non-SSI) selection

Table: Logistic regression analysis for independent predictors of SSI

Label		Odds Ratio (95% Confidence Interval)	p-value
Histologic Chorioamnionitis	Yes vs No	1.54 (0.56 – 4.24)	0.41
Presence of Labor	Yes vs No	1.33 (0.46 – 3.84)	0.60
ROM prior to delivery	Yes vs No	1.47 (0.52 - 4.13)	0.46
Pre-pregnancy BMI		1.07 (1.03 - 1.11)	**<0.001**

185 | Exploring Postpartum Social Determinants through Patient-Reported Outcome Measures: a Systematic Review

Elizabeth Soyemi[1]; Sydney L. Raucher[2]; Molly Beestrum[3]; Laura Diaz[2]; Brittney R. Williams[2]; Joe M. Feinglass[2]; Lynn M. Yee[2]
[1]Northwestern University Feinberg School of Medicine, Providence, RI; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Galter Health Sciences Library, Northwestern University Feinberg School of Medicine, Chicago, IL

10:30 AM - 12:30 PM

Objective: Social determinants of health (SDOH) pose specific challenges for the postpartum (PP) period. Although existing tools screen SDOH generally, few address SDOH in this unique life stage. We aimed to evaluate patient-reported outcome measures (PROMs) used to screen for SDOH during the PP period.

Study Design: This PROSPERO-registered systematic review included studies using a PROM to assess at least one SDOH in the PP period (up to 12 months after birth) in the United States. An academic librarian conducted a strategic search across 6 platforms using a protocol developed with clinical experts (Figure 1). Two authors independently screened all search results. For articles meeting inclusion criteria, authors extracted data and assessed quality of evidence with GRADE criteria and risk of bias using NIH tools.

Results: Of 4952 articles screened, 6 studies used a PROM to evaluate SDOH in PP people (Figure 2). Most studies were rated low-quality evidence and fair risk of bias. Among 11 PROMs identified across studies, only 5 were created specifically for PP administration. Of the 5 CDC-designated SDOH domains, Economic Stability was measured most through food or housing insecurity, followed by Social and Community Context through assessing social support. Only 6 PROMs measured social stability (e.g., employment status), and none covered all 5 SDOH domains.

Conclusion: Few PROMs exist to screen for PP SDOH. Areas such as change in insurance, childcare support, and maternal food assistance are rarely assessed even though these impact the PP period. To improve effectiveness for this population, PROMs should address PP-specific challenges, account for medical factors impacting level of social needs, such as parity and comorbidities, and measure resource access longevity through social stability metrics. Developing a comprehensive PP-specific SDOH PROM for routine PP care can address this evidence gap to better target unmet social needs and promote patient-centered care. Collaboration between community stakeholders, social workers, and clinicians to create a PP-specific SDOH PROM is vital for this process.

186 | Low Renin Angiotensin Aldosterone System (RAAS) Activation and Delivery Outcomes in Preeclampsia with Severe Features

Elizabeth L. Mirsky[1]; Robin Shoemaker[1]; Neil B. Patel[2]; Dolph Davis[1]; Hong Huang[1]; John A. Bauer[1]; John O'Brien[1]
[1]University of Kentucky, Lexington, KY; [2]Ascension Sacred Heart - Pensacola, Pensacola, FL

10:30 AM - 12:30 PM

Objective: To determine if a correlation exists between defects in RAAS activation and adverse delivery outcomes in patients diagnosed with preeclampsia with severe features.

Study Design: Prospective cohort study of patients admitted with preeclampsia with severe features from 2022 to 2024. Demographics, medical history and laboratory parameters were collected on admission. Serum samples were also analyzed from enrollment for angiotensin I, angiotensin II, and aldosterone by LC-MS/MS using RAAS-Triple A and compared based on serum aldosterone concentration. Maternal and fetal outcomes were compared between those with a low aldosterone concentration (Shoemaker et al., 2023) vs. the remainder of the cohort. A composite of delivery outcome complications including fetal growth restriction, abnormal umbilical artery Doppler, oligohydramnios, pulmonary edema, eclampsia, and postpartum hemorrhage was compared between subgroups, in addition to individual elements of the composite.

Results: 50 patients were enrolled. RAAS profiling revealed two distinct subpopulations: 35 patients had low serum aldosterone [median 120.0 pmol/L; IQR (35.0–132.2 pmol/L)]. In contrast, 15 patients had normal pregnancy concentration [median 589.8 pmol/L; IQR (402.2 - 769.6 pmol/L)]. Demographic variables were similar between the two populations, apart from enrollment serum creatinine (Table 1). Delivery outcomes were mostly similar (Table 2). The rate of pulmonary edema varied between groups, but the composite complication rate did not reach statistical significance (RR 1.71, 95% CI 0.79-3.70). Neonatal length of stay was longer in the low aldosterone population [median 16.5,

IQR (7-69) vs. 5, IQR (3-25)], and maternal length of stay similarly approached significance.

Conclusion: Serum aldosterone concentration in patients with severe features may be associated with select maternal complications of preeclampsia at or near delivery. Additional studies are needed due to the rarity of these complications.

187 | Cell-Free DNA Screening Results by Stage of Maternal Malignancy

Emily Zhao[1]; Kristen Miller[2]; Angie C. Jelin[3]

[1]Johns Hopkins School of Medicine, Baltimore, MD; [2]Johns Hopkins Hospital, Division of Maternal Fetal Medicine, Baltimore, MD; [3]Johns Hopkins Medicine, Baltimore, MD

10:30 AM - 12:30 PM

Objective: Cell-free DNA (cfDNA) screening is increasingly used for non-invasive fetal aneuploidy screening. Maternal malignancy is associated with abnormal or non-reportable cfDNA screening results but the impact of tumor staging and origin on cfDNA screening remains unclear. Our objective was to characterize the types and stages of malignancies that result in atypical cfDNA results.

Study Design: We present a single center, retrospective review of cases with a known, suspected, or incidentally diagnosed malignancy during pregnancy who underwent cfDNA fetal aneuploidy screening between 2015-2023. We queried patients using ICD9/10 codes for malignancy. We excluded patients who did not have a confirmed malignancy during pregnancy or within 2 years post-partum, and those who did not undergo cfDNA testing. We extracted maternal history, cancer type/stage, cfDNA results, and fetal outcomes from the medical record. We used Fisher's exact test to analyze categorical variables.

Results: 97 cases of malignancy in pregnancy were identified, of which 37 patients underwent cfDNA screening. Eleven patients (30%) had abnormal or non-reportable cfDNA results: 2/8 (25%) patients with blood cancers and 9/29 (31%) patients with solid tumors. Overall, the fraction of stage 0, I, II, III, and IV solid cancers with abnormal cfDNA screening results was 0/3 (0%), 0/5 (0%), 2/6 (33%), 1/4 (25%), and 6/11 (50%), respectively. Pregnant patients with stage 2-4 cancers were more likely to have an abnormal cfDNA result than those with stage 0-1 cancers ($p = 0.03$). No fetuses had a confirmed cytogenetic abnormality.

Conclusion: Our data suggest that early stage, solid tumors are not reliably detected by prenatal cfDNA screening, while metastatic tumors are more likely to result in atypical cfDNA results. Larger patient cohorts are needed to further characterize the association of different tumor types and the pattern of cfDNA results. Ultimately, cfDNA may be more likely to incidentally diagnose certain types of maternal malignancy than others.

188 | Maternal Mortality According to State Abortion Legislation Following the Supreme Court Dobbs v. Jackson Ruling

Emily Nuss[1]; Mari Iwasaki[2]; Lindsay S. Robbins[1]; Peggy Ye[3]; George R. Saade[1]; Tetsuya Kawakita[1]
[1]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [2]Ross University School of Medicine, Miramar, FL; [3]MedStar Washington Hospital Center, Washington, DC

10:30 AM - 12:30 PM

Objective: Following the 2022 *Dobbs v Jackson* United States Supreme Court case, many states passed legislation limiting abortion access. We assessed how maternal mortality rates (MMR) were affected by the ruling, accounting for the coronavirus (COVID-19) pandemic.

Study Design: This was a difference-in-difference (DID) analysis using data from CDC WONDER (Center for Disease Control and Prevention, Wide-ranging ONline Data for Epidemiologic Research) from January 2018 to December 2023. We split this timeframe into three periods: pre-COVID (Jan 2018 to Feb 2020), pandemic (Mar 2020 to Jun 2022), and post-Dobbs (Jul 2022 to Dec 2023). We classified U.S. states as either abortion-restrictive (AR) or abortion-supportive (AS) based on their legislation at the time of this analysis. The primary outcome was maternal mortality, defined as "the death of a woman while pregnant or within 42 days of termination of pregnancy." We fitted generalized estimating equations with a Poisson distribution and a log link function to calculate DID estimates with 95% confidence intervals (95% CI).

Results: Of 16,417,081 births included in this analysis, 5,740,974 were in AR states and 10,676,107 were in AS states. Compared to the pre-COVID period, the pandemic had a higher MMR in both AR states (15.1 per 100,000 births; 95% CI 10.6, 19.6) and AS states (5.6 per 100,000 births; 95% CI 1.3, 9.9). The increase in MMR during COVID-19 was greater in AR states (DID 9.5 per 100,000 births; 95% CI 3.3, 15.7). Compared to the pre-COVID period, the post-Dobbs period was not associated with a higher MMR in AR states (1.3 per 100,000 births; 95% CI -4.6, 7.2) or AS states (1.3 per 100,000 births; 95% CI -1.3, 3.9).

Conclusion: MMR were consistently higher in AR states compared to AS states. COVID-19 exacerbated this difference, but the gap did not increase following the Dobbs ruling. These findings highlight the disparities in pregnancy outcomes across the US, underscoring the need for policies that address these differences.

Table 1. Outcomes according to state legislative climate and time periods (pre-COVID, pandemic, and post-Dobbs).

	Abortion-restrictive	Abortion-supportive	Difference (95% CI)
	Pre-COVID	Pre-COVID	Pre-COVID
Maternal mortality to 42 days (per 100,000 births)	23.8 (18.7-28.9)	14.6 (12.0-17.2)	9.2 (3.6-14.8)
Maternal mortality to 365 days (per 100,000 births)	32.8 (25.0-40.7)	22.2 (18.0-26.3)	10.7 (1.9-19.5)
Preterm birth (%)	11.1 (10.6-11.7)	9.1 (8.8- 9.5)	2.0 (1.4- 2.6)
Cesarean delivery (%)	33.9 (32.1-35.7)	31.2 (30.0-32.3)	2.7 (0.4- 5.1)
Overall mortality per 100,000 reproductive women	8.5 (6.8-10.3)	5.9 (5.2- 6.5)	2.7 (0.9-4.5)
	Pandemic	Pandemic	Pandemic
Maternal mortality to 42 days (per 100,000 births)	38.9 (35.4-42.3)	20.2 (14.5-25.9)	18.7 (12.1-25.3)
Maternal mortality to 365 days (per 100,000 births)	52.7 (47.5-57.9)	31.3 (24.7-37.8)	21.4 (13.1-29.8)
Preterm birth (%)	11.4 (10.9-11.9)	9.2 (8.9- 9.6)	2.1 (1.5- 2.7)
Cesarean delivery (%)	34.0 (32.3-35.7)	31.5 (30.3-32.7)	2.5 (0.3- 4.7)
Overall mortality per 100,000 reproductive women	11.4 (9.2-13.7)	7.5 (6.8- 8.3)	3.9 (1.6-6.2)
	Post-Dobbs	Post-Dobbs	Post-Dobbs
Maternal mortality to 42 days (per 100,000 births)	25.1 (22.6-27.6)	15.9 (12.0-19.8)	9.2 (4.6-13.7)
Maternal mortality to 365 days (per 100,000 births)	35.2 (32.1-38.3)	23.7 (17.9-29.6)	11.5 (4.8-18.1)
Preterm birth (%)	11.4 (10.9-11.9)	9.3 (9.0- 9.6)	2.1 (1.5- 2.7)
Cesarean delivery (%)	33.9 (32.3-35.4)	31.9 (30.8-33.0)	2.0 (-0.0- 4.0)
Overall mortality per 100,000 reproductive women	9.8 (8.0-11.6)	6.8 (6.1- 7.4)	3.0 (1.2-4.8)

Abbreviations: CI (confidence interval); COVID (coronavirus disease)
Pre-COVID (January 2018 to February 2020); Pandemic (March 2020 to August 2022); and Post-Dobbs (September 2022 to March 2024).
Outputs are obtained from Poisson regression using generalized estimating equations with exchangeable correlation structure and robust standard errors.

Table 2. Difference-in-Differences Estimates of Outcomes after Pandemic and Post-Dobbs.

Pandemic vs Pre-COVID	Abortion-restrictive [a]	Abortion-supportive [b]	Difference-in-differences
Maternal mortality to 42 days (per 100,000 births)	15.1 (10.6-19.6)	5.6 (1.3- 9.9)	9.5 (3.3-15.7)
Maternal mortality to 365 days (per 100,000 births)	19.9 (14.0-25.7)	9.1 (5.2-13.0)	10.8 (3.7-17.8)
Preterm birth (%)	0.3 (0.2- 0.3)	0.1 (-0.0- 0.2)	0.2 (0.0- 0.3)
Cesarean delivery (%)	0.1 (-0.1- 0.3)	0.3 (0.0- 0.7)	-0.2 (-0.6- 0.1)
Overall mortality per 100,000 reproductive women	2.9 (2.3-3.4)	1.7 (1.4-1.9)	1.2 (0.6-1.8)
Post-Dobbs vs. Pre-COVID	**Abortion-restrictive [c]**	**Abortion-supportive [d]**	**Difference-in-differences**
Maternal mortality to 42 days (per 100,000 births)	1.3 (-4.6- 7.2)	1.3 (-1.3- 3.9)	-0.0 (-6.5- 6.5)
Maternal mortality to 365 days (per 100,000 births)	2.4 (-4.4- 9.1)	1.6 (-2.4- 5.5)	0.8 (-7.2- 8.8)
Preterm birth (%)	0.3 (0.1- 0.4)	0.2 (0.0- 0.3)	0.1 (-0.1- 0.3)
Cesarean delivery (%)	-0.0 (-0.4- 0.3)	0.7 (0.4- 1.1)	-0.7 (-1.2--0.3)
Overall mortality per 100,000 reproductive women	1.2 (1.0-1.5)	0.9 (0.6-1.2)	0.3 (-0.1-0.7)

Pre-COVID (January 2018 to February 2020); Pandemic (March 2020 to August 2022); and Post-Dobbs (September 2022 to March 2024).
Abbreviations: CI (confidence interval); COVID (coronavirus disease)
[a] Estimates (95% CI) represent the difference between predicted outcomes in the pandemic period and predicted outcomes in the pre-COVID period for the Abortion-restrictive states.
[b] Estimates (95% CI) represent the difference between predicted outcomes in the pandemic period and predicted outcomes in the pre-COVID period for the Abortion-supportive states.
[c] Estimates (95% CI) represent the difference between predicted outcomes in the post-Dobbs period and predicted outcomes in the pre-COVID period for the Abortion-restrictive states.
[d] Estimates (95% CI) represent the difference between predicted outcomes in the post-Dobbs period and predicted outcomes in the pre-COVID period for the Abortion-supportive states.

189 | Amniotomy Versus Deferral at ≥4cm during Standardized Induction of Labor: A Propensity Score-Matched Study

Emily G. Gleason; Lisa D. Levine; Rebecca F. Hamm
University of Pennsylvania Perelman School of Medicine, Philadelphia, PA

10:30 AM - 12:30 PM

Objective: To determine the impact of artificial rupture of membranes (AROM) at first exam ≥4cm vs. deferring AROM at that exam while undergoing otherwise standardized labor induction (IOL).

Study Design: This is a secondary analysis of a prospective cohort evaluating the implementation of standardized IOL management of patients undergoing ≥37 weeks IOL at 2 sites from 2018-2022 with a singleton pregnancy, intact membranes, and unfavorable cervix without prior cesarean delivery (CD). For this analysis, patients who underwent AROM or spontaneous rupture at < 4cm were excluded. Patients were grouped by whether AROM was performed at first exam ≥4cm or deferred. 1:1 propensity score matching balanced parameters associated with AROM at the ≥4cm exam, including clinician type (midwife vs. physician), study year, maternal age, parity, gestational age, cervical ripening agent used, and adherence to the IOL protocol prior to the ≥4cm exam, including time from first to last misoprostol if used, and time Foley balloon in place if used. The primary outcome was length of IOL. Secondary outcomes included length of each stage of labor, CD, and maternal/neonatal morbidity. Time-to-event regression analyses for labor length, censored for CD, were modeled with a Cox proportional hazard model. Analyses were stratified by parity.

Results: Among 8509 inductions in the parent study, 5784 (67.0%) remained unruptured by first exam ≥4cm. After propensity score matching, 1592 were included (n = 796/group). Overall, AROM was associated with shorter IOL compared to deferral at first exam ≥4cm (21.3h[14.4-29.0] vs. 22.7h[16.1-31.2]), $p = 0.001$; Table), a finding consistent across parity. AROM at first exam ≥4cm was also associated with shorter latent and active phases. Once censored for CD, these findings were no longer significant (Figure). There were no differences by AROM vs. deferral in CD or morbidity.

Conclusion: Even in the context of otherwise standardized IOL management, AROM at first exam ≥4cm may still be associated with shortened IOL without increasing morbidity, but this finding is not significant once censored for CD.

Table: Outcomes compared amniotomy vs. deferral during IOL at first exam ≥4cm among propensity score matched cohort

	Amniotomy (n=796) Median or No. [IQR] (%)	No Amniotomy (n=796) Median or no. [IQR] (%)	*p*-value	aRR (95% CI)

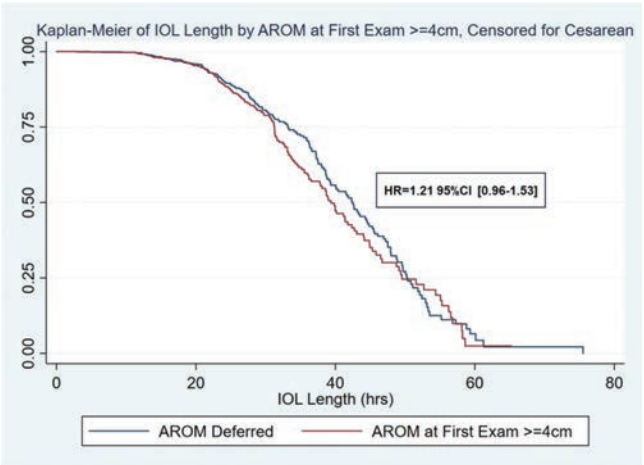
[a] Any one of the following: endometritis, EBL≥1L, blood transfusion, wound infection/separation, venous thromboembolism, unplanned hysterectomy, intensive care unit admission, readmission, or maternal death within 30 days of delivery [b] Any one of the following: severe respiratory distress syndrome or neonatal sepsis



190 | A Predictive Model for Preterm Birth Among Individuals Diagnosed with Early-Onset Fetal Growth Restriction

Emily K. Guernsey[1]; Anam Farooqui[2]; Vanya Manthena[1]; Andrew Rausch[1]; Kelly Nelson Kelly[1]; Ryan E. Longman[1]; Ashish Premkumar[1]
[1]*Pritzker School of Medicine, University of Chicago, Chicago, IL;* [2]*University of Chicago, Chicago, IL*

10:30 AM - 12:30 PM

Objective: Fetal growth restriction (FGR) affects 3-7% of all pregnancies and is associated with high rates of preterm delivery. Yet it remains unclear what factors beyond gestational age (GA) at onset of FGR and abnormal umbilical artery Dopplers affect the odds of preterm birth.

Study Design: We performed a single-site retrospective cohort analysis of all individuals with a singleton gestation diagnosed with early-onset FGR (i.e., ≤32w0d) from 2020 to 2023. Fetuses with genetic or infectious abnormalities were excluded. The exposure was GA at onset of FGR, defined categorically (20-28 weeks v. 28-32 weeks). The primary outcome was preterm delivery. Bivariate and multivariate logistic regression analyses were performed, and their results were compared using a test of equality for receiver operating characteristics (ROC) areas. Abnormal umbilical artery Doppler values were considered in the model as an a priori covariate. Covariates eligible for inclusion in the model were selected based on $p < .05$ on bivariate analyses. Stepwise backward selection was used to identify covariates that would be retained in the model.

Results: 93 individuals were available for analysis (Table). The unadjusted logistic regression model resulted in an area under the

ROC curve (AUC) of 0.63. The adjusted logistic regression model included insurance payor and an interaction term associated with chronic hypertension and a hypertensive disorder of pregnancy. Gestational age (0.23, 95% CI 0.08-0.74), insurance payor (OR 7.45, 95% CI 2.12-26.22) and the interaction term (OR 14.22, 95% CI 3.35-60.41) were associated with preterm delivery. The adjusted logistic regression resulted in an AUC of 0.80. The ROC curves for the unadjusted and adjusted logistic regression models were compared (Figure) and found to differ significantly (p< .01).

Conclusion: Gestational age at onset, insurance payor, and hypertension are associated with preterm birth in individuals diagnosed with FGR prior to 32 weeks. These data highlight both biological and social determinants of perinatal health and call for further research on these topics.

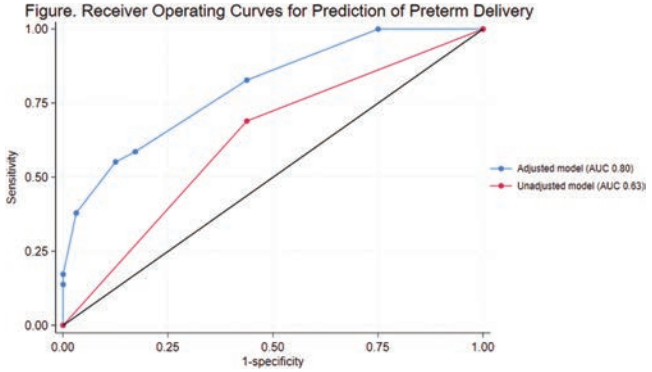
Figure. Receiver Operating Curves for Prediction of Preterm Delivery



191 | Nicotine and Mental Health: Risk of Neonatal Outcomes in Pregnancy

Emily J. Mize[1]; Bharti Garg[1]; Adam Crosland[1]; Rachel A. Madding[2]; Aaron B. Caughey[1]; Jamie O. Lo[1]
[1]Oregon Health & Science University, Portland, OR; [2]Oregon Health and Science University, Portland, OR

10:30 AM - 12:30 PM

Objective: Maternal mental health and substance use in pregnancy are leading causes of maternal mortality. Nicotine is the most used substance in pregnancy and the prevalence of mental health disorders in pregnancy is rising. In this study, we analyzed the impact of nicotine use and mental health disorders, separately and together, on neonatal outcomes, an understudied area.

Study Design: This retrospective cohort study used California linked vital statistics and hospital discharge data (2008-2020). Patients were categorized into nicotine users, mental health disorders, both, or neither. We included singleton gestations delivered between 23-42 weeks and excluded individuals using other substances. Exposure (mental health disorders) and outcomes were identified using birth certificate and ICD-9/10 codes. Results were analyzed by chi-square tests and multivariable Poisson regression models. Adjusted risk ratios (aRR) with 95% confidence intervals (CI) were estimated.

Results: 5,466,352 pregnant individuals were included, of whom 1.6% (89,278) had a nicotine-use diagnosis, 2.9% (161,590) had a mental health disorder, and 0.2% (9,722) had both in pregnancy. The impact of nicotine-use and mental health disorders (0.5%; aRR = 3.35 (2.51-4.46)) had an additive effect compared to either nicotine use (0.3%; aRR = 1.98 (1.74-2.25)) or mental health disorders (0.1%; aRR = 1.26 (1.09-1.45)) on post-neonatal deaths. Compared to no nicotine use or mental health disorders, the risk of NICU admissions was higher with both nicotine-use and mental health disorders (16.8%; aRR = 1.50 (1.44-1.57)), nicotine use (10.0%; aRR = 1.28 (1.26-1.31)) and mental health disorders (11.2%; aRR = 1.12 (1.10-1.14)). Similarly, the risk of infant deaths and preterm delivery was significantly higher in individuals with both nicotine use and mental health disorders.

Conclusion: The risk of infant and post neonatal death, and neonatal morbidity is significantly higher in individuals with mental health disorders that use nicotine. This patient population will benefit from nicotine cessation counseling.

192 | Emergency Care Use in Early Pregnancy Among North Carolina Medicaid Beneficiaries

Emma Trawick Roberts[1]; Lauren Kucirka[2]; Clara Busse[2]; M. Kathryn Menard[2]; Catherine Vladutiu[3]
[1]University of North Carolina, Chapel Hill, NC; [2]University of North Carolina, Chapel Hill, Chapel Hill, NC; [3]University of North Carolina, Chapel HIll, Chapel Hill, NC

10:30 AM - 12:30 PM

Objective: We sought to describe those seeking emergency care (EC) in early pregnancy and identify risk factors, including social drivers of health (SDOH), for EC use.

Study Design: Linked Medicaid hospital claims, live birth records, and North Carolina (N.C.) Pregnancy Medical Home risk screen (https://bit.ly/NCpregriskscreen) data were used to identify risk factors for EC use among 154,353 pregnant Medicaid beneficiaries in N.C. who had a live birth between 1/2014 and 12/2019. EC use included visits to the Emergency Department or obstetric triage unit prior to 20 weeks' gestation. Demographic characteristics, SDOH, medical co-morbidities, and pregnancy characteristics were compared by the number of EC visits. Among those with ≥1 EC visit, visit diagnoses were assessed by the number of SDOH risk factors. Multivariable ordered logistic regression modeled the association between potential risk factors for EC use and the number of EC visits (0,1,2, ≥3).

Results: A total of 73,836 women (47.8%) had an EC visit prior to 20 weeks' gestation; 39,367 had one visit, 18,751 had two, and 15,718 had ≥3 visits. Demographic, SDOH, medical, and pregnancy characteristics by number of EC visits are described in Table 1. Among those with ≥3 SDOH risk factors, 62.4% had an EC visit related to substance use, and 17.5% had a visit related to mental health. In the regression model, selected SDOH, medical comorbidities, and a history of adverse pregnancy outcomes were associated with increased odds of EC use before 20 weeks' gestation (Table 2). SDOH most associated with increased odds of ED use were physical assault within the last year, food insecurity, unstable living, undesired pregnancy, and substance use among family, friends, or partners.

Conclusion: Nearly half of pregnancies among Medicaid beneficiaries in NC had ≥1 EC visit prior to 20 weeks' gestation. Given the association between SDOH and increased odds of EC use, early EC use in pregnancy may signal social vulnerability and opportunity for targeted intervention.

193 | Patient Characteristics and Unexpected Delivery Complications Predict Cessation of Exclusive Breastfeeding by 4-8 Weeks Postpartum

Emma Trawick Roberts[1]; Sarah Heerboth[1]; Tracy A. Manuck[1]; Alison M. Stuebe[2]
[1]University of North Carolina, Chapel Hill, NC; [2]UNC School of Medicine, Chapel Hill, NC

10:30 AM - 12:30 PM

Objective: Although exclusive breastfeeding (BF) is recommended for the first 6 months of life, many women encounter barriers to meeting their BF goals. We analyzed predictors of early cessation of exclusive BF to identify women who may benefit from more intensive lactation support in the early postpartum period.
Study Design: Secondary analysis of a multicenter randomized controlled trial of elective labor induction vs. expectant management of low risk nulliparas at 39 weeks' gestation (MFMU ARRIVE trial). Participants were included in this analysis if they reported infant feeding data at 4-8 weeks postpartum. Logistic regression modeled the association between participant characteristics, unexpected delivery complications, and cessation of exclusive BF by 4-8 weeks postpartum. We defined unexpected delivery complications as neonatal morbidity (as per the initial RCT), neonatal intensive care unit (ICU) admission, intrapartum cesarean, operative vaginal delivery, 3rd or 4th degree perineal lacerations, preeclampsia, magnesium administration, chorioamnionitis, postpartum hemorrhage, blood transfusion, maternal ICU admission, labor pain scores ≥90%ile, and postpartum stay ≥4 days. Backward selection identified independent predictors of cessation of exclusive BF at 4-8 weeks postpartum. Model accuracy was assessed via the area under the ROC curve.
Results: 5,412 individuals were included in the analytic sample; 33% were exclusively BF at 4-8 weeks postpartum. In the backward elimination model, predictors of cessation of exclusive BF included Black race, non-Hispanic ethnicity, not being employed, having public or no insurance, smoking, body mass index ≥30, NICU admission, and intrapartum cesarean (Table). The model had an area under the ROC of 0.73 (95%CI 0.72-0.75).
Conclusion: In a cohort of low risk nulliparas, we identified maternal characteristics and unexpected delivery complications that predicted cessation of exclusive BF at 4-8 weeks postpartum. Targeted postpartum lactation support to individuals at high risk of BF cessation has the potential to enable more women to meet their infant feeding goals.

Table. Maternal factors and delivery complications independently associated with cessation of exclusive breastfeeding at 4-8 weeks postpartum.

Variable	Beta coefficient	Odds ratio	95% CI
Black race+	0.85	2.27	1.89-2.72
Smoking	0.83	2.27	1.68-3.07

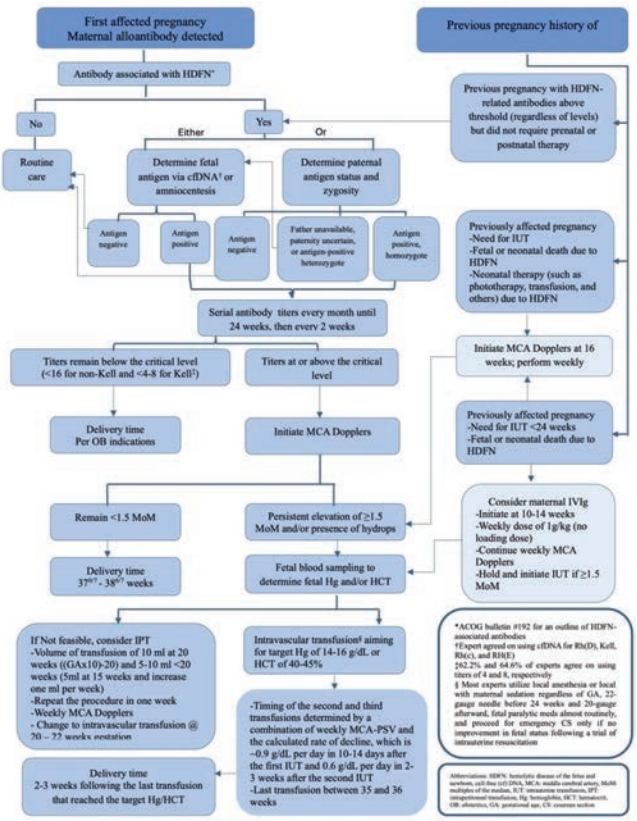
10:30 AM - 12:30 PM
Objective: To develop structured, expert-based clinical guidance on the prenatal and postnatal management of hemolytic disease of the fetus and newborn (HDFN).
Study Design: A Delphi procedure was conducted among an international panel of experts in fetal medicine, neonatology, and hematology. Experts were selected based on their expertise, relevant publications, and affiliations. The domains were (i) prenatal workup, (ii) prenatal monitoring and management, (iii) intrauterine transfusion, (iv) delivery, and (v) postnatal management. The pre-defined cut-off for consensus was ≥ 70% agreement.
Results: A total of 107 experts completed the first round and 100 (93.45%) completed the subsequent round. 75.3% agreed on the use of cfDNA to determine fetal antigen status, particularly for RhD, Kell, Rhc, and RhE antigens. The critical titer is considered when the threshold of 16 is for non-Kell and 4-8 for Kell antigens. 70% agreed on the use of maternal IVIg in pregnancies with prior IUT < 24 weeks or fetal/neonatal death due to HDFN. The minimum GA for IUT is 16-18 weeks and the maximum is 35-36 weeks. Guidance on the procedure, if it was technically not feasible, follow-up, and delivery is reached as shown in the workflow.
Postnatal management consensus was reached for the following: Anemia labs should be investigated in the affected neonates before hospital discharge (92% agreement) and if they received IUT then the labs are to be repeated within one week of discharge (84% agreement). 96% agreed that exchange transfusions should be centralized in hospitals with sufficient exposure and experience and 92% agreed that the Hg cut-off level to consider transfusion following hospital discharge is 7g/dL, and the newborns need to be monitored until 2-3 months of age (96% agreement).
Conclusion: The Delphi method facilitated the development of a consensus-based clinical workflow for the management of pregnancies at risk or affected by alloimmunization. These

workflows are intended to enhance clinical practice, improve outcomes, and facilitate future research.



195 | Nationwide Nursing Perspectives Survey on Intrapartum Maternal Position Changes

Erin K. Johnson[1]; Drew M. Hensel[1]; Rachel Paul[2]; Adia Woodson[3]; Jeannie C. Kelly[4]; Antonina I. Frolova[2]; Nandini Raghuraman[4]
[1]Washington University in St. Louis, St. Louis, MO; [2]Washington University School of Medicine, St. Louis, MO; [3]Barnes Jewish Hospital, St. Louis, MO; [4]Washington University School of Medicine in St. Louis, St. Louis, MO

10:30 AM - 12:30 PM

Objective: To characterize nursing perspectives and practices regarding intrapartum maternal position changes.
Study Design: We performed an anonymous, nationwide survey of nurses that had worked on a labor and delivery unit in the past year. The survey was disseminated through social media and email via snowball sampling. The primary objective was to determine the proportion of respondents using intrapartum position changes and why they used these position changes. Our secondary outcomes included use of a circuit of position changes and the reasons position changes were not utilized. We used descriptive statistics to characterize responses and bivariate analyses to compare respondents who employed a circuit to inform further research.
Results: Our sample included 498 respondents. Nearly all (98.8%) respondents use intrapartum position changes and 95.6% believe labor maneuvers are effective and improve maternal and neonatal outcomes. Nurses routinely use positional maneuvers for the indications of slow labor progress (91.5%), suspected occiput posterior fetal position (86.2%), and suspected asynclitic fetal position (83.5%). Commonly reported reasons for not using position changes included patient BMI (67.3%), patient preference (66.3%), fetal monitoring (64.9%), and lack of knowledge or references (64.7%). Approximately two-thirds of nurses utilizing maneuvers (67.1%) employ a circuit of position changes. Of the 20 listed maneuvers, 7 were used by >50% of respondents **(Figure 1)**. These maneuvers were also perceived as the most efficacious and were the most commonly used in a circuit. Nurses that employ circuits were younger ($p = 0.03$) and more likely to work in the Southwest or Midwest ($p = 0.04$, **Table 1**).
Conclusion: Maternal position changes are a frequently used intrapartum intervention despite lack of supporting Level I evidence. Labor and delivery nurses utilize position changes in the setting of protracted labor or fetal malposition. Further research is needed to elucidate the effectiveness of circuit-based position changes in labor.

196 | Cost Drivers in Inpatient Care for Placenta Accreta Spectrum: A National Analysis

Eve Overton[1]; Gabriela F. Tessler[1]; Brittany Arditi[2]; Maria Andrikopoulou[2]; Alexandre Buckley de Meritens[2]; Kartik K. Venkatesh[3]; Alexander M. Friedman[2]; Mirella Mourad[1]; Timothy Wen[4]
[1]Columbia University Medical Center, New York, NY; [2]Columbia University Irving Medical Center, New York, NY; [3]The Ohio State University, Columbus, OH; [4]University of California, San Diego, Irvine, CA

10:30 AM - 12:30 PM

Objective: Management of placenta accreta spectrum (PAS) frequently includes prolonged hospitalization and antepartum inpatient care, but cost estimates are limited. We evaluated costs for inpatient care associated with cesarean hysterectomies for PAS and patient factors associated with increased cost.

Study Design: A serial cross-sectional analysis of cesarean hysterectomies for PAS occurring between 23-35 weeks were identified in the 2016-2021 Nationwide Readmission Database stratified by antepartum inpatient care in three groups. Cesarean hysterectomies were categorized by those with no antepartum admission and with $\leq$ 2 day pre-delivery length of stay (LOS) (Group 1); those with prolonged pre-delivery LOS (>2 days) (Group 2); and those distinct antepartum admission of any length prior to delivery (Group 3). Total inpatient costs for each group were assessed. The primary outcome was high cost, defined as >80th percentile of inpatient costs in this cohort, and secondarily, total inpatient costs as a continuous measure adjusted for inflation to represent 2023 US dollars. Adjusted logistic and linear regression models assessed the association between groups with the primary and secondary outcomes, adjusting for clinical, demographic, and hospital factors.

Results: From 2016-2021, 3,309 cesarean hysterectomies for PAS were identified with 1,684 (50.9%), 1,065 (32.2%), and 560 (16.9%) in Groups 1, 2, and 3 respectively. High costs (≥$49,706) were noted in 9.3%, 39.6%, and 28.0% of deliveries in Groups 1, 2, and 3, respectively. In adjusted analyses, Group 2 had the highest mean costs (Figure 1, $p < 0.05$). Groups 2 (aOR 9.33, 95% CI: 6.45, 13.50) and 3 (aOR 5.18, 95% CI: 3.48, 7.71) had higher likelihood of high costs, and on average had $23,477 and $17,204 higher costs versus Group 1 (Figure 2). Disseminated intravascular coagulopathy, placenta increta/percreta, and postoperative LOS was on average associated with $12,940, $6,500, $3,941 (per day) higher costs ($p < 0.01$).

Conclusion: In the US between 2016 to 2021, prolonged pre-delivery hospitalization for PAS was associated with increased cost of care.

10:30 AM - 12:30 PM

Objective: Trans-amniotic trans-uterine suturing approaches have been associated with a reduced incidence of preterm premature rupture of membranes (PPROM). Our study aimed to explore the feasibility and effectiveness of employing a vascular closure device for trans-amniotic trans-uterine suturing in a sheep model.

Study Design: We employed multiple orthogonal methodologies to evaluate the Abbott Perclose for suturing the membranes at the uterine entry site of 12 French cannulas. Feasibility was defined as successful suture placement by two separate teams at two different gestational ages. Efficacy was demonstrated by the watertight closure of the entry site during in-vivo gross examination, along with the organizing fibrosis and healing of membranes and myometrium at post-delivery histopathologic evaluation. The following three approaches were used for uterine entry: midline laparotomy, 2-cm mini laparotomy, and percutaneous. The Perclose stitches were placed either before or after cannula insertion, utilizing one of three techniques: single, double vertical, or double parallel closures. Histopathological examination of samples from the entry sites was conducted using

H&E and trichrome staining, as well as immunohistochemistry for connexin 43. This study was approved by IACUC(AN-2010).
Results: Ten pregnant sheep were included in this study, and 4 of 10 were twin gestations. The median gestational age at the first and second rounds of intervention was 85.5 and 104 days, respectively. Overall, 32 Perclose devices were used and 75% were successfully placed. Watertight closure of all sutures was observed during the 1st and 2nd interventions, at cesarean delivery, and in situ. Histopathological examination confirmed membrane healing and organizing fibrosis surrounding the device entry site in addition to overexpression of connexin 43.
Conclusion: Employing multiple orthogonal approaches, we have demonstrated for the first time that the Perclose is both feasible and efficacious as a uterine port closure in our preclinical sheep model.

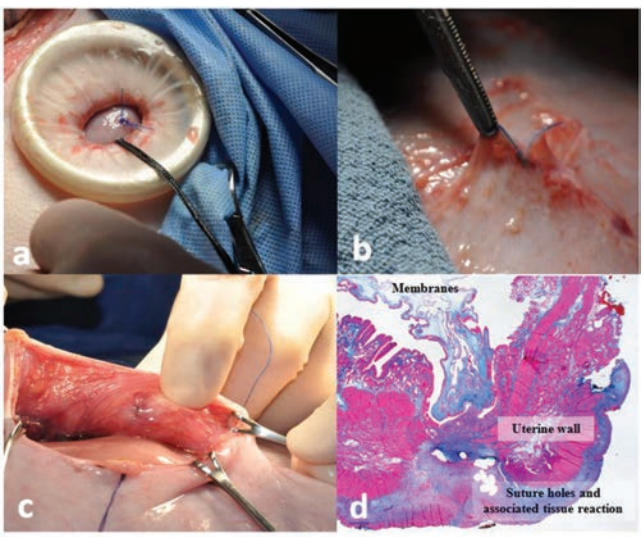

Figure 1: (a) Stitch placed in the mini-laparotomy approach, **(b)** Stitch visualized during cesarean delivery, **(c)** The stitch demonstrated from the interior following hysterotomy, **(d)** Full wall-thickness section of the uterine wall (inked serosal surface toward the bottom) with attached membranes. The suture holes show associated granulation tissue and early fibrosis (*Masson's trichrome stain, 1.25X*).

* Twin pregnancy, two devices were used per uterine horn.
* Two attempts were made: the first reached the bowel serosa, while the second reached the uterus and fascia, and the thread tore when pulling on the uterus.[1] There were two attempts; the first failed, and the second was successful.
# This case underwent three tries of Perclose device placement, two first attempts were not successful due to Knob coming out and membrane rupture, and for the third attempt, the less traction caused deployment of the suture into the uterus and thus the stitch did not hold.

198 | Failure-to-Rescue Following Severe Cardio-Pulmonary Morbidity at Delivery: Assessment of Race and Ethnic Differences

Fay Pon[1]; Zaira Chavez Jimenez[1]; Erin Yu[1]; Jennifer Yao[2]; Shinya Matsuzaki[3]; Rachel S. Mandelbaum[1]; Joseph G. Ouzounian[1]; Koji Matsuo[1]

[1]University of Southern California/Los Angeles General Medical Center, Los Angeles, CA; [2]Keck School of Medicine, University of Southern California, Los Angeles, CA; [3]Osaka University Graduate School of Medicine, Osaka, Osaka

10:30 AM - 12:30 PM
Objective: To assess the association between race / ethnicity and maternal mortality following severe cardio-pulmonary morbidity at delivery.
Study Design: This cross-sectional study queried the Healthcare Cost and Utilization Project's National Inpatient Sample. The study population included 19,724,839 delivery hospitalizations from 2016-2021. Under the Centers for Disease Control and Prevention-provided definitions of severe maternal morbidity indicators, six severe cardio-pulmonary morbidity subtypes were identified, including acute myocardial infarction, acute respiratory distress syndrome, cardiac arrest / ventricular fibrillation, conversion of cardiac rhythm, heart failure / arrest during surgery or procedure, and pulmonary edema / acute heart failure. Failure-to-rescue, defined as mortality event following these severe cardio-pulmonary events, was assessed by race and ethnicity in multivariable log-Poisson generalized linear model.
Results: A total of 36,090 patients developed severe cardio-pulmonary morbidity, of which Black and Native American patients had the two highest incidence rates followed by Asian, Hispanic, and White (32.2, 31.4, 19.9, 17.5, and 14.3 per 10,000 deliveries, respectively, $P < .001$) Failure-to-rescue rate following severe cardio-pulmonary morbidity at delivery was highest in Asian (5.8%), followed by Native American (5.3%), Black (4.1%), Hispanic (3.5%), and White (3.2%) ($P < .001$). In multivariable analysis, Asian (adjusted-OR 1.75, 95%CI 1.45-2.13) and Native American (adjusted-OR 1.68, 95%CI 1.12-2.54) pregnant patients were 75% and 68% more likely to die, respectively, following severe cardio-pulmonary events compared to White pregnant patients.
Conclusion: Our analysis suggest that there are racial and ethnic differences in failure-to-rescue following severe cardio-pulmonary morbidity at delivery: Although the incidence rate was highest in Black pregnant patients, failure-to-rescue risk following with these morbidities was highest in Asian pregnant patients.

199 | Buprenorphine Treatment for Maternal Opioid Use Disorder: Differences between High and Low Retention Groups

Felicitas A. Huber[1]; Nandini Raghuraman[2]; Bridget Galati[3]; Michael Wenzinger[3]; Antonina I. Frolova[4]; Megan L. Lawlor[3]; Jeannie C. Kelly[2]

[1]Washington University in St Louis, St. Louis, MO; [2]Washington University School of Medicine in St. Louis, St. Louis, MO; [3]Washington University in St. Louis, St. Louis, MO; [4]Washington University School of Medicine, St. Louis, MO

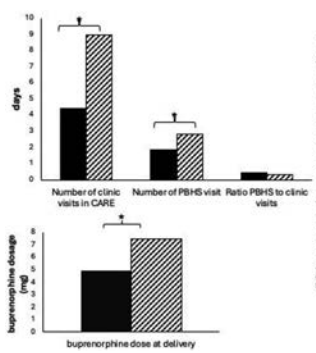
10:30 AM - 12:30 PM
Objective: Prevalence of maternal opioid use disorder (OUD) has substantially increased over the past decade. Medications for OUD are essential for effective treatment. Yet, factors that impact retention of opioid agonist treatment during pregnancy and beyond are poorly understood. Our objective was to examine

differences in biopsychosocial factors between individuals with high versus low buprenorphine treatment retention.

Study Design: We used a prospective database from CARE, an interdisciplinary, wrap-around clinic providing prenatal, OUD, and extended postpartum care for patients with OUD at an urban tertiary care center. Data were analyzed from patients who received buprenorphine treatment (June 2018-August 2022), dichotomized into two groups of low (< 31 days of buprenorphine tx) and high (≥32 days) retention. Differences between groups on demographics, medical, behavioral, and psychological variables were assessed via chi-square & independent samples t-tests.

Results: 79 patients were included for analysis; 63% identified as non-Hispanic White, 46% had a history of hepatitis C, and 72% had public insurance. ½ of patients fell into low and ½ into high retention groups. There were no differences in race, age, hepatitis c dx, time until buprenorphine induction, OUD length, polysubstance use, psychiatric tx, or anxiety/depression between groups. However, greater buprenorphine dosage at delivery, more clinic visits, and more behavioral health visits were found in the high retention group. No difference between groups was found when examining ratio of behavioral health to clinic visits.

Conclusion: Behavioral and medical factors differed between groups such that those who stayed on buprenorphine >31 days were more engaged with clinical and behavioral health care and had higher buprenorphine dosage at delivery. That the ratio of behavioral health to clinic visits did not significantly differ suggests that the cumulative amount of positive clinic contact may be more relevant than specific interventions. Results demonstrate the importance of treating OUD from a biopsychosocial and interdisciplinary perspective.



Variable	Low retention group (N=39)			High retention group (N=40)			Test statistic

200 | Assessing the Risk of Chorioamnionitis by Type of Suture Used for Cerclage

Frank I. Jackson[1]; Moti Gulersen[2]; Rupsa C. Boelig[3]; Vincenzo Berghella[2]; Matthew J. Blitz[1]

[1]Northwell, New Hyde Park, NY; [2]Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA; [3]Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA

10:30 AM - 12:30 PM

Objective: A recent randomized trial comparing cerclage suture type identified a possible increased rate of chorioamnionitis with braided suture; however this was evaluated as one of many secondary outcomes. We aimed to assess whether braided sutures are associated with increased odds of chorioamnionitis in pregnancies undergoing cerclage.

Study Design: This is a retrospective cohort study of singleton gestations who underwent a cerclage within a large healthcare system from 01/2019–06/2023. Patients with missing delivery data or suture type were excluded. The primary outcome was incidence of chorioamnionitis at delivery and was compared between patients who underwent cerclage with a monofilament suture (monofilament polypropylene (Prolene)) compared to those with a braided suture (ethylene terephthalate (Mersilene) or braided polyester suture (Tri-Cron)). Multivariate logistic regression was performed to adjust for the following confounders: indication for cerclage, gestational age at cerclage placement, and nulliparity. Data were presented as adjusted odds ratios (aOR) with 95% confidence intervals (CI).

Results: Of the 719 patients included, 200 (28%) had a monofilament polypropylene suture, 519 (72%) had braided suture. Baseline characteristics were similar except obesity (Table). The odds of chorioamnionitis was similar between the monofilament vs braided sutures (4/200 [2.0%] vs. 16/519 [3.1%]; aOR 1.36 [0.54-4.14].

Conclusion: This study suggests a lower rate of chorioamnionitis than previously reported among patients with braided sutures. These findings suggest there is no difference in the rate of chorioamnionitis based on the use of braided versus monofilament sutures at time of cerclage. Currently evidence supports clinicians using their preferred suture type.

Table. Baseline characteristics compared between the two groups.

	Monofilament (n=200)	Braided (n=519)	P value

201 | First Versus Early Second Trimester Dating: Accuracy in Predicting Small for Gestational Age Neonates

Gabrielle K. Concepcion-Taveras[1]; Jenna S. Silverstein[2]; Emily Schneider[3]; Meralis V. Lantigua-Martinez[1]; Carlos Parra[1]; Martin Chavez[4]; Shilpi S. Mehta-Lee[5]; Jennifer Blakemore[6]; Christina A. Penfield[6]

[1]NYU Grossman School of Medicine, New York, NY; [2]Sister of Charity Hospital, Buffalo, NY; [3]NYU Grossman Long Island School of Medicine, Mineola, NY; [4]NYU Langone Hospital, New York, NY; [5]NYU Langone Health, Brooklyn, NY; [6]NYU Langone Health, New York, NY

10:30 AM - 12:30 PM

Objective: While "optimal" pregnancy dating is defined as any ultrasound confirmation prior to 22 weeks, evaluation in

the first trimester may provide a more accurate assessment of gestational age (GA). This is important when early fetal growth restriction (FGR) is detected, as inaccurate dating can cause a false positive diagnosis. We sought to compare the accuracy of FGR in predicting small for gestational age (SGA) using first versus early second trimester dating.

Study Design: We conducted a multi-center observational study of singleton pregnancies with FGR (EFW < 10th percentile) diagnosed during a 16-24 week anatomy scan between 1/2016 and 12/2021. Pregnancies with estimated date of delivery (EDD) confirmed by first trimester ultrasound were compared to those with dating confirmation in early second trimester (between 14 and 22 weeks). Cases with suspected anatomic, genetic, or infectious etiologies of FGR were excluded. The primary outcome was SGA at birth (< 10th percentile for gestational age). Secondary outcomes were GA at delivery, hypertensive disorders of pregnancy (HDP), mode of delivery, indicated preterm delivery, and a composite of adverse neonatal outcomes. Data were analyzed using Pearson's Chi-Square (Fisher's-Exact) and Mann-Whitney U tests.

Results: Of 385 cases of FGR, 319 (83%) had dating confirmation in first trimester and 66 (17%) in the early second trimester. The prevalence of SGA was similar between groups with 30% in the first trimester cohort and 26% in the early second trimester cohort ($p = 0.24$). Both groups had a similar median GA at delivery, and similar rates of medically indicated preterm delivery, HDP, and composite neonatal morbidity.

Conclusion: In pregnancies with FGR, first trimester dating confirmation was not superior to early second trimester dating in predicting SGA. This lends support to the current definition of optimal dating utilized by the American College of Obstetricians and Gynecologists. Future studies with a larger second-trimester dating cohort as well as FGR diagnosed later in pregnancy would help further validate these findings.

Table 1. Baseline Demographic and Clinical Characteristics

	First Trimester Dating Confirmation (n = 319)	Early Second Trimester Dating Confirmation (n = 66)	*P* value
Median maternal age (years) (IQR)	32.19 (26.90-36.18)	30.59 (25.95-35.55)	0.238

Need for respiratory support	63 (20)	12 (18)	0.77
Neonatal hypoglycemia	39 (12)	7 (11)	0.71
Neonatal death	3 (1)	0 (0)	0.43
Maternal Outcomes:			
Hypertensive disorder of pregnancy – no. (%)	48 (15)	7 (11)	0.35
Mode of delivery – no. (%)			0.32
Vaginal delivery	199 (62)	45 (68)	
Cesarean delivery	120 (38)	21 (32)	

Small for gestational age (SGA) = birth weight <10th percentile for gestational age
Hypertensive disorder of pregnancy (HDP): comprises any maternal hypertensive disorder including gestational hypertension (gHTN), preeclampsia without severe features (PEC without SF), preeclampsia with severe features (PEC with SF), chronic hypertension with superimposed preeclampsia without severe features (siPEC without SF), and chronic hypertension with superimposed preeclampsia with severe features (siPEC with SF).
Need for respiratory support is defined as requiring supplemental oxygen for >2hrs
Neonatal hypoglycemia is defined as a point of care glucose <30mg/dL at <24hrs of life, <45 mg/dL thereafter during birth admission

202 | Intrapartum Continuous Glucose Monitor Profiles and the Association with Neonatal Hypoglycemia

Gianna L. Wilkie[1]; Nillani Anandakugan[2]; Shani Snow[2]; Heidi K. Leftwich[2]
[1]University of Massachusetts Chan Medical School, Worcester, MA; [2]University of Massachusetts Chan School of Medicine, Worcester, MA

10:30 AM - 12:30 PM

Objective: Use of continuous glucose monitors (CGMs) is becoming more common among pregnant patients with pregestational diabetes, but little is known about the optimal intrapartum CGM glycemic profiles in pregnancy. The objective of this study was to characterize intrapartum CGM glycemic profiles and any association with neonatal hypoglycemia.

Study Design: This was a retrospective cohort study among subjects with pregestational diabetes between July 1, 2022 and June 1, 2024 that utilized a CGM intrapartum for glycemic monitoring. Demographics and perinatal outcomes were abstracted from the medical record while glycemic profiles (time in range, above range, and below range) were abstracted from the CGM portal. Glucose range was defined as 70-140 mg/dL. Pearson's correlation coefficient was used to assess association.

Results: During the study period, 25 subjects with intrapartum CGM data available were identified. Participants were 31.3 years old (±5.8 years), predominately White (72%), and have type 1 diabetes melitus (68%). The average intrapartum glucose was 136.8 mg/dL (±24.4 mg/dL), with subjects spending a mean 39.2% of time above range, 59.4% of time in range, and 1.7% of time below range. The mean neonatal glucose immediately after birth was 46.3 mg/dL (±15.0 mg/dL) and mean glucose 24 hours after birth was 59.2 mg/dL (±13.2 mg/dL). Approximately 52% of neonates required treatment for hypoglycemia, with 25% of those requiring treatment needing intravenous therapy. There was a moderate negative correlation (r = -0.52) between percentage of time in range and mean neonatal glucose within the first 24 hours after birth and a moderate positive correlation (r = 0.55) between percentage of time above range and mean neonatal glucose within the first 24 hours after birth.

Conclusion: Characterizing CGM profiles is the first step to better utilization in labor. Despite small numbers, our study shows a correlation with time above range and increased neonatal

glucose. Larger studies with standardized intrapartum treatment strategies are needed to determine the optimal intrapartum CGM glycemic profiles.

Table 1. Demographic and Glycemic Outcomes of Patients with Pregestational Diabetes

Demographics	n=25

203 | Exploring the Risk Factors for Re-Laparotomy Following Cesarean Delivery

Gil Gutvirtz[1]; Tamar Wainstock[2]; Gali Pariente[2]; Eyal Sheiner[2]
[1]Soroka University Medical Center, Metar, HaDarom;
[2]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom

10:30 AM - 12:30 PM

Objective: Cesarean delivery (CD) is the most common obstetrical surgery with increasing rates worldwide. Although considered relatively safe, intra- and post-operative complication including bleeding, bladder and intestinal injury and wound infection have been reported. One rare, but significant, complication after CD is re-laparotomy. We conducted this study to define risk factors for re-laparotomy after CD.

Study Design: A retrospective cohort study was conducted comparing all singleton CD that took place in a tertiary medical center between the years 1991-2021. Cesarean deliveries complicated by re-laparotomy were compared with uncomplicated CD. Generalized estimation equation (GEE) models were constructed to control for possible confounding variables.

Results: During the study period, 49,922 cesarean deliveries met our inclusion criteria, of them, 97 (0.2%) had undergone re-laparotomy. The group of women complicated with re-laparotomy tended to be multiparous and to have undergone a previous CD. Furthermore, these women had higher rates of placental complications (placenta previa, abruption and placenta accreta). They also had higher rates of cervical tears and post-partum hemorrhage (**Table 1**). In a GEE model, several independent risk factors for re-laparotomy following CD, with cervical tear being the most prominent one, were noted (adjusted OR = 24.39, 95%CI 8.20-72.55, p < 0.001, **Table 2**).

Conclusion: Independent risk factors for relaparotomy following CD include cervical tear, placenta previa, placental abruption and placenta accreta, preeclampsia and a previous CD. These risk factors should be taken into account when dealing with high-risk patients expected to undergo repeated cesarean delivery.

Table 1. Maternal characteristics, pregnancy complications and perinatal outcomes of women with and without re-laparotomy after cesarean delivery: Univariate analysis

204 | Does Maternal Chronic Hypertension Increase the Risk for Offspring Long-Term Respiratory Morbidity?

Gil Gutvirtz[1]; Tamar Wainstock[2]; Eyal Sheiner[2]
[1]Soroka University Medical Center, Metar, HaDarom;
[2]Department of Obstetrics and Gynecology, Soroka University

Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom

10:30 AM - 12:30 PM

Objective: Maternal chronic hypertension has been associated with various adverse pregnancy and neonatal outcomes, including superimposed preeclampsia and preterm labor. Both complications have been shown to expose the offspring for both short and long-term adverse consequences. However, most studies investigating offspring long-term outcomes included mothers with all types of hypertensive disorders of pregnancy and did not discern them from mothers with preexisting disease. We decided to explore a possible association between maternal chronic hypertension and long-term respiratory morbidity of the offspring.

Study Design: A population-based retrospective cohort study comparing offspring of mothers with and without chronic hypertension or any hypertensive disorders. We included singleton deliveries that took place between the years 1991-2021 at a tertiary center. Offspring long-term (up to 18 years) respiratory morbidity was compared using registered diagnoses from hospitalization of the offspring involving a respiratory disease. A Kaplan–Meier survival curve was used to compare the cumulative incidence of respiratory morbidity, and a Cox regression model was constructed to control for confounders.

Results: A total of 342,365 singleton deliveries were included. Among them 3,097 (0.9%) were deliveries of mothers with chronic hypertension. The total respiratory morbidity rate of children exposed to maternal chronic hypertension was significantly higher than children from pregnancies without hypertensive disorders (**Table**). However, the cumulative incidence of respiratory morbidity over time was comparable between the groups (**Figure**). Furthermore, using the Cox regression model, controlling for maternal and gestational age, the association between maternal chronic hypertension and long-term respiratory morbidity of the offspring was no longer significant (**Table**).

Conclusion: In our cohort, although the crude rates of respiratory morbidity are higher for exposed offspring, careful analysis found that maternal chronic hypertension is not an independent risk factor for offspring long-term respiratory morbidity.

Figure. Kaplan-Meier survival curve demonstrating the cumulative incidence of respiratory morbidity in children exposed and unexposed to maternal chronic hypertension

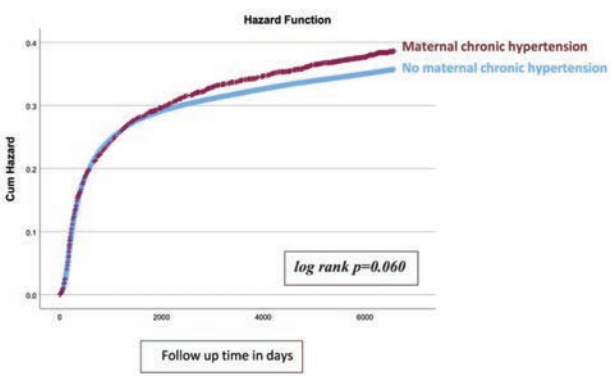

Table. Long-term respiratory morbidity of children born to mothers with and without chronic hypertension: crude and adjusted hazards ratio (HR)

	Maternal chronic hypertension (n=3,097)	No maternal chronic hypertension (n=339,538)	Odds ratio (95%CI)	Adjusted* HR (95%CI)
Total respiratory morbidity, n (%)	936 (30.2%)	89,829 (26.5%)	1.20 (1.11 – 1.30)	1.03 (0.96 – 1.09)

205 | Postpartum Hemorrhage Risk in Patients with a Low-Lying Placenta: A Systematic Review and Meta-Analysis

Giulia Bonanni[1]; Maria C. López-Girón[2]; Sofia Maria Tarchi[3]; May Abiad[4]; Camille Shantz[5]; Elisa Bevilacqua[6]; Kjersti M. Aagaard[7]; Vincenzo Berghella[8]; Alireza A. Shamshirsaz[9]
[1]Postdoctoral Research Fellow Fetal Care and Surgery Center Division of Fetal Medicine and Surgery Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Facultad de Ciencias de la Salud, Universidad Icesi, Cali, Colombia, Facultad de Ciencias de la Salud, Universidad Icesi, Cali, Colombia, Valle del Cauca; [3]Department of Biomedical Sciences, Humanitas University, Milan, Lombardia; [4]Maternal Fetal Care Center, Boston Children's Hospital, Boston, MA; [5]Johns Hopkins University, Baltmore, MD; [6]Department of Women, Children, and Public Health Sciences, IRCCS Agostino Gemelli University Polyclinic Foundation, Catholic University of the Sacred Heart, Rome, Lazio; [7]Boston Children's Hospital, Division of Fetal Medicine and Surgery, Boston, MA; HCA Healthcare and HCA Healthcare Research Institute, Nashville, TN; HCA Texas Maternal Fetal Medicine, Houston, TX; Baylor College of Medicine and Texas Children's Hospital, Houston, TX, Boston, MA; [8]Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA; [9]Fetal Surgeon Chief, Division of Fetal Medicine and Surgery Director of the Maternal Fetal Care Center Director of the Perinatal Surgery Fellowship Professor of Surgery, Boston Children's Hospital Harvard Medical School, Boston, MA

10:30 AM - 12:30 PM

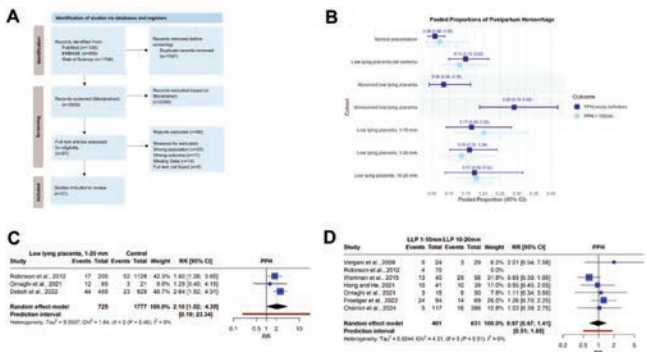
Objective: Postpartum hemorrhage (PPH) is a major cause of maternal morbidity and mortality. We hypothesized that low-lying placenta (LLP) imparts underappreciated risk for PPH. We conducted a **systematic review and meta-analysis to quantify the PPH risk accompanying an antepartum diagnosis of LLP**.

Study Design: We systematically searched PubMed, Embase, and Web of Science (inception - 4/30/2024) and included RCTs, prospective and case-control studies per PICO framework: **Population - singleton pregnancies; Intervention - low-lying placenta; Comparators - normal placentation (non-LLP); Outcomes - PPH and Placenta Accreta Spectrum (PAS) disorders (Fig.1A).** Subgroup analyses by cervical os distance and resolution status were conducted. The Newcastle-Ottawa Scale was used to assess study quality. Risk Ratios (RRs) and pooled proportions were computed using R. PROSPERO registration: CRD42024558043.

Results: We included 21 studies (n = 3,704 LLP, n = 2,555 normal placenta). **Antepartum diagnosis of LLP, at any gestational age, imparted a significant PPH risk** (RR 2.10, 95% CI 1.02-4.35, p = 0.0477, I^2 = 0%; Fig.1B). PPH incidence was 15% (95%

CI 10-22%, I^2 = 93%) in LLP versus 6% (95% CI 4-9%, I^2 = 83%) in non-LLP. **When parsed by clinically meaningfully strata, significant risk of PPH persisted with resolved LLP** (resolved 8%, 95% CI 4-16%, I^2 = 85% vs unresolved 29%, 95% CI 19-42%, I^2 = 71%; Fig.1B) with **no difference in PPH risk at under 2cm from the os (LLP 1-10 mm** vs 10-20 mm; RR 0.97, 95% CI 0.67-1.41, p = 0.84, I^2 = 0%; Fig.1C, D). Importantly, PAS disorders affected 9% (95% CI 5-17%, I^2 = 89%) of all LLP cases.

Conclusion: **Antepartum diagnosis of LLP, including presumptively resolved cases, is associated with a twofold increased risk of PPH when compared to pregnancies without LLP.** This is the first meta-analysis to reliably quantify the risk of LLP, emphasizing a previously underrecognized role of rigorous monitoring and delivery management of pregnancies with LLP in reducing the burden of PPH on maternal morbidity.



206 | Association between Maternal Age at First Delivery and Long-term Risk for Cardiac Morbidity

Hagar Brami[1]; Eyal Sheiner[2]; Tamar Wainstock[2]; Ruslan Sergienko[3]; Roy Kessous[1]

[1]Soroka, Beer-Sheva, HaDarom; [2]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom; [3]Ben-Gurion University of the Negev, Beer Sheva, HaDarom

10:30 AM - 12:30 PM

Objective: While the global trend of advanced maternal age at first delivery is on the rise, the potential long-term risk for the mothers is yet to be fully elucidated. In our study, we have sought to examine the association between advanced maternal age at first delivery and maternal cardiac morbidity.

Study Design: A population-based cohort analysis was conducted including all primigravida at a tertiary hospital occurring between 1991 to 2021 divided by four groups of ages (less than 30 years, between 30-35, 35-40 and older than 40 years). Data were collected from medical records according to pre-defined ICD-9 codes. Cardiac outcomes were compared and analyzed. Women with prior cardiac disease were excluded. A Kaplan-Meier survival curve was used to assess cumulative cardiac morbidity. A Cox proportional hazards model was used to control for confounders.

Results: Out of the 74,543 primigravida included in the study, 1187 women had their first delivery when they were at the ages of 35-40 and 315 were older than 40 years. A linear correlation was found with regard to maternal age at first delivery and cardioac morbidity, showing increasing cumulative incidence of cardiac morbidity with the highest risk for women that delivered first over the age of 40 (Kaplan-Meier log-rank p < 0.001; Figure). This correlation was significantly found in the univariable analysis for overall cardiovascular disease (16.5% vs. 10.3%) and moreover, for specific related diagnoses such as hypertension (10.6% vs. 3.3%) and ischemic heart disease (1.1% vs. 0.2%) (p < 0.001 for all, **Table**). A Cox proportional hazards model confirmed that maternal age at first pregnancy is an independent risk factor for cardiovascular morbidity of the mother, and that the risk is higher as maternal age advanced at the first pregnancy (**Table**). regarding mothers age reaching a peak in women that give birth for the first time after the age of forty (adjusted HR = 1.96, 95% CI 1.45–2.63, p < 0.001; **Table**).

Conclusion: Maternal age at first delivery in an independent risk factor for cardiac morbidity later in life.

Figure. The association between maternal age at first delivery and long-term cardiac morbidity of the mother: Univariate analysis, Kaplan-Meier survival curve

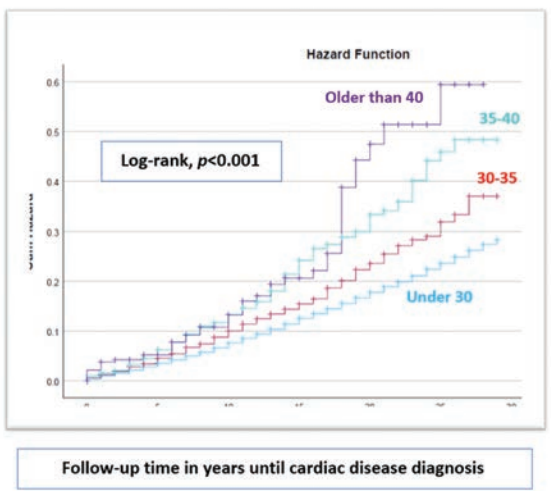


Table. Comparison of long-term cardiac morbidity of the mothers divided by age at first delivery.

Maternal age, years	<30 (n=68,216)	30-35 (n=4867)	35-40 (n=1187)	>40 (n=273)	*p* value
Hypertension	3.3%	5.4%	9.6%	10.6%	<0.001
Arrhythmia	7.4%	5.9%	6.8%	7.7%	0.002

207 | Racial and Health Care Disparities of Pregnancies Affected by Late Stillbirth

Harbinder Brar[1]; Leila Magistrado[2]; Guillermo Gomez[3]; Rodolfo Saenz[4]; Serafin Salazar[2]

[1]Riverside Genomics And Perinatal Institute, Riverside, CA; [2]Raincross Medical Group, Raincross Medical Group, CA; [3]Magnolia OB/GYN, Magnolia OB/GYN, CA; [4]Altais Medical Group, Riverside, CA

10:30 AM - 12:30 PM

Objective: Late stillbirths are commonly defined as fetal demises occurring after 28 weeks and may potentially be preventable in high risk pregnancies with antenatal testing. Our objectives were to analyze the rate of late stillbirth and assess the influence of varying types of insurance coverage and race on late stillbirth.

Study Design: A retrospective review of late stillbirths over a 2 year period was performed. Demographics, sonograms, and risk factors for stillbirth were abstracted. Patients were divided into three groups (group 1: patients with PPO and HMO insurance, group 2: patients with Medicaid insurance, and group 3: patients with managed care Medicaid insurance). The overall late stillbirth rate was calculated as were the rates of late stillbirth for each group. Potentially preventable late stillbirths were defined as those in which no antenatal testing was performed within a week of the stillbirth.

Results: A total of 6108 pregnancies with 61102 antepartum tests were analyzed. There were 42 late stillbirths with an overall late stillbirth rate of 6.87 per 1000 births. Group 1 had the lowest late stillbirth rate of 3.26 per 1000 births (8/2452) and group 2 had a late stillbirth rate of 6.57 per 1000 (12/1825) births. Group 3 had a late stillbirth rate of 12.01 per 1000 births (22/1831). There was a greater proportion of patients in group 2 and group 3 with three or more risk factors for stillbirth (736/1825 = 40.3% and 786/1831 = 42.9%) than in group 1 (17.9%), $p < 0.05$. There were no potentially preventable late stillbirths in group 1 whereas there were 5 potentially preventable late stillbirths in group 2 and 13 potentially preventable late stillbirths in group 3. One out of 8 late stillbirths in group 1 was African American, in comparison to 6/12 in group 2 and 12/22 in group 3 ($p < 0.05$).

Conclusion: Health care disparities with respect to the late stillbirth rate exist, with a higher rate being seen in the indigent and African American population as well as in those with Medicaid and managed care Medicaid insurance. Future research should focus on efforts to address these healthcare inequities.

208 | Statewide Utilization of Telemedicine for Prenatal Care Visits

Harini Pennathur[1]; Rachel A. Clark[2]; Kenechukwu Odenigbo[2]; Shayla Parthasarathy[2]; Michelle Moniz[3]; Lisa Kane Low[3]; Alex Peahl[4]

[1]Texas A&M University School of Engineering Medicine; [2]University of Michigan Medical School, Ann Arbor, MI; [3]University of Michigan, Ann Arbor, MI; [4]Michigan Medicine, Ann Arbor, MI

10:30 AM - 12:30 PM

Objective: To investigate statewide telemedicine practices for prenatal care, including barriers and facilitators of widespread adoption.

Study Design: Prenatal care providers were identified across Michigan through systematic web searches and snowball sampling. Semi-structured surveys assessed prenatal care practices, including use of telemedicine or not and modalities employed. We evaluated telemedicine utilization across clinic characteristics: clinic type, number of patients served, region, EHR type used, and insurance type limitations. Free-response questions about perceived barriers and facilitators of telemedicine implementation were summarized using qualitative content analysis. Funding support from Blue Cross Blue Shield of Michigan.

Results: In total, 19 clinics representing 8/10 state designated prosperity regions completed the survey, with an average of 408 (range 20-1700) patients per site. Telemedicine prenatal visits were offered at 13/19 (68.4%) clinics, of which, 5 offered video-only, 1 offered telephone-only, and 7 offered both. Fewer clinics that had restrictions on patient enrollment (e.g., do not accept patients with Medicaid) utilized telemedicine, but telemedicine availability did not differ across clinic types (Table 1). Key implementation barriers included provider willingness, patient comfort with/access to technology, scheduling, and lack of patient-provider connection through telemedicine. Facilitators were COVID-19 initiatives, time savings, existing telemedicine infrastructure, and training.

Conclusion: While stakeholders identified numerous advantages to the implementation of telemedicine in prenatal care, both infrastructure and interpersonal barriers exist. Realizing the potential improvements in accessibility, convenience, and efficiency for all patients requires thoughtful implementation across varied care settings.

209 | Association of Chorionicity and Severe Maternal Morbidity in Twin Pregnancies

Heather N. Czarny[1]; Amanda M. Baucom[2]; Isabella Toledo[3]; Braxton Forde[1]; Robert M. Rossi[1]

[1]University of Cincinnati College of Medicine, Cincinnati, OH; [2]University of Cincinnati, Cincinnati, OH; [3]Indiana University School of Medicine, Indianapolis, IN

10:30 AM - 12:30 PM

Objective: Twin gestations are associated with higher risks for adverse neonatal and perinatal outcomes, with chorionicity known to influence these risks. However, the impact of

chorionicity on severe maternal morbidity (SMM) is unclear. This study assessed the risk of SMM and obstetric complications by chorionicity in twin gestations.

Study Design: Population-based, retrospective cohort study of U.S. delivery hospitalizations from 2015-2021 using the National Inpatient Sample database. ICD-10 codes identified delivery hospitalizations, chorionicity, and outcomes. SMM was defined by the CDC criteria (excluding transfusion) and individual indicators grouped by organ system. The primary objective was to compare SMM risk by chorionicity in twin versus singleton gestations, with secondary analysis of obstetric complications. Adjusted relative risks (aRR) and 95% confidence intervals (CI) were estimated using multivariate logistic regression.

Results: Of 22,482,597 delivery hospitalizations, 98.5% were singleton, 0.3% monochorionic and 1.2% dichorionic twins. SMM risk was higher in mono- (1.9%, aRR 2.07, 95% CI 1.81-2.37) and dichorionic (2.3%, aRR 2.38, 95% CI 2.23-2.53) gestations compared to singletons (0.8%), however, composite SMM did not vary by chorionicity. Eclampsia, thromboembolic SMM, and hysterectomy risk was significantly increased in dichorionic twins (aRR 2.25, 95% CI 1.84-2.76; aRR 1.51, 95% CI 1.13-2.01; aRR 2.31, 95% CI 1.99-2.68) compared to singletons, but did not differ by chorionicity (Figure 1). Cesarean section risk was elevated in both mono- (aRR 8.43, 95% CI 8.09-8.79) and dichorionic (aRR 8.89, 95% CI 8.69-9.10) twins compared to singletons. Monochorionicity had the highest risk for vasa previa (aRR 8.25, 95% CI 6.43-10.6) and intrauterine fetal demise (aRR 8.93, 95% CI 8.29-9.63), while dichorionicity had the highest risk of severe preeclampsia (aRR 3.22, 95% CI 3.12-3.31) (Figure 2).

Conclusion: SMM risk is higher in twin gestations compared to singletons, but SMM risk is not altered by chorionicity. This is valuable information for maternal counseling in the setting of twin pregnancy.

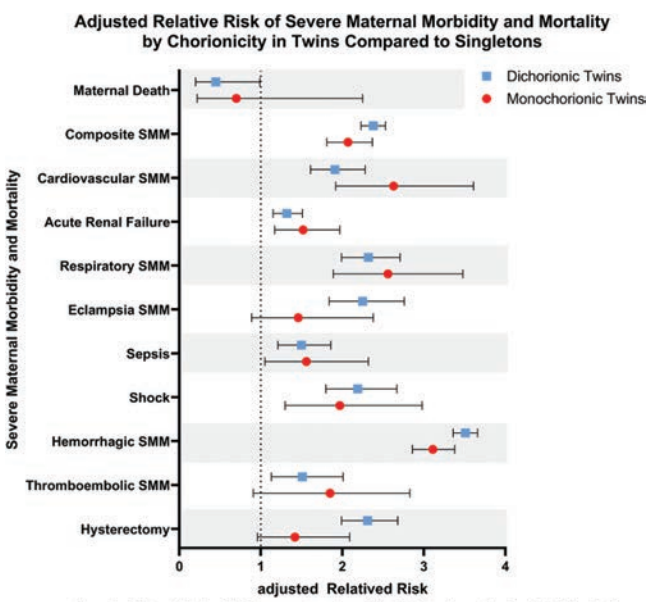

Figure 1. Adjusted relative risk of severe maternal morbidity (SMM) and mortality by chorionicity in twin compared to singleton pregnancies (dotted line). Composite SMM indicates any event falling within the following categories (excluding blood transfusion): Cardiac SMM (acute myocardial infarction, aneurysm, cardiac arrest or ventricular fibrillation, conversion of cardiac rhythm, heart failure or arrest during surgery, puerperal cerebrovascular disorders, pulmonary edema or acute heart failure), acute renal failure, respiratory SMM (adult respiratory distress syndrome, temporary tracheostomy, ventilation, severe anesthesia complications), eclampsia, sepsis, shock, hemorrhagic SMM (blood transfusion, disseminated intravascular coagulation), thromboembolic SMM (air and thrombotic embolism, sickle cell disease with crisis, amniotic fluid embolism), and hysterectomy.

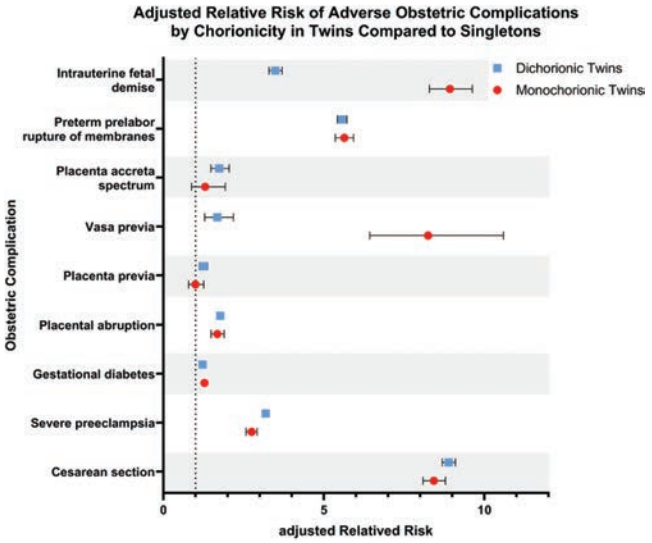

Figure 2: Adjusted relative risk of adverse pregnancy outcomes by chorionicity in twins compared to singleton gestations (dotted line).

210 | Severe Maternal Morbidity and Mortality With Periviable and Preterm Birth

Heather N. Czarny[1]; Stefany Hernandez[1]; Isabella Toledo[2]; Elizabeth Kelly[1]; William Moravec[1]; Carri Warshak[1]; Emily A. DeFranco[3]; Robert M. Rossi[1]

[1]*University of Cincinnati College of Medicine, Cincinnati, OH;* [2]*Indiana University School of Medicine, Indianapolis, IN;* [3]*Department of Obstetrics and Gynecology, University of Kentucky, Lexington, KY*

10:30 AM - 12:30 PM

Objective: Preterm and periviable birth are associated with adverse maternal outcomes, yet the association between severe maternal morbidity (SMM) and mortality risk with gestational age at delivery is limited. We aimed to assess the risk of SMM among those with periviable or preterm birth.

Study Design: This was a population-based cohort study of U.S. delivery hospitalizations from 2015-2021 using data from the National Inpatient Sample database. ICD-10 codes were used to identify delivery hospitalizations and gestational age at delivery. SMM was defined by CDC criteria (excluding transfusion). The primary outcome was the risk of SMM and mortality in patients with a periviable (20-25 weeks) or preterm (26-36 weeks) compared to term (37-42 weeks) birth. Secondary analyses included risk assessment by organ system-based SMM indicators. Subgroup analyses of outcomes were also performed for 3-week gestational age groupings (i.e. 20-22 weeks). Adjusted relative risks (aRR) were estimated using multivariable logistic regression analysis.

Results: Among 22,193,863 delivery hospitalizations, 0.6% were periviable, 9.4% preterm, and 90.0% term births. The rate and risk of SMM and mortality were significantly higher with periviable (4.4%, aRR 6.7, 95% CI 6.3-7.2 and 0.1%, aRR 27.0, 95% CI 17.1-42.6, respectively) and preterm birth (2.3%, aRR 3.5, 95% CI 3.4-3.7 and 0.03%, aRR 8.7, 95% CI 6.4-11.7, respectively) compared to term (0.5% and 0.0027%). Risk for nearly all individual morbidity indicators were increased with periviable or preterm birth (Figure 1). Periviable birth was associated with the highest risk of cardiovascular, renal, respiratory, sepsis, shock, and hemorrhagic

events, while preterm birth had the highest risk of eclampsia. Previable deliveries (20-22 weeks) had a disproportionate burden of maternal death among those with an SMM event (Figure 2).

Conclusion: Periviable and preterm deliveries are associated with increased risk of SMM and mortality compared to term deliveries. This study highlights the substantial dual burden of preterm and periviable delivery on patients and their infants.

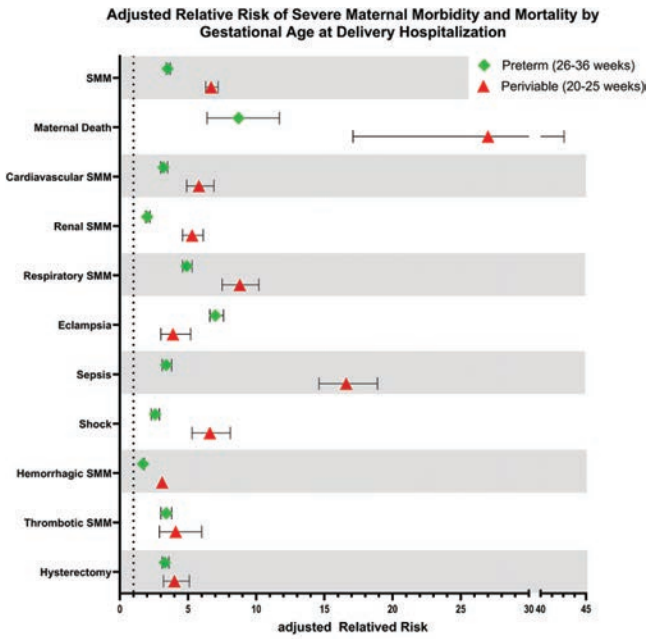

Figure 1: Adjusted relative risk of severe maternal morbidity (SMM), maternal death, and SMM indicator category in perivable (20-25 weeks) and preterm (26-36 weeks) births at delivery hospitalization compared to term births (37-40 weeks, dotted line). SMM indicates any event falling within the following categories (excluding blood transfusion): Cardiac SMM (acute myocardial infarction, aneurysm, cardiac arrest or ventricular fibrillation, conversion of cardiac rhythm, heart failure or arrest during surgery, puerperal cerebrovascular disorders, pulmonary edema or acute heart failure), acute renal failure, respiratory SMM (adult respiratory distress syndrome, temporary tracheostomy, ventilation, severe anesthesia complications), eclampsia, sepsis, shock, hemorrhagic SMM (blood transfusion, disseminated intravascular coagulation), thrombotic SMM (air and thrombotic embolism, sickle cell disease with crisis, amniotic fluid embolism), and hysterectomy.

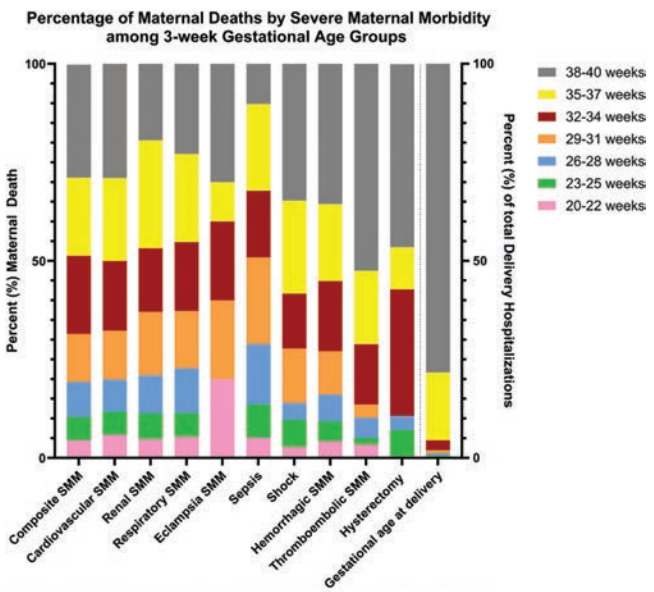

Figure 2: Percentage of maternal deaths within each category of severe maternal morbidity (SMM) by 3-week gestational age group at delivery hospitalization. Total population by 3-week gestational age group proportion indicated on the far right as comparison. Composite SMM includes all of the following SMM indicators (except blood transfusion): Cardiac SMM (acute myocardial infarction, aneurysm, cardiac arrest or ventricular fibrillation, conversion of cardiac rhythm, heart failure or arrest during surgery, puerperal cerebrovascular disorders, pulmonary edema or acute heart failure), acute renal failure, respiratory SMM (adult respiratory distress syndrome, temporary tracheostomy, ventilation, severe anesthesia complications), eclampsia, sepsis, shock, hemorrhagic SMM (blood transfusion, disseminated intravascular coagulation), thromboembolic SMM (air and thrombotic embolism, sickle cell disease with crisis, amniotic fluid embolism), and hysterectomy.

211 | Age as an Independent Risk Factor for Cesarean Delivery

Hillary Kroll[1]; Elena Martinez[2]; Jane C. Lin[3]
[1]Kaiser Permanente Los Angeles Medical Center, Kaiser Permanente Los Angeles Medical Center, CA; [2]Kaiser Permanente Los Angeles, Kaiser Permanente Los Angeles, CA; [3]Kaiser Permanente Southern California, Pasadena, CA

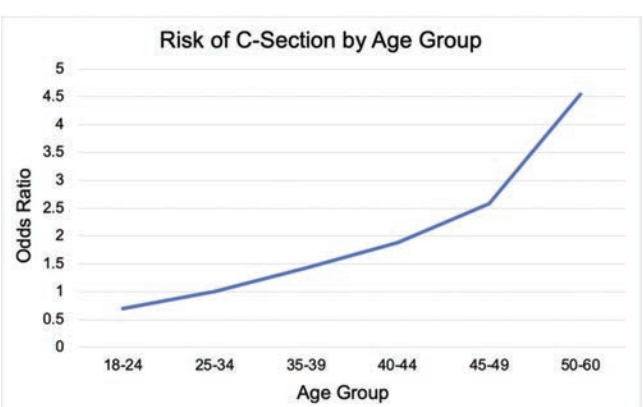
10:30 AM - 12:30 PM

Objective: Few studies have examined the impact of maternal age on risk of C-section, especially at very advanced maternal ages. We sought to evaluate the association between maternal age at delivery and risk of C-section.

Study Design: This is a multicenter retrospective cohort study within a large integrated healthcare system. We examined all live births that occurred between 2012-2022. We excluded preterm deliveries, multifetal gestations, scheduled C-sections, patients with infrequent prenatal care, and patients not between the ages of 18-60 years old. We carried out a logistic regression analysis adjusted for race and ethnicity, parity, BMI, hypertension, pre-eclampsia, gestational diabetes, pre-gestational diabetes, fetal distress, fetal growth restriction, large for gestational age fetuses, macrosomia, APGAR scores, chorioamnionitis, meconium staining, and pregnancies resulting from assisted reproductive technology. We compared the risk of C-section in 5-year age intervals to a reference group of ages 25-34 using odds ratios.

Results: A total of 328,145 participants were included in the study. The rate of C-section in the reference group was 16.1%. The age range of 18-24 years old had a C-section rate of 13% with an odds ratio of 0.7 (95% CI [0.68, 0.72]), yielding a 30% decreased risk of C-section compared to the reference group. The rate of C-section in 35-39-year-olds was 20.7% with an odds ratio of 1.43 (95% CI [1.40, 1.47]) or a 43% increased risk of C-section. The rate of C-section in 40-44-year-olds was 25.7% with an odds ratio of 1.88 (95% CI [1.80, 1.96]) or an 88% increased risk of C-section. The rate of C-section in 45-49-year-olds was 33.5% with an odds ratio of 2.58 (95% CI [2.21, 3.01]) or a 158% increased risk of C-section. The rate of C-section in 50-60-year-olds was 50% with an odds ratio of 4.54 (95% CI [2.55, 8.06]) or a 354% increased risk of C-section.

Conclusion: After adjusting for other factors, age appears to be an independent risk factor for C-section. The risk of C-section increases with increasing age.



212 | Association of Hemoglobin A1c and Glycosylated Albumin with Adverse Neonatal Outcomes in Gestational Diabetes

Sachie Suga[1]; Misao Fukuoka[2]; Kensuke Ashimoto[3]; Yusen Sugimura[4]; Nao Kurata[1]; Hiroshi Yamashita[1]; Ichiro Yasuhi[2]
[1]NHO Nagasaki Medical Center, Omura City, Nagasaki; [2]NHO Nagasaki Medical Center, Omura-City, Nagasaki; [3]Kameda Medical Center, Kamogawa, Chiba; [4]Juntendo University, Tokyo

10:30 AM - 12:30 PM

Objective: The predictive value of hemoglobin A1c (HbA1c) and glycosylated albumin (GA) levels for neonatal outcomes in women with gestational diabetes mellitus (GDM) remains controversial. This study aimed to investigate the association between these biomarkers and neonatal composite adverse outcomes and determine if this association depends on gestational age.
Study Design: This retrospective study used the GDM clinical database of a tertiary perinatal care center in Japan. We included singleton pregnant women who had biomarker measurements during late pregnancy, after 30 weeks of gestation (WG). Biomarkers were measured monthly and collected within a three-week window for the periods of 31-33 WG, 33-36 WG, and 37-39 WG. Neonatal composite adverse outcomes included large-for-gestational-age infants, asphyxia, hypoglycemia, respiratory issues, and hyperbilirubinemia. A receiver operating characteristic curve was used to establish a cutoff value. We adjusted for body mass index, insulin therapy, gestational week at diagnosis and delivery, gestational weight gain, and hemoglobin values at 35 WG in assessing the association between the biomarkers and the composite adverse outcomes.
Results: Among 460 neonates, 103 (22%) experienced composite adverse outcomes. HbA1c values at 34-36 WG were significantly associated with composite outcomes, with crude and adjusted odds ratios of 2.58 (95% confidence interval 1.36-4.86) and 2.36 (1.21-4.61) with a cutoff value of 5.9%, respectively. HbA1c values in the other two windows were not associated with adverse outcomes. GA values in any gestational week window showed no significant association with composite adverse outcomes.
Conclusion: In women with GDM, HbA1c values at 34-36 WG were predictive of neonatal composite adverse outcomes. An HbA1c value of < 5.9% by 33 WG was associated with favorable outcomes, while GA measurements in any gestational week window were not useful.

213 | Association between Early Postpartum Appendicular Skeletal Muscle Mass Volume and Insulin Resistance during Pregnancy

Megumi Koga[1]; Katsuhito Hayashi[2]; Ichiro Yasuhi[3]
[1]NHO Nagasaki Medical Center, Omura City, Nagasaki; [2]Ureshino Medical Center, Ureshino, Saga; [3]NHO Nagasaki Medical Center, Omura-City, Nagasaki

10:30 AM - 12:30 PM

Objective: Reduced appendicular skeletal muscle (ASM) mass is linked to insulin resistance and a higher risk of type 2 diabetes, especially in non-obese women. However, the association between ASM volume and insulin dynamics during pregnancy is unclear. This study aimed to investigate if early postpartum ASM is associated with insulin resistance during pregnancy.
Study Design: We conducted a prospective observational study on the association between postpartum trunk and ASM volume and low back pain in Japanese singleton pregnant women recruited at 35 weeks' gestation. ASM was measured using the impedance method (Tanita MC780A-N) at four weeks postpartum. ASM/body mass index (BMI) was calculated as an ASM volume index. We included women who underwent an oral glucose tolerance test (OGTT) during pregnancy due to a positive gestational diabetes (GDM) screen. During the OGTT, HbA1c, fasting, and postprandial insulin levels were measured to calculate the homeostatic model assessment for insulin resistance (HOMA-IR) and the insulin sensitivity index (ISI). We examined the association between ASM/BMI and fasting glucose, HbA1c, and insulin sensitivity indices during pregnancy.
Results: We included 226 women who underwent an OGTT at 25 weeks' gestation. Postpartum ASM/BMI was significantly and negatively correlated with fasting glucose ($r^2 = 0.04$, $p = 0.0042$), HbA1c ($r^2 = 0.04$, $p = 0.0045$), and HOMA-IR ($r^2 = 0.20$, $p < 0.001$), while positively correlated with ISI ($r^2 = 0.16$, $p < 0.0001$). These correlations remained significant after controlling for age, gestational age at OGTT, and GDM status. ASM/BMI < 25th percentile was associated with >75th percentile HOMA-IR and < 25th percentile ISI, with adjusted odds ratios (95% confidence interval) of 6.27 (3.15-12.90) and 4.73 (2.40-6.57), respectively.
Conclusion: This is the first report demonstrating that early postpartum ASM volume is associated with hyperglycemia and insulin resistance during pregnancy. Reduced ASM volume may contribute to gestational glucose intolerance.

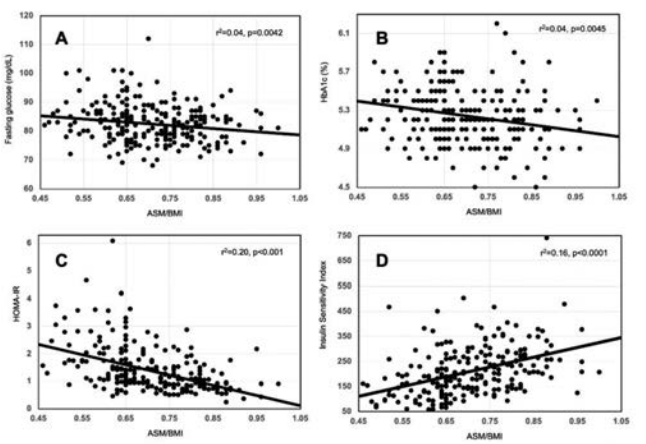


Figure. Relationship between early postpartum ASM/BMI and fasting glucose (**A**), HbA1c (**B**), HOMA-IR (**C**), and ISI (**D**) during pregnancy

ASM, appendicular skeletal muscle; BMI, body mass index; HOMA-IR, homeostatic model assessment for insulin resistance; ISI, insulin sensitivity index

214 | Early Pregnancy Metal Levels in Maternal Blood and Pregnancy Outcomes

[1]Ben Gurion University Of The Negev, beer sheva, HaDarom; [2]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom; [3]Ben Gurion University of the

Negev, Beer Sheva, HaDarom; [4]Ben Gurion University of the Negev, Ramat Gan, HaMerkaz

10:30 AM - 12:30 PM

Objective: This study examines the association between early pregnancy maternal blood levels of Lead (Pb), arsenic (As), cadmium (Cd), and selenium (Se) and adverse pregnancy outcomes, while also addressing the differences between low-risk and high-risk groups based on having a history of preterm birth (PTB).

Study Design: This prospective cohort study recruited multigravida women at 11-13 gestational weeks, categorized into low-risk and high-risk groups. Participants completed a questionnaire, and heavy metal levels were measured in blood samples. Pregnancy outcomes were recorded following delivery. Multivariable analyses were conducted to evaluate the independent associations between heavy metal levels and pregnancy outcomes, while adjusting for variables associated with the metals levels based on the univariable analyses.

Results: Among 404 participants, the mean (±SD) levels were Pb: 3.12±1.82 µg/L, As: 0.41±0.4 µg/L, Cd: 0.26±0.34 µg/L, and Se: 119.84±21.05 µg/L. Significant differences in Pb, Se, Cd and As levels were observed between the low-risk and high-risk groups, with higher levels in the low-risk group. However, no significant associations were found between heavy metal levels and PTB, low birth weight (LBW), gestational age at delivery, birth weight, and head circumference in either univariable comparison or multivariable models, which adjusted for maternal age, BMI, employment, smoking, fertility treatments, and education.

Conclusion: While significant differences in heavy metal levels were found between low-risk and high-risk groups, early pregnancy heavy metal levels showed no association with adverse pregnancy outcomes. These findings highlight the need for further research to understand the potential impact of these metals on pregnancy, considering population-specific factors and exposure timing.

Table 1- Maternal mean ±SD levels of the studied metals by history of PTB

Heavy metal level mean±SD (µg/L)	Low risk	High risk	P-value
Pb	3.58±2.02 (n=189)	2.7±1.49 (n=187)	<0.001
Se	122.7±22.25 (n=201)	117±19.43 (n=203)	0.006
Sqrt_Cd*	0.5±0.26 (n=198)	0.36±0.26 (n=192)	<0.001
Sqrt_As*	0.62±0.31 (n=198)	0.51±0.32 (n=203)	<0.001

215 | Maternal Morbidity and Mortality at Delivery Hospitalization Among Patients with Cardiac Disease

Isabella Toledo[1]; Heather N. Czarny[2]; Emily A. DeFranco[3]; Carri Warshak[2]; Robert M. Rossi[2]

[1]*Indiana University School of Medicine, Indianapolis, IN;* [2]*University of Cincinnati College of Medicine, Cincinnati, OH;* [3]*Department of Obstetrics and Gynecology, University of Kentucky, Lexington, KY*

10:30 AM - 12:30 PM

Objective: Cardiovascular disease (CVD) is associated with maternal mortality and adverse perinatal outcomes. Although cardiac outcomes in pregnancy are well defined in those with CVD, there are limited studies evaluating the risk of non-cardiac severe maternal morbidity (SMM). We evaluated the prevalence and association of CVD and SMM.

Study Design: This was a population-based, retrospective cohort study of U.S. delivery hospitalizations from 2010-2020 utilizing the National Inpatient Sample database. International Classification Diagnoses codes (9th and 10th edition) identified delivery hospitalizations and pre-existing CVD. SMM was defined by the Centers for Disease Control and Prevention criteria. Adjusted relative risks (aRR) and 95% confidence intervals (CI) were estimated using multivariate logistic regression analyses. Subgroup analyses were performed by CVD subtype, race and ethnicity, and individual SMM indicators.

Results: Among the 38,374,326 deliveries included in this study, 203,448 (0.5%) had CVD. CVD was associated with an increased risk of SMM (aRR 12.5, 95% CI 12.0-13.1) and maternal death (aRR 44.1, 95% CI 35.4-55.0) compared to those without CVD. Risk for each individual SMM indicator was increased among those with CVD. Those with chronic heart failure had the highest risk of SMM (aRR 354, 95% CI 301-417) and death (aRR 688, 95% CI 525-902), while those with non-rheumatic valvular heart disease (SMM: aRR 8.1, 95% CI 7.5-8.8; death: aRR 23.9, 95% CI 15.9-35.7) had the lowest risk. Black individuals in this study had a disproportionately increased burden of high-risk cardiac lesions and had the highest SMM risk (aRR 15.9, 95% CI 14.7-17.1). CVD accounted for 7.3% (95% CI 7.1-7.6) of the observed SMM in the study population, as calculated by the population attributable risk (PAF) and was associated with more than 1 in 3 maternal deaths at delivery hospitalization.

Conclusion: CVD in pregnancy is associated with a nearly 5-fold increased risk of non-cardiac-related SMM and 44-fold increased risk of death, with Black individuals bearing a disproportionate risk for SMM.

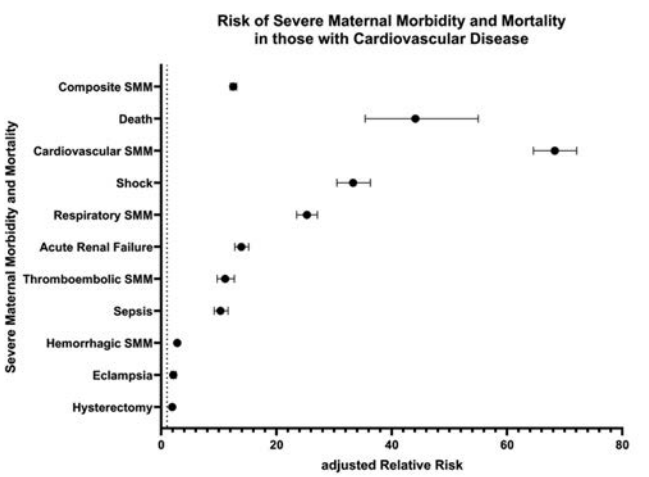

Figure 1: Adjusted relative risk of severe maternal morbidity (SMM) and mortality in those with cardiovascular disease compare to those without at delivery hospitalization. Composite SMM indicates any event falling within the following categories (excluding blood transfusion): Cardiac SMM (acute myocardial infarction, aneurysm, cardiac arrest or ventricular fibrillation, conversion of cardiac rhythm, heart failure or arrest during surgery, puerperal cerebrovascular disorders, pulmonary edema or acute heart failure), acute renal failure, respiratory SMM (adult respiratory distress syndrome, temporary tracheostomy, ventilation, severe anesthesia complications), eclampsia, sepsis, shock, hemorrhagic SMM (blood transfusion, disseminated intravascular coagulation), thrombotic SMM (air and thrombotic embolism, sickle cell disease with crisis, amniotic fluid embolism), and hysterectomy.

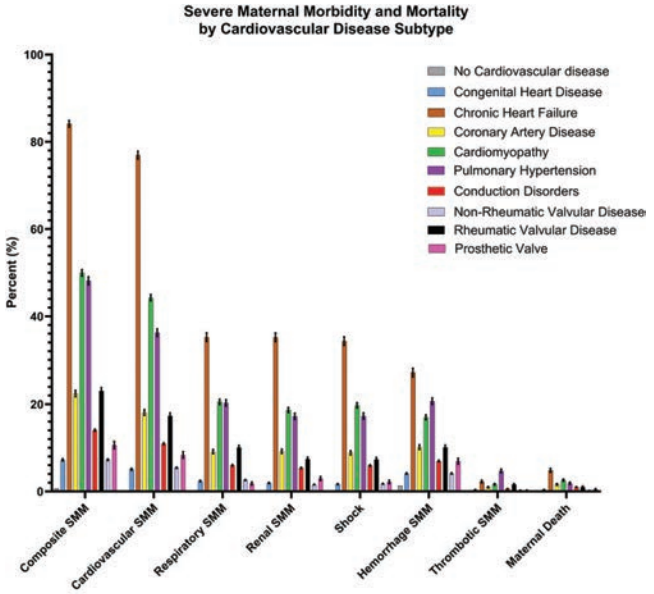

Figure 2: Incidence of severe maternal morbidity (SMM) indicator and mortality by cardiovascular disease subtype. Error bars represent 95% confidence intervals. Composite SMM includes all of the following SMM events (except blood transfusion): Cardiac SMM (acute myocardial infarction, aneurysm, cardiac arrest or ventricular fibrillation, conversion of cardiac rhythm, heart failure or arrest during surgery, puerperal cerebrovascular disorders, pulmonary edema or acute heart failure), acute renal failure, respiratory SMM (adult respiratory distress syndrome, temporary tracheostomy, ventilation, severe anesthesia complications), eclampsia, sepsis, shock, hemorrhagic SMM (blood transfusion, disseminated intravascular coagulation), thrombotic SMM (air and thrombotic embolism, sickle cell disease with crisis, amniotic fluid embolism), and hysterectomy.

216 | The Association between Term Stillbirth and Maternal Care Access at the US County Level

Isabella F. McNamara[1]; Mohak Mhatre[1]; Phinnara Has[2]; Bianca Alonso-Bermudez[3]; Sebastian Z. Ramos[1]
[1]Tufts University School of Medicine, Boston, MA; [2]Lifespan Biostatistics, Epidemiology, and Research Design, Providence, RI; [3]Tufts University School of Medicine, Tufts Medical Center, MA

10:30 AM - 12:30 PM

Objective: Access to comprehensive maternal care is associated with a reduction in stillbirth rates, yet maternal care access is decreasing across the US. We aim to study the association of maternal care access with stillbirth at term.

Study Design: This is a cross-sectional study using CDC Vital Statistics birth certificate data from 2016-2019. All non-anomalous, singleton births ≥ 37 weeks were included. Maternal care access level was defined by the 2020 March of Dimes Maternal Care Access Report County data using their classification of maternal care access (full, moderate, low, or desert), which is based on proximity to hospitals providing obstetric care, number of obstetric providers per 10,000 births, and percent of uninsured women. The primary outcome was stillbirth at term (≥ 37 weeks gestational age). Mixed effects multivariable models were used and adjusted for clinical, demographic and county level factors, including access to community resources using the CDC's Social Vulnerability Index (SVI).

Results: A total of 3,138 counties were included in this analysis with 1,100 (35%) of those counties located in maternity care deserts. Out of 13,304,743 births, term stillbirth occurred in 16,402 deliveries (0.12%); 13% of these stillbirths occurred in counties without full access to maternity care. In mixed effects multivariable models, there were increased odds of stillbirth in maternity care deserts (OR 1.13, 95% CI 1.04-1.22) when compared to full maternity care access. However, this was not statistically significant after adjusting for individual and county level factors (aOR 0.99, 95% CI 0.89-1.09).

Conclusion: More than a third of US counties are in maternal care deserts and 13% of term stillbirths occur in areas without full access to maternal care. Further studies are needed to identify underlying factors of maternal care access that may contribute to this adverse pregnancy outcome.

Table 1. Crude and Adjusted Odds Ratio of Stillbirth by Maternal Care Access Level at the US County Level from 2016-2019 (N= 13,304,743)

Still birth	OR (95% CI)	*p*-value	aOR (95% CI)[1]	*p*-value
Total Still Births				
Maternal care desert	1.13 (1.04 , 1.22)	0.003	0.99 (0.89 , 1.09)	0.89
Low access to maternal care	1.08 (0.99 , 1.16)	0.055	1.01 (0.93 , 1.09)	0.79
Moderate access to maternal care	1.07 (0.97 , 1.18)	0.19	1.06 (0.96 , 1.18)	0.24

217 | Prediction Model for Intrapartum Cesarean Delivery among Women with Gestational Diabetes Mellitus

Itamar Gilboa[1]; Daniel Gabbai[1]; Emmanuel Attali[1]; Liran Hiersch[2]; Yariv Yogev[3]; Anat Lavie[4]
[1]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel-Aviv, Tel Aviv; [2]Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv University, Israel, Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel Aviv; [3]Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv University, Tel Aviv Sourasky Medical Center, Tel Aviv; [4]Tel Aviv Sourasky Medical Center, Tel Aviv Sourasky Medical Center, Tel Aviv

10:30 AM - 12:30 PM

Objective: To identify risk factors and develop a predictive model for intrapartum cesarean delivery (CD) in women with gestational diabetes mellitus (GDM).

Study Design: This retrospective cohort study was conducted at a university-affiliated tertiary medical center with approximately 12,000 deliveries annually from 2011-2023. Inclusion criteria included all patients with GDM who had a trial of vaginal delivery. Exclusion criteria included multiple gestations, non-viable fetuses, and elective cesarean delivery. Univariate and multivariate analyses compared characteristics of women delivering vaginally (control group) with those having intrapartum CD (study group). A risk prediction score model was developed.

Results:

1. Out of 11,817 women, 782 (6.6%) underwent intrapartum CD, while 11,605 (93.4%) delivered vaginally.
2. Independent risk factors for CD included: maternal age ≥40 years (OR = 1.9, 95%CI 1.4-2.6, p < 0.001); pre-gestational BMI >30kg/m^2 (OR = 1.4, 95%CI 1.1-1.8, p = 0.003); gestational weight gain >15kg (OR = 1.6, 95%CI 1.3-1.9, p < 0.001); maternal height < 1.6m (OR = 2.0, 95%CI 1.6-2.4, p < 0.001); nulliparity (OR = 4.0, 95%CI 3.2-5.2, p < 0.001); previous cesarean delivery (OR = 19, 95%CI 12.8-28.1, p < 0.001); induction of labor (OR = 2.7, 95%CI 2.2-3.3, p < 0.001); use of oxytocin (OR = 1.6, 95%CI 1.2-2.1, p < 0.001); antibiotics during labor (OR = 5.9, 95%CI 4.9-7.2, p < 0.001); preeclampsia (OR = 2.7, 95%CI 1.8-3.9, p < 0.001); birthweight ≥3,750g (OR = 1.6, 95%CI 1.2-2.0, p < 0.001); and male fetus (OR = 1.3, 95%CI 1.1-1.6, p = 0.003).

3. Reduced risk factors for intrapartum CD included previous VBAC (OR = 0.05, 95%CI 0.01-0.2, p < 0.001), and epidural analgesia (OR = 0.7, 95%CI 0.9-1.5, p = 0.005).
4. The score model demonstrated an AUC of 0.856 (95%CI 0.84-0.87, p < 0.001), with a cutoff score of 9, sensitivity of 82%, and specificity of 76%.

Conclusion: The predictive model for intrapartum CD in GDM patients aids caregivers in providing informed consultations and identifying high-risk patients for optimal delivery planning.

218 | Incidental Meconium-Stained Amniotic Fluid During Elective Cesarean Deliveries: A Potential Concern?

Itamar Gilboa[1]; Guy Beresteanu[2]; Yariv Yogev[3]; Yael Raz[1]
[1]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel-Aviv, Tel Aviv; [2]University of Pittsburgh, Pittsburgh, PA; [3]Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv University, Tel Aviv Sourasky Medical Center, Tel Aviv

10:30 AM - 12:30 PM

Objective: To evaluate the association of meconium-stained amniotic fluid (MSAF) incidentally found during elective cesarean delivery (CD) with maternal morbidity and adverse neonatal outcomes.

Study Design: A retrospective cohort study in a single university affiliated tertiary center with approximately 12,500 deliveries annually, including all women who underwent elective CD with singleton and twin pregnancies between 2011 and 2023. Data analysis encompassed demographic, pregnancy, intraoperative, postoperative and neonatal characteristics. Deliveries with clear amniotic fluid (CAF), MSAF, and thick MSAF were compared for singletons and twins.

Results:

1. During the study period, 13,111 patients with singleton pregnancies and 884 patients with twin pregnancies underwent elective CD.
2. The incidence of MSAF and thick MSAF was 452 (4.4%) and 21 (0.16%) in singleton deliveries and 14 (1.6%) and 2 (0.2%) in twin deliveries, respectively.
3. In singleton pregnancies, patients with MSAF underwent CD at a more advanced gestational age, were more likely to be nulliparous and have had no history of previous cesarean section compared with patients with CAF.
4. Intraoperative complications were comparable between the groups (Table 1).
5. Postoperative maternal morbidity did not differ between the groups, with similar rates of postpartum fever, need for RBC transfusion, postpartum hemorrhage, ICU admission, PE/DVT, surgical site infection, relaparotomy and readmission (Table 1).
6. In singleton pregnancies, NICU admission rates were higher in the thick MSAF group (24%) compared to CAF (3%) and MSAF (4%) groups (p < 0.001). (Table 2).
7. MSAF and thick MSAF remained a significant risk factor for NICU admission in multivariate analysis, with OR of 2.08 (CI 1.259 to 3.274) and 14.84 (CI 4.462 to 42.79), respectively.

Conclusion: In singleton pregnancies, a more advanced gestational age is associated with incidental MASF in elective CD. However, the later seem to not impact adverse maternal outcomes. In singleton pregnancies, MSAF is linked to increased risk of adverse neonatal outcomes.

Table 1: Intra- and Post-operative Maternal Complications in the Study Cohort.

219 | Microplastic and Microparticle Pollutants in Fetal Growth Disorders

Jacob M. Garcia[1]; Rodrigo Weingrill[2]; Men-jean Lee[1]; Johann Urschitz[2]
[1]*University of Hawaii John A. Burns School of Medicine, Honolulu, HI;* [2]*University of Hawaii at Manoa, Honolulu, HI*

10:30 AM - 12:30 PM

Objective: Microplastic and microparticle pollutants have been increasingly detected in a variety of human tissues including lung, gut, kidney, atherosclerotic plaque and the placenta. The effects of these microparticles on human health, reproduction, and development are poorly understood. We aimed to examine if the accumulation of microparticle pollutants contributes to fetal growth disorders.

Study Design: To investigate the effects of microplastics (MPs) and micropollutants on fetal growth disorders 150 term placenta samples were retrieved for analysis from the Hawaii Reproductive Biospecimen Repository. Samples were matched by gestational outcomes and clinical data. Samples included controls (n = 50), macrosomia (n = 50), and fetal growth restriction (n = 50). Samples were weighted (~13g), washed in glass-microfiltered water, and digested in glass-microfiltered 10% KOH solution for 7 days at room temperature. A rigorous environmental control protocol was utilized, where biospecimen tube effluents, bench-air-exposed glass filters, and working solution controls were analysed. Digested tissue was glass-filtered and microparticles identified with Micro Raman spectroscopy and analysed with Know-it-all software. ANOVA, T-test, and descriptive analysis were performed were appropriate.

Results: Microplastic particles, polymeric dyes, and inorganic dyes were identified among all groups. Our analysis revealed no differences between the FGR and the control group. The macrosomia samples on the other hand showed a significantly higher incidence of inorganic dye particles compared to the control samples ($p < .001$).

Conclusion: Our study reveals that microparticle pollutant accumulation, and in particular inorganic dyes may be associated with certain fetal growth disorders such as in macrosomia. Further research is required to elucidate the underlying mechanisms and effects of microplastics and microparticles on placental and fetal health.

220 | Effect of the Dobbs Decision on Severe Maternal Morbidity in Wisconsin

Jacqueline M. Powell[1]; Janine S. Rhoades[1]; Ronald E. Gangnon[2]; Kara K. Hoppe[1]
[1]*University of Wisconsin School of Medicine and Public Health, Madison, WI;* [2]*University of Wisconsin Department of Population Health Sciences, Madison, WI*

10:30 AM - 12:30 PM

Objective: With maternal mortality rates increasing in the US, efforts to reduce perinatal morbidity and mortality are imperative. Recent policy changes have restricted abortion access which is a pillar of perinatal care. Wisconsin (WI) was significantly affected by the Dobbs decision. The aim of this study is to examine the effect of the Dobbs decision on the rate of severe maternal morbidity (SMM) in WI.

Study Design: A retrospective cohort of all births from 1/1/2021 to 11/1/2023 in WI was constructed using Wisconsin Hospital Association coding data. Pre Dobbs was defined as 1/1/2021–6/23/2022 and post Dobbs was defined as 6/24/2022–11/1/2023. Generalized additive logistic regression models were constructed for the change in the SMM rate as a function of geographic location (ZIP code). Statistical analyses were performed using the mgcv package in R.

Results: There were 160,649 births– 79,796 pre Dobbs and 80,853 post Dobbs and 8,426 SMM events (5.2%)–4,148 (5.2%) pre Dobbs and 4,278 (5.3%) post Dobbs (RR 1.02, 95% CI 0.97-1.06, p = 0.47). There was modest evidence (p = 0.07) of geographic variation in the impact of the Dobbs decision on the SMM rate. There were nominally significant (p < 0.05) elevations in the SMM rate for 101 ZIP codes in southeast WI and nominally significant reductions in the SMM rate for 1 ZIP code in northwest WI.

Conclusion: There is little evidence for a statewide effect of the Dobbs decision and restricted abortion access on the rate of SMM in WI. However, there is modest evidence of geographic variation in the effect (a SE to NW gradient) with elevated rates of SMM in southeastern WI. Given that geographic variation exists, this suggests that location of residence may impact rates of SMM with limited abortion access during pregnancy. SMM should be evaluated in each state to identify vulnerable areas with limited abortion access. Future work will analyze all 2024 births as there may be more SMM given incomplete data for patients unrepresented in this data set, but affected by the Dobbs decision during early pregnancy.

221 | Effect of the Covid-19 Pandemic on Severe Maternal Morbidity Based on Location in Wisconsin

Jacqueline M. Powell[1]; Janine S. Rhoades[1]; Ronald E. Gangnon[2]; Kara K. Hoppe[1]

[1]University of Wisconsin School of Medicine and Public Health, Madison, WI; [2]University of Wisconsin Department of Population Health Sciences, Madison, WI

10:30 AM - 12:30 PM

Objective: Access to obstetrical care is of concern to millions of women, especially those living in rural areas, which is estimated to be 49% of Wisconsin females. National emergencies have a disproportionate impact on rural areas especially when access to tertiary care centers is limited. The aim of this study is to examine the effect of the COVID-19 pandemic on the rate of severe maternal morbidity (SMM) across Wisconsin (WI) based on geographic location.

Study Design: A retrospective cohort study of all births in Wisconsin from March 1, 2017 to March 31, 2023 was constructed using Wisconsin Hospital Association coding data. The pre COVID-19 pandemic was defined as March 1, 2017–February 29, 2020, and the COVID-19 pandemic was defined as March 1, 2020 to March 31, 2023. Generalized additive logistic regression models were constructed for the change in the SMM rate as a function of geographic location (ZIP code). Statistical analyses were performed using the mgcv package in R.

Results: There were 334,366 births in WI during the study period–172,737 pre pandemic and 161,629 during the pandemic. There were 17,598 SMM events (5.3%) during the study period–9,173 (5.3%) pre pandemic and 8,425 (5.2%) during the pandemic (RR 0.98, 95% CI 0.96-1.01, $p = 0.28$). There was very strong evidence ($p < 0.0001$) of geographic variation in the impact of the pandemic on the rate of SMM. There were nominally significant ($p < 0.05$) elevations in the SMM rate for 33 ZIP codes in north central WI and nominally significant reductions in the SMM rate for 75 ZIP codes in south central and northwest WI.

Conclusion: North central WI, a rural area with fewer hospitals compared to urban areas, had increased rates of SMM during COVID-19. Rural areas are known to have worse health outcomes and these data show that the obstetric population is no exception. When access to tertiary care centers is limited, novel ways to increase access to critical care services for obstetric population needs to be developed to optimize perinatal outcomes.

222 | Chatgpt and Prenatal Diagnosis: is There a Role for Artificial Intelligence in Fetal Ultrasound?

Jacqueline A. Erler[1]; Emily E. Daggett[2]; Haylea S. Patrick[3]
[1]Rutgers Robert Wood Johnson Medical School, NJ; [2]Rutgers Robert Wood Johnson Medical School, Edison, NJ; [3]Rutgers Robert Wood Johnson Medical School MFM Division, New Brunswick, NJ

10:30 AM - 12:30 PM

Objective: Anecdotal evidence indicates a rising popularity of generative machine learning models, like ChatGPT, as adjunct diagnostic tools in clinical medicine. Current evidence is limited for ChatGPT's utility in diagnosing fetal syndromes when given ultrasonographic findings. We sought to assess ChatGPT's ability to give an accurate fetal diagnosis based on standardized imaging vignettes for prenatal conditions with well-described fetal ultrasound findings.

Study Design: We wrote 50 vignettes on a broad scope of prenatal conditions. Each vignette included up to 5 characteristic ultrasound findings adapted from *Callen's Ultrasonography in Obstetrics and Gynecology* and peer-reviewed literature. A second-year Maternal-Fetal Medicine (MFM) fellow and board-certified MFM physician reviewed vignettes for clinical accuracy. Vignettes were entered into ChatGPT-4o, and the program was asked to generate a differential diagnosis in decreasing order of likelihood. ChatGPT responses were scored on the inclusion of an accurate diagnosis anywhere in the differential, in the top three most likely conditions, and as the single most likely diagnosis.

Results: The differential diagnosis generated by ChatGPT included the correct prenatal diagnosis in 82% (n = 41) of the 50 tested cases. The correct diagnosis was in the top three most likely conditions in 76% (n = 38) of cases and was selected as the single most likely diagnosis in 68% (n = 34). The correct diagnosis was generated more frequently for common chromosomal abnormalities, including Trisomy 21, Trisomy 18, and Trisomy 13. Vignettes describing rare conditions with nonspecific ultrasound findings were less likely to result in a correct diagnosis.

Conclusion: ChatGPT gave an accurate prenatal diagnosis for a wide variety of fetal syndromes based on standardized descriptions of ultrasound findings. This study validates the use of ChatGPT to assist in prenatal diagnosis. Future studies aim to investigate the accuracy of ChatGPT in diagnosing real de-identified patient cases, and to compare the diagnostic accuracy of ChatGPT to that of expert clinicians.

223 | From Routine to Remarkable: When Carrier Screening Incidentally Reveals a Chromosomal Abnormality

Jaleesa Garner[1]; Eneka Lamb[2]; Vivian C. Romero[3]; Marcos Cordoba[4]; Mili Thakur[3]
[1]Michigan State University College of Human Medicine, Flint, MI; [2]Michigan State University College of Human Medicine, Grand Rapids, MI; [3]Michigan State University College of Human Medicine/Corewell Health Hospital, Corewell Health Hospital /Grand Rapids, MI; [4]Michigan State University College of Human Medicine/Corewell Health Hospital, Corewell Health Hospital/ Grand Rapids, MI

10:30 AM - 12:30 PM

Objective: Routine preconception care includes expanded carrier screening. We report a case of incidental detection of an unbalanced chromosomal X-autosome translocation after carrier screening identified a sizable deletion.

Study Design: A 22-year-old nulliparous woman underwent preconception expanded carrier screening by the 436 gene panel by gene sequencing with deletion and duplication analysis.

Results: Testing detected a heterozygous 15.6 Mb deletion of the q-arm of X chromosome spanning 10 panel genes (ABCD1, AFF2, EMD, F8, FMR1, G6PD, IDS, L1CAM, MTM1, SLC6A8) in the submitted sample. Genetic counseling and further cytogenic studies, including chromosomal microarray and karyotype analysis, revealed one normal X chromosome and one X chromosome with a 15.73 MB terminal deletion of Xq27.1- >q28 and a 2.03 MB terminal duplication of 3p26.3- >p26.3. This abnormality results in monosomy for part of the X chromosome long arm (Xq27.1->qter) and trisomy for part of the short arm of chromosome 3

(3p26.3- >ter); involving multiple OMIM genes (most proximal SOX3) and genes (CHL1 and CNTN6), respectively. There is a 50% chance of passing this unbalanced X-autosome translocation offspring. Due to the sizable X chromosome deletion, this translocation is expected to be lethal in male offspring. Female offspring who inherit it may exhibit variable phenotypic manifestations, including intellectual disability, developmental delay, and distinct facial features, depending on the ratio of X-inactivation. The patient has no health concerns and plans to proceed with in vitro fertilization (IVF) with preimplantation genetic testing for structural rearrangement (PGT-SR) for conception.

Conclusion: Expanded carrier screening through gene sequencing can detect chromosomal translocations by identifying deletions on chromosomes. Comprehensive genetic evaluation, counseling, and further testing are crucial to understand these findings. Regardless of PGT, IVF patients should receive counseling on prenatal genetic screening and diagnostic testing for chromosomal disorders and undergo a detailed anatomy ultrasound during pregnancy.

224 | Association of Intended Mode of Delivery with Neonatal and Maternal outcomes at 22-25 Weeks' Gestation

Jameaka L. Hamilton; On behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network
The Ohio State University, Columbus, OH

10:30 AM - 12:30 PM

Objective: To compare the risk of neonatal and maternal morbidity and mortality among individuals delivered between 22-25 weeks' gestation by planned cesarean delivery (CD) or trial of labor (TOL).

Study Design: Secondary analysis of an observational cohort including participants with a singleton pregnancy delivered via planned CD or after a trial of labor (TOL) from 22w0d through 25w6d. This analysis was limited to those who received both antenatal steroids and neonatal resuscitation. The primary outcome was a composite of neonatal death or severe neonatal morbidity. Secondary outcomes included measures of neonatal and maternal morbidity. Multivariable logistic regression analyses were used to adjust for prespecified covariates. Planned interaction analyses were performed between planned mode of delivery and gestational age (GA) at delivery (22-23 weeks; 24-25 weeks), then within GA groups between planned mode of delivery and presentation.

Results: Among 277 eligible individuals, 149 (53.8%) had a planned CD and 128 (46.2%) had a TOL of which 12 (9.4%) delivered by CD (Table 1). The two groups were similar except for lower birthweight (622g vs. 663g, p = 0.02) and more frequent hypertensive disorders (47.7% vs. 26.6%, p < 0.001) among those with planned CD. There was no difference in the primary neonatal composite outcome (73.8% vs. 79.7%, aOR 0.57, 95% CI 0.30-1.07) between groups. There were no differences in secondary neonatal outcomes except for higher frequency of intraventricular hemorrhage (IVH) in the TOL group (16.8% vs. 30.5%, aOR 0.50, 95% CI 0.28-0.90) (Table 1). Planned CD was associated with eight-fold greater odds of maternal sepsis and 12-fold greater odds of postpartum readmission; other outcomes were more frequent among planned CD but did not achieve statistical significance (Table 2). All interaction analyses were not significant.

Conclusion: In this multi-site registry, there was no difference in composite neonatal mortality or severe morbidity based on intended mode of delivery. Planned CD was associated with increased maternal morbidity but less risk of neonatal IVH.

Table 1: Neonatal morbidity and mortality associated with planned cesarean delivery compared trial of labor at 22-25 weeks[1]

	Planned CD N=149	TOL N=128	aOR (95% CI)
Neonatal primary outcome[2]	110 (73.8%)	102 (79.7%)	0.57 (0.30-1.07)
Neonatal death	44 (29.5%)	41 (32.0%)	0.93 (0.52-1.68)

Postpartum hemorrhage	11 (7.4%)	12 (9.4%)	0.59 (0.24-1.46)
Sepsis	9 (6.0%)	2 (1.6%)	**8.28 (1.32- 51.80)**
Stroke	0 (0%)	0 (0%)	NA
Venous thromboembolism	0 (0%)	0 (0%)	NA
Endometritis	5 (3.4%)	2 (1.6%)	2.32 (0.42-12.84)
Postpartum readmission	12 (8.1%)	1 (0.8%)	**12.03 (1.48-97.47)**

[1] All data presented in the table as n (%). Models adjusted for maternal age, chorioamnionitis, prior CD, and hypertensive disorders.
[2] Defined as maternal death, intensive care unit admission, transfusion of one or more blood products, postpartum hemorrhage, maternal sepsis, stroke or thromboembolism by maternal discharge; individual components of the primary outcome (if appropriate), postpartum endometritis, and maternal readmission following delivery up to 42 days postpartum
Abbreviations: CD, cesarean delivery; TOL, trial of labor; aOR, adjusted odds ratio; ICU, intensive care unit

225 | Is a Refractory Headache with Preeclampsia Under 34 Weeks Associated with High-Grade Maternal Vascular Malperfusion?

James Hearn[1]; Jacqueline Dukes[1]; Robert Wild[1]; Hanh Tran[1]; Zhongxin Yu[2]; Hugh Nadeau[1]; Marvin Williams[1]

[1]The University of Oklahoma College of Medicine, Oklahoma City, OK; [2]University of Oklahoma, Oklahoma City, OK

10:30 AM - 12:30 PM

Objective: An unexplained, persistent headache (PH) refractory to medication is a disease-defining characteristic of preeclampsia (PreE) with severe features (SF), requiring delivery regardless of gestational age (GA). High-grade maternal vascular malperfusion (HG-MVM) has been reported in ~95% of cases delivered with very preterm PreE, with its absence suggesting an alternate headache etiology. We sought to assess the prevalence of placental HG-MVM in cases delivered < 34 weeks for a PH associated with PreE, and correlate cases by MVM status with objective clinical values.

Study Design: All placental pathology reports from 2021 and 2022 at our tertiary center were reviewed. 52 cases delivered for PreE with a PH < 34 weeks GA were identified. Two pathologists analyzed placenta histology and noted specific MVM lesions. A score of low or HG MVM was assigned based on lesion frequency from a previously published scale, and correlated with maternal, neonatal and placental demographic values relevant to PreE. Tests of normality, descriptive statistics, and appropriate comparisons via chi-squared or t-test were performed.

Results: HG-MVM was found in 23/52 (44.2%) of cases. Cases with HG-MVM had a significantly lower birth weight percentile (40.4% vs 73.0%) and placental weight percentile (10.8% vs 64.1%), with a higher prevalence of nephrotic range proteinuria (30.4% vs 3.4%), and protein:creatinine ratio [0.5(3.6) vs 0.3(0.8) mg/dL]. Maternal serum values were similar but limited by the absence of abnormal values. A summary of results is provided (Table 1).

Conclusion: Placental HG-MVM prevalence was only 44.2% in this case series, suggesting that most persistent headaches prompting delivery were due to an etiology other than PreE with SF (i.e., migraines). HG-MVM appears likely when objective clinical findings consistent with PreE are seen, and less likely when absent. Placental weight, which is correlated with volumetric measurements on ultrasound, may be particularly informative. This information is useful in considering additional workup or pursing delivery for a refractory headache with known or suspected PreE.

Characteristic / Outcome	High grade MVM present (n=23)	High grade MVM absent (n=29)	Significance
Birth weight percentile	40.4%	73.0%	p<0.001*
Placenta weight percentile	10.8%	64.1%	p<0.001*

226 | History of Cured Syphilis Prior to Pregnancy and Risk of Congenital Syphilis

James D. Toppin[1]; Shannon McCloskey[2]; Meena Mishra[2]; Mariella Gastanaduy[3]; Talia Suner[3]; Joseph R. Biggio, Jr[1]; Frank B. Williams[2]
[1]Ochsner Health, New Orleans, LA; [2]Ochsner Clinic Foundation, New Orleans, LA; [3]Ochsner Clinic, New Orleans, LA

10:30 AM - 12:30 PM

Objective: Syphilis rates have sharply increased in the United States over the past decade, increasing the number of people entering pregnancy with a history of syphilis. Despite well-established and effective treatments, congenital syphilis (CS) has likewise increased over that time. We aim to compare rate of CS among pregnancies with and without history of cured syphilis.

Study Design: We performed a retrospective cohort study of singleton or twin pregnancies care from 2015 to 2023 at a large regional health system. Historical and prenatal laboratory values classified pregnancies as either history of syphilis or no history of syphilis. Patients with new diagnosis of syphilis at initiation of pregnancy care and those with initial prenatal rapid plasmin reagin (RPR) titer ≥ 1:8 were excluded. Pregnancies were stratified based on the history of adequately treated syphilis infection before pregnancy. Patients with history of syphilis and RPR < 1:8 were classified as serofast. Primary outcome was CS, defined by Centers for Disease Control case criteria. Secondary outcome was pregnancies with new or reinfection. Subanalysis evaluated for odds of CS among serofast patients. Chi square or T-test were used evaluate demographics and outcomes.

Results: A total of 57,704 pregnancies were included, of which 189 had a history of adequately treated syphilis infection prior to pregnancy, including 154 serofast patients. Those with history of syphilis were more likely to be Black and have public insurance (Table) CS incidence was significantly higher in pregnancies with a history of treated syphilis infection compared to those without (688 vs 8 per 10,000 live births, OR 93.3, 95% CI: 47.4, 171.7, Figure. CS rate among serofast patients was 779.2 per 10,000 live births (OR 91.1, 95% CI 45.4, 168.6). Maternal syphilis occurred more frequently in those with a positive history (847 vs 30 per 10,000 live births, OR 19.3, 95% CI 10.9–31.6).

Conclusion: History of syphilis before pregnancy is associated with a dramatically increased risk of maternal reinfection and congenital syphilis, particularly among serofast patients.

227 | Regional Health Unit Presence by Parish and Congenital Syphilis Rate in Louisiana

James D. Toppin[1]; Shannon McCloskey[2]; Talia Suner[3]; Meena Mishra[2]; Mariella Gastanaduy[3]; Joseph R. Biggio, Jr[1]; Frank B. Williams[2]
[1]Ochsner Health, New Orleans, LA; [2]Ochsner Clinic Foundation, New Orleans, LA; [3]Ochsner Clinic, New Orleans, LA

10:30 AM - 12:30 PM

Objective: Health units in Louisiana parishes serve as regional access points of essential health services, including screening, treatment, and prevention of syphilis. Clinic location is varied; some parishes have two while others have none. The increased congenital syphilis rate highlights the potential of these state-run clinics to target localities with high burdens of syphilis. We hypothesize that residing in a parish without a health unit increases risk for maternal and congenital syphilis.

Study Design: We performed a retrospective cohort study of pregnancies receiving prenatal and delivery care from 2015 to 2023 in a large health system in Louisiana. Historical and prenatal laboratory values determined syphilis infection status. Patients were compared based on the presence or absence of a health unit in the parish of their home address. The primary outcome was congenital syphilis (CS), as defined by Centers for Disease Control case criteria. A subanalysis of CS limited to maternal syphilis cases was performed. Regression analysis controlling for payor status generated adjusted odds ratios with 95% confidence intervals.

Results: A total of 42,684 pregnancies were included, of which 25.7% resided in a parish with no health unit. Patients in health unit parishes were younger, more likely to use public insurance and more likely to reside in a high-deprivation neighborhood (Table 1). No difference in CS cases were observed between groups (0.1% vs 0.1%, aOR 1.60, CI 0.75–3.93). New maternal syphilis infections were less common in parishes without health units (0.3% vs 0.7%, OR 0.38, 95% CI 0.26–0.56). When limiting analysis to maternal syphilis cases, living in a parish without a health unit was associated with increased odds for CS (51.6% vs 16.5%, aOR 5.42, 95% CI 2.47–11.88).

Conclusion: Parishes with health units had higher area deprivation and higher public insurance, and were associated with increased maternal syphilis infections. Syphilis during pregnancy in non-health unit parishes was associated with substantial increased odds for congenital syphilis compared to health unit parishes.

228 | The Influence of Social Determinants on Antenatal Anxiety and Physical Activity: A Step Forward

Janet Hurtado; Samantha L. Simpson; Hayley E. Miller; Ana C. Boncompagni; Chi-Hung Shu; Nima Aghaeepour; Brendan Carvalho; Pervez Sultan; Jane Chueh; Maurice L. Druzin; Danielle M. Panelli
Stanford University, Palo Alto, CA

10:30 AM - 12:30 PM

Objective: Physical activity is important for physical and mental health, yet most pregnant people do not achieve the recommended 150 minutes of aerobic exercise per week. People from lower socioeconomic backgrounds are even less likely to meet this target, yet it is unclear why. To see if socioeconomic stress is a contributing factor, we evaluated whether socioeconomic status (SES) modified the association between anxiety and physical activity.

Study Design: In 2021 and 2022, this prospective study recruited pregnant outpatients with singleton gestations between 16 and 36 weeks. Clinical anxiety was the mental health exposure, defined as State-Trait Anxiety Inventory [STAI] score > 80 at enrollment. The primary outcome was average daily physical activity (steps, metabolic equivalent tasks [METs], and moderate-to-vigorous-physical-activity bursts [MVPAs]), obtained from accelerometer watches worn for 7 days. Socioeconomic variables were self-reported via surveys: low household income, education ≤ high school, or public insurance were defined as low SES. The relationship between physical activity and anxiety was assessed using linear generalized estimating equations adjusting for maternal age, body mass index and low SES. We assessed effect modification between anxiety and SES using interaction terms.

Results: 40 pregnant people were enrolled. Anxiety was significantly associated with lower steps, METs, and MVPAs per day ($p = 0.01$, $p = 0.02$, $p < 0.01$, Table 1). Effect modification was detected, such that people with positive anxiety screening scores and low SES had fewer steps [ß coefficient -3619, 95% confidence interval (CI) -6451, -788, p-interaction = 0.01, Figure 1].

Conclusion: Positive anxiety screening was associated with lower physical activity over the subsequent 7 days. This was heightened for people with anxiety and lower SES, who had 3619 fewer daily steps than those with higher SES and no anxiety. Improving physical activity among pregnant people with anxiety, especially those from lower SES backgrounds, is warranted.

Table 1. Differences in physical activity between pregnant individuals with and without positive anxiety screening scores (N=40).

PHYSICAL ACTIVITY MEASURE	No Clinical Anxiety N = 33 Mean (SD)	Clinical anxiety N = 7 Mean (SD)	ß coefficient (95% Confidence Interval)	p-value[a]
Average steps/day	9236 (2163)	6655 (2430)	-2013 (-3589, -438)	0.01
Average METs/day[b]	1.5 (0.2)	1.5 (0.2)	-0.1 (-0.2, -0.02)	0.02
Average MVPAs/day[c]	85.6 (37.6)	128.7 (40.9)	-42.2 (-67.5, -16.9)	<0.01

229 | Decidual Cell-Mediated Paracrine Inhibition of IL1b Signaling in Extravillous Trophoblasts Contributes to Pregnancy Maintenance

Jasmine Edghill[1]; Umit Kayisli[2]; Ozlem Guzeloglu-Kayisli[2]; Charles Lockwood[2]; Asli Ozmen[2]
[1]Department of Obstetrics & Gynecology, University of South Florida, Tampa, FL; [2]USF Health Morsani College of Medicine, Tampa, FL

10:30 AM - 12:30 PM

Objective: Decidual cells (DCs) and extravillous trophoblasts (EVTs) interact at the maternal-fetal interface to establish an anti-inflammatory state and maintain pregnancy. Dysregulation of these interactions causes inflammation and initiates labor. Interleukin 1 receptor 1 (IL1R1) binds IL1b and IL1R antagonist (IL1RN) similarly to cause inflammation or anti-inflammation, respectively. We previously found higher IL1R1 and lower IL1RN levels in DCs from in-labor *vs.* non-in-labor term samples, suggesting a shift in these levels that activates inflammation, initiating labor. We hypothesize a similar shift of IL1R1 and IL1RN expression in EVTs in labor; though prior to, DCs prevent said shift via paracrine mediators to maintain pregnancy.
Study Design: Paraffin sections from gestational age-matched term non-in-labor (n = 7) *vs.* in-labor (n = 6) placentas were immunostained for IL1R1 and IL1RN and analyzed by HSCORE. DC cultures (n = 3) from 1st trimester (FTDC) and term (TDC) were primed for 7d with 10^{-8}M estradiol + 10^{-7}M medroxyprogesterone acetate and condition media supernatants (CMS) collected and used to treat human trophoblast cultures (n = 3) of term placentas. *IL1R1* and *IL1RN* mRNA levels were analyzed by qPCR. Statistical analysis used a *t*-test with $p< 0.05$ considered significant.
Results: Analysis revealed that EVTs from in-labor *vs.* non-in-labor decidua basalis had: 1) higher IL1R1 levels (Mean±SEM 184.1±10.1 *vs.* 120.1±15.6, p = 0.007); 2) lower IL1RN levels (121.3±13.1 *vs.* 186.5±10.1; p = 0.002); and 3) ~two-fold higher IL1R1/IL1RN ratio (0.73±0.1 *vs.* 1.58±0.2; p = 0.002). CMS from TDCs caused 2.28-fold higher *IL1R1* (p = 0.001) and 6.6-fold *IL1RN* (p = 0.03) levels in trophoblast cultures *vs.* untreated controls with similar results from FTDC CMS.
Conclusion: Our *in-situ* results indicate that EVTs undergo a shift to lower IL1RN and higher IL1R1 levels, activating IL1b signaling in the transition to labor. In contrast, *in vitro* results support the thesis that paracrine signals from DCs preferentially induce IL1RN (7-fold) over IL1R1 (2-fold) expression in EVTs to block IL1b signaling across gestation to maintain pregnancy.

230 | Racial and Ethnic Disparities in Cesarean Complication Rates using NSQIP Database

Jaxon C. Olsen[1]; Brittany Davidson[2]; Tracy Truong[3]; Sarahn M. Wheeler[3]; Leyi Sun[3]; Jeremy M. Weber[4]
[1]Duke University Hospital, Durham, NC; [2]Duke University, Durham, NC; [3]Duke University School of Medicine, Durham, NC; [4]Duke Clinical Researach Institute, Durham, NC

10:30 AM - 12:30 PM

Objective: This study aims to examine the relationship between patient race and ethnicity and complication rates in cesarean sections while controlling for general surgical risk using the National Surgical Quality Improvement Program (NSQIP) database from the American College of Surgeons (ACS).
Study Design: Women ages 18 and older with a CPT code for cesarean delivery recorded in 2019-2022 in the NSQIP database were included in the analysis. The primary variables were self-reported race and ethnicity. Outcomes of interest were surgical complications reported in the NSQIP database. The association between race (and separately for ethnicity) and complications was assessed using linear regression with robust standard errors for continuous outcomes and modified Poisson regression for

binary outcomes. Models were adjusted for age, body mass index, diabetes, hypertension requiring medication, American Society of Anesthesiologist physical status (ASAPS) class, chronic steroid use, and current smoker within one year.

Results: Among 56,635 patients in the study cohort, the average age was 30.8 (standard deviation of 5.6). Race was significantly associated with all outcomes considered. After controlling for covariates, the major complication rate was significantly higher among all race groups compared to White, and unknown group had a significantly lower major complication rate. Black patients had 43% higher risk of a major complication compared to White patients (95% CI = 1.28, 1.59). Hispanic patients had a 20% higher risk of major complications compared to non-Hispanic patients (95% CI = 1.09, 1.33). Patients with unknown or unreported race had 45% higher risk of a minor complication compared to White patients (95% CI = 1.33, 1.59). There was a notable amount of concurrence between unknown race and unknown ethnicity.

Conclusion: Self-identified race is associated with significantly higher rates of surgical complications following cesarean delivery even after controlling for surgical risk factors. More comprehensive obstetrics data is needed to measure and improve maternal morbidity and mortality nationwide.

231 | Risk Factors for Persistent Hypertension Requiring Anti-Hypertensive Medications Beyond 6 Weeks Postpartum

Jenny Y. Mei[1]; Audra Fain[2]; Kate Corry-Saavedra[3]; Tina A. Nguyen[2]; Thalia Mok[2]; Aisling M. Murphy[2]

[1]Stanford University, Mountain View, CA; [2]University of California, Los Angeles, Los Angeles, CA; [3]University of California, Irvine, University of California, Irvine, CA

10:30 AM - 12:30 PM

Objective: Hypertensive disorders of pregnancy increase risk for developing chronic hypertension. We evaluate risk factors for persistent hypertension at 6 weeks postpartum requiring continuation of anti-hypertensive (anti-HTN) medication.

Study Design: A retrospective cohort study of birthing patients with peripartum hypertension (HTN) at a quaternary care center over 2 years. This study is part of an ongoing postpartum quality improvement project that entails lower BP targets and universal remote BP monitoring. Inclusion criteria were delivery at the study institution, prescription of anti-HTN at some point postpartum, and having BP data at 6 weeks postpartum. Primary outcome was continuation of anti-HTNs past 6 weeks postpartum. We compared maternal and hypertensive risk factors between groups.

Results: Out of 6410 deliveries between April 2022-April 2024, 2019 (31.5%) were affected by HTN disorder of pregnancy, of which 775 (38.4%) met inclusion criteria. Total 211 (27.2%) patients were continued on anti-HTNs past 6 weeks. After adjusting for cesarean delivery and patients on anti-HTN entering pregnancy, we found significantly higher odds of continuing anti-HTN past 6 weeks with non-Hispanic Black race (adjusted odds ratio [aOR], 2.97; 95% confidence interval [CI], 1.91-4.62; $p < 0.001$), prenatal aspirin use (aOR, 1.43; 95% CI, 1.00-2.05, $p = 0.048$), and having public or no insurance (aOR, 1.66; 95% CI, 1.09-2.53, $p = 0.02$). Other risk factors included preeclampsia with severe features (aOR, 1.62; 95% CI, 1.12-2.34, $p = 0.01$), taking more than one antihypertensive (aOR, 2.80; 95% CI, 1.76-4.45; $p < 0.001$), requiring anti-HTN adjustment (aOR, 1.96; 95% CI, 1.37-2.79, $p < 0.001$), and postpartum ED visit or readmission (aOR, 2.45; 95% CI, 1.17-5.11, $p = 0.02$). Compliance with remote BP monitoring had lower odds of persistent HTN (aOR, 0.23; 95% CI, 0.07-0.79; $p = 0.02$).

Conclusion: Rates of persistent HTN requiring anti-HTN past 6 weeks postpartum are notable with certain patient cohorts at significantly higher risk. Continued intervention is needed to lower future cardiovascular morbidity in these high-risk groups.

Table 1. Characteristics by Need for Anti-Hypertensive Medications Beyond 6 Weeks Postpartum

Characteristic	Continuing anti-HTN past 6 weeks (n=211)	No anti-HTN past 6 weeks (n=564)	P-value[a]

Postpartum readmission or ED visit	2.84 (1.47-5.48)	2.45 (1.17-5.11)

Abbreviations: CI, confidence interval; anti-HTN, anti-hypertensive; ED, emergency department

a. Logistic regression was performed controlling for cesarean delivery and patients with chronic hypertension who were on anti-hypertensive medication entering pregnancy

b. Race and ethnicity were self-classified by the patient according to options defined by the study institution. They were assessed due to findings in previous studies of race and ethnicity being a risk factor for postpartum hypertension readmission.

232 | Nifedipine is Associated with Improved Postpartum Hypertension Outcomes Compared to Labetalol

Jenny Y. Mei[1]; Audra Fain[2]; Kate Corry-Saavedra[3]; Tina A. Nguyen[2]; Thalia Mok[2]; Aisling M. Murphy[2]
[1]Stanford University, Mountain View, CA; [2]University of California, Los Angeles, Los Angeles, CA; [3]University of California, Irvine, University of California, Irvine, CA

10:30 AM - 12:30 PM

Objective: Postpartum hypertension (HTN) is one of the most frequent reasons for readmissions and has been associated with developing chronic hypertension. We compare labetalol and nifedipine in postpartum hypertension outcomes.

Study Design: A retrospective cohort study of birthing patients with peripartum HTN at a quaternary care center over 2 years. This study is part of an ongoing postpartum quality improvement project that entails lower blood pressure (BP) targets and universal remote BP monitoring. Inclusion criteria were delivery at the study institution, diagnosis of HTN disorder of pregnancy, and discharge on either labetalol or nifedipine. Patients discharged on both medications were excluded. Primary outcome was postpartum readmission for HTN. Secondary outcome was persistent hypertension at 6 weeks postpartum defined by continuation of anti-hypertensives (anti-HTN). Labetalol was compared to nifedipine for both outcomes.

Results: Out of 6410 deliveries between April 2022-April 2024, 2019 (31.5%) were affected by HTN disorder of pregnancy. Of the 541 (26.8%) discharged on a single medication, 105 (19.4%) were labetalol and 436 (80.6%) nifedipine. In baseline characteristics between groups, labetalol was associated with higher rate of chronic hypertension (50.5% vs 17.9%, $p < 0.001$) and prenatal aspirin use (62.9% vs 46.8%, $p = 0.003$), and lower rate of cesarean delivery (34.3% vs 48.6%, $p = 0.008$). After adjusting for these 3 characteristics, labetalol use had significantly higher odds of readmission compared to nifedipine (adjusted odds ratio [aOR], 8.69; 95% confidence interval [CI], 1.45-52.11; $p = 0.02$). Patients on labetalol compared to nifedipine also had significantly higher odds of needing to continue anti-HTN medication past 6 weeks postpartum (aOR, 2.78; 95% CI, 1.62-4.79; $p < 0.001$).

Conclusion: Labetalol was significantly associated with higher odds of postpartum readmission and persistent hypertension at 6 weeks postpartum compared to nifedipine. Further research is needed to help tailor anti-HTN medications to clinical needs of high-risk patients.

Table 1. Baseline Characteristics Between Labetalol and Nifedipine

Baseline Characteristic	Labetalol (n=105)	Nifedipine (n=436)	P-value[a]
Maternal age in years (mean±SD)	34.0±5.8	34.3±5.6	0.59
Maternal age 35 and above	47 (44.8%)	220 (50.5%)	0.30

a. *P*-value significance was set at <0.05 and significant values are bolded.

b. Race and ethnicity were self-classified by the patient according to options defined by the study institution. They were assessed due to findings in previous studies of race and ethnicity being a risk factor for postpartum hypertension readmission.

Table 2. Hypertension Outcomes Between Labetalol and Nifedipine

Risk Factor	Labetalol (n=105)	Nifedipine (n=436)	P from Unadjusted X^2 Test[a]	Adjusted odds ratio (95% CI)[b]
Postpartum readmission	5 (20.8%)	2 (2.4%)	**0.001**	**8.69 (1.45-52.11)**
Postpartum ED visit	2 (8.7%)	6 (6.9%)	0.77	1.03 (0.17-6.23)
Postpartum ED visit or readmission	7 (6.7%)	8 (1.8%)	**0.007**	2.84 (0.91-8.86)
Outpatient Medication Changes	32 (30.5%)	117 (26.8%)	0.45	1.03 (0.62-1.70)
Hypotension[c]	3 (3.1%)	21 (5.3%)	0.37	0.65 (0.18-2.32)
On anti-HTN at 6 weeks postpartum	48 (50%)	87 (22.6%)	**<0.001**	**2.33 (1.39-3.92)**
Continuing anti-HTN past 6 weeks postpartum	43 (44.8%)	64 (16.6%)	**<0.001**	**2.78 (1.62-4.79)**

Abbreviations: CI, confidence interval; ED, Emergency Department; anti-HTN, anti-hypertensive

a. *P*-value significance was set at <0.05 and significant values are bolded.
b. Multivariate logistic regression was performed controlling for chronic hypertension, prenatal aspirin use, and cesarean delivery.
c. Hypotension was defined as blood pressure less than 100/60 while on anti-hypertensive medication.

233 | ELISpot Assay for Fetus-Specific T Cell Response in Human Pregnancy

Jessica C. Morgan[1]; Grace Hynes[2]; Anita Chong[3]
[1]The University of Chicago/Endeavor Health, NYP-Columbia, Cresskill, NJ; [2]University of Chicago, Chicago, IL; [3]The University of Chicago, The University of Chicago, IL

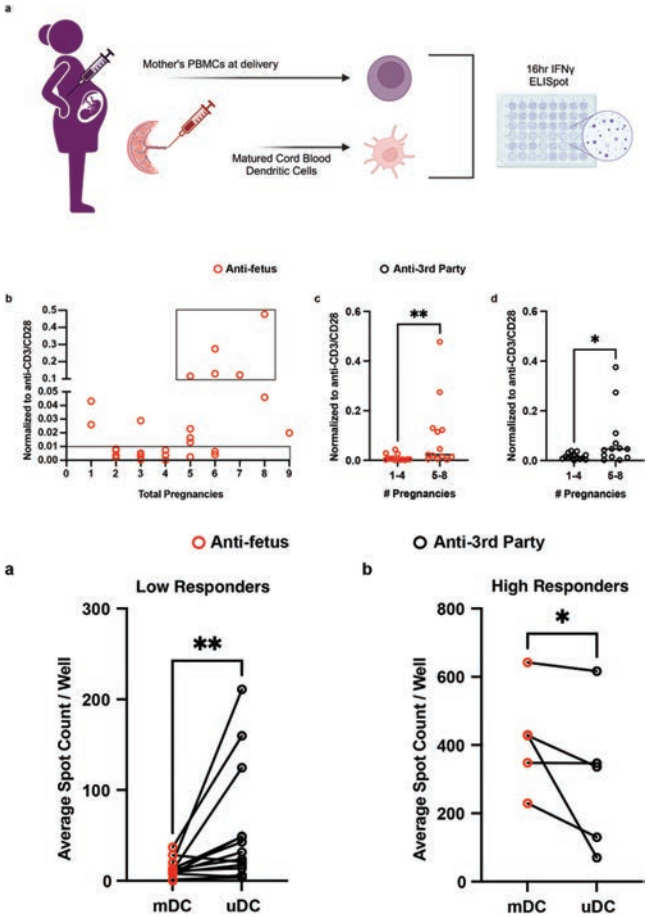
10:30 AM - 12:30 PM

Objective: Evidence from mouse models show that healthy pregnancies induce T cell hypofunction against fetus-specific antigens (FSA) as a mechanism of tolerance to the fetus. Inappropriate regulation of fetus-specific T cells is implicated in obstetric complications such as preterm birth, preeclampsia, miscarriage. Our hypothesis is that maternal T cells are tolerized (hyporesponsive) against FSA in successful human pregnancy, and produce less IFN-gamma (IFNg) when exposed to matched (mDCs) compared to unmatched/3rd-party fetal dendritic cells (uDCs).

Study Design: This is a prospective, proof of concept, pilot study. IRB approval and patient consent was obtained. Maternal peripheral blood and umbilical cord blood (UCB) was collected at delivery. DCs were matured from UCB, and used as stimulators of maternal peripheral blood mononuclear cells (PBMC). ELISpot assay was used to measure IFNg production by maternal T cells against mDC and uDC. The frequency of IFNg-producing cells was normalized against positive control stimulation with anti-CD3/CD28. Additional controls included influenza vaccine ± DCs.

Results: A total of 27 participants were included in analysis. The majority (n = 14 of 27; 55.6%) exhibited no or very low response to mDC, significantly lower than to uDCs. Notably a subset of patients (n = 5 of 12, 41.7%) with high gravidity (≥5 pregnancies) exhibited hyper responsiveness to mDCs compared to uDCs, suggesting aberrant T cell response.

Conclusion: We developed an IFNg ELISpot assay to quantify the magnitude of maternal T cell responses to FSA. T cell IFNg responses to mDC were lower compared to uDCs in a majority of pregnancies. Higher gravidity was associated with sensitized responses to mDCs. In some pregnancies, increased gravidity may override pregnancy-induced T cell tolerance. This suggests that additional mechanisms constrain memory T cell responses to ensure successful pregnancy. Future directions include measuring T cell responses to paternal antigens in patients with obstetric complications, as well as investigating how therapeutically targeting aberrant T cells may treat these complications.



234 | Blood Pressure Machines and Attendance of Follow-up Visit within 10 Days of Delivery

Jessica Greenberg[1]; Ashley Eng[2]; Patricia Greenberg[3]; Chavi Eve Karkowsky[2]; Lama R. Noureddine[4]; Joseph J. Apuzzio[4]; Shauna F. Williams[4]; Lisa N. Gittens-Williams[4]
[1]Rutgers New Jersey Medical School, South Orange, NJ; [2]Rutgers New Jersey Medical School, Rutgers NJMS, NJ; [3]Rutgers School of Public Health - Department of Biostatistics & Epidemiology, Piscataway, NJ; [4]Rutgers New Jersey Medical School, Newark, NJ

10:30 AM - 12:30 PM

Objective: Hypertensive disorders of pregnancy (HDP) contribute to maternal morbidity and mortality in the postpartum period and disproportionately affects Black, Indigenous and people of color (BIPOC). ACOG recommends that women with a HDP have a blood pressure evaluation within 10 days of delivery. This study assessed whether access to a blood pressure machine (BPM) with direction to self-monitored blood pressure (SMPB) increased adherence to this recommendation at our tertiary care center.

Study Design: This was a retrospective chart review of patients with HDP who delivered between July 1, 2020 and June 30, 2021. BPM were provided to HDP patients without one, with recommendation for SMBP. The primary outcome was attendance of follow-up visit within 10 days of delivery. Fisher's exact and Mann-Whitney U tests, and multivariable logistic regression were used. Self-identified race and ethnicity, maternal age, delivery mode, severe features, postpartum day of discharge, prescription

for anti-hypertensive medications at discharge, and ownership of a BPM were included in the model.
Results: 381 patients met inclusion criteria. 211(55.4%) identified as non-Hispanic Black and 146 (38.3%) as Hispanic; 105(27.6%) had severe HDP. 110(28.9%) patients were discharged with anti-hypertensive medication. 270(70.9%) patients had a BPM; 38(14.1%) owned and 232 (85.9%) were provided a BPM. 194 (50.9%) patients attended 10-day follow-up visit. 108(57.8%) patients with a BPM and 86(44.3%) patients without a BPM (p = 0.01) attended follow-up visit. Attendance of 10-day visit was predicted by ownership of a BPM (OR 1.8, 95% CI 1.1-3.0), cesarean delivery (OR 3.2, 95% CI 1.8-5.6), and Hispanic identification (OR 1.7, 95% CI 1.1-2.7).
Conclusion: In patients with HDP, BPM ownership predicted returning for a visit within 10 days. Provision of BPM likely connected patients more effectively to their postpartum care. Universal BPM provision with SMBP guidance could improve postpartum follow and reduce hypertension-related morbidity and mortality in this vulnerable population of historically minoritized patients.

235 | Discharge with Furosemide and Emergency Department Visits for Hypertension-Related Care in Patients with Severe Preeclampsia

Jessica Greenberg[1]; Ashley Eng[2]; Patricia Greenberg[3]; Chavi Eve Karkowsky[2]; Lama R. Noureddine[4]; Joseph J. Apuzzio[4]; Lisa N. Gittens-Williams[4]; Shauna F. Williams[4]
[1]Rutgers New Jersey Medical School, South Orange, NJ; [2]Rutgers New Jersey Medical School, Rutgers NJMS, NJ; [3]Rutgers School of Public Health - Department of Biostatistics & Epidemiology, Piscataway, NJ; [4]Rutgers New Jersey Medical School, Newark, NJ

10:30 AM - 12:30 PM
Objective: Preeclampsia with severe features (PEC-SF) contributes to maternal morbidity and mortality. Prior studies have shown that use of furosemide postpartum leads to a faster reduction in blood pressure (BP) in patients with hypertensive disorders of pregnancy. This study assessed whether prescribing postpartum furosemide to patients with PEC-SF would lead to a decrease in hypertension-related emergency department (ED) visits in our predominantly Black, Indigenous, and people of color population (BIPOC).
Study Design: This was a retrospective chart review of patients with PEC-SF who delivered July 1, 2020 - June 30, 2021. Institutional practice is to prescribe postpartum 20mg furosemide daily for five days to patients with PEC-SF. The primary outcome was ED visit for hypertension-related care within 12 weeks of delivery. Fisher's exact and Mann-Whitney U tests, and Firth multivariable logistic regression were used. Race and ethnicity, maternal age, delivery mode, postpartum day of discharge, furosemide prescription at discharge, other anti-hypertensive medication prescription at discharge, and ownership of a blood pressure machine (BPM) were used in the model.
Results: Among 105 patients with PEC-SF, 54 (51.4%) self-identified as non-Hispanic Black and 47 (44.8%) as Hispanic. 74(70.5%) patients were prescribed furosemide, 63 (60.0%) were prescribed another BP medication, and 76(72.4%) had a BPM. 16(15.2%) patients presented to the ED. Of the patients prescribed furosemide, 5(6.8%) returned to the ED; of those not prescribed furosemide, 11(35.5%) returned ($p < 0.001$). Furosemide prescription at discharge was a predictor of presentation to the ED (OR = 0.11, 95% CI: 0.02-0.38). After adjusting for demographic and clinical factors, the odds of an ED visit were 89% lower in patients who were discharged with furosemide.
Conclusion: Postpartum furosemide significantly decreased the odds of postpartum ED visits in patients with PEC-SF. Standardizing this regimen could decrease the need for ED visits, decrease patient morbidity and healthcare costs, while improving patient experience in a BIPOC community.

236 | Impact of Outpatient Cervical Ripening Prior to Term Induction of Labor - Prospective Randomized Trial

Joanne N. Quiñones[1]; Meredith Rochon[1]; Samira Hassan[2]; Shekinah Dosunmu[1]; Vincent Tang[1]; Danielle Durie[1]; Kara Coassolo[1]; Kyle Shaak[3]; Guillermo De La Vega[1]
[1]Lehigh Valley Health Network, Allentown, PA; [2]HCA UCF Lake Nona Hospital, Orlando, FL; [3]Network Office of Research and Innovation, Lehigh Valley Health Network, Allentown, PA

10:30 AM - 12:30 PM
Objective: To determine if there is an advantage to preadmission outpatient cervical ripening with a transcervical (Foley) balloon (FB) prior to induction.
Study Design: Prospective randomized trial of pregnant persons ≥ 39 wks scheduled for induction requiring cervical ripening (Bishop score < 6). Those with maternal/fetal complications, amniotic fluid abnormalities, and/or non-reassuring non stress test (NST) were excluded. Participants were randomized to FB placement as outpatient 12 hours (h) prior to induction admission (Outpt) or on admission (Inpt). Labor management was otherwise routine. Analysis was intention-to-treat (ITT). Planned sample size was 200; study was ended at 140 due to slow enrollment.
Results: 140 women were randomized from 11/2021-3/2024, 73 Outpt and 67 Inpt. Baseline characteristics between groups were similar (Table 1) with most inductions elective (95%). In the Outpt group, FB placement was successful in 65/73 (84%); 3/65 (4.6%) required immediate admission due to abnormal post-FB NST (2) or labor (1). Of 8 unsuccessful Outpt FB placements, 5 had bleeding or membrane rupture and 3 could not be placed. In the Inpt group, 59/67 (88.1%) had successful FB placement on admission; 5 no longer required cervical ripening and for 3 the FB could not be placed. In ITT analysis, time from FB placement to delivery was longer in Outpt group (28.5 vs 20.2 h, $p < 0.001$). There was no difference in use of other induction agents, mode of delivery, infection, neonatal outcomes, median maternal total length of stay (65.4 vs 65.3 h, $p = 0.762$), admission to delivery time (20.9 vs 21.4 h, $p = 0.507$), or total inpatient charges ($36,843 vs $36,269, $p = 0.899$) (Tables 2-4). When comparing outcomes for those that actually received the FB as planned (62 Outpt, 62 Inpt), there was a trend towards a decrease in median time from admission to delivery (18.6 vs 22.8 h, $p = 0.054$) but no difference in maternal length of stay or cost.
Conclusion: Outpatient cervical ripening with transcervical balloon prior to term induction is safe and feasible but may not be associated with clinical benefit or cost savings.

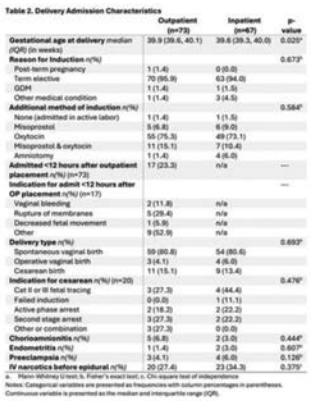


Table 3. Neonatal Outcomes

	Outpatient (n=73)	Inpatient (n=67)	p-value
Birthweight (grams) *mean (sd)*	3425.3 (396.5)	3498.0 (349.7)	0.254[b]
Admission to NICU *n(%)*	5 (6.8)	7 (10.4)	0.447[a]
Arterial cord gas value (pH) *median (IQR)* (n=135)	7.3 (7.2, 7.3)	7.3 (7.2, 7.3)	0.471[c]
Neonatal length of stay *median (IQR)*	2.0 (1.0, 2.0)	2.0 (1.0, 2.0)	0.318[c]

a. Chi-square test of independence; b. Independent-samples t-test; c. Mann-Whitney U test

Notes: Categorical variables are presented as frequencies with percentages in parentheses. Continuous variables are presented as the mean (with standard deviation) or median (with interquartile range (IQR)), as appropriate.

Table 4. Healthcare Utilization Outcomes (intention-to-treat)

	Outpatient (n=73)	Inpatient (n=67)	p-value
Time spent in office for balloon placement (minutes) *median (IQR)* (n=72)	86.0 (80.3, 92.0)	n/a	---
Time of fetal monitoring (hours) *median (IQR)*	20.4 (12.1, 29.3)	20.8 (13.5, 27.1)	0.972[a]
Time on oxytocin infusion (hours) *median (IQR)*	15.3 (7.2, 25.9)	15.3 (8.4, 20.1)	0.569[a]
Oxytocin max rate (mU/minute) *median (IQR)*	12.0 (6.0, 19.0)	12.0 (6.0, 18.0)	0.918[a]
Total charges (dollars) *median (IQR)*	36,843 (29,954, 48,271)	36,269 (31,051, 45,916)	0.899[a]
Maternal length of stay (hours)[a] *median (IQR)*	65.4 (51.8, 86.5)	65.3 (59.0, 87.7)	0.762[a]
Time from admission to delivery (hours) *median (IQR)*	20.9 (11.8, 29.0)	21.4 (14.9, 27.5)	0.507[a]
Maternal time from delivery to discharge (hours) *median (IQR)*	47.1 (36.9, 55.0)	43.3 (35.0, 52.8)	0.257[a]
Time from foley placement to delivery (hours) *median (IQR)* (n=131)	28.5 (21.1, 37.9)	20.2 (13.1, 25.5)	<0.001[a]

a. Mann-Whitney U test; b. Defined as time from admission to discharge.

Notes: Continuous variables are presented as the median and interquartile range (IQR).

237 | Safety of Cerclage Retention after PPROM: International Collaborative for Cerclage Longitudinal Evaluation And Research (IC-CLEAR)

Joanne N. Quiñones[1]; Joseph Bell[2]; Rupsa C. Boelig[3]; Shirin Azadi[4]; Onyinyech Anosike[4]; Dahiana M. Gallo[5]; Adam Taylor[6]; Vincenzo Berghella[7]; Leah Carnick Ledford[8]; Monica Rincon[9]; Susana Villegas-Sanchez[10]; Richard M. Burwick[11]; Luisa López-Torres[12]; Jorge E. Tolosa[13]

[1]Lehigh Valley Health Network, Allentown, PA; [2]St. Luke's University Health Network, Department of Obstetrics & Gynecology, Maternal Fetal Medicine, Bethlehem, PA, 18015, Bethlehem, PA; [3]Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA; [4]Lehigh Valley Health Network, Department of Obstetrics & Gynecology, Allentown, PA; [5]St. Lukes University Health Network, Bethlehem, PA; [6]St. Luke's University Health Network, Department of Obstetrics & Gynecology, Bethlehem, PA; [7]Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA; [8]Atrium Health's Women's Institute, Charlotte, NC; [9]Oregon Health & Science University, Portland, OR; [10]Department of Obstetrics & Gynecology, Universidad CES, Medellin, Colombia, Medellin, Antioquia; [11]San Gabriel Valley Perinatal Medical Group; Pomona Valley Hospital Medical Center, Pomona, CA; [12]Universidad Pontificia Bolivariana, Medicina Materno Fetal, Medellin, Colombia, Medellin, Antioquia; [13]St. Luke's University Health Network, Bethlehem, PA

10:30 AM - 12:30 PM

Objective: Previous IC-CLEAR data suggested an increase in latency from PPROM to delivery with delayed cerclage removal (SMFM 2023). Our objective is to determine the safety of cerclage retention in women who experience PPROM before 34 weeks (w) gestation.

Study Design: Retrospective cohort study of singleton pregnancies with cerclage for history, ultrasound or physical exam indications between 6/2016-6/2020 at 8 sites across United States and Colombia. Primary exposure: time from PPROM to cerclage removal (CR) categorized as early < 48 hours (h)– or delayed (≥ 48 h). Maternal safety outcomes included clinical or histologic chorioamnionitis, postpartum endometritis, hemorrhage, sepsis, and ICU admission. Neonatal safety outcome was a composite of sepsis, prematurity complications and death. Statistical analysis included bivariate and multivariate techniques.

Results: Of 839 singleton pregnancies managed with cerclage, 128 (15.3%) experienced PPROM < 34w. 36 underwent immediate CR for labor, bleeding or chorioamnionitis. 92 patients included in final analysis–60 early CR (65.2%) and 32 delayed CR (34.8%). Clinical chorioamnionitis and postpartum endometritis were higher in delayed CR vs. early CR (40.6% vs. 20.3%, P = 0.04 and 15.6% vs 0%, P = 0.002, respectively). Composite neonatal outcome was similar by CR timing when excluding PPROM < 24w (delayed 81.8% vs. early 64.9%, p = 0.16). Neonatal mortality was higher in early CR, but similar when only including PPROM ≥24w (Table). In adjusted analyses, clinical chorioamnionitis was lower with early CR [AOR 0.36 (95% CI 0.14, 0.94), p = 0.04), composite neonatal outcome was lower with early CR [AOR 0.34 (95% CI 0.12, 0.97), p = 0.04] and neonatal mortality was lower with corticosteroid use [AOR 0.15 (95% CI 0.02, 0.94), p = 0.04] and higher in PPROM< 24w [AOR 10.7 (95% CI 1.90, 60.0), p = 0.007).

Conclusion: Delayed CR after PPROM increases maternal infectious morbidity and neonatal composite morbidity/mortality. Delaying cerclage removal requires careful counseling about maternal and neonatal risks.

Flow Diagram. International Collaborative for Cerclage Longitudinal evaluation and Research (IC-CLEAR)

Table. Characteristics and safety outcomes in pregnancies with cervical cerclage complicated by PPROM before 34 weeks gestation

Baseline characteristics for entire cohort (n = 128)			
Maternal age (years)#	30.7 (31.0 (27.0 – 35.0)		
GA at cerclage placement#	19.6 (15.4 – 21.2)		
Primary indication for cerclage placement, n (%) • History • Ultrasound • Physical exam • Unknown	 32 (25.0%) 61 (47.6%) 34 (26.6%) 1 (0.8%)		
GA at PPROM#	26.0 (22.0 – 29.5)		
PPROM before 24 weeks, n (%)	48 (37.5%)		
GA at cerclage removal#	26.4 (22.5-29.7)		
Immediate CR for labor, chorioamnionitis and/or bleeding, n (%)	36 (28.1%)		
GA at delivery#	26.9 (23.0-30.1)		
Baseline characteristics for patients without labor, chorioamnionitis or bleeding at time of PPROM (n=92)			
Characteristic	**Early removal (n = 60)**	**Removal ≥ 48 h (n = 32)**	**p value**
GA at PPROM#	24.8 (21.6-29.2)	26.6 (22.8-28.3)	0.75
PPROM before 24 weeks, n (%)	23 (38.3)	10 (31.3)	0.50
GA at cerclage removal#	24.9 (21.6-29.2)	28.0 (25.4-29.7)	0.05
Days from PPROM to removal#	0 (0-0.7)	5.6 (3.5–14.4)	<0.001
Days from PPROM to delivery#	0.7 (0 – 2.8)	7 (3.5 – 16.8)	<0.001
Days from removal to delivery#	0.7 (0 – 2.8)	0 (0 – 1.4)	0.27
Corticosteroid administration, n (%)	38 (63.3)	27 (84.4)	0.09
Safety maternal outcomes			
GA at delivery#	26.1 (22.1 – 29.9)	28.7 (25.5 – 30.0)	0.20
Clinical chorioamnionitis, n (%)	12 (20.3)	13 (40.6)	0.04
Histologic chorioamnionitis, n (%)	33 (56.9)	22 (68.8)	0.27
Postpartum endometritis, n (%)	0 (0)	5 (15.6)	0.002
Postpartum hemorrhage, n (%)	5 (8.6)	2 (6.5)	0.25
Maternal sepsis, n (%)	1 (1.7)	2 (6.3)	0.25
Maternal intensive care unit, n (%)	3 (5.2)	0 (0)	0.19
Safety neonatal outcomes			
Admission to neonatal ICU, n (%)	37/48 (77.1)	26/30 (86.7)	0.30
Neonatal weight (grams)#	1227.5 (800-1480)	1327 (1083-1685)	0.19
Composite neonatal morbidity/mortality*, n (%) • All • PPROM ≥24w	 34 (56.7) 24/37 (64.9)	 26 (81.3) 18/22 (81.8)	 0.02 0.16
Perinatal death, n (%) • All • PPROM ≥24w	 13/42 (31.0) 5/31 (16.1)	 3/28 (10.7) 0 (0)	 0.048 0.06

Data analyzed with chi square, Fisher's exact tests, Wilcoxon-Rank sum as indicated.
#Data expressed as median (interquartile range)
*Composite outcomes: one or more of the following: respiratory distress syndrome, bronchopulmonary dysplasia, culture proven sepsis, retinopathy of prematurity, intraventricular hemorrhage, necrotizing enterocolitis or neonatal death

238 | Metal Staples Do not Increase Wound Complications After Cesarean Delivery in Obese Patients: a Meta-Analysis

Jordan A. McKinney[1]; Gustavo Vilchez[2]; Julio Mateus Nino[3]; Lifeng Lin[4]; Luis Sanchez-Ramos[5]
[1]*University of Florida College of Medicine, Gainesville, FL;* [2]*UTHealth Houston, Houston, TX;* [3]*Atrium Health, Wake Forest University School of Medicine, Charlotte, NC;* [4]*University of Arizona, Tucson, AZ;* [5]*University of Florida College of Medicine, Jacksonville, FL*

10:30 AM - 12:30 PM

Objective: To assess the rate of wound complications when using metal staples versus sutures for post-cesarean wound closure in obese individuals.

Study Design: We conducted a systematic search of electronic databases from inception to December 31, 2022, to identify relevant randomized controlled trials (RCTs). Eligible studies were RCTs comparing metal staples and sutures for wound closure following cesarean delivery in obese individuals. We performed a meta-analysis using random-effects models to report odds ratios (OR) with 95% confidence intervals (CI). Additionally, we assessed 95% prediction intervals to indicate the range of the true effect estimates of future studies. We also conducted a fragility index and a reverse fragility index to assess the robustness of our findings.

Results: This systematic review and meta-analysis included data from 8 RCTs involving 1,748 participants. We found that metal staples were not inferior to subcuticular sutures for post-cesarean wound closure in obese patients regarding wound complications (OR 1.20; 95% CI 0.69-2.09) and wound separation (OR 0.98; 95% CI 0.58-1.65). However, skin closure with metal staples, compared to sutures after cesarean delivery in obese individuals, on average reduced surgical site infection by 54% (OR 0.46; 95% CI 0.25-0.83). Fragility analyses revealed that the statistically insignificant results for wound complications and wound separation were robust, while the statistically significant reduction in surgical site infection with metal staples was fragile.

Conclusion: Our findings suggest that metal staples are not inferior to suture for post-cesarean wound closure in obese patients in terms of wound complications and wound separation. However, the optimal method of wound closure for obese patients remains uncertain. Our study highlights the need for further research in this area to establish the most effective technique for post-cesarean wound closure in obese patients.

Outcome	No. of Studies	Staples Group, n/N (%)	Suture Group, n/N (%)	OR (95% CI)	P-value	FI / Reverse FI	Heterogeneity, I^2
Wound complications	8	120/881 (13.6)	105/867 (12.1)	1.20 (0.69-2.09)	0.51	20	67%
Surgical site infection	4	19/363 (5.2)	38/363 (10.5)	0.47 (0.26-0.84)	0.01	1	0%
Wound separation	4	33/363 (9.1)	34/363 (9.4)	0.98 (0.59-1.63)	0.93	15	0%

239 | Does the Definition of Significant Proteinuria Matter? a Retrospective Cohort Study

Jordan A. McKinney[1]; Rebecca Meiser[2]; Luis Sanchez-Ramos[2]
[1]*University of Florida College of Medicine, Gainesville, FL;* [2]*University of Florida College of Medicine, Jacksonville, FL*

10:30 AM - 12:30 PM

Objective: Preeclampsia poses significant risks to maternal and perinatal health, with proteinuria serving as a key diagnostic criterion. However, the optimal definition of significant proteinuria remains uncertain, prompting this study to compare the impact of two definitions—based on concentration (>300 mg per liter per 24 hours) or per volume (>300 mg per 24 hours)—on maternal and perinatal outcomes in patients diagnosed with preeclampsia. This retrospective cohort study aimed to assess the influence of these two different definitions of significant proteinuria on maternal and perinatal outcomes in patients with preeclampsia.

Study Design: Medical records-based registry data from a teaching hospital in northeast Florida were collected during two distinct periods: March 2007 to November 2010 and January 2017 to December 2022. Pregnant patients diagnosed with preeclampsia were divided into two groups based on two definitions of significant proteinuria. Data analysis compared baseline characteristics, maternal outcomes, and neonatal outcomes.

Results: A total of 242 pregnancies were included in the analysis. Patients with proteinuria of >300 mg per liter per 24 hours were more likely to have severe preeclampsia, elevated systolic blood pressure, require intravenous antihypertensive treatment, undergo cesarean delivery, exhibit abnormal biochemical tests, and deliver at an earlier gestational age compared to patients with proteinuria of >300 mg per 24 hours.

Conclusion: In this study, the concentration-based definition of significant proteinuria in preeclampsia was associated with worse neonatal and maternal outcomes. These findings suggest that the

amount of proteinuria may help stratify risk among pregnant patients. However, further research is needed to corroborate these findings and to refine the diagnostic criteria for preeclampsia to enhance management protocols and improve patient care.

Maternal Outcomes by Proteinuria Definition

Outcome	Proteinuria by volume, (n/N, %)	Proteinuria by concentration, (n/N, %)	p-value
Severe preeclampsia	52/104 (50%)	111/138 (80.4%)	0.00
Maximum SBP >160	67/104 (64.4%)	116/138 (84.1%)	0.00
Maximum DBP >110	32/104 (30.8%)	56/138 (40.6%)	0.15
Need for Acute Antihypertensive Treatment	48/104 (46.2%)	98/138 (71.0%)	0.00
Cesarean Delivery	47/104 (45.2%)	86/138 (62.3%)	0.01

Proteinuria by volume (>300mg protein per volume in 24 hours), Proteinuria by concentration (>300mg protein per liter in 24 hours), SBP (systolic blood pressure), DBP (diastolic blood pressure)

240 | Efficacy and Outcomes of a 4 French Aortic Occlusion Balloon in Complex Placenta Accreta Surgery

Joseph C. Mulhall[1]; Yamely H. Mendez[1]; Christina C. Reed[2]; Arthur Ladron De Guevara[1]; Keneshia Lane[1]; Jonathan Gross[1]; Amir A. Shamshirsaz[1]; Hendrik A. Lombaard[3]; Michael A. Belfort[4]; Claire Hoppenot[1]; Jessian L. Munoz[1]
[1]Baylor College of Medicine, Houston, TX; [2]Baylor College of Medicine at Texas Children's Pavilion for Women, Houston, TX; [3]Texas Children's Hospital, Houston, TX; [4]Texas Children's Hospital and Baylor College of Medicine, Houston, TX

10:30 AM - 12:30 PM

Objective: Placenta Accreta Spectrum (PAS) is associated with significant maternal morbidity at time of cesarean hysterectomy. Aortic balloon occlusion is a technique used to reduce blood loss in cases of PAS, yet there is a risk of vascular injury at the point of arterial access. Traditional balloon devices require a 12 French arterial sheath. We evaluated our surgical outcomes using an innovative 4 French balloon occlusion device.

Study Design: This was a retrospective cohort study of patients with ultrasound findings consistent with complex PAS (placenta increta or percreta) who were delivered at a single tertiary care center from January 2020 to June 2024 with confirmed PAS on histopathology. Patients delivered after March 2022 were eligible to receive the 4 French balloon occlusion device. The patients delivered in the 28 months preceding this date served as historical controls. Uni- and multivariate analyses were performed for outcomes and confounding variables.

Results: There were 22 patients who received a 4 French aortic balloon occlusion device during the study period and 25 patients in the control group. There were no differences in baseline demographics between the two groups, and each group had similar distribution of pathologic PAS diagnoses (Table 1). Twelve patients (55%) had the balloon occlusion device deployed during delivery with an average deployment time of 39 minutes. There were no differences in estimated blood loss, transfusion rate, ICU admission, or postoperative length of stay between groups. Patients who received a balloon occlusion device had significantly longer operative time (341 min vs 289 min, p = 0.04) and higher readmission rate (27% vs 4%, p = 0.04). There were no cases of vascular injuries.

Conclusion: In our cohort, placement of a 4 French aortic occlusion balloon was associated with higher operative time and readmission rates, with no difference in other operative outcomes. There were no cases of vascular complications related to balloon placement. Larger studies are needed to identify patients who may benefit from this aortic balloon occlusion device.

241 | Antenatal Factors Associated with Inflation of 4 French Aortic Occlusion Balloon in Placenta Accreta Surgery

Joseph C. Mulhall[1]; Yamely H. Mendez[1]; Christina C. Reed[2]; Arthur Ladron De Guevara[1]; Keneshia Lane[1]; Jonathan Gross[1]; Claire Hoppenot[1]; Amir A. Shamshirsaz[1]; Hendrik A. Lombaard[3]; Michael A. Belfort[4]; Jessian L. Munoz[1]
[1]Baylor College of Medicine, Houston, TX; [2]Baylor College of Medicine at Texas Children's Pavilion for Women, Houston, TX; [3]Texas Children's Hospital, Houston, TX; [4]Texas Children's Hospital and Baylor College of Medicine, Houston, TX

10:30 AM - 12:30 PM

Objective: Aortic balloon occlusion is a technique used to reduce blood loss in cases of placenta accreta spectrum (PAS). Currently, there is no consensus on which patients would most benefit from aortic balloon device placement. We evaluated differences in antenatal clinical factors between patients who had the device inflated from those who had the device placed but not inflated.

Study Design: This was a retrospective case-control study of patients with ultrasound findings consistent with PAS who were delivered at a single tertiary care center from March 2022 through June 2024 and had a 4 French aortic occlusion balloon placed prior to surgery. Patients who had the balloon inflated intraoperatively were compared to patients who had the device inserted but not inflated. Uni- and multivariate analyses were performed for outcomes and confounding variables.

Results: There were 59 patients who had the 4 French aortic occlusion balloon placed during the study period, 28 of which had the balloon inflated during surgery. The average duration of balloon inflation was 35 minutes. There were no differences in demographic factors and medical histories between groups, including number of uterine surgeries (2.7 vs 2.8, p = 0.80) or timing of delivery (32.4 vs 33.0 weeks, p = 0.40). Additionally, there was no significant difference in the number or type of PAS ultrasound findings between groups. The suspected PAS diagnoses were similar in each group. Patients who had balloon inflated were more likely to have greater than two episodes of antenatal bleeding episodes though this did not reach statistical significance (18% vs 3%, p = 0.08). Antepartum complications were similar between both groups.

Conclusion: In our cohort we were unable to identify demographic, ultrasonographic, or antepartum factors that were associated with inflation of 4 French aortic occlusion balloon. These findings highlight the challenge in identifying patients who would most benefit from this device. Further research is needed to stratify patients for use of aortic occlusion balloon in PAS surgery.

242 | Stage 1 Hypertension Before 20 Weeks of Gestation is Associated with Postpartum Anti-Hypertensive Use

Julia Whitley[1]; Julia Burd[1]; Bree A. Goodman[1]; Bethany Sabol[2]; Antonina I. Frolova[3]; Jeannie C. Kelly[4]; Roxane Rampersad[1]; Nandini Raghuraman[4]

[1]Washington University in St. Louis, St. Louis, MO; [2]University of Minnesota, Minneapolis, MN; [3]Washington University School of Medicine, St. Louis, MO; [4]Washington University School of Medicine in St. Louis, St. Louis, MO

10:30 AM - 12:30 PM

Objective: Stage 1 hypertension (HTN), as defined by the American Heart Association, is associated with an increased risk of hypertensive disorders of pregnancy (HDP). Our objective was to evaluate if stage 1 HTN before 20 weeks of gestation was associated with persistent anti-hypertensive medication use at 6 weeks postpartum (PP).

Study Design: This was a retrospective cohort study at a single tertiary care center of all patients who delivered singleton gestations after 20 weeks of gestation between 2014-2016. Patients with chronic HTN and those who did not have 6 week PP data were excluded. Stage 1 HTN was defined as a maximum blood pressure (BP) of 130-139/80-89 before 20 weeks of gestation. Normotensive patients were those with all BPs < 130/80 before 20 weeks of gestation. The primary outcome was anti-hypertensive medication use at the 6 week PP visit, and the secondary outcome was PP re-admission for HDP. Multivariable logistic regression was used to adjust for potential confounders.

Results: 1546 normotensive patients were compared to 465 patients with stage 1 HTN before 20 weeks of gestation. Patients with stage 1 HTN were more likely to develop a HDP. Compared to normotensive patients, those with stage 1 HTN were significantly more likely to require anti-hypertensive medication at 6 weeks PP (8.8% vs. 2.9%, aOR 2.23; 95% CI, 1.41-3.54), even when the analysis was restricted to patients who developed a HDP (P = 0.02). Patients with stage 1 HTN were also significantly more likely to be re-admitted for a HDP (3.9% vs. 1.5%, aOR 2.11; 95% CI, 1.10-4.06).

Conclusion: Stage 1 hypertension before 20 weeks gestation should be considered a risk factor for persistent anti-hypertensive use at 6 weeks PP and re-admission for HTN, and targeted for future study.

Table: Maternal outcomes in patients with and without stage 1 hypertension before 20 weeks of gestation

Outcomes	Normotensive (n=1546) *Ref*	Stage 1 HTN before 20 wk (n=465)	OR (95% CI)	aOR[a] (95% CI)
Anti-hypertensive medication at 6 wk postpartum	45 (2.91)	41 (8.82)	**3.22 (2.08, 4.99)**	**2.23 (1.41, 3.54)**
Postpartum re-admission for HDP	23 (1.49)	18 (3.87)	**2.67 (1.43, 4.99)**	**2.11 (1.10, 4.06)**

243 | The Performance of an Automated Risk Stratification Tool for Postpartum Hemorrhage Prediction

Juliet Musabeyezu[1]; Kaitlyn E. James[2]; Christina M. Duzyj[2]; William H Barth, Jr.[2]; Thomas H. McCoy[3]; Roy H. Perlis[2]; Anjali J. Kaimal[4]; Mark A. Clapp[2]

[1]Massachusetts General Brigham, Boston, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Massachusetts General Brigham, boston, MA; [4]University of South Florida, Tampa, FL

10:30 AM - 12:30 PM

Objective: PPH is one of the most common causes of morbidity during labor and delivery. Most current risk stratification tools rely on manual completion of checklists at multiple time points, increasing non-patient-facing tasks for the care team and relying on information recorded in multiple places in the EHR. Our objective was to automate a common PPH risk stratification tool using data routinely captured in the EHR and assess its performance to predict PPH.

Study Design: We automated the assignment of the AWHONN PPH Risk Tool designation using structured, real-time data in

the EHR at the time of admission, pre-delivery, and postpartum. Individuals were classified as low, medium, or high risk using the AWHOON PPH Tool risk factor framework (v1.2). We assessed the performance of the automated tool to predict PPH (EBL≥1,000 mL) by measuring sensitivity, specificity, PPV, and NPV for the high-risk group at each timepoint using data from all individuals who delivered at a single academic institution between July 2023 and April 2024.

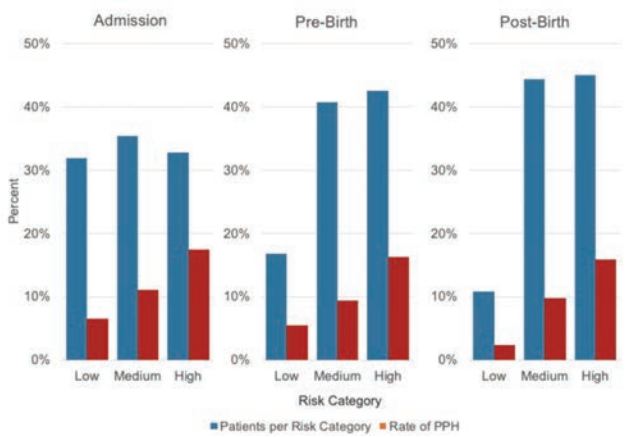
Results: 1208 participants were included, of which 141 (11.8%) had a PPH. The distribution of patients between the risk categories at the three timepoints and the rate of PPH are shown in the Figure. 32.8%, 42.5%, and 45.0% were high-risk on admission, pre-birth, and post-birth, respectively. The rate of PPH increased with corresponding risk categories at each time point, demonstrating the tool's value in stratifying risk. On admission, the rate of PPH in the low risk compared to the high-risk group was 6.5% vs. 17.4%. Among those classified as high risk, the sensitivity increased from 48.9% to 61.0% from admission to post-birth, and the PPV decreased from 17.4 to 15.8%.

Conclusion: A real-time, automated version of a common PPH risk assessment tool can stratify the PPH risk using clinical EHR data. Future work is focused on the ability of this tool to reduce administrative burdens of the team and improve team awareness and communication through the triggering of real-time, automated alerts for PPH risk.

Table: Performance Characteristics of the Automated High-Risk Designation at Three Time Points during the L&D Admission

Time Point	Sensitivity	Specificity	Positive Predictive Value	Negative Predictive Value
Admission	48.9%	69.3%	17.4%	91.1%
Pre-birth	59.6%	59.8%	16.3%	91.8%
Post-birth	61.0%	57.2%	15.8%	91.7%

Figure: Distribution of Patients per Risk Category and the Rate of Postpartum Hemorrhage at Three Time Points during the L&D Admission



244 | Effect of a High Dose Oxytocin Protocol for Management of Labor

Kaitlyn M. Dorn[1]; Sarah Oliver[1]; Maggie Ross[1]; Le'Nisha Williams[1]; Frank B. Williams[1]; Joseph R. Biggio, Jr[2]; Jane Martin[1]

[1]Ochsner Clinic Foundation, New Orleans, LA; [2]Ochsner Health, New Orleans, LA

10:30 AM - 12:30 PM

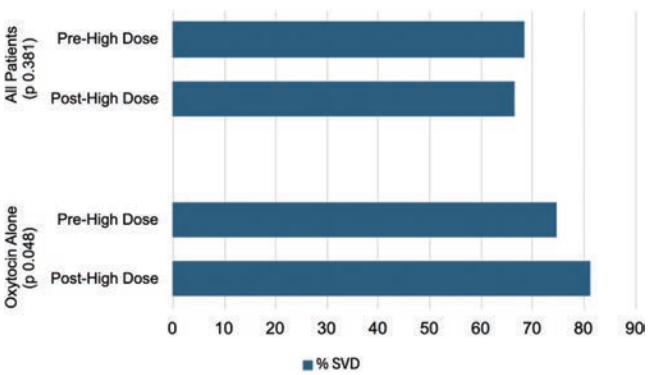
Objective: Randomized data suggest high dose oxytocin reduces duration of labor without increasing adverse outcomes. Among nulliparous patients without contraindications to labor, we compared low versus high dose oxytocin on rate of spontaneous vaginal delivery (SVD) within 24 hours of oxytocin initiation.

Study Design: We conducted a retrospective cohort study of nulliparous women 36w0d gestation or greater undergoing labor induction or augmentation at a single tertiary care center from April 2021 to August 2023. Patients with a history of uterine surgery or non-cephalic presentation were excluded. Low dose oxytocin protocol was standard of care prior to September 2022 and consisted of a starting dose of 2 mU/minute, titrated by 2 mU/minute every 30 minutes. Patients delivering after September 2022 received high dose oxytocin protocol, which consisted of a starting dose of 4 mU/minute, titrated by 4 mU/minute every 30 minutes. Primary outcome was SVD within 24 hours of oxytocin initiation. Secondary outcomes included median duration of labor, delivery mode, intra-amniotic infection (IAI), postpartum hemorrhage (PPH), and five-minute Apgar less than 7.

Results: There were 2,147 patients eligible for enrollment: 1058 in the low dose oxytocin arm and 1089 in the high dose oxytocin arm. There was no difference in rate of SVD within 24 hours according to oxytocin dose protocol (69 vs 67%, p 0.381). Similarly, there were no differences in secondary outcomes. A sub-analysis was performed to assess patients who received oxytocin alone without exposure to other methods of induction or augmentation. Rate of SVD within 24 hours increased (81 vs 75%, p 0.048) and labor duration decreased (10.5 vs 12.7 hours, $p < 0.001$) with high dose oxytocin when compared to low dose oxytocin.

Conclusion: When assessing all nulliparous patients admitted for labor induction or augmentation, implementation of a high dose oxytocin protocol did not result in increased rates of SVD within 24 hours. Rates of SVD within 24 hours were increased and median labor duration was shorter with oxytocin exposure alone.

	Pre-High Dose (N=1058)	Post-High Dose (N=1089)	p-value
Black, N (%)	267 (25.3)	288 (26.5)	0.555
Hispanic, N (%)	64 (6.1)	77 (7.1)	0.385
Age, Median (IQR)	30 (26, 33)	30 (25, 33)	0.985
BMI, Median (IQR)	31.24 (27.83, 36.04)	31.84 (28.22, 36.63)	0.029
EGA, Median (IQR)	276 (270, 281)	275 (269, 280)	0.063
Maximum Oxytocin Dose, Median (IQR)	14 (8, 22)	16 (8, 24)	< 0.001
Induction, N (%)	700 (85.6)	768 (85.5)	1.000



245 | Establishing the Most Accurate Due Date in Twin Gestation by Second and Third Trimester Ultrasound

Katelyn J. Rittenhouse[1]; Ambika V. Viswanathan[2]; Teeranan Pokaprakarn[2]; Yuri Sebastião[2]; Elizabeth M. Stringer[2]; William H. Goodnight[2]; Jeffrey S.A. Stringer[2]
[1]*University of North Carolina - Chapel Hill, Chapel Hill, NC;*
[2]*University of North Carolina at Chapel Hill, Chapel Hill, NC*

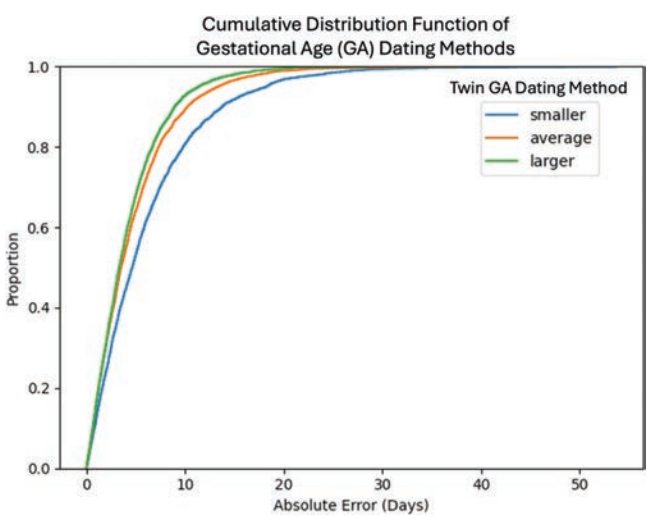
10:30 AM - 12:30 PM

Objective: We assessed the optimal sonographic dating approach for twin gestations presenting to antenatal care beyond the first trimester.

Study Design: We studied twin pregnancies receiving care at the University of North Carolina between Nov 2017 and Aug 2023 whose gestational age (GA) had been definitively established by first trimester ultrasound or in vitro fertilization ("ground truth"). We included all ultrasound studies with complete biometry conducted after 14 weeks gestation. We assessed the accuracy of Hadlock IV GA dating using the smaller, average, and larger twin's biometric data against "ground truth" gestational age.

Results: Our analysis dataset consisted of 2,103 studies from 593 twin pregnancies. 27% (161) pregnancies were monochorionic and 1% (8) were monoamniotic. The mean absolute error ± standard error (MAE ± SE) was 5.77 ± 0.12 days for the smaller twin, 4.41 ± 0.09 days for the average twin, and 4.06 ± 0.07 days for the larger twin. The average error (AE) showed that all three measurements underestimated gestational age when compared to ground truth, with the larger twin having the least bias (smaller twin -4.53 ± 0.14; average twin -2.28 ± 0.12; larger twin -0.03 ± 0.12). These results held across sensitivity analyses including only one ultrasound scan per pregnancy and stratifying by chorionicity.

Conclusion: In the 2nd and 3rd trimesters, gestational age dating is more accurate and less biased when using the biometry of the larger twin, as compared to the smaller twin or an average of the two twins. Guidelines should be updated to provide clear guidance on establishing twin GA when the dating ultrasound is performed beyond the first trimester.



Comparison of twin gestational age using the smaller, average, and larger twin biometric data

		Twin Gestational Age Comparison (N = 593 pregnancies, 2,103 studies)		
		Smaller	Average	Larger
Mean Absolute Error (SE), days		5.77 (0.12)	4.41 (0.09)	4.06 (0.07)
Mean Error (SE), days		-4.53 (0.14)	-2.28 (0.12)	-0.03 (0.12)
2nd trimester†	Mean Absolute Error (SE), days	4.18 (0.11)	3.27 (0.08)	3.11 (0.07)
	Mean Error (SE), days	-3.02 (0.14)	-1.35 (0.12)	0.32 (0.11)
3rd trimester‡	Mean Absolute Error (SE), days	8.08 (0.22)	6.06 (0.17)	5.43 (0.14)
	Mean Error (SE), days	-6.73 (0.27)	-2.28 (0.23)	-0.53 (0.23)
Absolute Error < 7 days (SE), %		70.28 (1.0)	80.65 (0.86)	84.02 (0.80)
Absolute Error < 14 days (SE), %		92.49 (0.57)	96.72 (0.39)	98.05 (0.30)

†2nd trimester is defined as 98-195 days, 557 pregnancies, 1,246 studies
‡3rd trimester is defined as 196 days to 280 days, 431 pregnancies, 857 studies

246 | Association Between Abnormal Umbilical Artery Doppler and Stillbirth in a Zambian Cohort

Katelyn J. Rittenhouse[1]; Margaret P. Kasaro[2]; Yuri Sebastião[3]; Elizabeth M. Stringer[3]; Bellington Vwalika[4]; Jeffrey S.A. Stringer[3]
[1]*University of North Carolina - Chapel Hill, Chapel Hill, NC;* [2]*UNC Lusaka, UNC Zambia, Lusaka;* [3]*University of North Carolina at Chapel Hill, Chapel Hill, NC;* [4]*University Teaching Hospital, Lusaka, Lusaka*

10:30 AM - 12:30 PM

Objective: We sought to estimate the association between abnormal 3rd trimester UAD and stillbirth in an unselected, well-characterized Zambian cohort.

Study Design: The Zambian Prematurity Prevention Study (ZAPPS) is a prospective antenatal cohort in Lusaka with continuous enrollment since 2015. Since 3/2020, UAD were routinely obtained during 3rd trimester ultrasound. FGR was defined as an estimated fetal weight (EFW) < 10%ile. Abnormal UAD was defined as 1) reversed or absent end diastolic flow (EDF) or 2) systolic/diastolic (S/D) ratio >95%ile for gestational age. FGR and S/D ratio were estimated using INTERGROWTH-21st standards. The primary outcome was stillbirth, defined as fetal death ≥20wks gestation. Using marginal standardization, we estimated crude and adjusted risk of stillbirth among singleton gestations. We also estimated risk of NICU admission and 5 minute APGAR < 7.

Results: Between 9/2020-12/2022, 988 singletons were enrolled in ZAPPS with a 3rd trimester growth ultrasound performed (range: 31-34wks). Delivery outcome was available on 978 pregnancies (99%) with 11 (1%) cases of stillbirth. During 3rd trimester ultrasound, 92 (9%) pregnancies were diagnosed with FGR and 77 (8%) had abnormal UAD (absent EDF: 32; S/D >95%ile: 45). Both FGR (ARR: 4.1; 95%CI: 1.1,15.1) and abnormal UAD (ARR: 5.5; 95%CI: 1.6, 18.7) were associated with increased risk of stillbirth in analyses adjusted for advanced maternal age and hypertension. The association between abnormal UAD and stillbirth was present even among normally grown fetuses (ARR: 6.6; 95%CI: 1.6,27.3). Abnormal UAD were also associated with NICU admission (RR: 2.0 95%CI 1.1 3.4) and 5 minute APGAR < 7 (RR: 3.1 95%CI: 1.3,7.6).

Conclusion: In this well characterized urban African cohort, abnormal UAD was common, only rarely comorbid with FGR, and independently associated with stillbirth. Further research is needed to understand the role of screening for abnormal UAD in this population.

Table 1: Association between stillbirth and three stratified sonographic groups

Group	Sonographic Findings	N	Risk	Unadjusted RR	Adjusted RR*
1	EFW≥10%	886	1% (8)	1.0 (reference)	1.0 (reference)

247 | Implementation Barriers of a Community-Based Doula Program in an Academic Medical Center

Katherine Quinn[1]; Erica Marion[1]; Joni Williams[1]; Jessica Olson[1]; Dalvery Blackwell[2]; Anna Palatnik[1]
[1]*Medical College of Wisconsin, Milwaukee, WI;* [2]*African American Breastfeeding Network Inc., Milwaukee, WI*

10:30 AM - 12:30 PM

Objective: Community-based doula care is an evidence-based strategy to improve maternal and child health outcomes. However, building equitable partnerships between doulas and hospital-based labor and delivery clinicians presents challenges. Laying the groundwork for a collaborative clinician-doula program, this study aimed to identify multi-level barriers to developing and implementing a doula program for Black pregnant patients.

Study Design: In spring 2024, we conducted 19 in-depth interviews with obstetric clinicians (n = 13) and nurses (n = 6) from a single academic medical center and two focus groups with doulas (n = 11), from a local community-based non-profit organization. Conversations were audio-recorded, transcribed verbatim, and coded in MAXQDA qualitative analysis software. We used thematic analysis to understand program feasibility, acceptability, and key implementation barriers.

Results: Overwhelmingly, providers and doulas recognized the need for a collaborative clinician-doula program and believed it could improve patient experiences and outcomes. They described potential implementation barriers: 1) inconsistencies in doula training and knowledge across organizations; 2) lack of clarity around roles and expectations, particularly between nurses and doulas; 3) lack of trust between doulas and clinicians; and 4) hospital policies that limit collaboration. Overcoming these barriers will require developing a robust, collaborative training and implementation model that ensures equity between all partners.

Conclusion: Although community-based doulas improve equity in maternal and child health outcomes, the multi-level barriers identified in this formative study must be addressed to realize the full benefits of a collaborative clinician-doula program. To achieve equity goals, developing and implementing a clinician-doula collaborative model should be grounded in a health equity implementation science framework, informed by local data, and cooperatively led by doulas and healthcare providers.

10:30 AM - 12:30 PM

Objective: Recent work showing that placental membrane trophoblasts expand in the context of severe preeclampsia suggests a role for membrane trophoblasts in placental disease. Yet, the biology and function of membrane trophoblasts are poorly understood. We sought to determine the effects of inflammatory stress from maternal COVID-19 on membrane cytotrophoblast (CTB) and extravillous trophoblast (EVT) gene function.

Study Design: We analyzed placenta single-nucleus RNA sequencing data from patients with symptomatic COVID-19 at birth (n = 4) and healthy gestational age-matched controls (n = 4). To evaluate the effects of COVID-19 on membrane CTBs and EVTs, we identified differentially expressed genes (DEGs) in COVID-19 vs. control samples for each cell population using Seurat in R. GO Biological Process gene set enrichment analysis (GSEA) was conducted using the Fgsea R package (q-value threshold < 0.1).

Results: EVTs showed downregulation of mitochondrial genes (*MT-ND4, MT-ND5*) and matrix metalloproteinase inhibitors (*TIMP2, TIMP3*), which regulate tissue remodeling and apoptosis. EVTs also exhibited upregulated *PAPPA2,* a growth factor regulator, and *EGLN3*, a hypoxia inducible factor. CTBs showed similar downregulation of mitochondrial genes and upregulation of *EGLN3*, in addition to *PPARG*, whose increased expression has been linked to ameliorating placental dysfunction. GSEA of EVT DEGs revealed the upregulation of pathways involved in signal transduction and cell proliferation, including MAPK cascade. Oxidative phosphorylation and cellular respiration were downregulated (**Fig 1**). GSEA results for CTBs showed pathways involved in carbohydrate metabolism and cell proliferation, although these were not significant.

Conclusion: In the setting of placental stress due to COVID-19, membrane EVTs and CTBs demonstrate mitochondrial dysfunction, response to hypoxia, downregulation of aerobic respiration pathways, and upregulation of cell proliferation pathways, primarily observed in EVTs. This study uncovers adaptations of understudied membrane trophoblasts in the context of COVID-19.

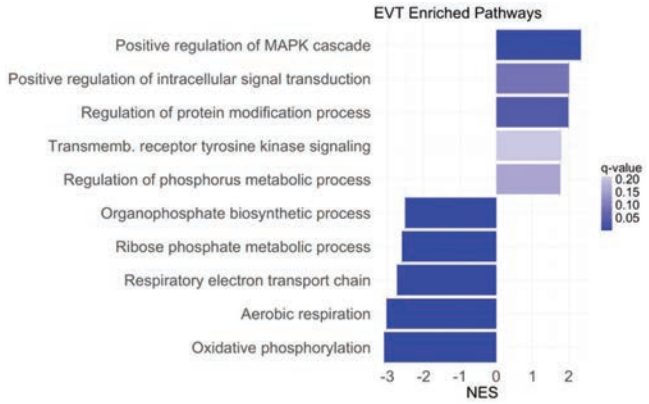

Figure 1. Gene Set Enrichment Analysis of the top 10 dysregulated pathways for EVTs, accompanied by normalized enrichment scores (NES) and q-values.

249 | Association of Maternal Serum 25-Hydroxyvitamin D Level in Mid-Gestation with Fetal Adiposity: a Longitudinal Study

Keisuke Akita[1]; Satoru Ikenoue[1]; Junko Tamai[1]; Naotsugu Ishikawa[1]; Yasuhiko Ogata[1]; Kaoru Kajikawa[1]; Yuka Fukuma[1]; Yuya Tanaka[1]; Toshimitsu Otani[2]; Yoshifumi Kasuga[1]; Mamoru Tanaka[1]
[1]Keio University School of Medicine, Shinjuku-ku, Tokyo; [2]Keio University School of Medicine, Nakano-ku, Tokyo

10:30 AM - 12:30 PM

Objective: 25-Hydroxyvitamin D (25(OH)D) regulates lipid metabolism, and its decrease is proposed as a pathogenesis of metabolic syndrome. Fetuses are dependent on supply of 25(OH)D from maternal circulation though pregnant women are described as a population at risk for decreased 25(OH)D. Recently, quantitative evaluation of fetal adiposity using ultrasonography has been established, and clinical investigations revealed that gestational diabetes mellitus (GDM) is associated with increased fetal adiposity. However, the influence of maternal serum 25(OH)D on fetal fat deposition remains unclear. This study aimed to investigate the association of maternal serum 25(OH)D level in mid-gestation with fetal adiposity.

Study Design: A prospective study was conducted in a cohort of 89 (including 22 GDM) singleton pregnancies. Maternal blood sample was obtained at 24 weeks. Fetal ultrasonography was performed serially at 24, 30 and 36 weeks. Estimated fetal adiposity (EFA) was calculated by integrating measurements of cross-sectional arm and thigh percentage fat area and anterior abdominal wall thickness as previously reported. The association between maternal serum 25(OH)D and EFA were determined by multiple linear regression adjusted for potential covariates including maternal age, parity, pre-pregnancy BMI, gestational weight gain and fetal sex. GDM was diagnosed by the national clinical practice guideline based on the 75g oral glucose tolerance test.

Results: Maternal serum 25(OH)D at 24 weeks was 16.2±7.7 ng/ml (mean±S.D.). Maternal serum 25(OH)D was not associated with EFA at 24 and 30 weeks, but significantly and inversely correlated with EFA at 36 weeks ($r = -0.223$, $p = 0.032$). The magnitude of this association was pronounced particularly in GDM group ($r = -0.447$, $p = 0.033$), and not significant in non-GDM group ($r = -0.147$, $p = 0.227$).

Conclusion: Maternal serum 25(OH)D level in mid-gestation was inversely associated with fetal adiposity in late gestation. Maternal 25(OH)D could be an early biomarker of fetal adiposity especially in the diabetic pregnancies.

250 | Optimal Interpregnancy Interval after Periviable Birth

Kelli M. McFarling[1]; Sarayu Parise[2]; Brittany Austin[2]; Rebecca Crowe[2]; Matthew M. Finneran[2]
[1]Medical University of South Carolina, Columbia, SC; [2]Medical University of South Carolina, Charleston, SC

10:30 AM - 12:30 PM

Objective: ACOG and SMFM recommend advising patients to avoid interpregnancy intervals of less than six months and to counsel regarding the risk and benefits of interpregnancy intervals of less than 18 months. The WHO specifies that after live births an interpregnancy interval of at least 24 months is recommended while after miscarriage an interpregnancy interval of at least 6 months is recommended. However, no guidelines specifically target patients who deliver periviable neonates, many of which do not survive. Our objective was to evaluate the impact of the interpregnancy interval on birth outcomes in women with a prior periviable birth.

Study Design: We performed a retrospective cohort study of women with a history of periviable birth (22w0d to 24w6d) from 2001-2020 with a subsequent singleton pregnancy with available outcome data. The primary outcome was gestational age at delivery while secondary outcomes included percent of miscarriage and mode of delivery. Categorical data was evaluated with Chi-square analysis and continuous data was analyzed with Kruskal-Wallis tests.

Results: 148 patients were included; 34 with an interpregnancy interval of < 6 months, 35 with an interpregnancy interval of 6-18 months and 79 with an interpregnancy interval of >18 months. Most patients were black, multiparous and delivered their index pregnancy due to preterm labor, preterm premature rupture or membranes or cervical insufficiency. Demographics were similar between groups. There were no significant differences in the primary outcome with the median gestational age at delivery for each groups at 37.1 weeks ($p = 0.898$). In addition, the risk of miscarriage (20.6%, 25.7% and 27.7%, $p = 0.776$) and mode of delivery (57.7%, 62.5% and 48.2%, $p = 0.453$) were similar between groups.

Conclusion: Our study does not indicate a higher risk of preterm birth or miscarriage in patients with short interpregnancy intervals after periviable birth.

251 | Closing the gap: Postpartum Transition of Treatment for Chronic Hypertension in the United States, 2008-2022

Kelly F. Darmawan[1]; Elizabeth B. Sherwin[2]; Brian T. Bateman[3]; Danielle M. Panelli[2]; Sara Siadat[1]; Stephanie A. Leonard[2]
[1]Stanford University, Stanford University, CA; [2]Stanford University, Palo Alto, CA; [3]Stanford University, Stanford, CA

10:30 AM - 12:30 PM

Objective: Medication treatment of chronic hypertension (cHTN) is effective for blood pressure control during and after pregnancy, which is imperative to reduce the risk of adverse outcomes. However, postpartum challenges, including switching to first-line antihypertensive medications that are recommended outside of pregnancy and transitions in primary care providers, may affect the use of antihypertensive medications during this time. We examined patterns of postpartum antihypertensive medication use among people with cHTN requiring medication.

Study Design: We used the Merative™ MarketScan Database of people in the U.S. with private insurance who gave birth between 2008-2022. The study included people with livebirths complicated by cHTN in pregnancy requiring labetalol, nifedipine, or methyldopa for treatment during the first 20 weeks of gestation. We analyzed prescription fills of all antihypertensive medications from 0-6 months postpartum, and examined differences in medication use by comorbidities and in each month postpartum.

Results: Among 20,168 people with cHTN requiring treatment during pregnancy, 83% received an antihypertensive medication in the first 6 months postpartum and 17% did not (Table 1). Labetalol was the most common medication used (47%), with < 10% use of antihypertensive medications other than nifedipine (23%) or methyldopa (17%). Use of lisinopril was higher in people with diabetes (14%), chronic renal disease (14%), class 3 obesity (11%), or lupus (13%) compared with the overall cohort (9.2%). Use of any medication was 60% in the first month postpartum, then decreased to 41% by six months postpartum (Figure 1).

Conclusion: In this national, contemporary cohort, 17% of people with cHTN who required treatment early in pregnancy did not receive an antihypertensive medication in the first 6 months postpartum. Use of any medication fell to less than 50% by 2 months postpartum. These findings show the need to improve adherence and transition to appropriate antihypertensive medications postpartum.

Table 1: Postpartum antihypertensive medication prescription fills, from delivery through six months postpartum, among people with chronic hypertension requiring treatment with labetalol, nifedipine, or methyldopa during the first 20 weeks of pregnancy.

252 | 6-Month Mental Health Outcomes Among Participants in a Postpartum Care in the NICU (PeliCaN) Trial

Kelly Zafman[1]; Niesha Darden[2]; Laura Walker[2]; Maggie Power[3]; Rachel Ledyard[2]; Sara Kornfield[3]; Sheila Shanmugan[3]; Heather Burris[2]
[1]Hospital of the University of Pennsylvania, Philadelphia, PA; [2]Children's Hospital of Philadelphia, Philadelphia, PA; [3]University of Pennsylvania, Philadelphia, PA

10:30 AM - 12:30 PM

Objective: To compare mental health outcomes among individuals randomized to a co-located postpartum care delivery model in the Neonatal Intensive Care Unit (NICU) (PeliCaN) to controls randomized to usual postpartum care.

Study Design: This was a secondary analysis of the PeliCaN trial in which postpartum parents of preterm infants < 34 weeks gestation admitted to the NICU with an expected length of stay >1 week were included. Doulas provided comprehensive informational and emotional support tailored to the unique needs of NICU parents and facilitated the coordination of a midwifery postpartum visit within the NICU. Mental health outcomes were assessed including Edinburgh Postnatal Depression Scale (EPDS) scores at enrollment and at 6 months postpartum and post-traumatic stress disorder (PTSD) Checklist for DSM-5 (PCL-5), an assessment of PTSD symptoms, at 6 months postpartum.

Results: 34/37 of the participants in the parent trial completed mental health screening and were included in this analysis. Participants in the intervention arm had lower mean EPDS scores (4.82 vs. 5.82, p = 0.56) and PCL-5 scores (18.7 vs. 22.2, p = 0.40) at 6 months postpartum compared to usual care though this did not reach significance. No participants in either group indicated thoughts of self-harm on question 10 of the EPDS at baseline or 6 months postpartum. However, two patients in the intervention arm experienced neonatal deaths and reported acute suicidality to the supporting doulas outside of screening. Both patients were connected to appropriate emergency psychiatric care.

Conclusion: While no significant differences in mental health screening scores were detected between intervention and control participants of the PeliCaN trial, doulas were able to successfully identify and intervene on acute suicidal symptoms of two patients. This underscores the value of the doula-led postpartum care model for vulnerable NICU parents, highlighted by the trusting relationships developed and the willingness of parents to seek assistance when facing mental health emergencies.

253 | Is Low Maternal Bp Associated with SGA in Those Treated for Chronic Hypertension in Pregnancy?

Kim Boggess[1]; Justin Leach[2]; On behalf of The CHAP Study Consortium
[1]*University of North Carolina at Chapel HIll, Chapel Hill, NC;*
[2]*University of Alabama at Birmingham, Birmingham, AL*

10:30 AM - 12:30 PM

Objective: In pregnant patients with mild chronic hypertension (CHTN), maintaining blood pressure (BP) < 140/90 optimizes perinatal outcome. However, treatment that leads to maternal hypotension could lead to placental hypoperfusion and subsequent poor fetal growth. Our objective was to estimate the association between maternal hypotension ('low BP') and a small for gestational age infant (SGA) infant in patients treated for mild CHTN in pregnancy.

Study Design: This is a secondary analysis of the Chronic Hypertension and Pregnancy (CHAP) Study, which randomized pregnant patients with mild CHTN to treatment to achieve BP < 140/90 versus < 160/105. For each participant we calculated mean BP between 28-34 weeks and excluded those with mean BP >140/90. We defined 'low BP' as either average BP < 110/70 or mean arterial pressure (MAP) < 80 and compared participants with low BP to those with average SBP 110-139 and/or DBP 71-89 or MAP > 80. Our primary outcome was SGA (birthweight < 5th percentile). Logistic regression was used to estimate association between low BP and SGA.

Results: Of 2408 CHAP participants, 1205 (50%) met analysis criteria [most common exclusions: 301 for mean BP > 140/90; 125 for missing birthweight]. Of 1205, 31 (2.6%) had mean BP < 110/70, and 33 (2.7%) had MAP < 80. SGA occurred in 62 (5.1%). Low BP by either mean BP or mean MAP was not associated with an SGA infant (Table). We found a nonlinear relationship between MAP as a continuous variable and probability of SGA. As shown in the Figure, lower MAP was associated with lower probability of an SGA infant (p = 0.02). As MAP increased from 80 to 97.5 the probability of SGA increased and then plateaued.

Conclusion: Less than 3% of patients treated for mild CHTN in pregnancy achieve average BP < 110/70 or MAP < 80, and those with low BP did not have increase in odds of an SGA infant. Patients can be reassured that pharmacologic treatment

of hypertension infrequently results in BP < 110/70 or MAP < 80 and low BP does not appear to increase risk for SGA.

Table. Association between low BP and SGA in CHAP participants with mean BP < 140/90 at 28-34 weeks (N=1205)

	N (%)	SGA <5th percentile, N(%)	OR (95% CI)	*Adjusted OR (95% CI)
Mean BP <110/70	31 (2.6)	1 (3.2)	0.61 (0.08-4.53)	0.46 (0.06-3.58)
Mean BP ≥ 110/70 and <140/90	1174 (97.4)	61 (5.2)	Referent group	
Mean MAP <80	33 (2.7)	1 (3.0)	0.57 (0.08-4.24)	0.53 (0.07-4.01)
Mean MAP ≥ 80	1172 (97.3)	61 (5.2)	Referent group

254 | A Model to Predict Latency in Preterm Prelabor Rupture of Membranes (PPROM)

Kira Anne Bromwich[1]; Kelly Zafman[2]; Markolline Forkpa[3]; Jesse Chittams[4]; Miatta Goba[1]; Nadav Schwartz[5]; Rebecca F. Hamm[1]
[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Hospital of the University of Pennsylvania, Philadelphia, PA; [3]Pennsylvania Medicine Women's Health Clinical Research Center, Philadelphia, PA; [4]University of Pennsylvania School of Nursing, Philadelphia, PA; [5]University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA

10:30 AM - 12:30 PM

Objective: We sought to develop a model to predict length of latency in patients with PPROM.

Study Design: This was a retrospective cohort study of singleton gestations presenting with PPROM between 24w0d-32w6d from 2017-2022 at two large academic centers. Patients presenting with active labor, clinical chorioamnionitis, contraindications to expectant management, or known fetal anomalies were excluded. Primary outcomes were latency ≥2 days and ≥7 days. We collected data on maternal and obstetric history, prenatal course, and symptoms, labs, vitals, and fetal data at presentation via individual chart review. Multivariable logistic regression was used to produce prediction models.

Results: Of 304 patients who presented with PPROM between 24w0d and 32w6d, 192 (63.1%) met inclusion criteria, with most exclusions due to active labor or fetal anomalies. Gestational age (GA; p = 0.02), presence of contractions (p = 0.02), and cervical dilation (p = 0.03) were significantly associated with latency ≥2 days. (Table 1.) After adjusting for confounders, patients presenting with contractions had 62% lower odds of a ≥2 day latency. Each additional centimeter of dilation and week of gestation reduced the odds of ≥2 day latency by 27% and 17%, respectively. Together, these variables achieved moderate prediction of the outcome (AUC: 0.72. Figure 1). Examples of variables not determined to be significant in the model included parity, obstetric history, maternal vitals and basic lab markers, and fetal heart rate patterns. For latency ≥7 days, only GA (p = 0.01) and cervical dilation (p = 0.01) were found to be significant, yielding an adjusted model with an AUC of 0.68.

Conclusion: In patients presenting with PPROM, it is possible to generate a predictive model for odds of latency ≥2 days. This can be used to individualize counseling and help set patient expectations, as well as to assist in guiding resource utilization and necessity or timing of hospital transfer.

Table 1: Multivariable regression odds estimates for latency > 2 days

	Latency > 2 days		Latency > 7 days	
Characteristic	Adjusted OR (95% CI)	P value	Adjusted OR (95% CI)	P value
Gestational age (weeks)	0.832 (0.715-0.968)	0.017	0.676 (0.506-0.904)	0.008
Dilation on presentation (cm)	0.727 (0.542-0.976)	0.03	0.859 (0.761-0.969)	0.131
Presence of contractions	0.381 (0.170-0.857)	0.02	N/A	N/A
AUC	0.716 +/- CI		0.679 +/- CI

255 | Neonatal Outcomes of Patients in Cases of Gestational Hypertension with Proteinuria

Kristen Warncke; Alesha M. White; Donald D. McIntire; C. Edward Wells
University of Texas Southwestern Medical Center, Dallas, TX

10:30 AM - 12:30 PM

Objective: Hypertensive disorders of pregnancy are associated with increased rates of adverse neonatal outcomes. The severity of these outcomes is greatest in patients with pre-eclampsia with severe features (SPE). Proteinuria was once considered a diagnostic criterium for SPE, however as of the 2013 ACOG Task Force of Hypertension In Pregnancy, it is no longer considered a diagnostic marker. The objective of this study was to evaluate the effects of maternal proteinuria in the presence of gestational hypertension (gHTN) on subsequent neonatal outcomes.

Study Design: This was a retrospective cohort study to evaluate neonatal outcomes of infants delivered to mothers with gHTN,

gHTN with proteinuria and SPE who delivered after 37 weeks gestation at a large public hospital between 2013 to 2022. Proteinuria was determined based on catheterized urine samples and defined as 2+ or greater. Patients with chronic hypertension were excluded. A multivariable logistic regression model was used to analyze rates of 5-minute Apgar < 3, pH < 7, birthweight less than the 3rd percentile, and neonatal intensive care unit (NICU) admission after adjusting for race, age, parity and body mass index.

Results: Of 94,115 live born infants 7,595 (8.1%) were delivered to mothers diagnosed with gHTN, 1,831 (1.9%) to mothers with gHTN with proteinuria, and 3,444 (3.7%) to mothers diagnosed with SPE. Infants from mothers with gHTN, when compared to gHTN with proteinuria, were significantly less likely to have birthweights less than the 3rd percentile (OR 0.53 95% CI 0.42,0.66) and less likely to be admitted to the NICU (OR 0.61, 95% CI 0.51,0.73). There were no significant differences between infants born to mothers with gHTN with proteinuria when compared to infants born to mothers with SPE (Table).

Conclusion: Although no longer considered a diagnostic criterium for SPE, maternal proteinuria in the setting gHTN is associated with significant adverse outcomes of neonatal growth restriction and NICU admission. The finding of proteinuria remains an important diagnostic marker when evaluating hypertensive disorders in pregnancy.

Table 1: Neonatal outcomes among infants born to mothers with hypertensive disorders of pregnancy

	GHTN N = 7,595	GHTN with proteinuria N = 1,831	Pre-eclampsia with severe features N = 3, 444	OR (95% CI)*	OR (95% CI)^

256 | Uptake of Prenatal Diagnostic Testing Before and After Implementation of Non-Invasive Prenatal Screening

Kristen Warncke[1]; Gayathri D. Vadlamudi[2]; Jessica E. Pruszynski[3]; Patricia Santiago-Munoz[2]; Elaine L. Duryea[1]
[1]University of Texas Southwestern Medical Center, Dallas, TX; [2]UT Southwestern Medical Center, Dallas, TX; [3]University of Texas Southwestern, Dallas, TX

10:30 AM - 12:30 PM

Objective: To compare the rate of invasive diagnostic testing before and after implementation of non-invasive prenatal screening (NIPS).

Study Design: We conducted a retrospective observational study 12 months before and after implementation of NIPS at a large county hospital. Prior to the availability of NIPS, all patients between 15-22 weeks were offered serum screening through the quadruple screen. Starting August 2023, this was replaced by universal implementation of NIPS for patients ≥ 10 weeks gestation using a non-sequencing based rolling circle replication on-site assay (Vanadis system, PerkinElmer, Waltham, MA, USA). In both groups, individuals with abnormal screening results were offered invasive diagnostic testing. Diagnostic testing rates following abnormal screening and other indications including fetal anomalies or targeted gene analysis were compared using Chi-square.

Results: From August 2022 to August 2023, of 13,533 patients receiving prenatal care, 7,149 patients underwent quadruple screening. In this group, 466 screened positive for trisomy 18 or trisomy 21, and 26 (5.6%) of these patients elected invasive diagnostic testing. Of the patients who elected diagnostic testing following an abnormal quad screen, aneuploidy was confirmed in 6 (23.1%). From August 2023 through July 2024, 11,631 (82.3%) of 14,127 patients receiving prenatal care underwent NIPS. In this group, 106 screened positive for either trisomy 13, 18, or 21. Diagnostic testing was elected by 22 (20.8%) of these patients, and aneuploidy confirmed in 10 (45.5%). The rate of invasive diagnostic procedures performed for any indication in the overall population did not change between the time epochs (116/13,533 vs 100/14,127, p = 0.16).

Conclusion: The rate of invasive diagnostic testing remained unchanged following the implementation of NIPS. However, following an abnormal screening result, the rate at which patients opted for invasive diagnostic testing increased fourfold, while the rate of diagnostic confirmation of aneuploidy through invasive testing rose twofold compared to the use of the serum screen.

Table 1: Uptake of diagnostic testing before and after implementation of non-invasive prenatal screening

	Screen positive	Diagnostic testing following abnormal screening	Aneuploidy confirmed on diagnostic testing	Diagnostic testing for any indications
Quad screen	466/7149 (6.5)	26/466 (5.6)	6/26 (23.1)	116/13533 (0.9)
NIPS	106/11631 (0.9)	22/106 (20.8)	10/22 (45.5)	100/14127 (0.7)
OR (95% CI)		4.43 (2.40-8.19)	2.78 (0.80-9.60)	0.82 (0.63-1.08)
P-value		< 0.001	0.106	0.159

Data reported as n (%). NIPS, non-invasive prenatal screening.

257 | Perfluorochemicals Paradoxically Exert Immunosuppressive Effects in Fetal Membranes: Implications for Preterm Premature Rupture of Membranes

Emilie M. Stylli[1]; Kristin M. Klohonatz[1]; Briana Ferguson[1]; Rita Leite[1]; Rachel Ledyard[2]; Heather Burris[2]; Lauren Anton[1]; Kristin D. Gerson[1]
[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Children's Hospital of Philadelphia, Philadelphia, PA

10:30 AM - 12:30 PM

Objective: Perfluorochemicals (PFCs) are ubiquitous xenobiotics used in the manufacturing of common household products. These "forever chemicals" persist in human tissues for many years and can exert immunomodulatory effects. Select PFCs have been implicated in adverse pregnancy outcomes, with higher concentrations detected in amniotic fluid and cord blood in spontaneous preterm birth. We leveraged a human pregnancy cohort and *in vitro* methodology to test the hypothesis that PFCs induce inflammation in fetal membranes, thus compromising membrane integrity and risk of preterm premature rupture of membranes (PPROM).

Study Design: Relative PFC abundance was assessed by untargeted metabolomics in amnion and chorion from cases of PPROM

(n = 25) and term controls (n = 25) in a prospective pregnancy cohort. Data were log_2 transformed and analyzed by two-way ANOVA ($p < 0.05$) with calculation of false discovery rates ($q < 0.1$). For *in vitro* experiments, amnion epithelial cells (AECs) were treated with PFCs (PFOS, PFOA, PFNA, or PFHxS) for 24h with doses based on physiologic concentrations. Proinflammatory cytokine IL-8 was measured in cell culture media (n = 3/condition) by ELISA. One-way ANOVAs with correction for multiple comparisons were performed.

Results: Demographic characteristics were similar between groups (Fig. 1). Amnion and chorion from PPROM had higher abundance of PFOS versus term though the difference did not persist after correction for multiple comparisons (Fig. 1). A similar trend was seen for PFOA. Unexpectedly, PFOS, PFOA, PFNA, and PFHxS all decreased basal levels of IL-8 in AECs in a dose-dependent manner (Fig. 2, $p < 0.05$).

Conclusion: PFC accumulation in fetal membranes, an understudied reproductive tissue, may drive immune perturbations underlying PPROM. Contrary to our hypothesis, these xenobiotics exert an immunosuppressive effect in the amnion, potentially rendering fetal membranes more susceptible to other sources of physiologic stress, including microbial challenge. Mechanisms by which PFCs drive reproductive outcomes, including preterm birth, warrant future investigation. Harrison Award (KG, LA)

258 | Common Vaginal Microbes Modify Energy Metabolism and Oxidative Balance: Potential Implications on Reproductive Health

Gregory W. Kirschen[1]; Olha Kholod[2]; Briana Ferguson[1]; Britt A. Goods[2]; Lauren Anton[1]; Kristin D. Gerson[1]

[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Dartmouth College, Hanover, NH

10:30 AM - 12:30 PM

Objective: Host-microbial interactions in the cervicovaginal space modify reproductive outcomes. While *Lactobacillus crispatus* (LC) supports vaginal health, anaerobes like *Gardnerella vaginalis* (GV) have been implicated in pathologic processes, such as preterm birth. Our study leveraged global metabolomics as a biochemical window into these complexities.

Study Design: We used an *in vitro* host cell-microbial coculture model. Vaginal, ectocervical, and endocervical epithelial cells, and THP-1-derived macrophages (MØs) were treated with 10^5-10^7 CFUs of LC or GV for 24h. We conducted untargeted metabolomics on cell culture media (n = 3/condition). Log_2 transformed batch-normalized data were analyzed by two-way ANOVA ($p < 0.05$) with calculation of false discovery rates ($q < 0.1$). Primary component analysis was performed with total variance as a sum of variances of predicted values of each component.

Results: Experimental groups clustered by treatment for epithelial cells, while MØs grouped separately (Fig. 1). Compared to non-treated control, both LC and GV increased numerous metabolites across pathways; fewer metabolites were decreased

by microbial exposure (data not shown). While both LC and GV increased branched chain amino acid metabolites, GV exerted a more robust effect, suggesting increased GV-utilization of nitrogen energy sources. LC increased lactate derivatives, reflecting rapid glucose utilization. GV increased polyamine, phospholipid, and oxidative stress metabolites, potentially signifying cell membrane breakdown or turnover. Top differentially detected metabolites, all increased by microbial exposure, are presented in Table 1.

Conclusion: Our data reveal differences in energy metabolism and oxidative balance in response to common vaginal microbes. As metabolites may serve as chemical messengers, our findings provide a biochemical lens through which the complexities of host-microbial communication may be more clearly discerned. Modification of this metabolic milieu carries translational potential to mitigate risk of adverse reproductive outcomes. University of Pennsylvania Research Foundation Award (KG)

259 | Fetal Growth Trajectories in Pregnancies Complicated by Type 2 Diabetes

Kundai Crites[1]; Armando Pena[2]; Joanna Izewski[1]; Erin M. Cleary[1]; Christina M. Scifres[1]
[1]*Indiana University School of Medicine, Indianapolis, IN;*
[2]*Indiana University School of Public Health, Bloomington, IN*

10:30 AM - 12:30 PM

Objective: We evaluated factors associated with small for gestational age (SGA) and large for gestational age (LGA) birth weight and ultrasound growth trajectories to better understand fetal growth among pregnancies with type 2 diabetes (T2DM).

Study Design: We conducted a retrospective cohort study of individuals with T2DM and a singleton gestation between 2018-2020 who had biometry measured between 16-23 weeks gestation. Maternal demographics, clinical factors, and serial ultrasound measurements were abstracted from the electronic health record. Birth weight was classified as small for gestational age (SGA), large for gestational age (LGA), and appropriate for gestational age (AGA) using a US birth weight standard. Multinomial logistic regression was used to assess the relationship between maternal characteristics and newborn birth weight category. Covariance pattern models with linear and quadratic terms were used to assess differences in fetal growth trajectories.

Results: LGA birth weight occurred in 81/300 (27%) and SGA birth weight in 25/300 (8.3%). After adjustment for covariates, a higher BMI at the first prenatal visit (aOR 0.91, 95% CI 0.83-0.99) and higher maternal weight gain across gestation (aOR 0.88, 95% CI 0.79-0.98) were associated with reduced risk for SGA birth weight, and a higher HbA1c after 20 weeks' gestation was associated with increased risk for LGA birth weight (aOR 1.41, 95% CI 1.06-1.87). In the mid-trimester, the EFW was higher in LGA birth weight infants compared to those born AGA, but there were no differences between those born AGA and SGA. EFW trajectories differed significantly over time by birth weight categories (Figure 1). Similar patterns were seen for the abdominal circumference, with no differences in head circumference and femur length either at baseline or over time.

Conclusion: Patterns of fetal overgrowth in pregnancies complicated by T2DM are established in early pregnancy. Further studies are needed to assess whether interventions to improve maternal glycemia in the second half of pregnancy can reduce the risk for LGA birth weight.

260 | Subclinical Hypothyroidism in Pregnancy: Assessment of Severe Maternal Morbidity

Laurel S. Aberle[1]; Katherine Bayard[1]; Jennifer Yao[2]; Shinya Matsuzaki[3]; Rachel S. Mandelbaum[4]; Joseph G. Ouzounian[4]; Koji Matsuo[4]
[1]LAGMC + USC OBGYN, Los Angeles, CA; [2]Keck School of Medicine, University of Southern California, Los Angeles, CA; [3]Osaka University Graduate School of Medicine, Osaka, Osaka; [4]University of Southern California/Los Angeles General Medical Center, Los Angeles, CA

10:30 AM - 12:30 PM

Objective: To assess the association between subclinical hypothyroidism and severe maternal morbidity at delivery.
Study Design: This cross-sectional study queried the Healthcare Cost and Utilization Project's National Inpatient Sample. The study population included 21,517,317 delivery hospitalizations from 2016-2021. Subclinical hypothyroidism was identified with the World Health Organization's International Classification of Disease 10th revision code of E02. Severe maternal morbidity followed the Centers for Disease Control and Prevention definition (20 indicators). Multivariable log-Poisson generalized linear model was created to examine the association of subclinical hypothyroidism and severe maternal morbidity.
Results: A total of 11,885 patients had a diagnosis of subclinical hypothyroidism, corresponding to 5.5 per 10,000 or one in 1,810 deliveries. Older maternal age, White / Asian race, hypertensive disorder (pregestational, gestational, and pre-eclampsia), diabetes mellitus (pregestational and gestational), obesity, asthma, fetal growth restriction, and early preterm delivery (< 34 weeks) were associated with subclinical hypothyroidism in multivariable analysis. After controlling for clinico-obstetric factors, subclinical hypothyroidism was independently associated with an increased risk of severe maternal morbidity at delivery (185.1 vs 81.1 per 10,000, adjusted-odds ratio [aOR] 1.48, 95% confidence interval [CI] 1.33-1.64). Among the individual indicators, the risk of eclampsia (25.2 vs 7.8, aOR 3.18, 95%CI 2.22-4.55), pulmonary edema (25.2 vs 7.0, aOR 2.34, 95%CI 1.63-3.34), and acute respiratory distress syndrome (29.4 vs 12.3, aOR 2.08, 95%CI 1.49-2.90) were particularly increased among patients with subclinical hypothyroidism (all, aOR >2.00).
Conclusion: The results of this contemporaneous nationwide assessment suggest that subclinical hypothyroidism may be associated with an increased risk of severe maternal morbidity at delivery. Whether or not universal thyroid testing in early pregnancy and treatment improve outcome in at risk-populations warrants further evaluation prospectively.

261 | Participation in a Remote Blood Pressure Monitoring Program and Engagement in Postpartum Care

Lauren Walheim[1]; Lisbet S. Lundsberg[1]; Jennifer F. Culhane[1]; Nicole Spaulding[2]; Christine Coffey[2]; Elizabeth Forbes[2]; Caitlin Partridge[1]; Katherine Campbell[1]; Anna Denoble[1]
[1]Yale School of Medicine, New Haven, CT; [2]Yale New Haven Hospital, New Haven, CT

10:30 AM - 12:30 PM

Objective: Remote postpartum (PP) blood pressure (BP) monitoring programs may improve postpartum visit (PPV) attendance for patients with hypertensive disorders of pregnancy (HDP). This study aims to compare patient characteristics and overall PP care utilization between patients who do and do not engage in a telehealth-based PP remote BP monitoring program.
Study Design: This was a retrospective study of participants in our institutional PP remote BP monitoring program from 11/1/2022-10/31/2023. Eligibility criteria included a diagnosis of chronic hypertension (HTN) or HDP. Patients were given a BP cuff, instructed on home BP monitoring, and scheduled for a telehealth visit within 1 week of discharge. Patients graduated when BP normalized off therapy or at 12 weeks PP. Participants were divided into 3 groups based on participation: 1) declined

or enrolled but never attended; 2) attended ≥1 visit but did not graduate; 3) graduated. Patient characteristics and PP care were extracted from the electronic health record. Primary outcomes were attendance at a PPV and a visit for HTN management within 6 weeks PP. Groups were compared using chi-square or Fisher exact tests for categorical and ANOVA for continuous variables. Logistic regression was used to determine the odds of the primary outcomes.

Results: 772 patients were approached for enrollment, of which 348 (45.1%) were in group 1, 126 (16.3%) in group 2, and 298 (38.6%) in group 3. Patients were similar between groups with two exceptions: the proportion of non-English language (6.9% v 7.9% v 14.1%, p = 0.007) and the proportion of HDP diagnosis (70.4% v 77.8% v 83.9, p = 0.0003). Odds of attending a PPV were greater in patients that initiated the program than those that did not (Group 2 adjusted odds ratio [aOR] 2.11; 95% CI 1.12-3.97, Group 3 aOR 1.67, 95% CI 1.02-2.72) as were the odds of attending a visit for HTN (Group 2 aOR 1.56, 95% CI 1.02-2.40, Group 3 aOR 1.82, 95% CI 1.26-2.63).

Conclusion: Participation in a remote BP monitoring program appears to improve rates of postpartum visit attendance and health care utilization up to 6 weeks postpartum.

10:30 AM - 12:30 PM

Objective: There is a paucity of evidence on the characteristics and significance of fetal heart rate tracings (FHRT) in the very preterm (22.0-31.6 weeks) period. We sought to address this and the associated neonatal outcomes.

Study Design: A retrospective review of all deliveries from January to December 2023 at a tertiary referral hospital. Criteria for inclusion were non-anomalous singleton deliveries at 22.0-31.6 weeks, where at least 10 minutes of FHRT was available, and neonatal resuscitation was initiated. A physician—blinded to all outcomes—reviewed the FHRT (0-120 min proximal to delivery, at 20 min epochs), and outcome data was obtained from chart review. The primary outcome was long term neonatal morbidity or mortality (LTNMM); the secondary outcomes were 5-min Apgar score of 4-6 and short-term neonatal morbidity or mortality (STNMM). Descriptive statistics with 95% confidence intervals (CI) were calculated with non-overlapping CI as significant.

Results: Among the 6,521 deliveries, 169 (2%) occurred at 22.0-31.6 weeks, of which 99 (58%) met the inclusion criteria. Intrapartum magnesium sulfate was administered in 97% of deliveries and antenatal corticosteroids in 98%. Moderate variability preceded delivery in 37.9% (95% CI 28.2-48.7%) of those with LTNMM; in 14.9% (95% CI 8.8-24.2%) of those with a 5-min Apgar score of 4-6; in 42.6% (95% 32.5 to 53.2%) of those with STNMM. Individuals with all types of decelerations–variable, late, and prolonged–had overlapping CI for all outcomes (Table 1). There were no cases of bradycardia or sinusoidal rhythm. Of the 38 newborns who met criteria for LTNMM, 20 (52.6%) also experienced STNMM while only 8 (21.1%) had Apgar of 4-6 at 5 min (Fig 1).

Conclusion: Among newborns delivered at 22.0-31.6 weeks, the likelihood of Apgar score 4-6 at 5 minutes and short- or long-term morbidity or mortality were similar irrespective of presence of moderate variability or decelerations. If confirmed, the reliance on moderate variability as a reassuring aspect to identify neonatal well-being at 22.0 to 31.6 weeks should be revisited.

10:30 AM - 12:30 PM

Objective: Current recommendations from professional organizations for ordering and obtaining consent for peripartum toxicology testing remain broad and best practices for both are lacking. We aimed to describe peripartum toxicology testing practices across birthing hospitals in the United States (US).

Study Design: A cross-sectional online survey was distributed through perinatal quality collaboratives, publicly available birthing hospital contacts, and professional organization electronic mailing lists. The survey captured birthing hospital characteristics and toxicology testing practices for both birthing people and neonates, including indication(s) for testing and consent practices. One response per hospital was included in the final analysis. Descriptive statistics were used to analyze responses.

Results: Respondents from 219 birthing hospitals across 42 states were included. 81.7% of hospitals reported risk-based testing, whereas 11.4% reported universal testing. Among hospitals employing a risk-based approach, the most common indications for ordering birthing person toxicology testing at delivery included: 1) disclosure of substance use in current pregnancy (96.6%), 2) positive toxicology test in current pregnancy (91.6%), 3) birthing person with signs of intoxication or withdrawal (89.4%), 4) neonate with signs of withdrawal (83.2%), and 5) late or limited prenatal care (80.4%). 69.4% and 28.3% of hospitals reported obtaining consent for birthing person and neonate toxicology testing, respectively; among hospitals who ordered testing without consent, 42.3% and 28.8% reported lack of disclosure for birthing person and neonate toxicology testing, respectively.

Conclusion: Our data reveal wide variations in toxicology testing and consent practices among US birthing hospitals. Given the unique and potentially harmful consequences of toxicology testing in this setting, clearer guidance from professional organizations is needed on clinically appropriate indications for testing and standardized approaches for obtaining consent.

Table 1. Survey Respondent and Hospital Characteristics

Question	n	%

264 | Administering Antibiotics to Women with Isolated Maternal Fever During Labor: a Decision-Tree Model

Michal Rosenberg-Friedman[1]; Omri Dominsky[2]; Daniel Gabbai[3]; Emmanuel Attali[3]; Moshe Leshno[4]; Yariv Yogev[5]; Lee Reicher[6]
[1]ichilov, ichilov, Tel Aviv; [2]Tel Aviv Sourasky Medical Center, Tel Aviv Sourasky Medical Center, HaMerkaz; [3]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel-Aviv, Tel Aviv; [4]Tel Aviv university, TAU, Tel Aviv; [5]Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv University, Tel Aviv Sourasky Medical Center, Tel Aviv; [6]Weizmann Instutute Of Science, Weizmann Institute of Science, HaMerkaz

10:30 AM - 12:30 PM

Objective: The ACOG recommends considering antibiotic treatment for women with isolated maternal fever during labor, when there are no other risk factors. However, there is limited information on the maternal and neonatal impacts of antibiotic treatment in this context of isolated maternal fever during labor. We used a decision-tree model to evaluate if antibiotic treatment for isolated maternal fever during labor yields better maternal and neonatal outcomes. Additionally, we conducted a cost-effectiveness analysis.

Study Design: A decision-tree model using the Expected Utility Theory (EUT) was employed to compare two strategies for managing isolated fever in women during labor:

1. Antibiotic Treatment: Administration of antibiotics.
2. No Treatment: Observation without antibiotics.

The Expected Utility Theory by Von Neumann and Morgenstern was used for theory of decision making under uncertainty (when the probabilities of the outcomes are known).

The assumptions used in the decision model, including the costs, probabilities, and utilities of various outcomes associated with the management of isolated maternal fever during labor were based on a study by Bank et al. (Bank TC et l. Am J Obstet Gynecol. 2022 Feb;226(2):255.e1-255.e7. (**Table 1**).

A one-way sensitivity analysis was conducted to explore the impact of variations in key variables. Outcome measures included expected utility (equivalent to QALYs) and cost effectiveness analysis.

Results:

1. The expected utility of the no-antibiotic strategy is 0.854, which is greater than the expected utility of the antibiotic strategy (0.797).
2. Among all the assumptions made in the model, the utility value assigned to the Neonatal Intensive Care Unit (NICU) has the most significant impact on the overall expected utility of the decision strategies (**Figure 1**).
3. The cost-effectiveness analysis shows that the no-antibiotic strategy is less costly and has better clinical outcomes.

Conclusion: The recommendation to administer antibiotics is questionable. Further clinical studies, including randomized clinical trials, should be conducted before drawing robust conclusions.

Table 1. Assumptions used in the decision model.

Name	Description	Value	Low	High
c_endometritis	cost of endometritis	4,000	0	3,956
c_NICU	cost of NICU	4,500	0	5,000
c_PPH	cost of PPH	3,500	0	3,500
p_Endometritis_antib	probability of Endometritis with antibiotics	0.0353	0.01	0.05
p_Endometritis_no_antib	probability of Endometritis without antibiotics	0.1131	0.08	0.13
p_NICU_antib	probability of NICU with antibiotics	0.4118	0.35	0.45
p_NICU_no_antib	probability of NICU without antibiotics	0.1788	0.15	0.2
p_PPH_antib	probability of PPH with antibiotics	0.0706	0.05	0.1
p_PPH_no_antib	probability of PPH without antibiotics	0.0657	0.05	0.1
u_endometritis	utility of endometritis	0.52	0	1
u_NICU	utility of NICU	0.6	0	1
u_PPH	utility of PPH	0.7	0	1

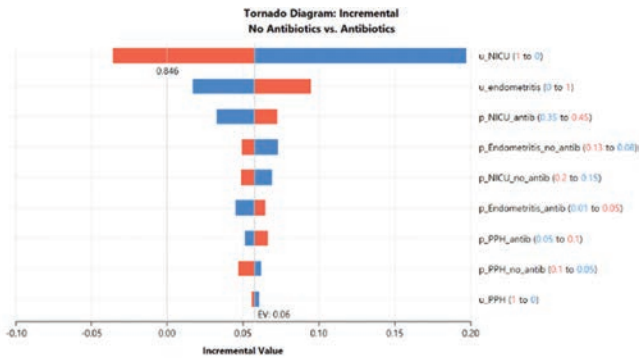

Figure 1. Tornado diagram of the utility analysis. A Tornado Diagram, which is used to display the results of a one-way sensitivity analysis, compares the incremental expected value of the "No Antibiotics" strategy versus the "Antibiotics" strategy for managing isolated maternal fever during labor. The utility of NICU (u_NICU) is the most critical assumption in determining the incremental expected value of the "No Antibiotics" strategy compared to the "Antibiotics" strategy. Changes in this parameter result in the largest variations in the model's outcome, highlighting its importance in the decision-making process.

265 | Cesarean Delivery in Life-Limiting Fetal Anomalies: All Risk and no Benefit?

Lena A. Shay; Madison Montgomery; Diana Crabtree; Anitra Beasley; April D. Adams
Baylor College of Medicine, Houston, TX

10:30 AM - 12:30 PM

Objective: Life-limiting anomalies (LLA) are a heterogeneous group of congenital malformations at high risk of poor outcomes. Pregnancy management options in LLA cases are limited in states with restrictive abortion laws, likely contributing to increased rates of infant and neonatal death. In these cases, conventional medical ethics call for maximization of maternal benefit. When pregnancy continues, avoidance of cesarean delivery (CD) is a harm-reduction strategy. Our objectives were to determine the CD rate, adverse pregnancy outcomes, and clinical drivers of CD in a cohort with LLA.

Study Design: Retrospective cohort study of pregnancies complicated by LLA from 2011-2023 (n = 131) (Table 1). Eligibility was determined by ultrasound findings or genetic testing. Spontaneous abortion, non-lethal anomaly, molar and ectopic pregnancy were excluded. Descriptive statistics were calculated, and Chi-square used for analysis.

Results: 37 cases underwent CD. CD rate did not differ from the institutional rate (28% vs. 29%, p = 0.86). Among CD cases, the average gestational age at delivery was 37.5 weeks (SD±2.6), with mean interval from diagnosis to delivery of 15.1 weeks (SD±5.2). Common indications for CD were fetal (46%) followed by elective repeat (30%) (Figure 1). 73% of patients received mode of delivery (MOD) counseling. 57% were offered palliative care, of which 62% accepted. Severe hypertension and postpartum hemorrhage rates did not differ from the institutional rate (16% vs. 21%, p = 0.52; 19% vs. 17%, p = 0.79). Fetal or neonatal death rate was 73%. All surviving children have significant medical comorbidities or developmental delays.

Conclusion: Cesarean delivery in pregnancy affected by LLA did not demonstrate increased morbidity related to hypertension or hemorrhage. Although CD rate was not higher, any maternal morbidity unbalanced by fetal benefit poses an ethical challenge. Fetal pathology, particularly cranial, played a significant role in MOD. This should be factored into candidacy for vaginal delivery and weighed against the surgical risks of CD. Further study of obstetric management of LLA is warranted.

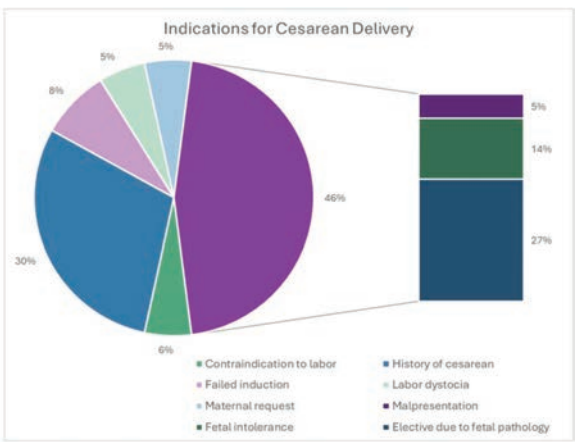

Figure 1. Indications for cesarean delivery performed in study cohort of life-limiting anomalies

Table 1. Types and distribution of life-limiting fetal anomalies within study cohort.

Anomaly Type	SVD (n =81)	CD (n =37)	Termination (n = 20)
CNS Anomaly (ex. Anencephaly, Hydrocephalus, Schizencephaly, HPE)	30	14	10
Cardiac Anomaly (ex. Ectopia Cordis, Heterotaxy, Rhabdomyoma)	2	4	0
Multiple Congenital Anomalies/Genetic Syndrome (ex. Limb-Body Wall, T18, T13)	40	14	6
Renal (ex. bilateral renal agenesis, bilateral MCDK)	4	3	1
Skeletal Dysplasia	2	2	1
Hydrops	3	0	2

266 | Modeling Stillbirth Using Machine-Learning

Lena A. Shay[1]; Michael D. Jochum, Jr.[2]; Jennifer R. McKinney[1]; April D. Adams[1]
[1]Baylor College of Medicine, Houston, TX; [2]Baylor College of Medicine and Texas Children's Hospital, Houston, TX

10:30 AM - 12:30 PM

Objective: Stillbirth, defined as fetal death at ≥20 weeks' gestation, complicates about 1 in 160 pregnancies. Methods to prevent stillbirth are lacking, in part, due to the inability to predict when stillbirth will occur. Machine learning (ML) offers an opportunity to develop sophisticated models to accurately predict stillbirth. Our objective was to develop a predictive model for stillbirth using contemporary data with patient-level detail not found in larger national datasets.

Study Design: A retrospective database of stillbirths was created from two tertiary care hospitals with delivery date-matched live births from 2016-2022. Data from stillbirths (n = 425) and livebirths (n = 440), were imported, preprocessed (centered, scaled, one-hot encoded) and split into training and testing sets (80-20 split), followed by training a Random Forest model using 10-fold cross-validation, repeated five times. Model evaluation was performed using confusion matrix metrics and variable importance scores were calculated.

Results: The model identified variables of interest and achieved an accuracy of 91% (sensitivity 91%, specificity 92%) using the testing data. Key variables of importance included the number of prenatal care visits, maternal age, gestational age at care entry, and the presence of fetal comorbidities, specifically structural anomalies (Figures 1 & 2).

Conclusion: Results provide additional support for using machine learning in stillbirth prediction with a contemporary cohort. The model revealed a strong association between fewer prenatal visits and stillbirth, irrespective of entry to care, suggesting that merely attending prenatal care may help reduce stillbirth risk. Continued refinement of this and other predictive models with additional clinical or biological data will enhance robustness. Ultimately, use of ML to generate a clinically useful risk calculator for stillbirth will allow for better identification of vulnerable patients and opportunities for prevention or intervention. As single-site data limits our model, future studies to validate this model against other stillbirth cohorts are planned.

267 | Management of Incidental Cardiac Disease Findings on Screening Maternal Echocardiograms for Advanced Maternal Age

Lilly Liu[1]; John Perino[2]; Anita Lasala[2]; Jason D. Wright[3]; Jennifer Haythe[2]; Sonia Tolani[2]; Mary E. D'Alton[4]; Stephanie Purisch[2]

[1]Columbia New York Presbyterian, NEW YORK, NY; [2]Columbia New York Presbyterian, New York, NY; [3]Columbia University Irving Medical Center, New York, NY; [4]Columbia University Medical Center, New York, NY

10:30 AM - 12:30 PM

Objective: The objective of this study is to investigate the utility of screening maternal echocardiograms for the diagnosis of incidental cardiac abnormalities in pregnancy in women of advanced maternal age.

Study Design: This is a retrospective study examining the diagnosis of incidental cardiac abnormalities and associated pregnancy outcomes in women over the age of 40 who received screening maternal echocardiograms for the sole indication of advanced maternal age at a single academic institution from 2020-2023. Clinical outcomes included significant incidental cardiac findings on echocardiogram, including decreased left ventricular ejection fraction (LVEF < 55%), moderate to severe valvular disease, diastolic dysfunction, abnormal left ventricular end diastolic diameter (LVEDD > 50mm), and elevated pulmonary artery systolic pressures (PASP > 30mmHg); as well as whether these findings necessitated referral to cardiology or initiation of cardiac medications, and whether they were associated with adverse cardiovascular outcomes.

Results: A total of 27 women met inclusion criteria during the study period. The LVEF was normal for all women in the study, which ranged from 55-70%. Incidental cardiac findings included mild valvular disease in 30% of cases (with no cases of moderate or severe valvular disease), left ventricular hypertrophy in 11% of cases, and elevated PASP >30mmHg in 27% of cases. None of these women experienced adverse cardiovascular outcomes such as postpartum cardiomyopathy, pulmonary edema, maternal ICU admission, or maternal or neonatal death as a result of these findings.

Conclusion: Screening maternal echocardiograms for the sole indication of advanced maternal age in women with no prior cardiovascular history did not result in significant cardiac findings that changed clinical management or affected maternal or neonatal outcomes. Thus, it may be more cost effective to use validated screening tools such as the California Cardiovascular Disease screening algorithm for pregnant and postpartum women to identify those at highest risk for cardiovascular complications in pregnancy.

Table 1: Cohort demographic and clinical characteristics for 27 women receiving screening echocardiograms in pregnancy for advanced maternal age (age ≥ 40)

Characteristic	Frequency

268 | Cost-Effectiveness of Early vs. Delayed Amniotomy Following Transcervical Balloon Ripening

Lily Ben-Avi[1]; Miranda O'Keefe[2]; Sarah K. Dzubay[3]; Amy Hermesch[1]; Aaron B. Caughey[3]
[1]Oregon Health & Sciences University, Portland, OR; [2]Oregon Health and Science University, Portland, OR; [3]Oregon Health & Science University, Portland, OR

10:30 AM - 12:30 PM

Objective: A recent randomized trial found a decrease in the time from balloon removal to the active phase of labor and delivery with an early amniotomy, as well as an increase in postpartum hemorrhage with delayed amniotomy among term pregnant patients undergoing labor induction. Our goal is to demonstrate the cost-effectiveness of early amniotomy (< 2 hours after balloon removal) compared to late (>4 hours after balloon removal) amniotomy.

Study Design: A decision-analytic model was constructed using TreeAge to compare outcomes in patients with induced pregnancies undergoing transcervical balloon ripening followed by early vs. late amniotomy. Our theoretical cohort included 583,231 pregnancies, an estimate of the annual term inductions in the United States. Our outcomes include postpartum hemorrhage, chorioamnionitis, hours saved in labor, costs, and quality-adjusted life years (QALYs). We used a willingness-to-pay for the incremental cost-effectiveness ratio of $100,000/QALY. Model inputs were derived from the literature, and QALYs were generated at a discount rate of 3%. Sensitivity analyses were performed to assess the robustness of our model.

Results: In the one-year theoretical cohort of 583,231 patients, early amniotomy was found to be the dominant strategy. Early amniotomy led to 63,530 fewer cases of chorioamnionitis and 18,971 fewer cases of postpartum hemorrhage. Additionally, in the early amniotomy group, approximately 2.1 million fewer hours were spent in labor, $255 million was saved, and there were 156 additional QALYs. Univariate sensitivity analysis demonstrated that an early amniotomy is cost-saving compared to a delayed amniotomy even if the cost of labor drops to zero (Figure 1).

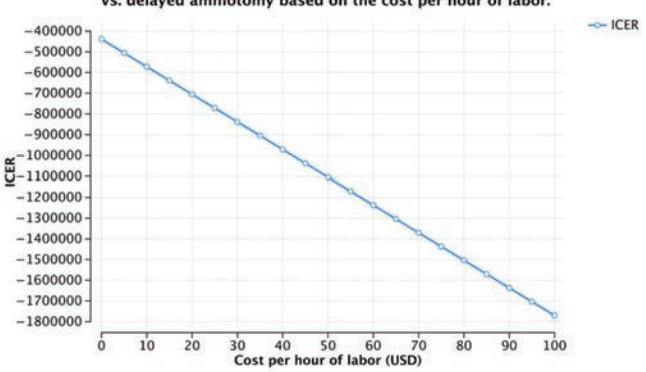
Conclusion: We found that the early amniotomy strategy resulted in savings of $255 million and 156 additional QALYs. Considering the significant decrease in morbidity and cost as well as the time savings associated with early amniotomy, the results of our model support early amniotomy following transcervical balloon ripening for the induction of term labor.

Table 1. Outcomes in a theoretical cohort of 583,231 pregnant patients.

	Early Amniotomy (<2 hours after balloon removal)	Delayed Amniotomy (>4 hours after balloon removal)	Difference (Early - Late)
Chorioamnionitis	54,692	118,222	-63,530
Postpartum hemorrhage	36,200	55,171	-18,971
Hours in labor	6,773,256	8,850,925	-2,077,668
Cost (in USD)	$688,237,646.85	$942,844,929.45	-$254,607,282.59
Effectiveness (QALYs)	15,748,793	15,748,637	156
Strategy	Dominant*	Dominated	

*In cost-effectiveness analysis, dominant strategies are those that are lower in cost and higher in effectiveness.

Figure 1. Univariate sensitivity analysis of the ICER for early amniotomy vs. delayed amniotomy based on the cost per hour of labor.



269 | Safety, Acceptability, and Effectiveness of Penicillin Allergy Testing in Pregnancy: A Systematic Review

Lindsay Reddeman[1]; Justin Lim[1]; Kellie Murphy[1]; David Fahmy[2]; Chris Walsh[3]; Kristin Harris[1]
[1]University of Toronto, Toronto, ON; [2]McMaster University, Hamilton, ON; [3]Mount Sinai Hospital Sidney Liswood Health Sciences Library, Toronto, ON

10:30 AM - 12:30 PM

Objective: An estimated 8-13% of pregnant patients report penicillin allergy (PA). Penicillins and other beta-lactams are widely used in pregnancy but often avoided in these patients, resulting in suboptimal therapy, antimicrobial resistance, higher costs, and increased morbidity and mortality for patients and neonates.

True penicillin allergy is rare and 95% of patients undergoing penicillin allergy evaluation (PAE) are delabelled. Although PAE is safe and recommended for pregnant patients, few are assessed. Recently, research concerning antenatal PAE has accelerated. We undertook a systematic review to summarize this growing body of evidence.

Study Design: A comprehensive search was conducted in collaboration with a medical information specialist, with no restriction on study language, date, or design. All peer-reviewed studies of pregnant people reporting unverified PA undergoing PAE with ≥5 participants were included. Title/abstract review, full text review, and data extraction were completed independently by 2 authors. Conflicts were resolved by a third author. Studies were evaluated using validated quality assessment tools.

Results: Seventeen studies (*N = 1720*) were eligible for inclusion. In total 1639 (95.3%) patients were delabelled through various approaches: direct oral challenge (12.8%), penicillin skin test (PST) and oral challenge (56.5%), PST and intravenous challenge (6.0%), PST alone (22.9%), and history review (1.8%). Acceptance of PAE among patients was 68.9%. Overall, 8 mild allergy-related adverse reactions and 5 mild delayed allergy-related adverse reactions occurred, requiring minimal intervention. There were 2 severe allergy-related adverse reactions which were managed with intramuscular epinephrine; no hospital transfers were required. No adverse antenatal events were recorded.

Conclusion: PAE in pregnancy is safe, acceptable, and effective, and the case for expanding access is strong. To our knowledge, this is the first systematic review to report on antenatal PAE acceptability and effectiveness; it builds on prior safety data drawn largely from low-quality and non-peer-reviewed evidence.

270 | Microbial Signatures in the Oral Cavity Associated with Pregnancy Loss

Ling liu[1]; Fang Wang[2]
[1]*Reproductive Medicine center, Second Hospital of Lanzhou University, Lanzhou, Gansu;* [2]*Lanzhou University Second Hospital, Lanzhou University Second Hospital, Gansu*

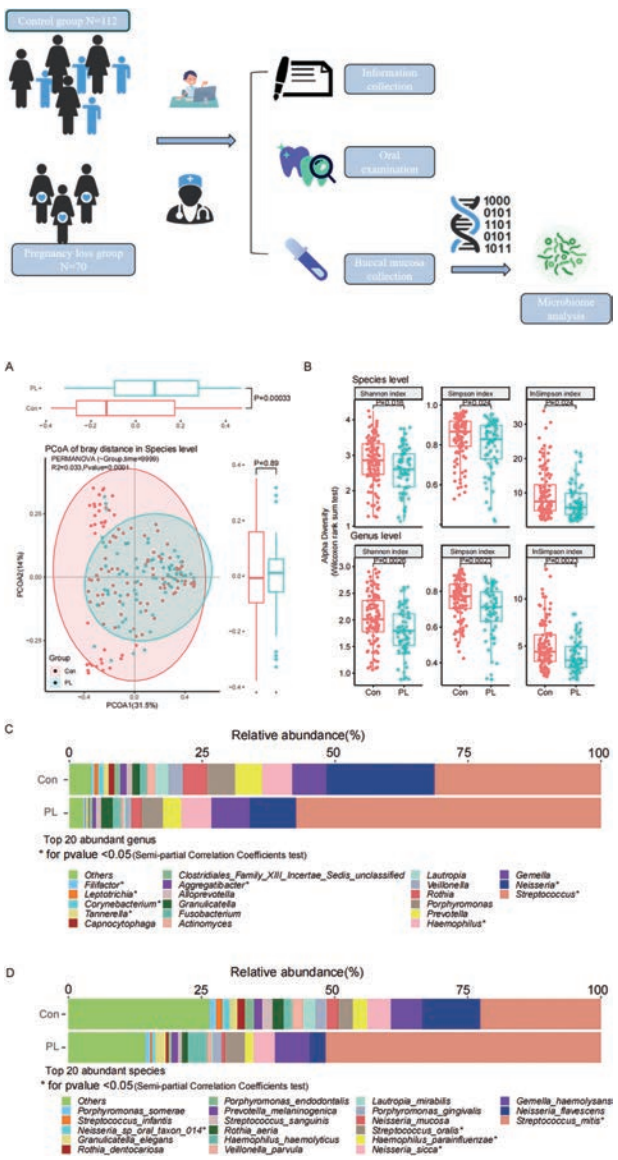
10:30 AM - 12:30 PM

Objective: The study aimed to elucidate the relationship between oral microbiota composition and pregnancy loss in Chinese women of childbearing age, hypothesizing that specific oral microbial signatures may be predictive of pregnancy outcomes.

Study Design: This prospective observational study adhered to the STROBE guidelines and enrolled 182 women of childbearing age. Participants were categorized into a pregnancy loss group (PL group, n = 70) and a control group (Con group, n = 112) based on their pregnancy history. Clinical assessments were conducted, and oral buccal mucosa samples were collected for comprehensive metagenomic analysis using shotgun sequencing. DNA was extracted, and sequencing was performed on the DNBSEQ-T1 platform. Taxonomic and functional profiling was conducted using Metaphlan 3.0 and HUMAnN 3.0. Alpha and beta diversities were assessed with indices and Bray-Curtis distances.

Results: The PL group exhibited lower oral microbiota richness and diversity. Genera such as Faecalibacterium, Roseburia, and Bacteroides were positively associated with pregnancy loss, while Pseudomonas and Leptotrichia were negatively associated. Metabolic pathways like plasminogen degradation and L-arginine degradation II (AST pathway) showed negative correlations with PL. Principal Coordinate Analysis (PCoA) revealed significant differences in oral microbiota composition and function between the groups.

Conclusion: Our findings suggest that specific oral microbiota compositions and metabolic pathways are associated with pregnancy loss, highlighting the potential role of oral microbiota in reproductive health. These insights could inform the development of targeted interventions aimed at modulating the oral microbiota to improve pregnancy outcomes.



271 | Association of Cesarean Characteristics with Opioid Use and Post-Operative Pain Scores

Luke P. Burns[1]; Xiao-Yu Wang[2]; On behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD) Maternal-Fetal Medicine Units (MFMU) Network
[1]*University of Chicago, University of Chicago, IL;* [2]*The Ohio State University, Columbus, OH*

10:30 AM - 12:30 PM

Objective: To evaluate the association between cesarean delivery (CD) characteristics, opioid use, and post-operative pain scores among patients who underwent CD.

Study Design: Secondary analysis of a multicenter randomized trial of individuals who underwent CD across 31 U.S. hospitals from 2020-2022. Primary outcome was total in-hospital post-operative morphine milligram equivalents (MME). Secondary outcomes included total postoperative in-hospital MME per day, total number of opioid tablets through 90 days post-discharge, and moderate-severe perceived pain (defined as worst pain score of ≥4 of 10 on Brief Pain Inventory (BPI)) assessed at randomization (within one day prior to discharge). CD characteristics included scheduled or unscheduled; whether done in the presence of labor or not; and primary or repeat. Multivariable modeling estimated the association between CD characteristics and selected outcomes adjusting for age, obesity, and insurance status.

Results: The 5477 participants included in this analysis were categorized into 6 mutually exclusive groups (Table 1). Labor before scheduled CD was excluded due to low frequency (n = 38). Age, BMI, insurance status, concurrent salpingectomy, postpartum hemorrhage, and birthweight differed significantly between groups (data not shown). In the simple multivariable model, total inpatient MME was greater after repeat CD without labor, whether scheduled or unscheduled; in adjusted analyses there was no association between CD characteristics and primary outcome (Table 2). Repeat CD was associated with a greater number of daily opioid tablets taken postoperatively until discharge (aOR 1.2, 95% CI 1.06, 1.4), total number opioids taken post-discharge (aOR 1.2, 95% CI 1.1-1.4) and increased moderate-severe pain (aOR 1.4, 95% CI 1.1, 1.4) compared with primary CD.

Conclusion: The total in-hospital postoperative MME did not differ by any of the evaluated CD characteristics. However, repeat CD was associated with more inpatient opioid use per day, outpatient opioid use, and moderate-severe perceived pain.

Table 1: Outcomes data stratified by cesarean delivery characteristics[1]

	Scheduled, no labor		Unscheduled, no labor		Unscheduled, with labor	
	Primary N=498	Repeat N=1369	Primary N=464	Repeat N=471	Primary N=2201	Repeat N=474
Total postoperative MME during hospitalization –median [IQR]	30 [2.5,82.5]	39 [7.5,82.5]	38.8 [7.5,90.0]	52.5 [15,97.5]	45 [7.5,96.5]	48.8 [11.8,97.5]
Total postoperative MME per day during hospitalization – median [IQR]	10.9 [0.7,27.6]	15.9 [3.5,32.8]	11.6 [2.8,27.5]	18.7 [4.7,32.9]	15.4 [2.9,32.2]	17.1 [4.8,36.3]
Total number of opioid tablets taken through 90 days post-discharge – median [IQR]	3 [0,14]	5 [0,15]	2 [0,12]	6 [0,17]	4 [0,14]	6 [0,16]
BPI Moderate-severe pain[2] – n (%)	434 (87.2)	1235 (90.4)	397 (85.6)	434 (92.3)	1972 (89.6)	439 (92.6)

MME, morphine milligram equivalent; BPI, Brief Pain Inventory

[1]Cesarean delivery characteristic examples:
Scheduled, no labor: planned CD scheduled prior to delivery, e.g., primary elective CD
Unscheduled, no labor: unanticipated CD prior to labor with new indication for delivery, e.g., non-reassuring fetal status
Unscheduled, with labor: CD following attempt at vaginal birth, e.g., 2nd stage arrest of descent
[2]Defined as BPI score of 4+ at baseline, with baseline assessed at randomization (within one day prior to discharge)

Table 2: Simple and adjusted logistic regression modeling of outcomes stratified by cesarean characteristics

	Odds Ratios & 95% CI from logistic regressions models					
	Repeat		Unscheduled		Labor	
Outcome	Simple model	Adjusted	Simple model	Adjusted	Simple model	Adjusted
Total postoperative MME during hospitalization, more than median	**1.25 (1.10, 1.42)**	1.09 (0.95, 1.23)	**1.35 (1.15, 1.59)**	1.19 (0.99, 1.43)	1.02 (0.87, 1.19)	1.02 (0.86, 1.22)
Total postoperative MME per day during hospitalization, more than median	**1.39 [1.22, 1.57]**	**1.23 [1.06, 1.41]**	1.14 [0.97, 1.34]	1.01 [0.84, 1.21]	1.14 [0.98, 1.34]	1.15 [0.96, 1.37]
Total number of opioid tablets taken through 90 days post-discharge, more than median	**1.34 (1.18, 1.52)**	**1.22 (1.06, 1.41)**	1.06 (0.90, 1.25)	1.04 (0.87, 1.24)	1.05 (0.90, 1.23)	0.99 (0.83, 1.18)
BPI Moderate-severe pain[1]	**1.55 (1.26, 1.91)**	**1.40 (1.10, 1.37)**	1.05 (0.81, 1.35)	1.02 (0.76, 1.37)	**1.30 (1.01, 1.66)**	1.20 (0.91, 1.59)

MME, morphine milligram equivalent; BPI, Brief Pain Inventory
Simple multivariable model contained three variables: repeat, unscheduled, and labor.
Adjusted multivariable models includes the three variables in the simple multivariable model with covariates adjusted for maternal age, obesity, and insurance status.
[1]Defined as BPI score of 4+ at baseline, assessed at randomization (within one day prior to discharge)

272 | Sex Differences in Cord Blood Inflammation at Birth in Offspring Exposed to Gestational Diabetes Mellitus

Sofia I. Torres Bigio[1]; Christine G. Ichugu[2]; Laura Ibanez-Pintor[2]; Daehee Han[2]; Prabhat Upadhyay[2]; Camille E. Powe[2]; Marie-France Hivert[2]; Andrea G. Edlow[2]; Lydia L. Shook[2]

[1]*Massachusetts General Hospital, San Juan, Puerto Rico;* [2]*Massachusetts General Hospital, Boston, MA*

10:30 AM - 12:30 PM

Objective: Exposure to gestational diabetes mellitus (GDM) *in utero* can lead to adverse offspring cardiometabolic and neurodevelopmental outcomes, with boys and girls at different degrees of risk. Programming of innate immune responses, i.e. "trained immunity," may be a key driver of vulnerability vs resiliency in the face of future immune challenges. Sex-specific mechanisms represent a significant knowledge gap. We have previously shown that in GDM, placental expression of *IGFBP1* – an anti-inflammatory biomarker of maternal insulin sensitivity – is reduced in pregnancies with a male fetus but increased with a female fetus. Here, we tested the hypothesis that cord blood markers of innate immune activation are increased in males exposed to GDM *in utero* but decreased in females.

Study Design: 40 pregnant individuals with live singleton term births enrolled in the MGH pregnancy biorepository (Aug. 2020 - Feb. 2024) were included: 20 with GDM (N = 10 females, 10 males) and 20 without GDM (N = 10 females, 10 males). Proinflammatory cytokines/chemokines associated with innate immune responses were quantified in umbilical cord plasma collected at delivery using a 20-Plex bead-based immunoassay (ThermoFisher). The impact of fetal sex and GDM on cord plasma analyte concentrations was assessed by two-way ANOVA. Spearman correlations were calculated between placental *IGFBP1* expression and cord plasma analytes.

Results: Placental *IGFBP1* is inversely correlated with cord plasma TNF-α ($p = 0.046$), a key proinflammatory cytokine–Fig. 1A. C-C motif chemokine ligand 3 (CCL3) levels are sexually dimorphic: higher in GDM-exposed males and lower in GDM-exposed females (GDM-sex interaction term on 2-way ANOVA $p = 0.007$); CCL4 showed a similar trend ($p = 0.088$)–Fig. 1B. IFN-α, IL-6, and IL-17A levels are elevated in males ($p = 0.029$, $p = 0.007$, $p = 0.047$) independent of GDM–Fig. 2.

Conclusion: In GDM, cord plasma levels of chemokines associated with innate immunity are sexually dimorphic and may relate to proinflammatory signaling pathways in the placenta. These results point to potential sex-specific mechanisms of immune programming in GDM.

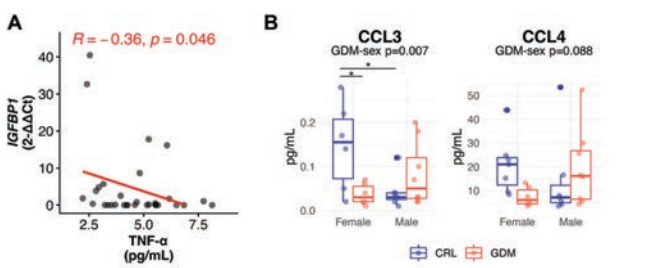


Figure 1: A. Placental *IGFBP1* expression is inversely correlated with cord plasma TNF-α concentration (N=31). B. Cord plasma CCL3 concentration in GDM is sexually dimorphic (2-way ANOVA, GDM-sex interaction term p = 0.007). Similar trend observed with CCL4. N=10 per group. *p<0.05, Tukey post-hoc comparison. GDM: Gestational diabetes mellitus. CRL: control.

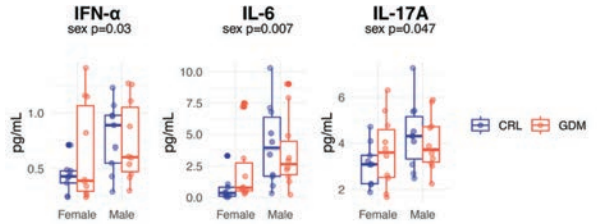

Figure 2: Proinflammatory cytokines IFNα, IL-6, and IL-17A are elevated in male cord plasma compared to females, with no effect of GDM. P-value shown for main effect of sex (2-way ANOVA). N=10 per group. GDM: Gestational diabetes mellitus. CRL: control.

273 | Trends in Risk Factors Associated with Syphilis Infection in Pregnancy from 2013-2023

Margaret R. Page[1]; Chloe Carroll[1]; Christina T. Blanchard[2]; Victoria C. Jauk[1]; Jodie A. Dionne[1]; Alan T. Tita[1]; Akila Subramaniam[2]

[1]University of Alabama at Birmingham, Birmingham, AL; [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL

10:30 AM - 12:30 PM

Objective: Rates of syphilis infection in pregnancy continue to increase in the United States, despite universal screening and well-defined treatment algorithms. We sought to evaluate the risk factors associated with syphilis infection in pregnancy and changes in these risk factors over a 10-year period at a single tertiary referral center in Alabama.

Study Design: We performed a retrospective case-control study of all pregnant individuals delivering at our institution from 2013-2023. All patients who received prenatal care at our institution and underwent laboratory testing for syphilis were included. We compared patients with confirmed syphilis (cases–definition in Table) to those without syphilis (controls). Baseline demographics, medical comorbidities, and infectious data (Table) were considered potential risk factors and compared between groups using bivariate analysis. Significant risk factors ($p < 0.05$) were analyzed via logistic regression to identify independent risk factors. Tests of heterogeneity were computed to analyze the differential effects of risk factors by year.

Results: During our study period, a total of 40,137 patients were analyzed, of which 114 (0.28%) had confirmed syphilis infection in pregnancy. Pregnant individuals diagnosed with syphilis were more likely to be younger, Black non-Hispanic race, obese, smoke cigarettes, have gonorrhea (GC) or chlamydia (CT) diagnosed during pregnancy, and have public insurance (Table). Of these risk factors, only Black, non-Hispanic race, increasing BMI, cigarette use, and concomitant GC/CT were noted to be independently associated with syphilis infection in multivariable analysis (Table). The only variable to statistically change over time was the increasing association of private insurance with no syphilis infection ($p = 0.046$).

Conclusion: Risk factors associated with syphilis in pregnancy at our institution largely remained stable over the past decade and consistent with known risk factors. Given rising rates of syphilis in pregnancy nationally, new public health strategies are warranted for these known at-risk populations.

Table: Baseline demographics compared between individuals with and without confirmed syphilis in pregnancy* (Data presented as mean ± SD or %).

274 | Organ Injury During Primary and Repeat Cesarean: Cross Sectional Analysis from the National Inpatient Sample

Margarita Berwick[1]; Cyndi Garvan[2]; Ting Wu[3]; Rodney Edwards[2]

[1]Orlando Health Winnie Palmer Hospital for Women and Babies, Orlando Health Winnie Palmer Hospital for Women & Babies, FL; [2]University of Florida College of Medicine, Gainesville, FL; [3]Orlando Health Winnie Palmer Hospital for Women & Babies, Orlando Health Winnie Palmer Hospital for Women & Babies, FL

10:30 AM - 12:30 PM

Objective: The incidence of cesarean delivery in the United States is rising. The objective of the present study is to present contemporary nationally-representative data regarding incidence of organ injury and hysterectomy during primary and repeat cesarean deliveries.

Study Design: We conducted a cross-sectional and weighted analysis of delivery admissions included in the National Inpatient Sample from 2019 to 2021. Any organ damage was defined as damage to the bladder, ureter, small bowel, or large bowel. We tested group differences using chi-square and Wilcoxon rank sum tests. We used logistic modeling to compare risk of any organ injury in primary versus repeat cesarean with adjustment for covariates of age, race, income, and year of delivery.

Results: Of the 673,525 cesarean deliveries in the dataset, most (52%) were primary cesareans. Rates of injury and unadjusted odds ratios in primary and repeat cesareans are shown in Table 1. After adjusting for age, race, income and year of delivery, compared to primary cesareans, those undergoing repeat cesarean had adjusted odds (95% CI) of any organ damage of 3.54 (3.13, 4.02), bladder repair of 4.17 (3.62,4.79), ureter repair of 1.65 (0.28, 9.86), small bowel repair of 1.99 (1.36,2.83), large bowel repair of 0.79 (0.45,1.39) and hysterectomy of 1.63 (1.38,1.92).

Conclusion: Rates of any organ injury, bladder repair, small bowel repair, and hysterectomy, but not ureteral repair or large bowel repair, are higher in repeat compared to primary cesarean

deliveries. However, although organ injuries during primary cesarean are less frequent than those in repeat cases, thousands occur annually in the US due to the large number of cesarean deliveries each year.

Table 1: Rates of Injury During Primary and Repeat Cesareans and Cesarean Hysterectomy not Associated with Placenta Accreta Spectrum Disorders

	Primary Cesarean (n = 352,490) n per 10,000	Repeat Cesarean (n = 320,900) n per 10,000	Odds Ratio 95% CI	p-value
Any organ damage*	9.22	29.07	3.54 [3.13, 4.02]	<0.001
Bladder Repair	7.04	29.26	4.17 [3.62,4.79]	<0.001
Ureter Repair	1.36	2.71	1.65 [0.28, 9.86]	0.5806
Small Bowel Repair	0.057	0.09	1.99 [1.36,2.83]	<0.001
Large Bowel Repair	0.82	0.65	0.79 [0.45,1.39]	0.4231
Hysterectomy	6.81	10.09	1.63 [1.38,1.92]	<0.001

*Any organ damage defined as bladder, ureter, small bowel or large bowel repair needed

275 | Association of Post-Cesarean Delivery Pain and Breastfeeding

Mariana Espinal[1]; Alexandra L. Berra[2]; Jeanette Boyce[3]; On behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network

[1]for the Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD; [2]Case Western Reserve University Metrohealth Medical Center, Cleveland, OH; [3]University of Pittsburgh, Pittsburgh, PA

10:30 AM - 12:30 PM

Objective: To evaluate whether pain severity after cesarean delivery (CD) is associated with breastfeeding initiation and continuation up to 90 days postpartum, and to evaluate whether there is an association of morphine milligram equivalents (MME) used and breastfeeding up to two-weeks postpartum.

Study Design: Secondary analysis of a multicenter randomized trial of an individualized opioid prescription protocol compared to a fixed quantity of opioids upon discharge after CD. People with a live singleton newborn were included. The primary outcome was breastfeeding initiation before hospital discharge, determined by chart abstraction. Secondary outcomes included participant-reported breastfeeding at several postpartum time points. The primary exposure was pain severity in the 24 hours prior to discharge, assessed using the Brief Pain Inventory (BPI). Secondary analyses evaluated MME used at each corresponding time point. Outcomes were compared using bivariable and multivariable analyses.

Results: Of 5,291 individuals, 56% reported severe pain (BPI 7-10) and 83% reported initiation of breastfeeding prior to discharge. Those who initiated breastfeeding were older, more likely to be non-Hispanic White, married, had higher income, and less likely to be obese, smoke tobacco, or use illicit drugs. Individuals who reported severe pain prior to discharge were less likely to initiate breastfeeding before discharge (81%) compared to individuals who reported moderate (85%) or mild (84%) pain (p = 0.001, Table). Severe pain prior to discharge was associated with lower breastfeeding rates at each postpartum time point (Table), which remained significant in adjusted analyses at and after two-weeks postpartum (Table). Compared to individuals not breastfeeding, those who breastfed took lower MME in the hospital and at one- and two-weeks post-discharge (Figure).

Conclusion: Individuals who experienced severe pain after CD were less likely to initiate and continue breastfeeding up to 90 days postpartum, and those breastfeeding took fewer MME.

Table: Association of baseline in-hospital pain scores in the 24 hours prior to discharge* with breastfeeding outcomes over the first 90 days postpartum

# Breastfeeding	No/mild pain† N=980	Moderate pain† N=1324	Severe pain† N=2983	Bivariable p-value	aOR (95% CI)§

Perinatal and Pediatric Epidemiology Research Team (Epopé), Center for Epidemiology and Statistics, FHU PREMA, Université de Paris, Paris, Ile-de-France

10:30 AM - 12:30 PM

Objective: Postpartum depression (PPD) is a common condition, with potential deleterious effects on mother and child. The involvement of disrespectful maternity care in negative childbirth experiences is increasingly studied, but its potential link with PPD remains under-evaluated. The objective was to assess the association between disrespectful maternity care and PPD at 2 months postpartum using national population-based data.

Study Design: Women from the 2021 Enquête Nationale Périnatale (all births in France during one week) who completed the 2-month follow-up questionnaire were included. Two-month PPD was defined as an Edinburgh Postnatal Depression Scale (EPDS) score ≥13. Disrespectful care (healthcare professional's inappropriate words, gestures or attitudes) during childbirth and/or postpartum were reported by women at 2 months postpartum. The association between disrespectful care and PPD was assessed using Poisson regression with robust variance, adjusted for confounders and weighted to account attrition. Sensitivity analyses were conducted using different EPDS cut-off and among subgroups of women at low pre-existing risk for PPD (antenatal well-being and no history of psychological / psychiatric care) or high pre-existing risk. Robustness against unmeasured confounding was assessed using E-value calculation.

Results: Among the 7189 women analyzed, 16.6% (95% confidence interval -CI- 15.7-17.6) had PPD at 2 months, and 24.9% (95% CI 23.8-26.0) reported experiencing disrespectful maternity care. After adjustment, women who reported disrespectful care were more likely to have 2-month PPD (adjusted relative risk –aRR 1.37; 95% CI 1.20-1.57, with E-value 2.08), including those at low pre-existing risk (aRR 1.69; 95% CI 1.34-2.15).

Conclusion: Experience of disrespectful care during childbirth or postpartum was associated with an increased prevalence of 2-month PPD. Given the concerning incidence of PPD and its consequences, these results underline the importance of raising awareness among healthcare professionals and enabling them to provide respectful care.

277 | Satisfaction with Continuous Glucose Monitoring and Time in Range Among Individuals with Gestational Diabetes

Marie J. Boller[1]; Lucy Ward[2]; Amy M. Valent[2]
[1]*Oregon Health and Science University, Portland, OR;* [2]*Oregon Health & Science University, Portland, OR*

10:30 AM - 12:30 PM

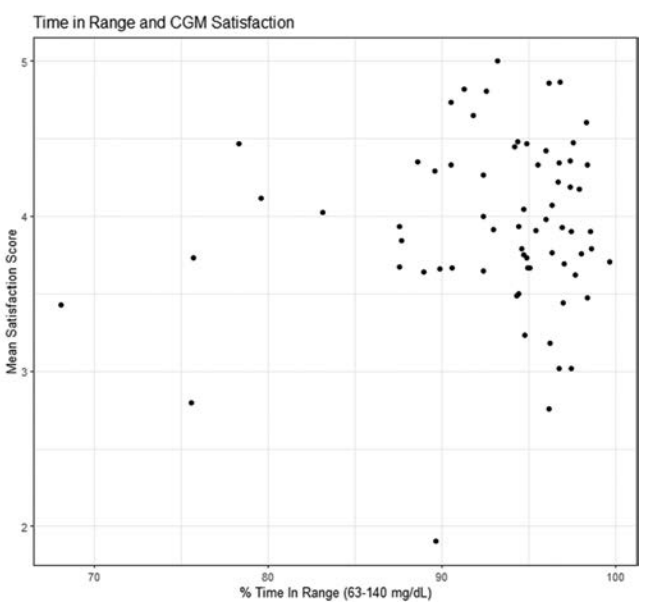
Objective: Satisfaction with continuous glucose monitoring (CGM) for management of diabetes has been shown to correlate with time in range (TIR) in individuals with Type 1 diabetes. Among individuals with gestational diabetes mellitus (GDM) using CGM, degree of satisfaction with use and correlation of satisfaction with TIR is unknown. We sought to describe satisfaction with CGM use and association with TIR among individuals with GDM.

Study Design: This was a secondary analysis of pregnant individuals with GDM randomized to CGM versus capillary blood glucose monitoring for GDM management. Participants randomized to CGM completed a 48-item Likert scale CGM satisfaction survey instrument (CGM-SAT). Among individuals with CGM-SAT responses, we examined the association between CGM-SAT scores and TIR, defined as glucose levels 63-140 mg/dL. We examined associations between CGM-SAT scores and screening instrument scores for food security and health literacy.

Results: Of 111 participants in the trial, 68 individuals were assigned to the CGM arm and provided CGM-SAT responses. Satisfaction with CGM was high with a mean CGM-SAT score of 3.9 ± 0.6. Mean TIR was also high at 93.0% ± 6.1. Degree of satisfaction did not differ between individuals with TIR ≥90% (n = 54), vs TIR <90% (n = 14): mean CGM-SAT scores were 4.0 ± 0.5 and 3.7 ± 0.7, respectively (two sample t-test p-value = 0.138). The cohort included individuals experiencing food insecurity (n = 8, 11.8%) and with limited health literacy (n = 6, 8.8%). Satisfaction did not differ between individuals with food security and adequate health literacy (mean CGM-SAT 3.9 ± 0.5) and individuals with food insecurity and limited health literacy (mean CGM-SAT 3.4 ± 2.1).

Conclusion: This study demonstrated high satisfaction levels and high mean percent TIR among a cohort assigned to CGM for management of GDM that included few individuals with limited health literacy and food insecurity. No significant correlation was identified between mean CGM-SAT scores and TIR in our population. Large clinical trials are needed to evaluate benefits of and barriers to CGM for management of GDM.

Figure: Time in range, defined as glucose levels 63-140 mg/dL and CGM satisfaction by mean CGM-SAT score.



278 | Maternal Morbidity Trends Among Abortion-Banned States Following Dobbs v. Jackson: An Interrupted Time Series Analysis

Marie-Julie Trahan[1]; Gabriela F. Tessler[2]; Yongmei Huang[3]; Jason D. Wright[4]; Alexander M. Friedman[4]
[1]Columbia University, New York, NY; [2]Columbia University Medical Center, New York, NY; [3]Department of Obstetrics and Gynecology, Columbia University Irving Medical Center, New York, NY; [4]Columbia University Irving Medical Center, New York, NY

10:30 AM - 12:30 PM

Objective: The objective of this study was to evaluate trends in maternal morbidity among states with the most limited access to abortion following *Dobbs v. Jackson*, the United States Supreme Court Decision, which overruled *Roe v. Wade*, on June 24, 2022.
Study Design: States were characterized as abortion-banned based on categories established by the Center for Reproductive Rights. Six states with the most restrictive laws (classified as illegal) were selected for this study: Alabama, Kentucky, Louisiana, Mississippi, Missouri, and Oklahoma. Maternal morbidity data were obtained from the Centers for Disease Control (CDC) and Prevention Natality on CDC WONDER Online Database for each state from 2020 Q1 to 2024 Q2. Morbidity incidence per 1000 births was measured for each quarter. An interrupted time series analysis was conducted to compare changes in maternal morbidity for selected states, before and after *Dobbs v. Jackson* (2020 Q1-2022 Q1: pre-*Dobbs*, 2022 Q2-2022 Q4: transition period, 2023 Q1-2024 Q2: post-*Dobbs*).
Results: Data from 1,398,504 pregnancies were analyzed. The average maternal morbidity rate for all studied states was 13.5 per 1000 births over the study period. Pre-*Dobbs*, the overall morbidity rate increased between 2020 Q1 and 2022 Q1 (12.5 to 14.3 per 1000 births; baseline trend: $\beta1 = 0.23$, $p = 0.0002$). Immediately post-*Dobbs*, the morbidity rate significantly decreased to 12.8 per 1000 births in 2023 Q1 (level change, $\beta2 = -1.24$, $p = 0.01$). The morbidity trends pre- and post-*Dobbs* did not change significantly ($\beta3 = -0.08$, $p = 0.34$), and the maternal morbidity rate continued to increase significantly post-*Dobbs*, to 14.0 per 1000 births in 2024 Q2 ($\beta1+\beta3 = 0.15$, $p = 0.02$).
Conclusion: Our study findings signal an increase in the rate of maternal morbidity in states with abortion bans prior to and after the overturning of *Roe v. Wade*. This is particularly concerning in the setting of an overall trend of increasing maternal morbidity in the United States.

Table 1. Quarterly morbidity rate per 1000 births in abortion-banned states from 2020 quarter 1 to 2024 quarter 2

Year	Quarter	Overall morbidity rate	Alabama	Kentucky	Louisiana	Mississippi	Missouri	Oklahoma
2020	1	12.59	10.86	11.57	12.92	10.12	12.46	17.41
	2	12.58	10.95	12.3	12.4	9.65	12.72	16.99
	3	12.28	11.15	13.21	12.41	9.52	12.78	13.81
	4	12.77	10.59	13.42	11.82	10.08	14.72	15.19
2021	1	14.61	12.41	14.08	12.11	11.54	16.63	20.31
	2	14.17	11.96	14.43	12.36	11	16.76	16.95
	3	13.65	11.63	14.57	13.24	9.39	14.43	17.54
	4	13.52	12.53	14.65	11.69	7.67	14.51	18.65
2022	1	14.32	13.22	15.52	10.15	11.52	15.99	18.81
	2	13.55	10.91	15.13	12.04	9.15	15.21	17.35
	3	13.50	14.08	13.79	10.6	11.69	14.37	15.96
	4	13.20	10.98	15.53	12.19	12.44	13.91	14.15
2023	1	12.81	10.41	13.78	11.56	11.13	13.48	16.45
	2	14.10	13.66	13.97	10.58	12.37	15.19	18.34
	3	13.61	13.55	14.21	11.49	11.57	14.87	15.26
	4	12.98	12.69	13.97	12.13	9.99	13.8	14.19
2024	1	14.11	13.93	14.87	10.59	12.18	16.44	15.48
	2	13.99	12.56	17.04	9.56	12.12	15.61	15.91

279 | Administration of and Delivery Timing after Antenatal Steroid Exposure: A Population-based Cohort Study

Mark A. Clapp[1]; Siguo Li[1]; Kaitlyn E. James[1]; Alexander Melamed[1]; Anjali J. Kaimal[2]
[1]Massachusetts General Hospital, Boston, MA; [2]University of South Florida, Tampa, FL

10:30 AM - 12:30 PM

Objective: Antenatal steroids are administered to individuals at high risk for preterm birth to reduce the risk of neonatal respiratory morbidity. However, predicting who is at high risk for preterm birth is challenging. Our objective was to examine steroid administration practices by gestational age (GA) to inform potential strategies focused on its optimal use.
Study Design: This was a retrospective cohort study of patients who delivered within a large health system between July 2016 and December 2023. Patients were included if they delivered a liveborn neonate ≥24 weeks of gestation. Data were obtained from the health system's EHR. GA at the start of the first course of betamethasone was used in the comparisons. Any prior steroid exposure was reported by GA at delivery. For individuals who received antenatal steroids, we reported the percent who delivered within 7 days and who delivered at term by GA at steroid exposure.
Results: Antenatal steroid administration was observed among 5,037 of 86,884 pregnant individuals (5.8%), including in 50.1% of 7,300 preterm births. Rates of prior steroid administration varied by gestational age at delivery (Figure 1), highest at 89.0% for deliveries between 32-33 completed weeks of gestation. 1.7% of all term deliveries had been exposed to betamethasone during pregnancy. Among those who received antenatal steroids, Figure 2 shows the percent delivered within 7 days, ranging from 22.6% at 24-27 to 67.2% at exposure 34-36 completed weeks of gestation. Across all exposure GAs, 25.1% of patients who received steroids ultimately delivered at term.
Conclusion: Antenatal steroid administration was not observed for 12.5% of births < 34 weeks of gestation and 66% of late preterm births. Conversely, only 38% of individuals received steroids and delivered in the upcoming week. This large cohort of deliveries demonstrates the challenges in optimally timing antenatal steroid administration. Future research should focus on identifying those at the highest risk for delivery who may receive the maximal benefit from appropriately timed steroid administration.

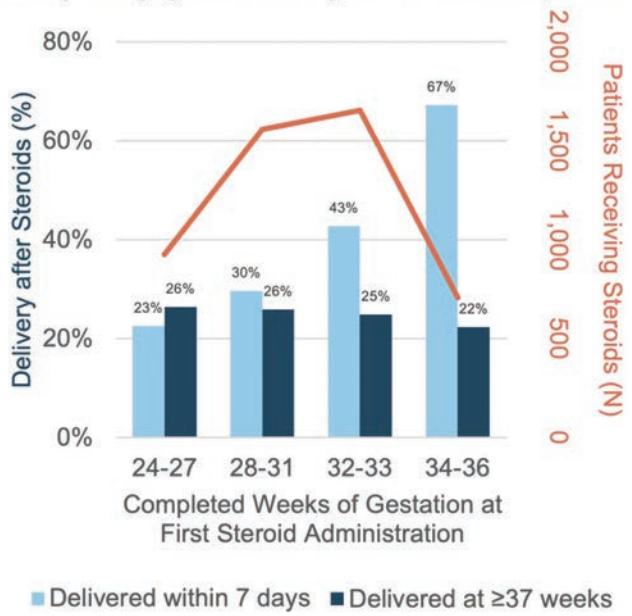
Delivery Timing by Gestational Age at First Steroid Exposure



280 | Patient-Reported Burdens of Antenatal Fetal Surveillance: Stillbirth Prevention at what cost?

Marta J. Perez[1]; Miriam Alvarez[1]; Sarah Lasater[1]; Alison G. Cahill[2]; Lorie M. Harper[1]
[1]Dell Medical School, Austin, TX; [2]Dell Medical School Health Transformation Research Institute, Dell Medical School, The University of Texas at Austin, Austin, TX

10:30 AM - 12:30 PM

Objective: Recommendations regarding the type, timing of initiation, and frequency of antenatal fetal surveillance (AFS) are based largely on expert opinion. Patient-centered experiences of AFS to guide AFS strategies that maximize stillbirth prevention and minimize cost and time burdens is lacking.

Study Design: We performed a cross-sectional survey of patients undergoing AFS in a maternal fetal medicine ultrasound unit. The primary aim was to describe the burden of AFS and determine if these burdens differed by frequency of AFS. Patients were eligible for inclusion if undergoing any type or frequency of AFS and were English or Spanish speaking. The survey responses of those undergoing once and twice-weekly testing were compared by creating a burden group (any "agree" response) and no burden group (any "disagree" response) by Chi square and Fisher's exact test as appropriate and by individual response as a continuous variable with student's t-test.

Results: Of 213 unique survey responses, 169 (79.3%) attended once and 44 (20.7%) twice-weekly. Most respondents had children and did not work outside the home. The most common self-reported indication for AFS was obesity. Patients reported that coming to clinic for AFS interfered with daily life (25.8%) and with work (14.6%), and 16.4% reported missing prenatal care to attend AFS. Twice-weekly patients were significantly more likely to report that AFS interfered with work ($p = 0.03$), was too expensive ($p < 0.01$), required cost cutting in other areas ($p < 0.01$), and reported missing AFS visits ($p = 0.03$) (Table 1).

Conclusion: Patients report financial and employment related difficulties attending AFS, and statistically significantly more burdens with twice compared to once-weekly testing. Strategies for stillbirth screening should consider potential harms of such regimens and the clinician should use shared decision-making when deciding on the frequency of AFS. Consideration should be given to innovation that relieves these burdens, such as remote, telehealth administered AFS.

	All	Once weekly	Twice weekly	p-value
Coming to clinic interferes with my day-to-day life.				
No	158 (74.2%)	128 (76.6%)	30 (65.2%)	
Yes	55 (25.8%)	39 (23.4%)	16 (34.8%)	0.12

281 | Prospective Evaluation of Obstetric Point of Care Ultrasound (POCUS) Competency Training in Bangladesh

Mary Sterrett[1]; Annaliese Neumann[2]; Meghan Beddow[3]; Jeff Pollard[4]

[1]Kaiser Permanente Southern California, SAN DIEGO, CA; [2]MedGlobal, Chicago, IL; [3]n/a, n/a, AK; [4]MedGlobal, Rolling Meadows, IL

10:30 AM - 12:30 PM

Objective: To improve knowledge and image acquisition in obstetric ultrasound via remote image review of obstetric POCUS following in person ultrasound education and training program in low resource settings. Secondary objective was to generate preliminary timelines and ultrasound volumes for the skill acquisition of basic obstetric point of care ultrasound.

Study Design: Prospective observational evaluation of a six-physician cohort from October 2023 to April 2024 in Bangladesh, following a 10-day ultrasound training intervention in refugee camps.

Results: 225 ultrasounds were remotely reviewed over a 24-week period. Written examinations assessed pre-intervention knowledge (average score 57%) and post-intervention knowledge (89%) with an average score increase of 36%. Basic obstetric POCUS competency was achieved in 83% (5 of 6) trainees. Median time from completion of training to competency was 133 days (range 55-169). Median number of ultrasounds to reach competency was 40 (range 26-59). A four-month post-intervention written knowledge assessment was performed, with an average score of 91%.

Conclusion: OB POCUS competency following in-person ultrasound education and remote image review was achieved in nearly all trainees, and written knowledge assessment at four months post intervention showed similar scores as immediate post educational assessments. This finding supports adding remote image review in obstetric POCUS education and generates preliminary timelines and ultrasound volumes to achieve competency.

282 | The Association between Use of Preoperative Antibiotics and Gestational Latency After Ultrasound-Indicated Cerclage

Maryama O. Ismail[1]; Taylor S. Freret[2]; Mark A. Clapp[3]; Malavika Prabhu[3]

[1]Mass General Brigham, Boston, MA; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]Massachusetts General Hospital, Boston, MA

10:30 AM - 12:30 PM

Objective: The use of perioperative antibiotics and indomethacin increase gestational latency (GL) for patients undergoing exam-indicated cerclage. We sought to determine if preoperative antibiotics for ultrasound-indicated cerclage (UIC) have similar benefits.

Study Design: This was a retrospective cohort study of patients undergoing UIC per the operative report within a single health-care system with a linked birth record (>20 weeks' gestation) from 2017 to 2023. Exclusion criteria included multiple gestation, multiple cerclages in the pregnancy, or receipt of postoperative antibiotics. Surgical case details, antibiotic administration, and delivery outcomes were abstracted from the electronic health record with chart review as required. The primary exposure was preoperative antibiotic administration. The primary outcome was GL, or the duration from cerclage placement to delivery. Secondary outcomes included gestational age (GA) at delivery and any preterm birth (PTB) < 28 or < 32 weeks. Multivariable linear and logistic regression analysis were used to control for prior preterm birth, vaginal progesterone use, and cervical length and GA at time of cerclage.

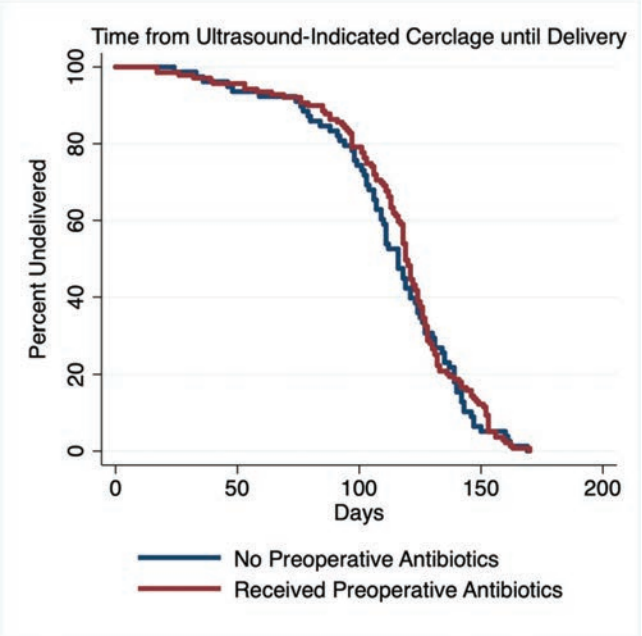
Results: During the study period, 231 patients received an UIC, of whom 219 (94.8%) met inclusion criteria. 140 patients (63.9%) received preoperative antibiotics. The groups were similar on baseline characteristics (Table). There was no difference in GL (116 vs 113 days, p = 0.46, Figure) or GA at delivery (37.0 vs 36.7 weeks, p = 0.62) between those who did and did not receive antibiotics. The PTB rates before 28 and 32 weeks were also similar (3.6 vs 5.1%, p = 0.59, and 10.1 vs 10.3%, p = 0.97, respectively). Results were unchanged in the adjusted analyses and in sensitivity analyses considering patients with and without a prior preterm birth as separate cohorts.

Conclusion: The use of preoperative antibiotics for UIC placement is not associated with increased GL or lower PTB rates compared to no antibiotics. Our findings may help promote antibiotic stewardship.

Table: Baseline Characteristics

	No Preoperative Antibiotics N=79	Received Preoperative Antibiotics N=140	P-value
Age	33.8 (5.2)	33.4 (5.2)	0.53
Self-Reported Race			
White	31 (39.2%)	54 (38.6%)	0.76
Black or African American	26 (32.9%)	40 (28.6%)	
Asian or Pacific Islander	10 (12.7%)	17 (12.1%)	
Other or Unknown	12 (15.2%)	29 (20.7%)	
Hispanic Ethnicity	15 (19.5%)	29 (21.3%)	0.75
Public Insurance	12 (16.0%)	30 (21.7%)	0.31
English Preferred Language	72 (91.1%)	136 (97.1%)	0.05
Nulliparous	34 (43.0%)	59 (42.1%)	0.90
Prior Preterm Birth	40 (50.6%)	56 (40.0%)	0.13
Ga At Time of Cerclage (weeks)	20.7 (18.9-22.4)	20.9 (18.6-22.0)	0.69
Cervical Length at Time of Cerclage (cm)	1.6 (1.1-2.1)	1.5 (1.1-2.0)	0.32
Received Indomethacin	72 (91.1%)	133 (95.0%)	0.26
Vaginal Progesterone Use	56 (70.9%)	109 (77.9%)	0.25

Data represented as n (percent), median (interquartile range), or mean (standard deviation)



283 | The Association between Antibiotic Prophylaxis Duration and Gestational Latency After Exam-Indicated Cerclage Placement

Maryama O. Ismail[1]; Taylor S. Freret[2]; Mark A. Clapp[3]; Malavika Prabhu[3]
[1]Mass General Brigham, Boston, MA; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]Massachusetts General Hospital, Boston, MA

10:30 AM - 12:30 PM

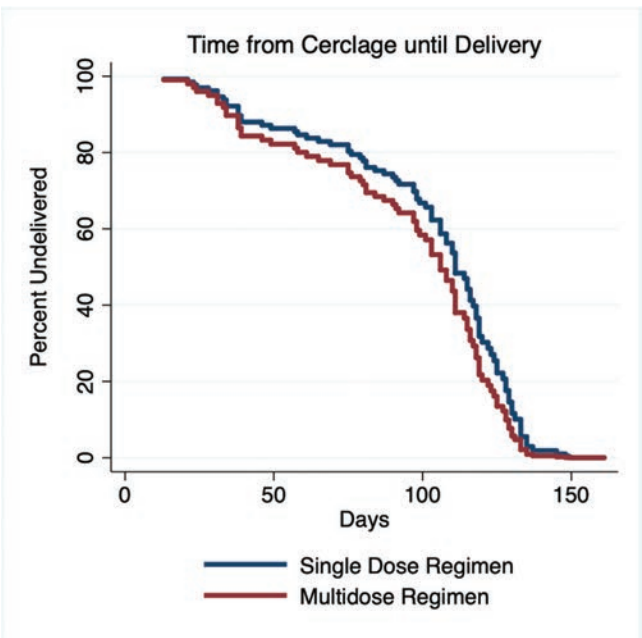
Objective: A 24-hour course of IV antibiotics and indomethacin at the time of exam-indicated cerclage (EIC) is superior to placebo at increasing gestational latency (GL). We sought to determine if a single dose regimen (SDR) of perioperative antibiotic prophylaxis provides similar benefits compared to a multidose regimen (MDR).

Study Design: This was a retrospective cohort study of patients undergoing an EIC within a single healthcare system from 2017 to 2023. Exclusion criteria included multiple gestation, multiple cerclages in the pregnancy, or no perioperative antibiotics. Surgical case details, antibiotic administration, and delivery outcomes were abstracted from the electronic health record. The exposure was antibiotic duration: SDR (preoperative antibiotics only) vs MDR (preoperative antibiotics with at least one postoperative dose). The primary outcome was time from cerclage placement to delivery (GL) among liveborn infants. Secondary outcomes included gestational age (GA) at delivery. Linear regression analyses controlled for amniocentesis prior to EIC, and cervical dilation (cm) and GA at placement.

Results: 122 patients underwent an EIC; 93 (76.2%) met inclusion criteria. 38 patients (40.9 %) received SDR, and 55 (59.1%) received MDR. Ninety-five percent of patients received indomethacin. The MDR group had a higher amniocentesis rate (54 vs 30%, p = 0.02) and baseline cervical dilation (1 cm [IQR 1–2] vs 1 cm [IQR 1–1]). Unadjusted GL (88 vs 106 days, mean difference -18 d, p = 0.02) and delivery GA (33.3 vs. 35.6 weeks, mean difference -2.3 weeks, p = 0.04) were lower in the MDR group. However, in the adjusted model, there was no significant difference in mean GL (-10.5 days, p = 0.20, Figure) or delivery GA (-1.5 weeks, p = 0.19, Table). Results were similar when adjusting for vaginal progesterone use.

Conclusion: A single dose of antibiotic prophylaxis is associated with similar GL to a multidose regimen when adjusting for other clinical factors. Limitations of our study include small sample size and that our model may not fully account for unobserved risk differences between the groups.

Gestational Latency (Days)	Unadjusted		Adjusted	
	Coefficient [95% CI]	p-value	Coefficient [95% CI]	p-value
Multidose Regimen	-17.6 [-32.7 – (-2.4)]	0.02	-10.4 [-26.4 – 5.5]	0.20
Amniocentesis	-10.8 [-26.5 – 4.9]	0.18	-8.9 [-24.9 – 7.1]	0.27
Cervical Dilatation (cm)	-14.9 [-25.9 – (-4.0)]	0.01	-13.5 [-24.7 – (-2.2)]	0.02
GA At Cerclage (weeks)	-2.4 [-6.5 – 1.6]	0.23	-2.8 [-6.9 – 1.4]	0.19
Gestational Age at Delivery (weeks)	**Unadjusted**		**Adjusted**	
	Coefficient [95% CI]	p-value	Coefficient [95% CI]	p-value
Multidose Regimen	-2.36 [-4.55 – (-0.17)]	0.03	-1.51 [-3.78 – 0.75]	0.19
Amniocentesis	-1.99 [-4.23 – 0.25]	0.08	-1.3 [-3.56 – 0.96]	0.25
Cervical Dilatation (cm)	-2.18 [-3.66 – (-0.71)]	<0.01	-1.88 [-3.47 – (-0.30)]	0.02
Ga At Cerclage (weeks)	0.64 [0.06 – 1.22]	0.03	0.59 [-0.01 – 1.19]	0.05



284 | The Impact of an Informative Video on Patient Anxiety at Term Induction-of-labor: Randomized Control Trail

Matan Friedman[1]; Liat Mor[2]; Irit Segman[1]; Yossi Mizrachi[1]; Noa Ben Shushan[1]; Hagit Eisenberg[1]; Tamar Shieldkrot[1]; Eran Weiner[1]; Giulia Barda[1]
[1]Wolfson Medical Center, Wolfson Medical Center, Tel Aviv; [2]Edith Wolfson Medical Center, Holon, HaMerkaz

10:30 AM - 12:30 PM

Objective: Induction of Labor (IOL) is a medical intervention that is associated with discomfort and anxiety. Our aim was to study the impact of a detailed informative video presented prior to IOL on maternal anxiety and satisfaction

Study Design: In this randomized controlled trial, term women with an unfavorable cervix undergoing IOL between April-July 2024 were randomly assigned to either: a "video group", in which an informative video was presented prior to IOL and a "control group", in which women received standard counselling. Otherwise, all patients received the same medical care. A 5-minute video was produced by our staff and included detailed information about IOL methods, what to expect after insertion, and pain management. IOL was performed by either vaginal dinoprostone or extra-amniotic balloon, according to our protocol. The primary outcome was the difference between State-Trait Anxiety Inventory (STAI) score before and after IOL (ΔSTAI). Secondary outcomes included patient satisfaction rated between 1 and 5. The study was powered to detect a 25% difference in the primary outcome (ΔSTAI)

Results: Included were 167 participants: 81 in the video group and 86 in the control group. Demographics were comparable between the groups, as well as baseline STAI scores, indications and methods for IOL. The decrease in anxiety levels (ΔSTAI) was significantly higher in the video group, compared with the control group (4.4 vs. 0.6, p = 0.007). Watching the informative video remained associated with anxiety reduction after adjusting for confounders (β 4.11, 95% CI 1.22-7.0). Furthermore, patients in the video group reported lower anxiety levels after IOL (mean STAI 44.1 vs. 38.9, p = 0.002), and higher satisfaction of the overall IOL experience (4.4 vs. 4.1, p = 0.018)

Conclusion: An informative video prior to IOL significantly reduced patient anxiety and Improved satisfaction. This technology offers a simple, cost-effective and non-pharmacological method to reduce anxiety and improve patient experience during IOL

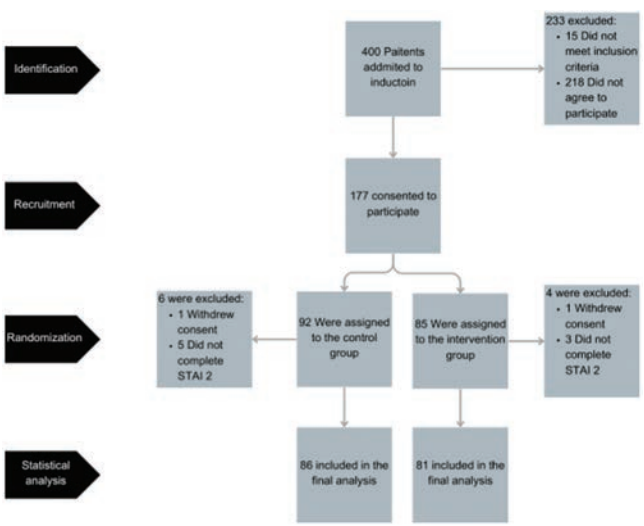


Table. Selected demographics and outcomes of women undergoing induction of labor with and without a pre-induction informative video

	Control group (n=86)	Video group (n=81)	*p*-value
Selected demographics			
Maternal age (years)	30.1 ± 5.7	30.9 ± 5.6	0.382
Gestational age at induction (weeks)	38.8 ± 1.1	38.9 ± 1.1	0.785
Nulliparity	33 (38.3)	32 (39.5)	1.0
Selected outcomes			
Pre-induction STAI score	44.8 ± 11.6	43.4 ± 11.6	0.437
Post-induction STAI score	44.1 ± 11.3	38.9 ± 11.0	0.002
Mean reduction in STAI score	0.6 ± 10.0	4.4 ± 7.9	0.007
Overall Satisfaction (scale 1-5)	4.1 ± 0.9	4.4 ± 0.6	0.018

Data are presented as mean ± SD, or n (%).

287 | Patient Perceptions of a One-Year Postpartum Patient Navigation Program for Low-income Birthing People

Maya J. Daiter[1]; Hannah M. Green[1]; Laura Diaz[1]; Brittney R. Williams[1]; Viridiana Carmona-Barrera[1]; Charlotte M. Niznik[1]; Michelle A. Kominiarek[2]; Joe M. Feinglass[1]; William A. Grobman[3]; Lynn M. Yee[1]

[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Northwestern Feinberg School of Medicine, Northwestern Feinberg School of Medicine/ Chicago, IL; [3]The Ohio State University, Columbus, OH

10:30 AM - 12:30 PM

Objective: Patient navigation, an intervention in which a trained individual supports patients in navigating the healthcare system, has emerged as a means to promote health equity in a variety of healthcare domains. Navigating New Motherhood (NNM) is a randomized trial that implemented a one-year postpartum patient navigation program for low-income birthing individuals. We aimed to understand patient perceptions of the NNM program and describe its implications for future program iterations.

Study Design: In this analysis of qualitative data from the NNM study, a random selection of participants who were receiving the navigation intervention underwent in-depth interviews at 4-6 and 11-13 months postpartum. Interviews focused on participants' perceptions of the relationship with their navigator and activities performed by the navigator. Using a codebook created through an iterative team-based process, two coders independently analyzed sets of interviews using the constant comparative method to identify underlying themes.

Results: In this analysis of 30 interviews from 15 navigated participants (mean age 28.4 years, 100% Medicaid insurance, 53% Black and 40% Hispanic), participants provided feedback regarding their navigators and the program. Major themes included 1) interpersonal connection between navigator and participant, 2) importance of logistical support provided by the navigator, 3) development of participant activation, 4) desired continuation of

the program, and 5) perception of breadth of services provided (Table). Some suggestions for improvement, albeit minimal in nature, were provided. Findings were similar at both time points.
Conclusion: Participant feedback on their experiences with postpartum navigation was overwhelmingly positive at both the mid-point and end of one year of participation. Participants cited navigation activities, program structure, and their relationship with navigators as program strengths. Findings support that patient navigation programs are welcomed by low-income birthing individuals, building on growing evidence for future investment in obstetric navigation.

Table: Patient Perceptions of Postpartum Navigation

Theme	Subtheme	Exemplary Quotation
Interpersonal connection between navigator and participant	Positive relationship with navigator	"I believe that we had a great relationship…It was just like a friend…I like that because it wasn't like she was prying or anything. It was just 'I'm here to help you out, how can I help you.'"
	Emotional support	"She was there to listen to me like if I wanted to text her and say hey, like 'I'm having postpartum depression' or whatever, that she would like help me out…it felt really nice to just have the extra support there."
Importance of logistical support provided by the navigator	Support for healthcare-related activities	"She helped me find a [primary] care physician…she helped me…cancel and reschedule appointments…I had to wait three months, two three months and she'd call and try to get something sooner. Things like that. She was really helpful"
	Navigator reduces participant's cognitive load	"I was so busy being a new mother, trying to finish school, so that kind of took a lot of weight off my shoulders where I had somebody helping me and checking on me. It was good for me."
	Connection to non-healthcare resources	"She let me know like places I can go get diapers, like a lot of resources and stuff that I may need…There's a program through my insurance and everything. I didn't know that…she was just encouraging me to ask them what's available. Without her I wouldn't have even known that."
	Appreciation of navigator attention to detail	"I know she's very detail oriented, so she definitely touches bases on a lot of different things. She brings up stuff that I'm not even thinking about"
Development of participant activation	Decrease in navigation needs at end of program	"…during the last six months, I haven't required so much support from [navigator]. I didn't demand as much support as during the first months of pregnancy and the first months of postpartum."
	Development of self-efficacy	"There's something important that she has done…[she] not only [taught me how] to manage the resources but also…how I can manage those things myself. [For example,] when I went to the clinic, she taught me how to use the MyChart application"
Desired continuation of program	Personal value of program	"I just want to say that the program was real helpful, [it] helped me in many ways…it should go forward"
	Desired future use	"if I get pregnant again I…will make sure I go see you guys office."
Perception of breadth of services provided	Patient satisfaction with breadth of services	"There is nothing that I've asked her that she has not gotten done and heck she even got it done before I asked her."
	Positive perception of attention to detail within program structure	"You're saying this is an early program you guys just start[ed]? You guys dotted a lot of I's and crossed a lot of T's with this."

288 | Integrating Complementary Medicine during Labor Induction: Insights from a Retrospective Cohort Study

Mays Awawdeh[1]; Tzlil Ganon[2]; Bat-Zion Zidenberg[2]; Dani Steinberg[2]; Elad Schiff[2]; Rami sammour[3]; Shlomi Sagi[3]; Inna Bleicher[4]

10:30 AM - 12:30 PM

Objective: The use of acupuncture and reflexology has been rapidly increasing in obstetrics and gynecology. Nevertheless, their effect on maternal and neonatal outcomes remains uncertain. The aim of this study was to compare outcomes between patients who had labor induction with and without complementary medicine integrated into their standard medical care.

Study Design: Retrospective study of patients who had IOL in a single tertiary medical center from 2020-2023. Those receiving acupuncture or reflexology integrated with standard care (study group) were compared to standard care (control group). Data was retrieved from electronic medical records. Inclusion criteria were live singleton fetus, cephalic presentation, > 34 weeks of gestation without contraindication for vaginal delivery. Patients with ruptured membranes before IOL and those lacking data on the IOL method were excluded. Primary outcome was oxytocin use. Secondary outcomes included mode of delivery, indications for immediate delivery, intrapartum maternal fever ≥ 38°C, Apgar at 5 min ≤ 7 and admission to neonatal intensive care unit.
Results: Of 1906 eligible patients, 410 had complimentary treatment and 1496 were in the control group. Nulliparity and induction with prostaglandins were more common in the study group. Complimentary medicine group had lower rates of oxytocin use (17.3% vs 23.6%, p = 0.007) but longer oxytocin to delivery interval. These differences remained significant after adjustment for nulliparity and prostaglandins for labor induction. The rates of cesarean delivery and intrapartum maternal fever were higher in the study group. Other maternal and neonatal outcomes were similar.
Conclusion: Integration of complementary medicine during induction of labor was associated with lower rates of oxytocin use but longer duration of oxytocin administration, higher rates of maternal fever and cesarean deliveries. Selection bias, local practices as well as other confounders warrant prospective studies in order to confirm these findings.

Table 1: Group Characteristics and Study Outcomes

	With complementary medicine (N=410)	Without complementary medicine (N=1496)	P-value	OR (95% CI)
Maternal age	31.2 ± 4.82	31.1 ± 5.20	0.765	1 (1 - 1)
Gestational age (weeks)	39.6 ± 1.30	39.5 ± 1.34	0.315	1 (0.9 - 1)

NICU admission	7 (1.7%)	41 (2.7%)	0.212	1.7 (0.7 - 3.8)

Data are presented as mean ± SD or n (%) NRFHR - Non reassuring fetal heart rate, GDM - Gestational diabetes mellitus, DM -Diabetes mellitus, IUGR - Intra uterine growth restriction, CD- cesarean delivery, NICU- neonatal intensive care unit

289 | Association of Glycemic Index in Early Pregnancy with GDM and LGA Risk in Nulliparous Individuals

McKenzie K. Jancsura[1]; William A. Grobman[2]; Jiqiang Wu[2]; Christina M. Scifres[3]; Rebecca B. McNeil[4]; Brian M. Mercer[5]; Hyagriv Simhan[6]; Uma M. Reddy[7]; Robert M. Silver[8]; Samuel

Parry[9]; George R. Saade[10]; Judith H. Chung[11]; Lynn M. Yee[12]; Kartik K. Venkatesh[2]
[1]The Ohio State University College of Nursing, Columbus, OH; [2]The Ohio State University, Columbus, OH; [3]Indiana University School of Medicine, Indianapolis, IN; [4]Research Triangle International, Durham, NC; [5]Case Western Reserve University, Cleveland, OH; [6]University of Pittsburgh Medical Center, Pittsburgh, PA; [7]Columbia University, New York, NY; [8]University of Utah, Salt Lake City, UT; [9]University of Pennsylvania, Philadelphia, PA; [10]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [11]University of California- Irvine, Irvine, CA; [12]Northwestern University Feinberg School of Medicine, Chicago, IL

10:30 AM - 12:30 PM

Objective: We determined whether glycemic index in early pregnancy is associated with the risk of gestational diabetes mellitus (GDM) or large-for-gestational-age (LGA) birth among nulliparous individuals.
Study Design: This is a secondary analysis of data from individuals without pregestational diabetes enrolled in the prospective cohort Nulliparous Pregnancy Outcomes Study: Monitoring Mothers-To-Be (nuMoM2b). The exposure was average glycemic index, which was determined by the Block Food Frequency Questionnaire administered in the first trimester. The glycemic index was categorized in quartiles from Q1 (best or foods with a slower blood sugar rise, reference) to Q4 (worst). Outcomes were GDM based on third trimester screening and LGA at birth per sex- and gestational-age standardized birthweight $\geq 90^{th}$ percentile. Modified Poisson regression was used and adjusted for age, body mass index, insurance status, and area deprivation index. Secondarily, we assessed for effect modification by dietary quality (using the Healthy Eating Index) and neighborhood-level food access (using the USDA Food Atlas).
Results: Among 7,817 assessed participants, the median glycemic index was 49.8 (IQR: 47.4, 52.1), and 94.9% had a low glycemic index score (≤ 55). Overall, 8.2% developed GDM and 4.2% had a LGA infant. The highest glycemic index (Q4) was not associated with an increased risk of GDM, but Q3 was associated a statistically increased risk of GDM versus the lowest quartile (Q3 vs. Q1 8.1% vs 9.0%: ARR: 1.51, 95% CI 1.11-2.05). Glycemic index was not associated with LGA birth. There was no evidence of effect modification by either dietary quality or neighborhood-level inadequate food access ($p \geq 0.05$ for all).
Conclusion: In a cohort of nulliparous individuals with generally good or low-glycemic-diets in early pregnancy, the glycemic index was not consistently associated with GDM or LGA. Further studies are needed to better understand the impact of diet-based glycemic changes on pregnancy outcomes.

TABLE. Association between glycemic index in early pregnancy and GDM and LGA birth in nulliparous individuals

	Frequency (row percentage)		Unadjusted and adjusted analysis	
	Yes	No	Unadjusted risk ratio (95% CI)	Adjusted risk ratio (95% CI)
GDM	N=640	N=7,177		
GI				
Quartile 1	176 (9.0)	1,787 (91.0)	Ref	Ref

290 | Better Maternal and Fetal Outcomes in Women with Self-Monitoring of Blood Pressure and Telemedicine Visit

Melanie Yee L Siaw[1]; Abraham Enyeji[2]; Alejandro Arrieta[3]; Marcia Klein-Patel[1]
[1]Allegheny Health Network, Pittsburgh, PA; [2]Mercer University School of Medicine, Macon, GA; [3]Florida International University, Miami, FL

10:30 AM - 12:30 PM

Objective: Hypertensive disorders of pregnancy (HDP) affect 13% of pregnancies in the United States. Without monitoring, HDP can rapidly develop and progress. Self-monitoring of blood pressure (SMBP) for timely detection and treatment of HDP in the United States is still limited. We examined maternal and fetal outcomes and health utilization rates among pregnant women with SMBP and telemedicine visits (SMBP+T) and pregnant women with usual care (UC).
Study Design: This multicenter, retrospective cohort study (from 2020 to 2022) included women aged 15-55 years with singleton pregnancies; no prior diabetes, gestational diabetes, or HDP; and no use of low-dose aspirin in prior pregnancies. Women were excluded if there was insufficient information, a severe mental health diagnosis, drug use complicating pregnancies or termination of healthy, viable pregnancies. Eligible women with SMBP and telemedicine visits (n = 533) during prenatal care were assigned to the SMBP+T group. Another matched cohort of eligible women (n = 533) was comprised of the UC group that received only in-person office visits during prenatal care.
Results: At baseline, the sociodemographic, body mass index, comorbidities, history of prior pregnancy outcomes and blood pressure levels were similar across groups (Table 1). During pregnancy, groups had similar rates of new onset of HDP, delivery modes, gestational ages at delivery and pregnancy outcomes such as term birth, preterm birth, and pregnancy termination. In the UC group, those with HDP had higher incidents of maternal cardiovascular events (16.9% UC vs 7.1% SMBP+T; $p < 0.05$) and fetal complications related to HDP (29.6% UC vs 17.1% SMBP+T; $p < 0.05$). In addition, the UC group visited a prenatal office at slightly higher frequency (68.9% UC vs 62.3% SMBP+T; $p < 0.05$).
Conclusion: SMBP with telemedicine visits during pregnancy was associated with lower rates of maternal cardiovascular events and fetal complications related to HDP. SMBP with telemedicine

visits also did not increase health utilization rate in low-risk pregnant women.

Table 1: Sociodemographic and clinical characteristics of pregnant women at baseline

	SMBP + telemedicine visit group	Usual care group
	Median (Q1, Q3)*	Median (Q1, Q3)*
Age (years)	30 (28, 33)	30 (28, 33)
Body mass index (kg/m^2)	24.9 (22.1, 29.2)	26.2 (23.0, 30.1)
Systolic blood pressure (mmHg)	114 (108, 122)	116 (110, 121)
Diastolic blood pressure (mmHg)	71 (67, 77)	72 (68, 78)
	%	%
Current smoker	9.4	10.3
Prior term birth	52.1	51.7
Prior preterm birth	4.5	5.3

291 | Tiktok and #Maternalmortality: a Content Analysis

Melissa Greene[1]; Lucero Hernandez[1]; Jenny Wu[2]; Jonas J. Swartz[2]; Charity Watkins[2]
[1]Duke University School of Medicine, Durham, NC; [2]Duke University Medical Center, Durham, NC

10:30 AM - 12:30 PM

Objective: Nearly 40% of Generation Z use TikTok as their primary search engine before other sites. Reproductive health posts frequently raise awareness and/or provide education. We systematically analyzed TikTok videos using #maternalmortality which has over 37 million views.

Study Design: Web-scraper Apify was used to compile information from the most-liked TikTok posts tagged #maternalmortality on February 6, 2023. Two independent reviewers (M.G. and L.H.) performed standardized coding on the top 100 videos with another reviewer (C.W.) to arbitrate differences. In addition to pre-determined descriptive data points, two standardized scales were used: a modified 5-point DISCERN scale to assess information quality and the Patient Education Materials Assessment Tool (PEMAT) to evaluate understandability and actionability.

Results: The top 100 #maternalmortality TikToks collectively had 11.9 million views and 1.1 million likes. 13 unavailable videos were excluded at the time of arbitration. Most creators were feminine presenting (86%), based in the U.S (99%), and 48% were healthcare professionals. Common themes included racial disparities in maternal deaths (33%) and causes and preventability of maternal deaths (22% and 13%, respectively). 5% of videos highlighted trust in healthcare while 31% highlighted distrust. Health information quality was moderate (median DISCERN score of 2 out of 5, IQR 2-3) and videos were understandable (PEMAT median 71%, IQR 62-83) but not actionable (PEMAT median 0%, IQR 0).

Conclusion: Popular #maternalmortality videos on TikTok highlight race or racism as contributing factors to maternal deaths. High scores in understandability but lower in information quality suggests that, though accessible, these videos may not be totally reliable.

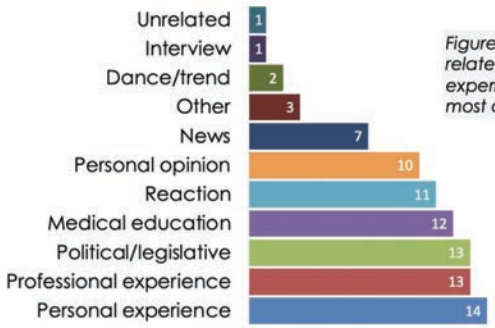

Figure 1: Videos related to personal experience were the most common

Theme	Videos containing theme, n (%)
Racial disparities in maternal deaths	29 (33.0%)
Race or racism as contributing factors to maternal deaths	27 (31.0%)
Causes of maternal deaths	19 (21.8%)
Maternal deaths in the U.S compared to other countries	17 (19.5%)
How healthcare professionals addressed patient concerns	12 (13.8%)
Preventability of maternal deaths	11 (12.6%)
Distrust in healthcare	27 (31.0%)
Trust in healthcare	6 (6.9%)

Table 1: Prominent themes among the videos included race, causes and preventability of deaths, U.S maternal mortality compared to other countries, and if & how healthcare professions addressed the patient's concerns. Distrust in healthcare was more common than trust in healthcare.

292 | Association of Primary Language with Pain and Opiate Use Following Cesarean Birth

Metabel T. Markwei[1]; Noor Joudi[2]; Janet Hurtado[2]; Samantha L. Simpson[2]; Nidhee S. Reddy[2]; Jordan J. Burgess[2]; Elizabeth B. Sherwin[2]; Stephanie A. Leonard[2]; Miriam Schultz[2]; Brendan Carvalho[2]; Pervez Sultan[2]; Katherine Bianco[2]; Danielle M. Panelli[2]
[1]Stanford Healthcare, Palo Alto, CA; [2]Stanford University, Palo Alto, CA

10:30 AM - 12:30 PM

Objective: Non-English speakers are at risk of experiencing healthcare disparities. The impact of patients' primary language on pain assessment and treatment is understudied. This study compared pain scores and opioid use in the first 48 hours post-Cesarean between English and Spanish-speaking patients.

Study Design: We conducted a pilot prospective cohort study that included postpartum patients over 18 years old with singleton pregnancies who underwent a low-transverse cesarean and were literate in English or Spanish. Primary language was self-reported. Pain assessments were based on 1) average daily standardized nursing evaluations and 2) the Short Form Brief Pain Inventory (SF BPI) 24-48 hours postpartum. Opioid use was measured by 1) total milligram morphine equivalents (MMEs) used within 48 hours postpartum, 2) total MMEs during postpartum admission, and 3) MMEs prescribed at discharge. Multivariable multinomial regression models were used to analyze the data.

Results: The study included 134 patients (94 English-speaking, 40 Spanish-speaking). Pain scores were similar in English and Spanish speakers, with the only difference seen related to the distribution of median Day 2 pain scores (English 3/10, Q1-Q3 2-5 versus Spanish 3/10, Q1-Q3 1.75-4.00; p = 0.04, Table 1). No significant differences were identified in median MME use in the first 48 hours postpartum (15 [Q1-Q3 0-38] in English speakers and 9 [Q1-Q3 2-23] in Spanish speakers, p = 0.13, Table 1). Similarly, no differences were seen after adjusting for confounders (Table 2). The median MMEs prescribed at discharge were identical in both groups (113, Q1-Q3 90-135; p = 0.93).

Conclusion: This study found no differences in pain scores or opioid use between Spanish and English-speaking patients post-cesarean. However, this may be related to our institution's efforts to standardize postpartum care, such as using language-concordant staff, in-person interpreters, and uniform opioid prescribing protocols. Additional research among larger cohorts is needed to explore the effectiveness of these standardized protocols in promoting equitable postpartum care.

Table 1. Pain and opiate outcomes compared by primary language in post-cesarean birth cohort, N=134

	N	English N = 94[1]	Spanish N = 40[1]	p-value[2]
Total MMEs used 0-48 hours postpartum	134	15 (0, 38)	9 (2, 23)	0.13
No Opioids used 0-48 hours postpartum	134	28 (30%)	10 (25%)	0.68
Total MMEs during postpartum admission	134	19 (0, 59)	15 (3, 26)	0.19
Total MMEs at discharge	133	113 (90, 135)	113 (90, 135)	0.93
SF BPI B6 Score	134	5.00 (3.00, 7.00)	4.00 (2.00, 6.00)	0.21
Average Day 1 Pain Scores	119	2.00 (1.00, 3.00)	2.00 (1.00, 2.25)	0.74
Average Day 2 Pain Scores	119	3.00 (2.00, 5.00)	3.00 (1.75, 4.00)	0.04
Average Day 3 Pain Scores	111	3.00 (2.00, 4.00)	2.00 (2.00, 4.00)	0.15
Overall Pain Score Averages During Postpartum Admission	133	2.00 (2.00, 4.00)	2.00 (1.00, 3.00)	0.11

293 | Effect of the Dobbs Decision on Sterilization Rates Based on Location Across Wisconsin

Michelle P. Lin[1]; Jacqueline M. Powell[1]; Megan Knutson Sinaise[1]; Janine S. Rhoades[1]; Ronald E. Gangnon[2]; Kara K. Hoppe[1]
[1]University of Wisconsin School of Medicine and Public Health, Madison, WI; [2]University of Wisconsin Department of Population Health Sciences, Madison, WI

10:30 AM - 12:30 PM

Objective: On June 24, 2022, the US Supreme Court's decision in *Dobbs v. Jackson* overturned the federal right to abortion established by *Roe v. Wade*, resulting in a ban on abortions in Wisconsin (WI) for 15 months. This structural barrier to managing pregnancy options may impact contraceptive decision-making. This study aims to examine the effect of the Dobbs decision on the rate of immediate and 3-month postpartum (PP) sterilization procedures in WI based on geographic location.

Study Design: A retrospective cohort of all births from 1/1/2021 to 9/30/2023 in WI was constructed using WI Hospital Association coding data. Pre-Dobbs was defined as 1/1/2021 - 6/23/2022 and post-Dobbs was defined as 6/24/2022 - 9/30/2023. Generalized additive logistic regression models were constructed for the rates of sterilization at birth and at 3 months PP as a function of geographic location (ZIP code). Statistical analyses were performed using the mgcv package in R.

Results: There were 147,877 births–79,806 pre-Dobbs and 68,071 post-Dobbs. There were 6,679 sterilization events at the time of birth (4.5%)–3,591 (4.5%) pre-Dobbs and 3,088 (4.5%) post-Dobbs (RR 1.01, 95% CI 0.96-1.06, p = 0.81). There was weak evidence (p = 0.15) of geographic variation in the impact of the Dobbs decision on the rate of immediate sterilization. There were nominally significant (p < 0.05) elevations in the immediate sterilization rate in 55 ZIP codes in southeast WI and nominally significant reductions in the immediate sterilization rate in 39 ZIP codes in western WI. Similar results were seen for sterilization at 3 months PP.

Conclusion: There was no change in overall sterilization rates across WI after Dobbs. There were subtle changes in the sterilization rate based on location, which contributes to evidence that location of residence impacts receipt of health services. Provisions to increase equitable access to care are needed. Further analysis is needed to determine if factors such as hospital religious affiliation, Medicaid status, or access to a surgical provider may influence this geographical difference in sterilization rates across WI.

294 | Understanding Maternal Infection in Late Preterm Prelabor Rupture of Membranes by Time of Ruptured Membranes

Milli Desai[1]; Dana R. Canfield[2]; Emma Roberts[3]; Timothy Wen[4]; Irene Su[5]; Cynthia Gyamfi-Bannerman[6]
[1]University of California, San Francisco, University of California, San Diego, CA; [2]UC San Diego Health, San Diego, CA; [3]UC San Diego Health, UC San Diego Health, CA; [4]University of California, San Diego, Irvine, CA; [5]UC San Diego Health, La Jolla, CA; [6]University of California, San Diego, San Diego, CA

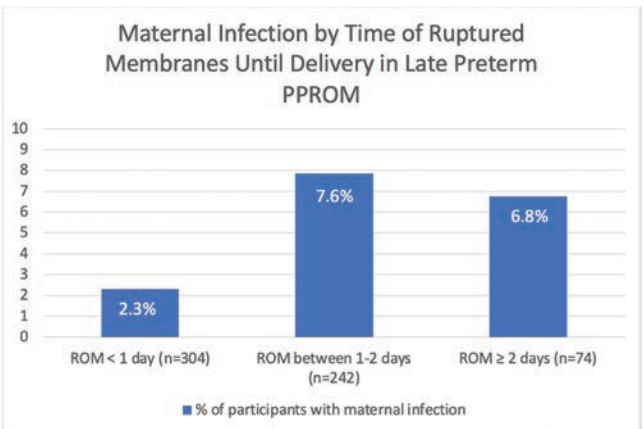
10:30 AM - 12:30 PM

Objective: Expectant management (EM) of late preterm PPROM is thought to improve neonatal outcomes without increasing the risk of neonatal sepsis. European clinical trials have described the median duration of EM as ~3-4 days, and suggest increased risk of maternal infection with EM. However, more data are required to corroborate these findings in a US population and to stratify risk based on time of rupture of membranes (ROM). We investigated the association between the length of time from ROM to delivery and maternal infection after PPROM between 34-36 weeks.

Study Design: Secondary analysis of RCT of singleton pregnancies at risk for preterm delivery between 34-36 weeks. Parent trial included subjects with PPROM occurring ≥34 weeks without signs of infection/plan for induction at ≤12 hours. Primary outcome, maternal infection composite (chorioamnionitis +/- endometritis), was compared in participants with ROM < 1 day (< 24 hours), between 1-< 2 days (24-< 48 hours), and ≥2 days (≥48 hours). Secondary outcomes: mode of delivery and selected neonatal outcomes. Baseline characteristics were compared between groups; multivariable logistic regression models were fit to control for confounders

Results: Of 620 individuals with PPROM, 31 (5.0%) had maternal infection: 2.3% of individuals with ROM < 1 day, 7.8% with ROM between 1-2 days, and 6.8% in those with ROM ≥ 2 days (p = 0.01, Figure 1). Participants with maternal infection had significantly more time with ROM. After adjusting for confounders, ROM between 1-2 days and ≥ 2 days was significantly associated with maternal infection compared to ROM < 1 day (Table). Cesarean delivery, neonatal sepsis, and NICU admission were more common with increasing time from ROM. Neonatal respiratory outcomes were not different between groups.

Conclusion: Maternal infection and cesarean delivery rates increased with time after ROM. Increasing time was associated with neonatal sepsis and provided no short-term respiratory benefits with a trend towards greater NICU admission. Our findings prompt further evaluation of delivery delay after late preterm PPROM in a larger US population.



Maternal outcomes			
	ROM < 1 day (n=304)	ROM between 1-2 days (n=242)	ROM ≥ 2 days (n=74)

295 | Adverse Outcomes Associated with Time from Neuraxial Anesthesia to Delivery: A Retrospective Cohort Study

Minhazur R. Sarker[1]; Dana R. Canfield[2]; Gladys (Sandy) A. Ramos[1]; Angela T. Bianco[3]; Chelsea A. DeBolt[3]
[1]University of California, San Diego, San Diego, CA; [2]UC San Diego Health, San Diego, CA; [3]Icahn School of Medicine at Mount Sinai, New York, NY

10:30 AM - 12:30 PM

Objective: Although studies have shown an inverse association between time from spinal anesthesia to delivery and umbilical

artery pH, these studies have been relatively small or excluded patients receiving other neuraxial anesthesia.

Study Design: Retrospective cohort study from 2013-2019 of singleton, term, non-anomalous births via planned cesarean delivery with neuraxial anesthesia. We assessed rates of adverse pregnancy outcomes associated with different time intervals from neuraxial placement to delivery: 1) < 20 minutes, 2) 20-39 minutes, 3) 40-59 minutes, and 4) ≥ 60 minutes. We further analyzed the time intervals for key portions of the surgical procedure among neonatal umbilical artery pH cohorts: 1) pH ≤ 7.00, 2) pH 7.01-7.10, 3) pH 7.11-7.20, 4) pH 7.21-7.30; and 5) pH ≥ 7.30. All statistical analyses were performed on STATA IC 15.1 and a p-value < 0.05 was considered statistically significant.

Results: Of the 5255 planned cesarean deliveries, 645 (12.3%), 4067 (77.4%), 468 (8.9%), and 75 (1.4%) delivered within 20 minutes, 20-39 minutes, 40-59 minutes, and ≥ 60 minutes from neuraxial anesthesia, respectively. As delivery time interval increased, there was positive association with number of prior cesarean delivery, BMI, and rates of multiparity, chronic hypertension, and diabetes. Increased time from neuraxial placement to delivery was associated with umbilical artery pH ≤ 7.1 and ≤ 7.2, umbilical artery base deficit > 8, and meconium-stained amniotic fluid (all p < 0.05). After adjusting for confounders and using > 20-minutes as a base comparator, increased time from neuraxial placement to delivery remained associated only with umbilical artery pH ≤ 7.2 (adjusted OR 1.83; 95% CI 1.01-3.28). In our secondary analysis, as the pH cohort decreased, there was association with increased time from neuraxial placement to delivery, skin incision to uterine incision, and uterine incision to delivery (all p < 0.01).

Conclusion: Findings suggest that during scheduled cesarean delivery, increased time from neuraxial anesthesia to delivery was associated with lower umbilical artery pH.

296 | Maternal Age and Elective Inductions of Labor in Nulliparous Patients: A Multicenter Cohort Study

Minhazur R. Sarker[1]; Dana R. Canfield[2]; Grace Noonan[3]; Gregory W. Poorman[4]; Barbara Levy[4]; Patrick Edmundson[4]; Ukachi N. Emeruwa[1]; Cynthia Gyamfi-Bannerman[1]; Leah M. Lamale-Smith[3]

[1]University of California, San Diego, San Diego, CA; [2]UC San Diego Health, San Diego, CA; [3]University of California San Diego, San Diego, CA; [4]Dorsata, Inc., Arlington, VA

10:30 AM - 12:30 PM

Objective: We aimed to investigate whether advanced maternal age is associated with adverse outcomes in nulliparous women undergoing elective induction of labor (eIOL).

Study Design: We queried a multicenter outpatient electronic medical record to perform a retrospective cohort study of nulliparous women undergoing eIOL between 39w0d to 40w6d from January 2017 to June 2024. To investigate the relationship between age and eIOL, we created multiple study cohorts: 1) age < 35, 2) age 35-39, and 3) age ≥ 40. We excluded pregnancies complicated by multifetal gestation, oligohydramnios, hypertensive disorders, diabetes requiring treatment, autoimmune disorders, or fetal growth restriction. The primary outcome of interest was the rate of cesarean delivery (CD). Chi-square, ANOVA, and Mann-Whitney U tests were performed to determine statistical significance, and a multivariable logistic regression determined the strength of associations. All statistical analyses were performed on SPSS version 29.

Results: Of the 84,156 eligible patients, 932 met our inclusion criteria with 728 (78.1%), 141 (15.1%), and 63 (6.8%) with age< 35, age 35-39, and age ≥ 40, respectively. We noted a difference in rates of in vitro fertilization (IVF) but otherwise no baseline differences (Table 1). We found an increased incidence of CD with increasing age (25.8% for age< 35, 41.1% for age 35-39, and 55.6% for age ≥ 40, p < 0.01) (Table 2). After adjusting for confounders including pre-pregnancy BMI, diet-controlled gestational diabetes, and IVF and using age < 35 as the base comparator, this relationship remained consistent (age 35-39 adjusted OR 1.82 (95% CI 1.14-2.91) and age ≥ 40 adjusted OR 3.70 (95% CI 1.90-7.22)) (Table 2). Aside from cesarean for arrest of dilation, there were no significant differences noted in the indications for CD or other adverse outcomes (Table 2).

Conclusion: Although similar to trends seen in CD rates with maternal age in the overall population, this specific insight into the nulliparous population undergoing eIOL can be incorporated into counseling for nulliparous pregnancies complicated by advanced maternal age.

297 | Nitrous Oxide: Safe, Effective Labor Analgesia in Patients Treated with Medications for Opioid Use Disorder

Molly R. Siegel[1]; Leah N. Schwartz[2]; Davida M. Schiff[3]; Brinda Kamdar[4]; Sarah N. Bernstein[1]

[1]Massachusetts General Hospital, Division of Maternal Fetal Medicine, Boston, MA; [2]Massachusetts General Hospital and Brigham and Women's Hospital, Boston, MA; [3]Massachusetts General Hospital, Department of Pediatrics, Boston, MA; [4]Massachusetts General Hospital, Department of Anesthesia, Massachusetts General Hospital, MA

10:30 AM - 12:30 PM

Objective: Nitrous oxide (NO) is an effective analgesic option for labor and postpartum laceration repair, but obstetric and anesthesia professional societies caution against its use in individuals treated with systemic opioids, including medications for opioid use disorder (MOUD), due to theoretical concerns about respiratory depression and sedation. We aimed to evaluate the safety of NO for labor analgesia in patients treated with MOUD.
Study Design: We evaluated a retrospective cohort of patients prescribed MOUD who received NO for labor analgesia utilizing an established dataset of opioid exposed pregnancies at an academic urban hospital from 2016-2023. Maternal demographic characteristics, respiratory status, delivery and neonatal outcomes were evaluated with univariate analyses.
Results: 26 patients treated with buprenorphine (17) or methadone (9) were included (Table) from a total of 361 opioid exposed pregnancies (7.2%). Safety data and maternal benefit are summarized in the Figure. There was no difference in maternal mean oxygen saturation before and after initiation of NO ($p = 0.87$). There was no maternal hypoxemia (lowest oxygen saturation 95%), respiratory depression (lowest respiratory rate 16), or documentation of maternal respiratory distress or somnolence related to NO therapy. Pain scores on 10-point scale significantly improved before and after NO (mean pain pre-NO 7 SD 2.2 vs post 3.5 SD 2.8, $p < 0.005$). Three (12.5%) had documented fetal intolerance of labor, all 4 or more hours after NO, which has a five-minute half-life. Six (25%) were admitted to the neonatal intensive care unit (NICU) and 13 (56.5%) to the special care nursery (SCN), most for neonatal abstinence syndrome (15/19, 78.9%). No NICU or SCN admissions were related to NO therapy.
Conclusion: Patients on MOUD are known to require higher doses of pain medication for adequate analgesia and have limited pain control options due to medication interactions. Our data suggests that NO is a safe and effective option for labor analgesia in patients treated with MOUD and should not be withheld.

Table: Participant Characteristics

Characteristic	
Age, mean years (SD)	31.4 (6.3)
Parity	
Nulliparous, n (%)	12 (46.2%)

298 | FGR Resolution Trends by Gestational Age at Diagnosis

Mona M. Makhamreh[1]; Sascha Wodoslawsky[2]; Madeline V. Smith[3]; Emily Ferguson[3]; Samantha Mauser[3]; Lucy Qi[3]; Rodney A. McLaren, Jr., Jr.[4]; Huda B. Al-Kouatly[4]

[1]Baylor College of Medicine, Houston, TX; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA; [4]Thomas Jefferson University Hospital, Philadelphia, PA

10:30 AM - 12:30 PM

Objective: There is little data on the incidence of resolution for fetal growth restriction (FGR) diagnosis. Thus, the objective was to determine the incidence of FGR resolution in women diagnosed with FGR, stratified by the gestational age (GA) at diagnosis.

Study Design: This was a retrospective cohort study at a single institution that included all singleton, non-anomalous pregnancies diagnosed with FGR (defined as estimated fetal weight (EFW) < 10th percentile or abdominal circumference (AC) < 10th percentile) and followed with subsequent ultrasounds. Data were stratified by the GA at FGR diagnosis. Cases were classified as resolved if follow-up ultrasounds demonstrated EFW and AC both at, or above the 10th %. Cases were categorized as persistent if follow-up ultrasounds continued to show FGR without resolution before birth. Data was presented as percentages.

Results: Of the 4900 records reviewed, 666 had FGR. Of these, 637 (95.6%) had follow-up ultrasounds. Among these, 178 (27.9%) resolved before birth. Figure 1 demonstrates the trends of FGR resolution by GA at diagnosis. Table 1 details the course of FGR by GA. The resolution rates varied by gestational age at diagnosis. For cases diagnosed before 20 weeks' GA, the resolution rate was 53.6%, while cases diagnosed with FGR at 36 weeks GA onwards, the resolution rate was 7.4%. Of 178 FGR cases that resolved, only 2 (1.1%) had elevated UA dopplers that later resolved with FGR resolution.

Conclusion: The incidence of FGR resolution varied with the timing of diagnosis. Early diagnosis was linked to higher resolution rates, while later diagnoses were associated with lower resolution rates. These findings offer valuable insights for counseling patients about FGR and emphasize the importance of follow-up ultrasounds in monitoring fetal growth progression.

Figure 1. FGR Resolution Trends by Gestational Age at Diagnosis

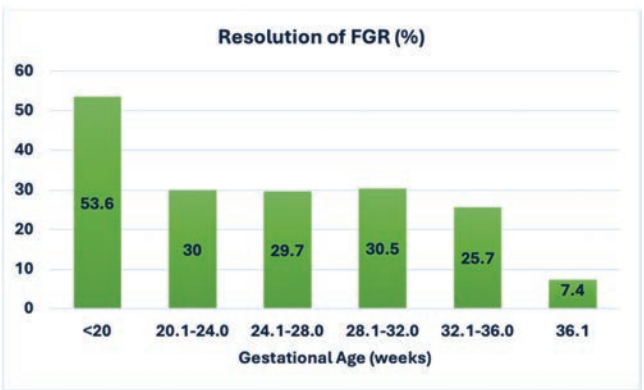

Table.1 FGR Resolution Trends by Gestational Age at Diagnosis

GA (weeks)	FGR cases	FGR that persisted	FGR that resolved	Resolution of FGR (%)

299 | Adverse Outcomes of the Second Twin Associated with Trial of Labor in Early Preterm Births

Moti Gulersen[1]; Erez Lenchner[2]; Mariella F. Toro[3]; Brooke E. Ciampaglio[1]; Huda B. Al-Kouatly[4]; Rodney A. McLaren, Jr., Jr.[4]
[1]Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA; [2]New York University Rory Meyers College of Nursing, New York, NY; [3]Sidney Kimmel Medical College at Thomas Jefferson University, Philadelphia, PA; [4]Thomas Jefferson University Hospital, Philadelphia, PA

10:30 AM - 12:30 PM

Objective: The Twin Birth trial demonstrated that there were no differences in neonatal outcomes between twins who had a trial of labor and those who had a planned cesarean delivery. However, twins < 32 weeks were excluded. Therefore, the objective of this study was to evaluate whether a trial of labor is associated with an increased risk of adverse outcomes of the second twin (Twin B) in preterm births < 32 weeks gestation.

Study Design: Retrospective analysis of the United States Centers for Disease Control and Prevention Natality Live Birth Database (2016-2022). All twin live births between 23 0/7-31 6/7 weeks were eligible for inclusion. Pregnancies initiating prenatal care >16 weeks' gestation, congenital anomalies, and unknown data were excluded. The primary adverse neonatal composite outcome of Twin B was compared between two groups: twin gestations who underwent a trial of labor (TOL) and those who underwent a cesarean delivery without labor (CD). A subgroup analysis of live births between 24 0/7-27 6/7 weeks' gestation was performed. Multivariable logistic regression was performed to adjust for potential confounders. Data were presented as adjusted odds ratios (aOR) with 95% confidence intervals (CI).

Results: Of the 39,769 twin live births included, 12,397 (31.2%) underwent a TOL. Baseline characteristics compared between the two groups are displayed in Table 1. TOL was associated with an increased risk of composite neonatal adverse outcome of Twin B compared to CD (45.1% vs 36.3%; aOR 1.28, 95% CI 1.22-1.35). The association remained statistically significant in twin live births between 24 0/7-27 6/7 weeks' gestation (TOL: 49.9% vs. CD: 47.7%; aOR 1.17, 95% 1.07-1.29).

Conclusion: This study suggests that TOL is associated with an increased risk of adverse neonatal outcomes for Twin B in preterm births < 32 weeks of twin gestation. Providers should consider these risks while counselling this patient population that was excluded from the Twin Birth trial. Future research evaluating outcomes associated with trial of labor in early preterm twins is needed.

Table 1. Baseline characteristics compared between the two groups.

	Trial of labor (n=12,397)	Cesarean delivery without labor (n=27,372)	*P* value
Maternal age, years	29.3 ± 5.7	29.9 ± 6.1	<0.001

**Low event outcome, thus only univariable analysis was performed

300 | Optimizing Antenatal Corticosteroid Timing in Patients at Risk of Spontaneous Preterm Birth

Moti Gulersen[1]; Adam Lin[2]; Ansaf Salleb-Aouissi[2]; Anita Raja[2]; Robert M. Silver[3]; Lynn M. Yee[4]; Judith H. Chung[5]; Ronald J. Wapner[2]; Vincenzo Berghella[1]; David M. Haas[6]; On behalf of the nuMoM2b Network
[1]Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA; [2]Columbia University, New York, NY; [3]University of Utah, Salt Lake City, UT; [4]Northwestern University Feinberg School of Medicine, Chicago, IL; [5]University of California- Irvine, Irvine, CA; [6]Indiana University School of Medicine, Indianapolis, IN

10:30 AM - 12:30 PM

Objective: To develop a prediction model aimed at optimizing the timing of antenatal corticosteroid (ACS) administration in patients at risk of spontaneous preterm birth (sPTB).

Study Design: Secondary analysis of a prospective cohort study evaluating mechanisms and prediction of adverse outcomes in singleton nulliparas (nuMoM2b). All participants who received ACS during their clinical care after presenting with preterm labor or preterm prelabor rupture of membranes (PPROM) were eligible for inclusion. Cases were stratified into 3 groups based on time interval from ACS (first dose) to delivery: < 2, 2-7, and >7 days. Multiclass multivariable logistic regression was utilized to assess clinical characteristics at the time of first dose of ACS as candidate predictors for optimal ACS timing (2-7 days). The first model differentiated patients who delivered 0-7 compared to >7 days after ACS, while the second differentiated those who delivered < 2 compared to 2-7 days after ACS. A leave-one-out approach was used validate our results. Predictive performances were assessed using the area under the receiver operating curve (ROC AUC), precision, and recall scores.

Results: Of 133 participants included, 28 (21.1%) delivered 2-7 days after ACS. Clinical characteristics compared among the 3 groups are displayed in the Table. The first model (0-7 vs. >7 days) achieved an AUC of 0.85, while the second model (< 2 vs. 2-7 days) achieved an AUC of 0.72 (Figure). Top predictors were PPROM, cervical dilation and effacement at admission, maternal age, gravidity, and self-reported non-Hispanic White race and ethnicity. Prediction results across the 3 time intervals (< 2, 2-7, and >7 days) yielded precision scores of 0.68, 0.36, and 0.81, and recall scores of 0.75, 0.32, and 0.80, respectively.

Conclusion: Among nulliparas, clinical characteristics in patients at risk of sPTB can be used to predict time to delivery after ACS with reasonable performance. Incorporating such a model into clinical practice may assist clinicians with optimizing the timing of ACS.

301 | Risk of Ischemic Placental Disease in Pregnant Individuals with Insomnia

Naima E. Ross[1]; Rebecca J. Baer[2]; Scott P. Oltman[2]; Rashmi N. Aurora[3]; Dana R. Gossett[3]; Laura L. Jeliffe-Pawlowski[2]; Justin S. Brandt[3]

[1]NYU Grossman School of Medicine, New York, NY; [2]University of California San Francisco School of Medicine, San Francisco, CA; [3]NYU Langone Health, New York, NY

10:30 AM - 12:30 PM

Objective: While obstructive sleep apnea (OSA) is known to be associated with ischemic placental disease (IPD), we sought to ascertain the association between insomnia and IPD and to compare the magnitude of the associations between these sleep disorders and IPD.

Study Design: We performed a cross-sectional study of liveborn singleton births in California (2011-2020). Birth certificates were linked to hospital discharge records for birthing people and their infants. Insomnia and OSA were identified using ICD-9 and 10 codes. The primary outcome was IPD, defined as hypertensive disorders of pregnancy (HDP), placental abruption, and small for gestational age (SGA) birth. Secondary outcomes included components of IPD and preterm birth. The relative risks and corresponding 95% confidence intervals (CI) were reported by sleep disorders using Poisson regression models.

Results: During the study period, there were 4,145,166 singleton live births with linked hospital and neonatal records. People with sleep disorders in pregnancy were predominantly age 18-34 at delivery, Hispanic, well educated, and BMI 18.5 to < 25 kg/m^2 (Table 1). There was minimal overlap between sleep disorder groups; only 72 (0.7%) of 10,497 patients with sleep disorders had comorbid insomnia and OSA. Patients with insomnia had higher rates of tobacco smoking (13.6% vs 6.6%) and depression (29.6% vs 17.1%) compared to those with OSA. Compared to patients with no sleep disorders, the risk of IPD was 1.7 fold higher (95% CI 1.6, 1.7) for those with insomnia and 1.8 fold higher (95% CI 1.8, 1.9) for those with OSA. The risk of IPD was 2.2 fold higher for those with comorbid insomnia and OSA (95% CI 1.5, 3.2). The magnitude of risk for abruption and SGA birth was greater for insomnia versus OSA, but the magnitude of risk was comparable for the other components of IPD and preterm birth (Table 2).

Conclusion: Similar to OSA, insomnia is associated with an increased risk for IPD and its components, especially abruption and SGA birth. Further study is needed to determine if identification and treatment of insomnia may prevent adverse pregnancy outcomes.

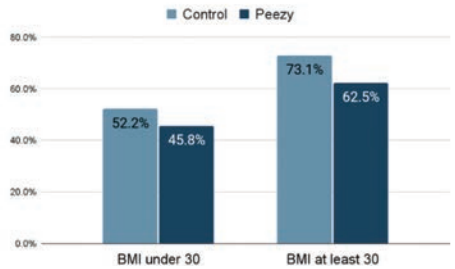
302 | Reducing Contamination of Midstream Voided Urine Specimens in an Obstetric Population: a Randomized Controlled Trial

Namisha Dhillon[1]; Aishah Kothawala[1]; Mark Khemmani[1]; Jasmin Nwachokor[1]; William Adams[1]; Alan J. Wolfe[2]; Thythy Pham[1]; Ann Lal[1]
[1]Loyola University Medical Center, Maywood, IL; [2]Loyola University Chicago, Maywood, IL

10:30 AM - 12:30 PM

Objective: Screening for asymptomatic bacteriuria in pregnancy has been part of routine prenatal care for decades, as untreated bacteriuria can lead to acute pyelonephritis and adverse pregnancy outcomes, typically complicated via the clean catch midstream urine collection method (CC). CC can be difficult to obtain and often results in contamination, making interpretation of a urine culture difficult. The Peezy urine collection device (Peezy) has shown promise in reducing contamination rates compared to CC but has not been studied in the pregnant population. This study aims to compare the rates of contamination in urine cultures collected early in prenatal care between the CC and Peezy urine collection methods.
Study Design: This randomized controlled trial at Loyola University Medical Center enrolled adult, English-speaking pregnant patients < 20-weeks gestation from August 2022 to January 2024. Exclusion criteria were urinary tract anomalies, ongoing antibiotic treatment, or recurrent urinary tract infections. Participants were randomized to either Peezy or CC for urine collection. The primary objective was to compare contamination rates of urine specimens collected using the Peezy versus CC. Logistic regression was used to compare the odds of contamination between Peezy and CC.
Results: 218 patients were included in our analysis. The contamination rate was not different between the 2 groups; 61.3% (n = 73/119) for CC and 52.5% (n = 52/99) for Peezy, (p = 0.19) There was no difference in rates of contamination between CC and Peezy, regardless of BMI status. There was no difference in ASB detection rate between CC and Peezy, p >0.05. Among our patients with contamination of their urine culture, 4% had a repeat sample.
Conclusion: Overall, the Peezy collection device did not demonstrate a significant advantage over CC in detecting ASB and reducing contamination of screening urine cultures in pregnant patients, and our study indicates that the Peezy device is more difficult to use, resulting in more sample collection failures.

Figure 3. *Frequency of urine contamination by assignment and BMI strata among randomized participants (N = 218)*



303 | Pregnancy Termination Outcomes in Singletons with Fetal Anomaly Using Mifepristone and Misoprostol Versus Misoprostol Alone

Natalie R. Anixter[1]; Lihong Mo[2]; Philip Strong[2]; Herman L. Hedriana[2]; Shinjiro Hirose[3]; Amy Powne[2]; Amelia Mclennan[4]
[1]UC Davis School of Medicine, Sacramento, CA; [2]UC Davis Health, Sacramento, CA; [3]UC Davis Health, UC Davis, CA; [4]UC Davis Health, UC Davis Health, CA

10:30 AM - 12:30 PM

Objective: Mifepristone (MIFE) and misoprostol (MISO) in combination has been shown to be more effective for induction terminations than MISO alone in the general population, however outcome data specific to singleton pregnancies with fetal anomaly or genetic disorder is lacking. Here, we compare the effectiveness and safety of the two regimens in this subpopulation.
Study Design: We conducted a retrospective cohort study in 66 induction terminations of singleton pregnancies with fetal anomaly between 2009-2023 at a single tertiary medical center. Induction characteristics and maternal outcomes were compared between inductions using MISO and MIFE (N = 45, 68%) versus MISO alone (N = 21, 32%).
Results: There was no significant difference in incidence of infection, post-partum hemorrhage, retained products requiring dilation and curettage (D&C) and six-week readmission; or median in induction duration, estimated blood loss and antibiotic duration. When stratified by early versus late gestational age (GA) at the time of induction (defined in relation to the median of 24w0.5d), a significant reduction in induction duration was found amongst patients who received both MIFE and MISO versus MISO alone only in the earlier gestational age strata.
Conclusion: The addition of MIFE is safe and has a trend to expedite termination induction when compared to MISO alone, although we did not observe a significance in outcome measures likely due to small sample size. The significant decrease in induction duration seen in the patients who received both MIFE and MISO in the earlier GA stratum supports that MIFE may have stronger effect on reducing induction duration when used earlier in pregnancy. Single center data and rarity of cases were

main limitations. A multicenter or state database should be used to further validate findings.

Table 1. Baseline Characteristics

304 | Maternal COVID-19 is Associated with Increased Proliferation of Placental Cytotrophoblasts

Natalie N. Lanners[1]; Katherine B. Le[1]; Teresa Chou[2]; Rachel Keuls[3]; Dilean J Murillo Gonzalez[3]; Tina Findley[1]; Jeffery A. Goldstein[4]; Ron Parchem[3]; Jacqueline G. Parchem[1]
[1]McGovern Medical School at UTHealth Houston, Houston, TX; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Baylor College of Medicine, Houston, TX; [4]Division of Perinatal Pathology, Department of Pathology, Northwestern University Feinberg School of Medicine, Chicago, IL

10:30 AM - 12:30 PM

Objective: Damage to the maternal-fetal interface can lead to cytotrophoblast (CTB) proliferation. Our objective was to determine how COVID-19 induced inflammation and stress affects CTB proliferation in the placental villi and membranes. **Study Design**: This study analyzed a single-nucleus RNA sequencing dataset and tissue from gestational age-matched COVID-19 (n = 4) and control (n = 4) placentas. We used the cell cycle scoring program in Seurat to quantify the proportion of trophoblasts in S phase (DNA replication phase) by trophoblast cell type in COVID-19 vs. control groups. Tissue immunostaining for Ki67 (proliferation marker) and KRT7 (trophoblast marker) was performed to validate trophoblast proliferation in the chorionic villi and membranes. To assess the consequences of trophoblast proliferation, the thickness of the membrane trophoblast layer was quantified by analyzing 5+ regions of interest per H&E slide using a novel cell-classification program to detect trophoblasts. **Results**: Analysis of RNA sequencing data revealed an increase in the proportion of trophoblasts in S phase in COVID-19 placentas compared to control placentas for villous syncytiotrophoblasts (1.56-fold change [FC]), villous CTBs (1.51 FC), membrane CTBs (1.79 FC), and membrane extravillous trophoblasts (2.48 FC). Consistent with the transcriptomics data, we observed an increased number of Ki67-positive trophoblast nuclei in the villi (mean 13 ± 5 nuclei for COVID-19 vs. 4 ± 1 for control per high power field, p = 0.0171) and membranes (mean 10 ± 2 nuclei for COVID-19 vs. 3 ± 1 for control, p = 0.0006; Fig 1). Increased proliferation was associated with a thickened membrane trophoblast layer (mean 178 ± 97.5 µm for COVID-19 vs. 123 ± 72.8 µm for control, p = 0.0127; Fig 2). **Conclusion**: COVID-19 induced damage in the placenta is correlated with proliferation of CTBs and thickening of the membrane trophoblast layer. Alterations in trophoblast proliferation suggest a compensatory response to inflammatory stress and imply further injury to the maternal-fetal interface.

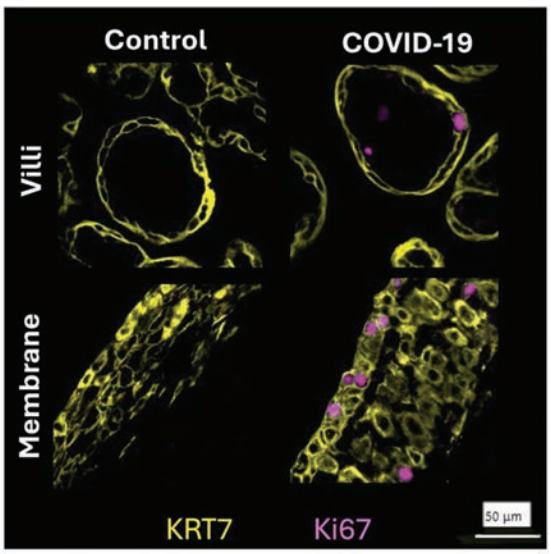

Figure 1. Increased number of Ki67-positive trophoblast nuclei seen in COVID-19 placental villi and membrane tissue compared to control tissue.

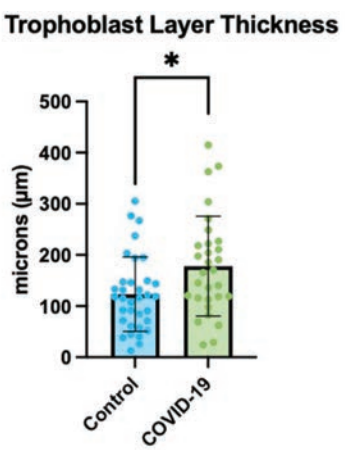

Figure 2. Quantification shows significantly increased trophoblast layer thickness in microns comparing COVID-19 (mean 178 ± 97.5 µm) to control (123 ± 72.8 µm) membranes (p=0.0127).

305 | Fetal Heart Rate Tracings and Adverse Outcomes Among Term Small- versus Appropriate for Gestational Age

Natalie L. Neff[1]; Kristen A. Cagino[2]; Aaron W. Roberts[3]; Rachel L. Wiley[4]; Shareen Patel[5]; Christina Cortes[5]; Kimen S. Balhotra[5];

Khalil M. Chahine[5]; Tala Ghorayeb[5]; Holly Flores[6]; Fabrizio Zullo[7]; Suneet P. Chauhan[8]; Hector M. Mendez-Figueroa[5]
[1]McGovern Medical School at UT Health, Houston, TX; [2]UT Houston, Houston, TX; [3]McGovern Medical School at UTHealth Houston, Houston, TX; [4]University of California, San Diego, San Diego, CA; [5]McGovern Medical School at UTHealth, Houston, TX; [6]University of Texas Health Science Center, Houston, TX; [7]University of Rome La Sapienza, Rome, Lazio; [8]Delaware Center of Maternal-Fetal Medicine at Christiana Care, Delaware, DE

10:30 AM - 12:30 PM

Objective: The purpose of this study was to compare the characteristics of fetal heart rate tracing (FHRT), and outcomes among small- (birthweight [BW] < 10% for gestational age [GA]; SGA) versus appropriate- (BW at 10-89% for GA; AGA) who labored at term (≥ 37 weeks).

Study Design: This is a large retrospective cohort study performed within a 15-month period at a Level IV center. FHRTs of all consecutive deliveries were reviewed by physicians blinded to maternal and neonatal outcomes. The inclusion criteria for the analysis were non-anomalous singletons, who labored at term, and were SGA or AGA using Alexander et al. nomogram. In 20 minute segments, the last 60 minutes of tracing were characterized. Rates of cesarean delivery and composite neonatal adverse outcomes (CNAO) were compared. Chi-square test was used to compare groups, with p-value < 0.05 considered significant.

Results: Of 5,160 consecutive deliveries, 3,029 (58.7%) met the inclusion criteria and among them, 422 (13.9%) were SGA and 2,607 (86.1%) AGA. Baseline characteristics were similar between groups, however SGA compared to AGA were more likely to be nulliparous (52.6% vs. 41.5%, p < 0.01), self-describe as Non-Hispanic Black race (49.8% vs 35.9%, p < 0.01), and have a BMI < 30 kg/m^2 (48.3% vs 35.2%, p < 0.01). There were no differences in FHRT baseline, variability or accelerations. Compared to AGA, SGA was more likely to have prolonged decelerations (1.2% vs. 2.9%, p = 0.04), variable plus late decelerations (53.1% vs. 47.8%, p = 0.04), recurrent decelerations (38.6% vs. 30.9%, p < 0.01), and category II FHRT (76.1% vs. 68.3%, p < 0.01). AGA was more likely to exhibit category I FHRT (p < 0.01). Cesarean delivery for non-reassuring FHRT occurred similarly in the two groups (p = 0.18). CNAO occurred in 0.7% of SGA and 0.8% of AGA neonates (p = 0.90). CMAO occurred in 6.4% of SGA and 7.6% of AGA neonates (p = 0.37).

Conclusion: In our cohort, category II fetal heart rate tracing was significantly more common in small for gestational age neonates, however we were not able to link these abnormalities with adverse outcomes.

Table 1. Individual Features of Fetal Heart Rate Tracings

SGA, small-for-gestational age (birthweight < 10th percentile using Alexander et al nomogram); AGA, appropriate for gestational age (birthweight at 10-89th percentile using Alexander et al nomogram).
[1]Obtained in 201 (47.6%) of SGA and 1227 (47.1%) of AGA.

306 | Assessing the Impact of Digital Patient Navigation Tool for Antepartum Anemia: a Hybrid Effectiveness-Implementation Trial

Natasha R. Kumar[1]; Zoya Pervaiz Butt[2]; Jonathan Calcei[3]; Markolline Forkpa[4]; Olivia Colarullo[5]; Meaghan G. McCabe[2]; Sunni Mumford[2]; Lisa D. Levine[2]; Rebecca F. Hamm[2]
[1]University of Michigan, Ann Arbor, MI; [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [3]Pennsylvania Hospital, Philadelphia, PA; [4]Pennsylvania Medicine Women's Health Clinical Research Center, Philadelphia, PA; [5]Pregnancy & Perinatal Research Center, Department of OBGYN, University of Pennsylvania, Philadelphia, PA

10:30 AM - 12:30 PM

Objective: While intravenous iron infusions (IVFe) are safe and effective in pregnancy, < 50% of patients with severe iron

deficiency anemia (IDA) receive a dose. Here we evaluated the impact of prospectively implementing a digital patient navigation tool for IDA on clinical and patient-reported outcomes.

Study Design: This type 1 hybrid effectiveness implementation trial utilized difference-in-differences (DiD) design to compare the pre- and post-implementation outcomes at an intervention site to a control site. The digital navigation tool, designed using a multi-phase qualitative, patient-centered approach, included logistics, education, and treatment mapping (Figure). While all patients with antepartum IDA could use the tool starting in the 1st trimester, only patients with severe IDA (3rd trimester Hgb < 9.5g/dL) were institutionally eligible for IVFe and thus included in this analysis. The dual primary outcomes were completion of at least 1 IVFe and perceived health competence (validated 8-item survey, score 0-5). Multivariable logistic and linear regression models controlled for differences within sites over time, using interaction terms to estimate DiD. Implementation outcomes included initial use of the tool and continued tool engagement.

Results: 378 patients were included in the study. In-group differences were noted in hypertension history and insurance status over time. While completion of IVFe increased at both sites (66% to 84% of patients at the intervention site vs 78% to 83% at the control site), there was no statistical difference between these increases (DiD 0.12, p-value 0.26; Table). Perceived health competence remained similar at both sites (DiD 0.15, p-value 0.21). There were no significant differences in secondary outcomes. 66% (n = 229) of eligible patients enrolled in the tool, but, of those, only 30% (n = 71) accessed the tool more than once.

Conclusion: While implementation of a digital patient navigation tool for IDA increased IVFe completion by 18%, this result was not significant. Future work optimizing continued tool engagement may further improve clinical outcomes.

Outcomes[a]	Intervention Site		Control Site		DiD Analysis[b]
	Pre-Implementation N=94	*Post-Implementation N=69*	*Pre-Implementation N=138*	*Post-Implementation N=77*	*P value*
Primary Outcomes					
IV iron infusion completion	62 (66.0%)	58 (84.1%)	107 (77.5%)	64 (83.1%)	0.26
Perceived health competence[c]	3.3 (3.0-3.5)	3.3 (3.0-3.4)	3.3 (3.1-3.5)	3.1 (3.0-3.4)	0.21
Secondary Maternal Outcomes					
Change in hemoglobin from nadir to delivery	1.1 (0.3-1.9)	1.6 (0.6-2.4)	1.7 (0.7-2.6)	2.1 (1.1-3.0)	0.23
Postpartum blood transfusion	8 (8.5%)	3 (4.4%)	11 (8.0%)	5 (6.5%)	0.80
Number of IV iron infusions	2 (1-3)	2 (2-3)	2 (2-3)	2 (2-3)	0.87
Time to IV iron initiation (days)	15.5 (7.0-30.0)	20.0 (11.8-41.8)	14.0 (7.0-29.0)	16.0 (9.8-30.3)	0.09

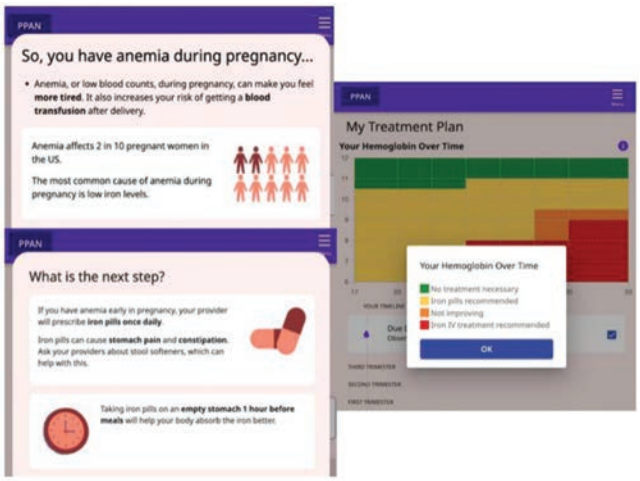
Secondary Neonatal Outcomes					
Preterm delivery	14 (14.9%)	6 (8.7%)	7 (5.1%)	10 (13.0%)	0.06
Neonatal birthweight (grams)[d]	3227.5 (2787.5-3526.3)	3190.0 (2877.5-3433.8)	3215.0 (2917.5-3497.5)	3060.0 (2820.0-3495.0)	0.91

[a] Categorical variables are reported as n(%) and continuous variables are reported as median(IQR).
[b] Multivariable regressions controlled for in-group differences in each hospital (chronic hypertension and insurance status). Difference in difference (DiD) estimator (interaction term) is not shown.
[c] Perceived health competence was measured using the Perceived Health Competence Scale and patient satisfaction was measured using the Patient Satisfaction Questionnaire Short Form.
[d] Twins were accounted for with a repeated measures adjustment in multivariable regressions.



307 | B Cells in Preeclampsia: Hypertension and Endothelial Dysfunction

Miriam Hankins; Nathan Campbell; Murphy Lemon; E. Hawthorne Cleveland; Emma Grace Joyner; Ella Goolsby; Baoying Zheng; Alexandra Demesa; Evangeline Deer; Rachael Morris; Babbette LaMarca

University of Mississippi Medical Center, Jackson, MS

10:30 AM - 12:30 PM

Objective: Pre-eclampsia (PE), new onset hypertension in pregnancy is associated with immune activation, agonistic autoantibodies to the angiotensin II type 1 receptor (AT1-AA), endothelial dysfunction and increased vasoconstrictor endothelin. The AT1-AA stimulates ET-1 and is produced 7 years postpartum. Prolonged production of AT1-AA indicates a memory immune response, specifically mature memory B cells, in the pathophysiology of PE. The objective of this study was to determine if these B cells cause hypertension and endothelial dysfunction via production of AT1-AA.

Study Design: Three hundred thousand placental CD20+ B Cells from normal pregnant (NP) or PE patients were isolated and injected i.p. into nude athymic rats on gestational day (GD) 12. Mini-osmotic pumps containing the AT1-AA inhibitor peptide, 'n7AAc', were inserted on GD14. On GD18, carotid catheters were implanted and mean arterial pressure (MAP) was measured on GD19. Renal Preproendothelin (PPET) was quantified using Real Time-PCR. AT1-AA was quantified using a cardiomyocyte bioassay. A one-way ANOVA was used for statistical analysis.

Results: Participants had similar age, BMI, and gestational age (36±1 (PE) vs 39±0 (control) weeks) at delivery. PE participants had higher mean arterial pressure (MAP) at delivery than controls ($p < 0.05$).

MAP was 104±4 mmHg ($n = 8$) in the recipient rats of NP CD20+ B cells which increased to 123±2 mmHg ($n = 8$, $p < 0.01$) in the recipients of PE B cells. This increase in MAP was lower with 'n7AAC', 114±4 mmHg ($n = 3$, $p = 0.070$), an AT1-AA inhibitor peptide. Renal PPET expression increased by 2.60±0.61 fold (ΔΔct) in PE B cell recipients ($p < 0.05$) compared to NP B cell recipients and tended to be lower in 'n7AAc' treated rats 0.85±0.35 Fold ($p = 0.19$). AT1-AA activity was elevated in the PE B cell recipients (14±2 ΔBPM) compared to NP B cell (1±1 ΔBPM,

$p < 0.01$) and 'n7AAc' treated PE B cell recipients (2±3 ΔBPM, $p < 0.05$).

Conclusion: CD20+ B cells from PE women contribute to hypertension and AT1-AA medicated endothelial activation during pregnancy, thereby supporting an important role for B cells in the pathophysiology of PE.

308 | Gestational Lipid Profile and Perinatal Morbidity: A Pilot Study

Nicola F. Tavella[1]; Camila Cabrera[1]; Dayana Mirzaliev[2]; Nicole Parkas[3]; Camila Johanek[1]; Laura Gilroy[2]; Joanne L. Stone[4]; Angela T. Bianco[1]; Luciana A. Vieira[5]; Samsiya Ona[1]; Nathan Kase[1]

[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Division of Maternal Fetal Medicine, Icahn School of Medicine at Mount Sinai West, New York, NY; [3]Division of Maternal-Fetal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [4]Division of Maternal Fetal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [5]Stamford Hospital, Stamford, CT

10:30 AM - 12:30 PM

Objective: Lipid profile is a key metabolic predictor of risk related to perinatal morbidity. The study's objective was to determine if gestational maternal lipids were associated with composite perinatal morbidity.

Study Design: This was a prospective cohort study of pregnant patients at one urban hospital. We enrolled patients with singleton gestations from July 2022 to February 2024. We excluded patients with hyperlipidemia, hypercholesteremia, and pregestational diabetes. Patients provided two fasting blood samples, one in the second trimester and one in the third trimester. Lipid profile included high-density lipoprotein cholesterol (HDLc), low-density lipoprotein cholesterol (LDLc), very low-density lipoprotein cholesterol (vLDLc), total cholesterol (TC), triglycerides (TG), C-peptides, and free fatty acids (FFA). Composite perinatal morbidity included preterm birth (< 37 weeks' gestation at delivery), gestational diabetes mellitus (GDM), hypertensive disorders of pregnancy (HDP), and a Fenton birth weight percentile < 10% or > 90%. Multivariable logistic regression models estimated odds ratios (aOR) of perinatal morbidity adjusted for maternal age and gestational weight gain.

Results: We included 100 patients in our analyses, and 35 (35.0%) experienced composite perinatal morbidity. Patients with an abnormal second-trimester TG (aOR 1.5) had a higher risk of perinatal morbidity. Patients with an abnormal third-trimester TG (aOR 2.3) had a higher risk of perinatal morbidity. Patients with a greater change in C-peptides (aOR 2.7), and FFA (aOR 36.2) had higher risk of perinatal morbidity. However, patients with a greater change in LDLc (aOR 0.97) had lower risk of perinatal morbidity.

Conclusion: Our results suggest significant associations between gestational lipid levels and composite perinatal morbidity. More detailed analyses among larger prospective cohorts are needed to further investigate these associations and determine the importance of gestational lipids in peripartum risk profiles.

309 | Enhancing Postpartum Contraception with QR code Technology in High-Risk Pregnancies

Nicolina Smith[1]; Shelby Masters[2]; Symone McClain[3]; Gregory Goyert[3]; D'Angela S. Pitts[3]; Sun Kwon Kim[3]; Courtney Rose[3]; Raminder Khangura[3]

[1]Henry Ford Health, Sterling Heights, MI; [2]Henry Ford Health, Grosse Pointe Woods, MI; [3]Henry Ford Health, Detroit, MI

10:30 AM - 12:30 PM

Objective: With the evolving landscape of abortion laws across the United States, the importance of postpartum contraception has increased, particularly for women experiencing high-risk pregnancies requiring antepartum hospitalization. Conversations about contraception are often overshadowed by the myriad of other discussions related to high-risk pregnancies. This is especially significant for birthing persons of color, given the historical context of systemic racism and coercion related to permanent sterilization. This quality improvement project aimed to address these issues by implementing a novel approach using technology to facilitate patient education and discussion about contraception.

Study Design: A standardized quick response (QR) code was placed in patient rooms, linking a comprehensive website detailing birth control options, safety profiles, and side effects each method. Our objective was to increase the establishment of postpartum contraception plans upon discharge.

Results: The project analyzed pregnancies admitted to our institution's antepartum unit, who delivered during the same admission, over two periods: one year before (n = 72) and one year after (n = 98) QR code implementation. Post-implementation, the proportion of patients establishing a birth control plan increased significantly (71.4% vs. 50%, p = 0.006). Postpartum tubal sterilizations rose from 11.1% to 16.3% (p = 0.379) and post-placental IUD placements from 1.4% to 4.1% (p = 0.397). More Black patients chose permanent contraception after QR education implementation (p = 0.016).

Conclusion: This quality improvement project showed significant improvements in addressing contraception methods and highlight the potential of leveraging technology to enhance patient education and empowerment, particularly in high-risk pregnancy settings. This novel proof-of-concept underscores the importance of innovative approaches to address healthcare gaps.

310 | Buprenorphine and Methadone Metabolites in Maternal and Neonatal Milieu: Relationship to Neonatal Opioid Withdrawal Syndrome

Justine Keller; Jonathan Oliva; Mohammad Abdul Motalleb; Nancy Shelley; Nikita R. Peramsetty; Zidong Zhang; Fran Sverdrup; Niraj R. Chavan
Saint Louis University School of Medicine, St. Louis, MO

10:30 AM - 12:30 PM

Objective: To evaluate the relationship between maternal dose of medications for opioid use disorder (MOUD) and levels of their metabolites in maternal and neonatal cord blood as well as the association between metabolite levels and neonatal opioid withdrawal syndrome (NOWS).

Study Design: We undertook a prospective observational study of pregnant patients with opioid use disorder (OUD) seeking prenatal care at a tertiary academic medical center between 7/2022 - 6/2024. Maternal blood was collected during the antepartum period and at the delivery admission in addition to neonatal cord blood. Plasma specimen was extracted and analyzed via LCMS/MS techniques to measure levels of the parent compound (buprenorphine/methadone) and their metabolites [norbuprenorphine, buprenorphine glucuronide, norbuprenorphine glucuronide and 2-ethylidene-1,5-dimethyl-3,3-diphenylpyrrolidine (EDDP)] in each biological pool. Multivariable regression analyses were undertaken to evaluate the relationship between maternal MOUD dose and neonatal cord levels as well as the occurrence of NOWS requiring pharmacologic treatment.

Results: Of the 66 patients recruited, paired maternal-infant dyad specimens were available from 35 patients, including 17 on methadone and 18 on buprenorphine. Overall, 8/35 (22.8%) neonates developed NOWS requiring pharmacologic treatment, including 2/17 (11.7%) in the buprenorphine vs 6/18 (33%) in the methadone group (p = .23). Regression analyses revealed that every 1mg increase in the maternal MOUD dose was associated with a 0.118 ng/ml increase (p< .05) in buprenorphine metabolite level (n = 15) and 1.3128 ng/ml increase (p< .05) of methadone metabolite level (n = 18) in neonatal cord blood. We found no significant differences in maternal or cord plasma metabolite levels among neonates with and without NOWS for any of the metabolites considered.

Conclusion: Our findings reinforce the lack of a relationship between maternal MOUD dose and occurrence of NOWS even at the metabolite level, thereby allaying concerns for impact of MOUD dose on NOWS and providing reassurance for continuation of MOUD in pregnancy.

Table 1: MAT metabolite dose concentrations (ng/mL)

Analyte	Maternal Antepartum Median (IQR)	Maternal Delivery Median (IQR)	Cord Serum Median (IQR)

311 | Perioperative Pain Management and Opioid Prescribing: Impact of Obstetric Enhanced Recovery After Surgery Protocol Implementation

Nikita R. Peramsetty[1]; Jennifer E. Powel[2]; Jessica Lawton[3]; Niraj R. Chavan[1]
[1]Saint Louis University School of Medicine, St. Louis, MO; [2]Hackensack Meridian Jersey Shore University Medical Center, Neptune, NJ; [3]Saint Louis University, St. Louis, MO

10:30 AM - 12:30 PM

Objective: To evaluate the effectiveness of an obstetric enhanced recovery after surgery (ERAS) protocol on perioperative pain management practices and postpartum opioid prescribing among patients undergoing cesarean delivery at a tertiary academic medical center.

Study Design: We conducted a retrospective cohort study of pregnant women undergoing cesarean delivery between April 2020 to April 2022–1 year before and after implementation of an institutional obstetric ERAS protocol. Data regarding

demographic characteristics, pregnancy comorbidities (chronic hypertension, hypertensive disorders of pregnancy, pregestational/gestational diabetes, and tobacco use), as well as improvement science-based process and outcome measures related to narcotic administration, postoperative pain scores, multimodal analgesia, and opioid prescribing at hospital discharge were extracted from electronic records and compared across 2 groups - pre- and post-ERAS implementation. Student t-test, Pearson's Chi-square, Mann-Whitney U, and/or Fisher's exact test were used as indicated. Statistical significance was set at $p \leq .05$.

Results: Demographic characteristics and pregnancy comorbidities were similar across pre (n = 494) and post (n = 432) ERAS implementation groups. Patients in the post-ERAS group had significantly higher pain scores at 6 ($p < .001$) and 12 hours ($p < .001$) but significantly lower scores at 48 hours ($p = .035$) postoperatively. Postoperative acetaminophen use was higher ($p < .001$) in the post-ERAS group with no significant differences in the overall postoperative narcotic use, number of narcotic doses needed and morphine milliequivalents (MME) on postoperative day 2, across both groups. While a similar proportion of patients in each group received narcotic prescriptions at discharge, patients in the post-ERAS group were prescribed fewer number of narcotic pills ($p < .001$) and lesser MME overall ($p < .001$) at hospital discharge.

Conclusion: Implementation of an obstetric ERAS protocol has the potential to facilitate more judicious postpartum opioid prescribing at hospital discharge without compromising postoperative pain control.

312 | Association Between Severe Features of Hypertensive Disorders in Pregnancy on the Outcome of Subsequent Gestation

Nimrod Dori-Dayan[1]; Keren Zloto[1]; Abraham Tsur[2]; Rakefet Yoeli-Ullman[1]; Shali Mazaki-Tovi[3]; Keren Ofir[1]; Sonya Bar-Adon[1]; Eyal Sivan[1]; Baha M. Sibai[4]; Michal Fishel Bartal[5]

[1]Sheba Medical Center, Ramat Gan, HaMerkaz; [2]Sheba Medical Center, Ramat Gan, Tel Hashomer, Israel, Ramat Gan, HaMerkaz; [3]Department of Obstetrics and Gynecology, Sheba Medical Center, Tel HaShomer, Ramat Gan, HaMerkaz; [4]McGovern Medical School at UTHealth Houston, Houston, TX; [5]UTH Houston & Sheba Medical Center Israel, Houston, TX

10:30 AM - 12:30 PM

Objective: History of hypertensive disorders of pregnancy (HDP) is associated with adverse outcomes in subsequent pregnancy. The effect of the severity of the disease on subsequent pregnancy is not well described. This study aims to investigate the outcome of subsequent pregnancy after a diagnosis of HDP and to evaluate the impact of disease severity on recurrent HDP (rHDP) rate and adverse outcomes.

Study Design: This was a retrospective study conducted at a single tertiary care center between 2012 and 2024. Individuals with singleton pregnancy complicated by HDP and a documented subsequent pregnancy were included. Subsequent composite adverse pregnancy outcomes included: rHDP, preterm birth, fetal growth restriction, and placental abruption. Multivariable regression models were used to estimate odds ratio (OR) and 95% confidence interval (95% CI) for rHDP.

Results: During the study period, 1778 individuals had a history of HDP and a documented subsequent pregnancy. Of them, 1724 (97%) met inclusion criteria, 1607 (90%) without severe features (SF) vs 117 (10%) with SF (Table 1). Overall, HDP reoccurred in 36% of pregnancies, and the rate of HDP and HDP with SF was significantly higher in the previous HDP with SF compared to without SF (58% vs 35% $p < 0.01$, and 40% vs 6%, $p < 0.01$, respectively). The rate of subsequent adverse pregnancy outcomes was higher in the previous HDP with SF compared to without SF (66% vs 42%, $p < 0.01$). Nulliparity (63.6% vs 53.7%, OR 0.7, 95% CI 0.57, 0.87) and a later gestational age at HDP diagnosis (37.3 vs 36.3 weeks, OR 0.97, 95%CI 0.95, 0.99) at first pregnancy were associated with a lower rHDP rate. History of preterm birth (15.5% vs. 7.6%, OR 2.05, 95% CI 1.53, 2.76) and HDP with SF (10.8% vs 4.5%, OR 1.79, 95% CI 1.19, 2.7) were associated with a higher rate of rHDP (Table 2).

Conclusion: Four out of ten individuals with a history of HDP will have adverse outcomes in their subsequent pregnancy. History of severe disease, earlier gestational age at diagnosis and preterm birth in the first pregnancy were associated with a higher rate of rHDP.

10:30 AM - 12:30 PM

Objective: Data regarding the counseling of pregnant people with prior intrahepatic cholestasis of pregnancy (IHCP) on subsequent pregnancy outcomes are based on a questionnaire survey (Williamson, BJOG 2004) and a subgroup analysis of 4 patients (Gonzalez, Journal of Hepatology, 1989). Our objectives were to ascertain the recurrence risk of IHCP (rIHCP), evaluate potential risk factors for rIHCP and adverse outcomes in subsequent pregnancy.

Study Design: This was a retrospective study conducted at a tertiary care center between 2012 and 2024. We included individuals with a history of IHCP and a subsequent documented pregnancy. Individuals with multiple gestation were excluded. The recurrence rate of IHCP maternal and neonatal outcomes were evaluated. Multivariable regression models were used to estimate odds ratio (OR) and 95% confidence interval (95% CI) for rIHCP.

Results: During the study period, 303 individuals had a history of IHCP and a documented subsequent pregnancy with 264 (87%) meeting eligibility criteria. Median gestational age at prior delivery of 37.4 (IQR 37, 38.4), with 67 individuals (26%) delivered preterm (< 37 weeks). Overall, IHCP reoccurred in 35% (95% CI 29-41%) of pregnancies, with 17% having preterm birth. History of in vitro fertilization (4.3% vs 14.6%, OR 0.26, 95%CI 0.08, 0.84) at first pregnancy was related to a lower recurrence rate for IHCP. Elevated liver enzymes at first pregnancy (OR 2.47, 95%CI 1.34, 4.54) and history of IHCP < 34 weeks were associated with a higher rate of rIHCP (OR 2.13, 95% CI 1.17,3.8).

Conclusion: Approximately 1 in 3 individuals with IHCP will develop IHCP in subsequent pregnancy. IHCP onset at < 34 weeks and elevated liver enzymes at first pregnancy were associated with a higher rate of recurrence. This information can be used for counseling and management of such pregnancies, for guidelines and planning trials.

314 | Fetoscopic Laser Outcomes by Placenta Location

Nkechinyelum Ogu[1]; Mariana Espinal[2]; Joy Ito[3]; Catherine Redden[3]; William S. Marriott[3]; Amir Alhajjat[3]; Bethany Stetson[1]; Aimen F. Shaaban[3]
[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]for the Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD; [3]Chicago Institute for Fetal Health, Chicago, IL

10:30 AM - 12:30 PM

Objective: Among complicated monochorionic twin gestations requiring fetoscopic intervention, it is unclear whether placenta locations affect surgical outcomes and is important in patient counseling. Thus, we aim to compare procedural and pregnancy outcomes from selective fetoscopic laser procedures for complicated monochorionic twin pregnancies by placenta location.

Study Design: We conducted a retrospective analysis of all fetoscopic laser procedures completed in monochorionic twin pregnancies at a single, large fetal center from November 2017 to May 2024. Outcomes were compared by placenta location based on preoperative ultrasound: anterior and posterior. Operative, obstetric, and neonatal outcomes were abstracted from the electronic medical record. Subgroup analysis was completed for twin pregnancies complicated by twin-to-twin transfusion syndrome (TTTS). Bivariate analyses were completed.

Results: Of the 126 fetoscopic laser procedure cases completed, 40.5% had anterior placenta and 59.5% had posterior placenta. The most common indication was selective fetoscopic laser photocoagulation (SFLP) for management of TTTS (108), followed by laser dichorionization for sFGR (18) and diagnostic fetoscopy (8). The total operative time was longer in cases with anterior placenta (75 vs. 68 minutes, respectively, p = 0.04), however laser time was similar (3.42 vs. 2.83 minutes, respectively, p = 0.61). There was no difference in rates of perioperative complications or preterm prelabor rupture of membranes (Table 2). There was no difference in donor or recipient demise or neonatal survival for cases completed for either TTTS by placenta location (Table 2).

Conclusion: Anterior placenta location is associated with increased operative duration for fetoscopic procedures, yet obstetric and neonatal outcomes are similar for procedures completed for both TTTS and sFGR regardless of placenta location.

Table 1: Clinical and operative factors in fetoscopic laser procedures by placenta location

315 | Group B Streptococcus Colonization: Is it a Risk Factor for Autism Spectrum Disorder of Offspring?

Noa Leybovitz Haleluya[1]; Tamar Wainstock[2]
[1]Soroka Medical Center, Meitar, HaDarom; [2]Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom

10:30 AM - 12:30 PM

Objective: The mechanisms driving autism spectrum disorder (ASD) development are not clear. Some obstetric conditions such as infections during pregnancy were linked to ASD, perhaps by affecting in-utero brain development. Group B *Streptococcus* (GBS) is a well-known organism which colonize the genital tract. GBS colonization during pregnancy and near delivery is associated with short-term infant morbidity, sepsis and mortality. Nevertheless, data regarding long-term pediatric effects is scarce. We aimed to study the association between GBS colonization in pregnancy and the risk of ASD development later in childhood.

Study Design: We performed a population based retrospective cohort analysis, in which ASD morbidity was compared between offspring to mothers with GBS colonization in pregnancy and offspring of mothers with negative or unknown GBS status. All singletons born between the years 2005 and 2021 at a single tertiary medical center were included in the study. Infants with known malformations, multiple gestations, and cesarean deliveries were excluded. Diagnoses were retrieved from a predefined set of ICD-9 codes, recorded in community-based clinics

and hospitalization records. Cox proportional hazards model was used to adjust for confounders to assess association between GBS colonization and the risk of ASD.

Results: The study population included 146103 singletons. Of them, positive GBS was recorded in 2225 (1.5%) women. Long-term autism rates were comparable between both groups (0.4% vs. 0.5%, OR 0.99, 95% CI 0.53-1.87, p = 0.995; Table). The cumulative incidence of long-term autism morbidity was higher in the group of positive GBS status (Figure, Log-rank p = 0.03). However, using a Cox proportional hazards model, controlling for maternal age, offspring gender and ethnicity, no association was noted between GBS colonization and ASD of offspring (Table, Adjusted HR = 1.51, 95% CI 0.78-2.93, p = 0.218).

Conclusion: GBS colonization in pregnancy is not independently associated with an increased risk for long-term autism of the offspring.

Table – ASD morbidity in the offspring in positive GBS and negative or unknown GBS groups

	Positive GBS %(2225)	No GBS %(143878)	Crude OR (95% CI)	Adjusted HR* (95% CI)
Autism morbidity	0.4%(10)	0.5%(648)	0.99(0.53-1.87)	1.51 (0.78-2.93)

*Using a Cox proportional hazards model, controlling for maternal age, offspring gender and ethnicity

316 | Balloon Induction in Women with Previous Cesarean Delivery: Maternal and Neonatal Outcomes

Noa Leybovitz Haleluya[1]; Alla Saban[2]; Reli Hershkovitz[3]; Adi Y Y. Weintraub[4]; Yael REICHER[5]; Tamar Eshkoli[4]

[1]Soroka Medical Center, Meitar, HaDarom; [2]Soroka University Medical Center, Beer Sheva, HaDarom; [3]Soroka medical center, Soroka medical center, HaDarom; [4]Soroka University Medical Center, Soroka University Medical Center, HaDarom; [5]Soroka Medical Center, Beer Sheba, HaDarom

10:30 AM - 12:30 PM

Objective: Patients planning a trial of labor after a previous cesarean (TOLAC) occasionally need to deliver before onset of labor due to maternal or fetal conditions and may require induction. There are concerns that induction might reduce chances of vaginal delivery and may increase the risk of uterine rupture.The ideal method for induction in this population have not been well-established and evidence is inconclusive. Balloon induction gained popularity due to minimal side effects. However, the adverse effects of balloon induction in women with previous CD remains unclear. We aim to study the influence of balloon induction on maternal and neonatal adverse effects in women with previous CD

Study Design: A population-based retrospective cohort study was conducted, including all term (≥37 weeks of gestation) singleton pregnancies that underwent balloon induction between February 2020 and January 2022, who had one previous CD at a tertiary medical center. Women who underwent non-mechanical induction, as well as those with no trial of labor, were excluded. Maternal, neonatal and obstetrical complications were compared based on balloon induction of labor exposure. Logistic regression models were used to adjust for confounders.

Results: The study population included 2352 deliveries. Of these, 285 (12.1%) underwent balloon induction of labor, while 2067 (87.9%) did not. Maternal and neonatal complications in both groups are shown in Table 1. The rate of vacuum delivery was significantly higher in the induction group (7.0% vs. 4.1%, p = 0.022). All other complications, including emergent CD, low Apgar scores, low cord Ph, and neonatal intensive care unit (NICU) admission were comparable between both groups. Logistic regression, controlling for maternal age, parity, ethnicity, epidural analgesia, and gestational age, showed that the association between balloon induction and vacuum delivery is not independently significant (Table 2: adjusted OR 1.32, 95% CI 0.78-2.25, p = 0.298).

Conclusion: Balloon induction of labor at term in women with previous one CD is not associated with obstetrical and neonatal complications.

Table 1:

Maternal and neonatal outcomes of women with prior cesarean delivery with and without balloon induction of labor

Characteristics	With balloon induction of labor n=285 (%)	Without balloon induction of labor n=2,067 (%)	p

317 | Failure Rate of First Trimester Medical Termination of Pregnancy, After Bariatric Surgery–Retrospective Study

Shay Ingram[1]; Uri Kaplan[2]; Gali Garmi[2]; Noah Zafran[2]
[1]The Ruth and Bruce Rappaport Faculty of Medicine, Technion, Haifa, Israel, Haifa, Hefa; [2]Emek Medical Center, Afula, Israel, Afula, HaZafon

10:30 AM - 12:30 PM

Objective: First trimester termination of pregnancy (TOP) is a common event. Approximately 50% of TOP are medical. Bariatric surgery (BS) is divided into restrictive procedures (adjustable gastric banding or sleeve gastrectomy) and malabsorptive procedures (mini gastric bypass or roux-en-Y gastric bypass). The objective of this study was to compare failure rate of first trimester medical TOP, among women who underwent BS prior to TOP, with women without previous BS.

Study Design: This Retrospective study, conducted on data collected between January 2019 and April 2024, in a single hospital in Israel. Our protocol enables TOP up to 9 weeks of gestation and utilizes oral mifepristone 200 mg followed by buccal misoprostol 800 mg, 48 hours apart. The study cohort consisted of consecutive women who underwent any BS undergoing medical TOP. The control group, matched for gestational age, had no history of BS, were collected in a 1:4 ratio. Exclusion criteria included malabsorption disorder. The primary outcome was failure rate measured by any medical or surgical intervention further needed to achieve complete TOP.

Results: We identified 405 women, 81 of them underwent BS prior to TOP. Restrictive BS was performed in 43 (53.1%) women and malabsorptive BS was performed in 38 (46.9%) women. Failure rate was comparable between the study and the control group (15 (18.5%) vs. 37 (11.4%), p = 0.09). Odds ratio, adjusted for smoking status, number of previous spontaneous abortions, number of previous TOP and previous cesarean section, for failure in women post BS was 1.95, CI 0.99-3.84. Failure rate was comparable between restrictive and malabsorptive BS (9 (23.7%) vs. 6 (14.0%), p = 0.26). Odds ratio, adjusted for less than 2 years elapsing from BS, for failure in women post restrictive BS relative to malabsorptive BS was 3.6 CI 0.81-16.25.

Conclusion: Overall failure rate of medical TOP in women who underwent BS is similar to women who had no history of BS. Failure rate was comparable for both surgical approaches.

318 | Adverse Childhood Experiences are Associated with Higher Opioid use and Pain After Cesarean Delivery

Noor Joudi[1]; Janet Hurtado[1]; Samantha L. Simpson[1]; Nidhee S. Reddy[1]; Jordan J. Burgess[1]; Metabel T. Markwei[2]; Elizabeth B. Sherwin[1]; Stephanie A. Leonard[1]; Miriam Schultz[1]; Brendan Carvalho[1]; Pervez Sultan[1]; Katherine Bianco[1]; Danielle M. Panelli[1]
[1]Stanford University, Palo Alto, CA; [2]Stanford Healthcare, Palo Alto, CA

10:30 AM - 12:30 PM

Objective: Adverse childhood experiences (ACEs) have been linked with increased post-operative pain and opioid use, yet they have been understudied in the postpartum period. We evaluated whether ACEs were associated with opioid use and pain after cesarean delivery (CD).

Study Design: This was a prospective cohort study of pregnant people who delivered a singleton liveborn infant via CD with neuraxial anesthesia in 2023-2024. We included those aged 18-55 years, literate in English or Spanish, and with no second stage of labor. The exposure was a history of any ACEs, derived from a validated questionnaire administered 24-48 hours (h) post-CD. The primary outcome was opioid use 0-48h post-CD in milligram morphine equivalents (MME). Pain was measured from average numerical rating pain scores (every 4h over 72h) and a validated questionnaire (Short-Form Brief Pain Inventory, SF-BPI) 24-48h post cesarean. Multivariable multinomial regression models were used, adjusting for confounders. Sample size was determined using an effect size of 20%.

Results: Among 134 participants, 55 (41%) had ACEs and 79 (59%) did not. Despite similar postpartum lengths of stay, median total MMEs during the postpartum admission was 23 (Q1-Q3 13-62) in people with ACEs and 11 (Q1-Q3 0-44, $p = 0.01$) in those without ACEs. In the first 48h, compared with the 1st (lowest) quartile of MME use, people with ACEs were more likely to use amounts in the 2nd [adjusted odds ratio (aOR) 7.97; CI 2.43-26.2], 3rd (aOR 4.41; CI 1.26-15.5), and 4th (highest) MME quartiles (aOR 3.60; CI 1.09-11.8) than people without ACEs (Table 1). Pain scores also differed; those with ACEs rated their average pain as 3/10 compared with 2/10 in those without ACEs (p = 0.02, Table 1, Figure 1).

Conclusion: Postpartum people with ACEs used more opioids and experienced more pain after CD compared to people without ACEs. These results highlight the importance of integrating trauma-informed care into peri-operative protocols, which could improve pain management and reduce opioid reliance after CD for people with a history of ACEs.

Figure 1: Distribution of opioid use (A) and average pain score (B) after cesarean among postpartum people with and without adverse childhood experiences (ACEs), N=134

[b] Adverse childhood experiences (ACEs), defined using a validated questionnaire.
[c] For the primary outcome (quartile of MME use 0-48 hours postpartum), results obtained from multivariable multinomial regression model adjusting for age, parity, whether labor preceded the cesarean, BMI, insurance type, education level, and primary spoken language as demographic, clinical, and socioeconomic confounders. Presented as adjusted odds ratios (aOR) with 95% confidence intervals (CI) and p-values.
[d] Secondary outcomes compared using Wilcoxon rank sum tests. Reported as median (Q1, Q3). Pain score=numerical pain score 0-10.

319 | Mild Fundal Pressure versus Vacuum Extraction to Shorten the Second Stage of Labor

Omri Dominsky[1]; Roza Berkovitz-Shperling[2]; Itamar Gilboa[3]; Yariv Yogev[4]; Anat Lavie[2]
[1]Tel Aviv Sourasky Medical Center, Tel Aviv Sourasky Medical Center, HaMerkaz; [2]Tel Aviv Sourasky Medical Center, Tel Aviv Sourasky Medical Center, Tel Aviv; [3]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel-Aviv, Tel Aviv; [4]Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv University, Tel Aviv Sourasky Medical Center, Tel Aviv

10:30 AM - 12:30 PM

Objective: To compare the efficacy and safety of mild fundal pressure (FP) versus vacuum extraction (VE) for shortening the 2nd stage of labor and the impact on maternal and neonatal outcomes.

Study Design: Retrospective cohort study in a university affiliated medical center with approximately 12,500 annual deliveries (2022-2024). Women with singleton pregnancies requiring shortening of the 2nd stage for medical reasons (non-reassuring fetal heart rate or prolonged 2nd stage) were divided into 2 groups: those who received FP and those who underwent VE. Deliveries involving both VE and FP were excluded. Decisions were made based on physician's preference.

Mild FP is performed at our hospital by trained obstetricians only after patient consent. The primary outcome was the duration of the 2nd stage of labor. Secondary outcomes included maternal and neonatal complications: 3rd–4th degree tears, postpartum hemorrhage, Apgar score, umbilical arterial cord pH < 7.1, and hospitalization duration.

Results:

1. During the study, 15,088 delivered vaginally, 1365 (9%) had FP and 624 (4.1%) underwent VE.
2. The 2nd stage of labor was shorter in the FP group (P< 0.001).
3. The rate of 3rd–4th degree tears was higher In the VE group (P = 0.005).
4. Hemoglobin decline and maternal hospitalization duration were lower in the FP group (P< 0.001).
5. Neonatal outcomes showed no significant differences in Apgar scores. However, the FP group had a lower incidence of umbilical arterial cord pH < 7.1 and shorter neonatal hospitalization (P< 0.001).
6. Multivariate analysis showed significant increased risk in the VE group for 2nd stage duration (aOR 1.3), 3rd–4th degree tears (aOR 4.4), Hemoglobin decline (aOR 1.4), maternal hospitalization (aOR 1.0), and umbilical artery cord pH < 7.1 (aOR 3.5).

Conclusion: Mild FP compared with VE may be associated with better maternal and neonatal outcomes, including a shorter 2nd stage of labor, fewer 3rd–4th degree tears, less hemoglobin decline, better umbilical cord pH, and shorter hospitalization for both mother and neonate. It is a safe and effective method when performed by a trained physician.

320 | Postpartum Hypertension Screening at Newborn Visits and Impact on Postpartum Outcomes

Paige M. Anderson[1]; Amanda Krauss[2]; Adrianna Phillips[3]; Julia Pantalone[3]; Ronit Kar[4]; Brianna Blake[4]; Gysella Muniz Pujalt[3]; Malamo Countouris[5]; Alisse Hauspurg[6]

[1]University of North Carolina Department of Obstetrics and Gynecology, Chapel Hill, NC; [2]University of Michigan Medical Center, Ann Arbor, MI; [3]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA; [4]University of Pittsburgh School of Medicine, Pittsburgh, PA; [5]University of Pittsburgh Medical Center, Pittsburgh, PA; [6]Alpert Medical School of Brown University, Providence, RI

10:30 AM - 12:30 PM

Objective: To assess how a novel maternal postpartum hypertension (HTN) screening program at newborn visits partnered with a remote blood pressure (BP) management program would impact maternal care utilization and outcomes.

Study Design: This is a prospective quality improvement initiative with previously described feasibility at a large academic primary care center that serves a majority non-White (68%) and publicly insured (77%) population. Maternal vital sign screening was performed by pediatric clinic staff. Elevated BP (≥ 140/90 mmHg) triggered algorithms that involved contacting an on-call Maternal-Fetal Medicine or Cardiology physician and/or enrollment into a remote BP management program. Controls were postpartum individuals with newborns receiving care at the same clinic on days when screening was not offered. Postpartum outcomes and care utilization data were compared between the two groups.

Results: Of 140 screened individuals and 248 controls, the screened group was more likely to be diagnosed with new postpartum HTN (16.0% vs. 8.2%; p = 0.049). The screened group was more likely to be initiated on anti-hypertensive medication postpartum (31.0% vs. 26.0%; p = 0.56) and had lower rates of Emergency Department (ED) visits (17.9% vs. 25.0%; p = 0.11) and readmissions (5.7% vs. 8.5%; p = 0.32) compared with controls, though not statistically significant. Postpartum visit rates were similar between groups (65.7% vs. 65.7%; p = 1.0).

Conclusion: Maternal HTN screening in a newborn clinic partnered with a remote BP management program was associated with higher diagnostic rates of postpartum HTN with subsequent treatment, without concomitant increases in ED visits or readmissions among a racially and socioeconomically diverse population. Screening for postpartum HTN during newborn visits may improve diagnosis and treatment of postpartum HTN in an at-risk population, however, more targeted interventions are likely needed to increase attendance at postpartum visits.

Table 1. Rates of Hypertension and Postpartum Care Utilization in Control v. Screened Group

	CONTROL GROUP N= 248	SCREENED GROUP N=140	P-VALUE
HTN DIAGNOSIS BY DISCHARGE OF DELIVERY, N (%)	65 (26.2%)	46 (32.9%)	0.16
ON ANTI-HYPERTENSIVE MEDICATIONS PRIOR TO DISCHARGE, N (%)	18 (28%)	9 (20%)	0.33
RATES OF POSTPARTUM HTN DIAGNOSIS, N (%)	15 (8.2%)	15 (16.0%)	**0.049**
RATES OF POSTPARTUM ANTI-HYPERTENSIVE INITATION, N (%)	16 (26%)	16 (31%)	0.56
POSTPARTUM VISIT ATTENDANCE, N (%)	163 (65.7%)	92 (65.7%)	1.00
EMERGENCY DEPARTMENT VISITS, N (%)	62 (25.0%)	25 (17.9%)	0.11
READMISSIONS RATES, N (%)	21 (8.5%)	8 (5.7%)	0.32
REMOTE BP MONITORING ENROLLMENT WITH HTN DIAGNOSIS, N (%)	51 (64%)	40 (66%)	0.82
REMOTE BP MONITORING PARTICIPATION, N (%)	44 (86%)	34 (85%)	0.86

10:30 AM - 12:30 PM

Objective: Intraamniotic infection (IAI) is a contraindication to cerclage placement. However, the benefit of amniocentesis to diagnose subclinical IAI must be weighed against the risks of the procedure and the limited accuracy of rapid amniotic fluid test results. We aimed to determine perinatal outcomes associated with amniocentesis compared to no amniocentesis before mid-trimester cerclage.

Study Design: This is a secondary analysis of the international collaborative for cerclage longitudinal evaluation and research (IC-CLEAR), a study that included singleton pregnancies without major anomaly and with mid-trimester cerclage placed at eight

different institutions in the United States and Colombia from June 1st, 2016 to June 1st, 2020. Inclusion criteria were ultrasound- or exam-indicated cervical cerclage at gestational age (GA) >16 weeks. The comparison group consisted of those who did not undergo amniocentesis. The primary outcome was latency to delivery following cerclage. Cerclage indication, maternal baseline characteristics, and maternal/neonatal outcomes were compared between groups in a multivariable analysis.

Results: In this study, a total of 468 participants who had a cerclage placed during pregnancy met inclusion criteria: 119 had an amniocentesis and no evidence of IAI before cerclage placement. Those who underwent amniocentesis had a mean latency to delivery of 12.5 weeks compared to 13.7 weeks without amniocentesis (p = 0.087). In a multivariable regression analysis, amniocentesis was not an independent contributor to decreased latency to delivery after accounting for cerclage indication, GA at cerclage placement, and cervical length at cerclage placement. The rate of premature rupture of membranes < 34 weeks was not significantly different between the two groups (21.2.% vs 21.0%, p = 0.853).

Conclusion: In this analysis, we did not find that amniocentesis before cerclage impacted latency to delivery compared to patients who do not undergo amniocentesis. These findings can be used to guide clinical counseling regarding amniocentesis before cerclage placement.

Jauk[1]; Alysia Campbell[1]; Donna Campbell Dunn[1]; Justin Leach[1]; Martha S. Wingate[1]; Janet M. Turan[1]; Casey Brian[4]; Jeff M. Szychowski[5]; Alan T. Tita[1]; Waldemar A. Carlo[1]; On behalf of the P3 EQUATE Network and POPPY Community Advisory Board

[1]University of Alabama at Birmingham, Birmingham, AL; [2]Florida State University, Tallahassee, FL; [3]ConnectionHealth, Birmingham, AL; [4]West Virginia University, Morgantown, WV; [5]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL

10:30 AM - 12:30 PM

Objective: Successful interventions for perinatal disparities are sparse. Our objective was to conduct a pilot randomized controlled trial(RCT) to determine the feasibility of randomizing participants in a health equity intervention trial and whether participants were accepting of the interventions.

Study Design: Single-center, parallel 2x2 RCT including participants of Non-Hispanic Black race/ethnicity, between 16-49 years, 8^0-22^6 weeks gestational age(GA), and residing in resource poor communities defined as Area Deprivation Index(ADI) 60-100. Participants were individually randomized to 1 of 4 arms: usual care(UC), UC+digital health intervention(DHI), UC+community health worker(CHW), or UC+DHI+CHW; providers were blinded. The primary outcome for this pilot was acceptability of the intervention defined as participant's affirmative response to: "I would recommend the care I received to someone in a similar situation". Secondary outcomes included participant's intervention satisfaction (1-10 scale, 10 highest satisfaction), number of prenatal care (PNC) visits and clinical outcomes.

Results: Forty participants were randomized from July-October 2023: 10 UC and UC+CHW, 9 UC+DHI, 11 UC+CHW+DHI. All participant data were analyzed. Median age, GA at enrollment and ADI were 29 years, 14 weeks, and 90; 78% were parous, 18% married, 60% ≤high school diploma, and 80% publicly insured. Of those randomized to UC, UC+DHI, UC+CHW, and UC+CHW+DHI, 70%, 89%, 80% and 91% recommended the care they received, respectively. Participants randomized to CHW who completed the satisfaction score were extremely satisfied(100% 10/10; n = 18); DHI participants were also highly satisfied (median satisfaction score 8, IQR 7—10, n = 18). Participants attended a median 11 PNC visits and delivered at a median GA of 37 weeks, but 5 (13%) experienced pregnancy loss and 25% were admitted to the neonatal intensive care unit(Table).

Conclusion: Participants randomized in a pilot health equity intervention trial reported high rates of satisfaction with DHI and CHW interventions, lending support for a large RCT powered for key clinical outcomes.

Table. POPPY Pilot Trial: Acceptability, Satisfaction and Clinical Outcomes					
	Overall	UC n=10	UC+DHI n=9	UC+CHW n=10	UC+CHW+DHI n=11
Acceptability and Satisfaction Outcomes					
Outcome	**n (%) or Median (Q1-Q3)**	**n (%) or Median**			
Community Health Worker (CHW)					
Recommend CHW to others§	18/21 (86%)			8 (80%)	10 (91%)

Abbreviation Key: CHW = community health worker, DHI = digital health intervention, NICU = neonatal intensive care unit, UC = usual care. §18 exposed to CHW responded, 8 UC+CHW and 10 UC+CHW+DWI; *Intervention rating: Scale 1-10 with 10 being the most satisfied. ^18 exposed to DHI responded, 8 UC+DHI and 10 UC+CHW+DWI; †2 missing responses; **6 missing responses.

323 | Nuchal Translucency as a Predictor of Fetal Growth Restriction in the Absence of Genetic Abnormalities

Rachel P. Gerber[1]; Lizelle Comfort[1]; Frank I. Jackson[1]; Riley Thompson[2]; Rajeevi Madankumar[1]; Matthew J. Blitz[1]
[1]Northwell, New Hyde Park, NY; [2]Zucker School of Medicine at Hofstra/Northwell, New Hyde Park, NY

10:30 AM - 12:30 PM

Objective: To evaluate association between first trimester nuchal translucency (NT) and fetal growth restriction (FGR) in fetuses without suspected aneuploidy or structural anomaly.

Study Design: Singleton gestations with NT of at least 2mm with available third trimester fetal growth scan were included. Multifetal gestations, gestations with abnormal genetic screening, and fetuses with identified genetic or structural anomaly were excluded. Primary outcomes were diagnosis of FGR, as defined by abdominal circumference or estimated fetal weight less than 10th percentile, and severe FGR, as defined by abdominal circumference or estimated fetal weight less than 3rd percentile. NT values were stratified by measurements: 2-2.5mm, 2.5-3mm, and > 3mm and were controlled for crown rump length (CRL) at the time of nuchal translucency measurement. Linear regression was used to analyze first trimester NT and third trimester fetal growth.

Results: 5394 patients met inclusion criteria. Of these, 83.7% had a NT of 2-2.5mm, 10.3% 2.5-3mm, and 6% > 3mm. Compared to fetuses with a normal NT (2-2.5mm), those with borderline (2.5-3mm) and elevated (>3mm) NT did not have a significantly higher incidence of FGR, though an association was seen. When adjusting for CRL, there was also no significant increased likelihood of FGR with an NT at the 95th percentile or higher (OR 1.06, 0.64-1.67). When evaluating severe FGR, there is an association between borderline NT (2.5-3mm) (OR 2.03, 0.75-4.69) and elevated NT (>3mm) (OR 4.77, 1.99-10.26) with a higher incidence of severe FGR. There is also a significant association when adjusting for CRL: NT measurement at the 95th percentile or higher was strongly associated with severe FGR (OR 3.29, 1.58-6.49).

Conclusion: Elevated nuchal translucency is associated with third trimester severe FGR, in the absence of known aneuploidy or structural fetal anomaly. This association is seen both at borderline NT measurements (greater than 2.5mm) and when adjusting for CRL with NT measurements at the 95th percentile or higher.

324 | Perceived Barriers and Facilitators to Implementation of Group Prenatal Care Among Michigan Prenatal Care Providers

Rachel A. Clark[1]; Harini Pennathur[2]; Kenechukwu Odenigbo[1]; Shayla Parthasarathy[1]; Lisa Kane Low[3]; Michelle Moniz[3]; Alex Peahl[4]
[1]University of Michigan Medical School, Ann Arbor, MI; [2]Texas A&M University School of Engineering Medicine; [3]University of Michigan, Ann Arbor, MI; [4]Michigan Medicine, Ann Arbor, MI

10:30 AM - 12:30 PM

Objective: To characterize the use of group prenatal care across the state of Michigan and describe implementation barriers and facilitators.

Study Design: Stakeholders in prenatal care in Michigan were identified using systemic web searches and snowball sampling. Stakeholders representing 19 clinics completed semi-structured interviews or a survey regarding clinic operations, including basic clinic information, if group prenatal care was offered, and barriers and facilitators of implementation. Open-ended questions regarding barriers and facilitators were summarized using qualitative content analysis.

Results: In total, 19 clinics representing 8/10 regions completed the survey, representing an average of 403 patients per site. One Federally Qualified Health Center of the 19 (5%) clinics interviewed offered group prenatal care. Stakeholders cited social support and efficiency as perceived advantages to a group prenatal care model, and thought that staff and patient buy-in could be important facilitators. Disadvantages included scheduling, space, patient discomfort sharing personal information in a group setting, and issues protecting confidentiality as perceived. Further barriers to implementation included insufficient number of patients, space, and lack of trained providers.

Conclusion: Though many obstetric care stakeholders have identified group prenatal care as an important intervention for improving care experience and outcomes, only one clinic in our sample offered this service. Future work is needed to understand how to overcome the notable barriers to implementing group prenatal care in diverse clinic types and practice settings.

Table 1: Facilitators and Barriers to Group Prenatal Care

	Themes	Sample Quote
Facilitators	Staff buy-in	"just a matter of having the right interested and motivated individuals"
	Patient buy-in	"[challenging] coordinating a group of people with similar gestational ages with interest in doing group prenatal care"
Barriers	Insufficient number of patients	"scheduling and finding enough patients"
	Space	"finding a space for them to all meet in the same place"
	Lack of trained providers	"[staffing] a midwife able to do that or a nurse or medical assistant to be able to facilitate"

325 | Metabolic Dysfunction-Associated Steatotic Liver Disease is Associated with Glucose Intolerance in Pregnancy

Rachel Meislin; Jeanette Rios; Lauren Alpert; Rhoda Sperling; Scott Friedman; Keith Sigel; Sonam Rosberger; Michal A. Elovitz; Tatyana Kushner
Icahn School of Medicine at Mount Sinai, New York, NY

10:30 AM - 12:30 PM

Objective: Metabolic dysfunction-associated steatotic liver disease (MASLD) comprises ultrasound-identified steatotic liver disease (SLD) along with cardiometabolic risk factors. Retrospective data suggests MASLD is independently associated with gestational diabetes (GDM). While both MASLD and GDM have implications for long-term maternal health outcomes, prospective research on MASLD in pregnancy is limited. The objective of this study was to prospectively determine the association between MASLD and GDM.

Study Design: A prospective cohort of pregnant individuals (n = 916) were assessed for MASLD and obstetrical outcomes. During obstetrical sonogram at 18-22 weeks for enrolled participants, images of the maternal liver were captured and evaluated by a radiologist for the presence and grading of SLD. GDM was diagnosed using ACOG guidelines. Logistic regression models evaluated the association of presence and severity of MASLD with GDM.

Results: High grade SLD (grade 2-3) was identified in 34 (4%) patients. The median (IQR) age was 29 (8); Most participants self-identified as Black race (41%) and/or Hispanic ethnicity (48%). 87% of SLD patients met criteria for MASLD with BMI ≥25. A total of 182 (22%) of participants screened positive (≥140 mg/dL) on a 1-hour glucose challenge test (GCT) and 107 (12%) were diagnosed with GDM. Patients with Grade 2/3 SLD were more likely to be of Hispanic ethnicity, have BMI≥25, and screen positive on GCT ($p < 0.01$Table 1). In unadjusted analyses, high grade SLD was associated with GDM (OR 1.8 [0.7-4.1]) and positive GCT (OR 4.0 [1.8-8.7]). In multivariate linear regression analyses controlling for age and BMI, the association between SLD and GDM was attenuated ($p > 0.05$).

Conclusion: Findings from a large, diverse, prospective cohort illustrate altered glucose metabolism with advanced steatosis. This effect was attenuated by BMI and age. Early screening for GDM in patients with hepatic steatosis should be considered. Pregnancy represents an ideal window for MASLD screening, and research into future metabolic health following a diagnosis of MASLD/SLD in pregnancy is needed.

Table 1. Demographic and outcome data by presence of high grade SLD

	Overall	SLD Grade 2-3	Grade 1- No SLD	p value
	n = 916 (%)	n = 34 (%)	n = 882 (%)	
Age (median, IQR)	29 (8)	32 (7.5)	29 (9)	0.03
Race and ethnicity				
Non-Hispanic Black	380 (41.5)	5 (14.7)	347 (39.3)	<0.001
Non-Hispanic White	53 (5.8)	2 (5.9)	52 (5.9)	
Hispanic ethnicity	539 (58.8)	24 (70.5)	515 (58.4)	0.02
Body mass index (BMI) (kg/m²) (median, IQR)	28.7(7.4)	32.2(5.4)	28.5 (7.5)	<0.001
BMI ≥25	697 (76.1)	33 (97)	664 (75.2)	<0.001
History of GDM	52 (5.7)	4 (11.8)	48 (5.1)	0.32
Pregestational DM	3 (0.3)	3 (0.3)	0	
1 hour GCT ≥ 140*	182 (22.3)	14 (51.8)	168 (21.3)	<0.001
1 hour GCT (median, IQR)*	112 (40)	141 (33)	112 (12.7)	<0.001
Fasting glucose >95± (n=196)	33 (16.8)	4 (26.7)	29 (16.0)	<0.001
Gestational DM	107 (11.7)	8 (23.5)	99 (11.2)	0.05

Continuous variables were compared with Student's t test. Categorical variables were compared using a Chi squared test or Fisher exact test.
*n= 817 participant data available, n=27 had SLD grade 2-3, n= 790 without SLD
±n=196 participants had 3 hour GTT data available

326 | Risk Factors for Myocardial Infarction and Coronary Artery Dissection in Pregnancy and Postpartum

Emerson Cobbley[1]; Stephanie Schreiber[2]; Rachel K. Harrison[3]; Renata Mukai[3]; Suwan Mehra[4]; Calla Holmgren[3]
[1]North Park University, Chicago, IL; [2]Endeavor Health, Evanston, IL; [3]Advocate Health Care, Advocate Health Care, IL; [4]Advocate Childrens Hospital, Advocate Childrens Hospital, IL

10:30 AM - 12:30 PM

Objective: Analyze the risks for myocardial infarction (MI) and coronary artery dissection (CAD) in a modern cohort of pregnant and postpartum subjects using a large national database.

Study Design: Retrospective case-control study of pregnant and postpartum subjects from the National Inpatient Sample database through HCUP/AHRQ from 2017-2021 using inpatient ICD-10 coding, encompassing antepartum, delivery, and postpartum admissions. We first identified the incidence of MI/CAD from 2017 to 2021 and compared the baseline characteristics of those who experienced MI/CAD to those who did not. Chi2 analysis and student's t-tests were used for comparison. A backwards regression was used to analyze the impact of individual patient characteristics and history on likelihood of MI/CAD.

Results: Over the 5 year period, a total of 1,159 pregnant subjects had an MI or CAD (0.03%). The incidence increased from 2017 to 2021 (0.027% to 0.034%, $p = 0.036$). Those who experienced MI/CAD were more likely to be older, publicly insured, in the lowest income bracket, and identify as non-Hispanic black. They were also more likely to be obese, use tobacco, have pregestational diabetes and experience a hypertensive disorder of pregnancy, in particular preeclampsia with severe features, superimposed preeclampsia, and HELLP or eclampsia. In regression analysis, age, non-Hispanic black race, obesity, tobacco use, DM, hypertensive disorders of pregnancy, public insurance or self-pay, and the lowest income quartile remained associated with MI/CAD in the pregnant and postpartum period.

Conclusion: The incidence of MI/CAD in the peripartum period increased steadily from 2017 to 2021. This increase was associated with identifiable risk factors including age, non-Hispanic black race, obesity, tobacco use, DM, hypertensive disorders of pregnancy, public insurance or self-pay, and the lowest income quartile.

327 | Evaluation of "Low Threshold" Early Diabetes Screening Practices at Mahec

Rajesh Paladugu; Lisa M. Foglia; Traci Carson; Katherine Grette
Mountain Area Health Education Center (MAHEC), Asheville, NC

10:30 AM - 12:30 PM

Objective: This study aims to evaluate if a stepwise approach to early gestational diabetes (GDM)screening, using A1c followed by fasting plasma glucose (FPG), is more predictive of early and overall treatment as compared to an approach using A1c alone. Additionally, if this stepwise approach was more predictive of early insulin use than the algorithm utilized in Sweet Success (SS) guidelines.

Study Design: This was a retrospective cohort study of pregnant patients undergoing GDM screening in the first trimester between 2011-2023 at a single institution. Patients underwent stepwise testing with an initial A1C measurement followed by FPG if A1C was between 5.0 and 6.4. Patients were treated as GDM if both tests were elevated. Patients were then classified into four groups based on A1C and FPG results (table 1). The primary outcomes were the need for insulin at any point in pregnancy and gestational age at initiation.

Results: 887 patients met criteria for inclusion (Table 1). Demographic characteristics were similar across all groups. Patients in group 2 were more likely than patients in group 1 to require insulin during pregnancy (32 v 4.2%, $p < 0.0001$) and required earlier initiation (20 v 32 wks, $p < 0.0001$). Additionally, the stepwise algorithm had a higher specificity for identification of patients who would not require insulin prior to 28 weeks as compared to the SS algorithm (95 v 88%) though the sensitivity was lower (48 v 65%). Negative predictive values were similar (97 v 98%). PPVs for both algorithms were low (32 v 22%).

Conclusion: Stepwise diabetic screening using a lower A1c threshold followed by FPG was associated with overall insulin use and with earlier initiation. However, the overall number of patients who were captured using this technique was low. The poor PPV for both algorithms for insulin initiation prior to 28 weeks when patients would be captured by traditional GDM screening casts doubt on the clinical utility of universal early screening. This is consistent with the results of a recent RCT on early treatment of GDM and revised ACOG guidelines.

Group	n(%)	A1C	FPG	Stepwise Algorithm	Sweet Success Algorithm
1	704 (79)	5.0-5.6	<92	Pass	Pass
2	52 (6)	5.0-5.6	≥92	Fail	Pass
3	117 (13)	5.7-6.4	<92 OR no FPG	Pass	Fail
4	13 (1.4)	5.7-6.4	≥92	Fail	Fail

*Result of screening by SS algorithm, had supplemental screening not been completed.

Algorithm	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
Stepwise	44.44	94.90	26.67	97.61
Sweet Success	66.67	87.59	18.32	98.44

328 | Standardizing Induction Management: a Mixed-Methods Evaluation of the Clinician Perspective

Rebecca F. Hamm[1]; Rinad S. Beidas[2]; Julia E. Scymczak[3]; Sindhu K. Srinivas[1]; Samuel Parry[4]; Lisa D. Levine[1]
[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Feinberg School of Medicine, Northwestern University, Chicago, IL; [3]University of Utah, Salt Lake City, UT; [4]University of Pennsylvania, Philadelphia, PA

10:30 AM - 12:30 PM

Objective: Standardizing labor induction (IOL) practices may reduce cesarean and improve obstetric disparities. IOL protocols focus on active management with recommendations for frequent cervical exams, early amniotomy, and intervention when no cervical change is made. Here, we aimed to characterize the clinician perspective on feasibility and acceptability of a standardized IOL protocol.

Study Design: This sequential mixed-methods study surveyed clinicians after implementation of a standardized IOL protocol at 2 sites in 2021. We used the 4-question validated Acceptability of Intervention Measure (AIM; total 4-20) as well as a single acceptability item (1-5) for each of 8 specific protocol components (Table). Total AIM scores were grouped into tertiles. Clinicians in the top (High Acceptability) and bottom (Low Acceptability) tertiles were invited to participate in a semi-structured interview. Topics included (a) acceptability of protocol components, (b) barriers/facilitators to adherence, and (c) strategies for overcoming barriers. Interviews were coded using an integrated approach with high inter-rater reliability ($k = 0.83$).

Results: 104 clinicians (57 physicians, 43 RNs, 4 CNMs) completed the survey. Median total AIM score was 15/20 IQR [12-19]. Protocol components with highest acceptability scores focused on not continuing "futile" cervical ripening and interventions for active labor dystocia. Components with less approval included frequent cervical exams and early amniotomy. 24 clinicians were interviewed (12 High, 12 Low Acceptability). Clinicians described barriers to implementation of less acceptable components, including staff/time constraints, best practice disagreements, and concerns around patient aversion. Clinicians recommended more education around the protocol's safety/efficacy, and communication about anticipated IOL steps to overcome barriers.

Conclusion: This work describes the clinician perspective on standardizing IOL and provides concrete recommendations to overcome implementation barriers.

Table: Induction protocol components with associated quantitative and qualitative data

Protocol component	% "comfortable"* N(%)	Exemplar Quote(s) for components with <70% "completely comfortable"
1. If Foley balloon did not expel prior to 12 hours, remove it and initiate/continue oxytocin.	72 (72.3)	*NA*
2. Misoprostol can be repeated for up to 6 and for no >24 hours. If remains in latent labor, initiate oxytocin.	73 (73.7)	*NA*
3. If it has been >6 hours since misoprostol placement, and AROM not yet feasible with no window for another misoprostol, start oxytocin.	56 (57.7)	**Barrier**: *"There is this kind of perpetuated fear of Pitocin in the community"* **Strategy**: *"Open dialogue with the patients and reeducation is the best strategy for patient hesitation"*
4. Latent labor exams at least every 4h.	43 (43.9)	**Barrier**: *"We're all fighting the personnel battle"* **Strategy**: *"...dividing and conquering as a team and then being sure to circle back"*
5. If patient is ≥4cm dilated and has intact membranes, recommend amniotomy.	41 (41.4)	**Barrier**: *"I think there's different provider preferences; they don't necessarily want to follow that step."* **Strategy**: *"I think we just have to go back to the evidence that we have that supports early amniotomy."*
6. Active labor exams at least ever 2h.	49 (50.0)	**Barrier**: *"The barrier is the census and acuity of the floor"* **Strategy**: *"From nursing it's helpful to just touch base with either the chief resident or the attending and be like hey, it's been an hour and 45 minutes are we going to check her in about 15 minutes. So, that I'm doing it ahead of time"*
7. If 2 exams the same in active labor 2h apart and already s/p A/SROM but not on oxytocin, start oxytocin.	73 (74.5)	*NA*
8. If 2 exams the same in active labor 2h apart and already s/p A/SROM and on oxytocin without IUPC in place, place IUPC.	62 (63.3)	**Barrier**: *"I found a lot of resistance to that component."* **Strategy**: *"Just educating them about the safety of an IUPC has been a little bit helpful."*

*"Comfortable" or "Completely comfortable" with this recommendation on Likert scale

329 | An "Equity in Labor Outcomes Dashboard": a 3-Phase Participatory Mixed-Methods Approach to Development

Rebecca F. Hamm; Emily G. Gleason; Mary C. Steele; Eashwar Kantemneni; Lisa D. Levine; Sindhu K. Srinivas

University of Pennsylvania Perelman School of Medicine, Philadelphia, PA

10:30 AM - 12:30 PM

Objective: Equity dashboards, showing individual clinician outcomes by patient race, may confront clinicians with their own care disparities, driving change. Here, we aimed to develop an acceptable obstetric Equity Dashboard.

Study Design: This 3 phase participatory mixed-methods study developed an Equity in Labor Outcomes Dashboard. In Phase 1, focus groups of obstetric clinicians were divided into nurses, trainees, and attending physicians at 2 sites, to understand: (1) experience with and perspectives on receiving individualized feedback on patient outcomes by race, (2) outcome attribution in a shift- and team-based labor unit, (3) which outcomes to include, (4) ideal distribution method and frequency, and (5) potential impact on care. Transcripts were coded using a structured approach with high inter-rater reliability (k >0.8). Phase 2 convened a multidisciplinary committee to synthesize Phase 1 results and develop a draft Dashboard. Phase 3 surveyed clinicians at the same sites to critically optimize the draft.

Results: In Phase I (1/2023), 5 focus groups (n = 18) were conducted, including nurses, CNMs, OBGYN, family medicine, and MFMs. Most had never received individual outcome feedback before (Table 1). While participants found receiving individual data by patient race "potentially uncomfortable," it was also highly desired. Participants recommended an outcome be attributed to a given clinician if there were "meaningful patient interactions" [e.g. writing a note during labor and/or delivery participation]. Recommended outcomes included cesarean, ICU, hemorrhage, and patient-centered outcomes like birth trauma. Clinicians requested to receive the Dashboard with individual outcomes compared to unit averages by email q4 months alongside a disparity reduction toolkit for actionable response. Phase 2 (4/2023) developed a draft Dashboard. 85 clinicians completed the Phase 3 survey (8-10/2023; Table 2), with high acceptability, affirming Phase 2's design.

Conclusion: This work generated an Equity in Labor Outcomes Dashboard acceptable to clinicians. Its potential to drive reduced disparities should be tested.

Table 1: Sampling of Phase 1 focus topics, with associated themes and exemplar quotes

Interview Topic	Interview Themes	Exemplar Quote
Prior experience with and general perspectives on receiving individualized feedback by patient race	Lack of prior experience	*"not that I know… [there is no] shared data anywhere centrally that talks about our C-section rates"*
	Strong desire for this information	*"I would love to know how I perform as an individual"*
	Potential for discomfort	*"It will feel uncomfortable to get data that says you treat patients inequitably … but I also hope that most of us would want to know that, and recognize that we have unconscious biases that might be influencing our care, and we would want to know that so we can try to fix it."*
Attribution of outcomes	Outpatient care impacts inpatient care	*"That outpatient aspect of things is … really critical, because I think … depending on who sends the patient up, like that really colors how the team receives the information"*
	Even one interaction can meaningfully impact outcomes	*"Because even if you're involved in someone's care 75% of the time, an outcome can be someone that was in the room for a hot second or just happenstance."*
	Trainees and nurses may not have a say in care decisions	*"We are at a hospital where residents are training under the supervision of attendings. And so how much of it is a decision that you're making and the attending is like sounds good … versus an attending making a decision that you don't necessarily agree with, but you are doing it, because you are learning from them."*
Potential to impact care	Potential for use to self-evaluate over time	*"This will prompt self-reflection"*
	Needs a planned actionable response	*"I think the goal probably is both to like identify where you're at and also to figure out ways to improve and to change too. So, I think the numbers on their own are good. I think it's the next component too that's like just as important."*

Table 2: Phase 3 Dashboard optimization survey responses. Distributed to all labor and delivery clinicians at 2 labor sites in a single academic health system.

Role	
Nurse, CNM, or NP	38 (44.7)
Trainee	19 (22.4)
Attending physician	28 (32.9)
Race	
Black	7 (8.2)
White	70 (82.4)
Asian	6 (7.1)
Other/declined to answer	5 (5.9)
Latinx ethnicity	4 (4.7)
Acceptability score[a,b]	16 [15-18]
Should outcomes be attributed to a clinician based on:[c,d]	
You were the last outpatient clinician to see the patient	38 (57.6)
You saw the patient for at least 3 outpatient visits	51 (77.3)
You were the admitting clinician	43 (65.2)
You documented on the patient during labor	49 (74.2)
You were on the delivering team	57 (86.4)
How would you most prefer clinician-level data be presented?[c]	
Outcomes are attached by clinician name and full dashboard distributed to all	9 (13.6)
Each clinician receives an anonymous code so only they can identify their own outcomes; full dashboard listed by code distributed to all	27 (40.9)
Clinicians are shown only their own outcomes compared to an averaged, overall rate	30 (45.5)
If you were to see disparities in your own outcomes, what resources/steps would you want to be available to you?[c,e]	
Nothing I can figure it out myself	1 (1.5)
Link to resources for reducing bias in healthcare and evidence-based practices for improving outcomes	37 (56.1)
Peer group meetings to advance equity in decision-making in obstetrics	39 (59.1)
Meet individually with a coach/mentor/leader to discuss and make personalized plan	47 (71.2)

330 | American Heart Association Blood Pressure Classification and Subsequent Risk of Preeclampsia

Rebecca Horgan[1]; Erkan Kalafat[2]; Elena Sinkovskaya[1]; Alfred Z. Abuhamad[1]; George R. Saade[1]

[1]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [2]Koc University Hospital, Istanbul, Istanbul

10:30 AM - 12:30 PM

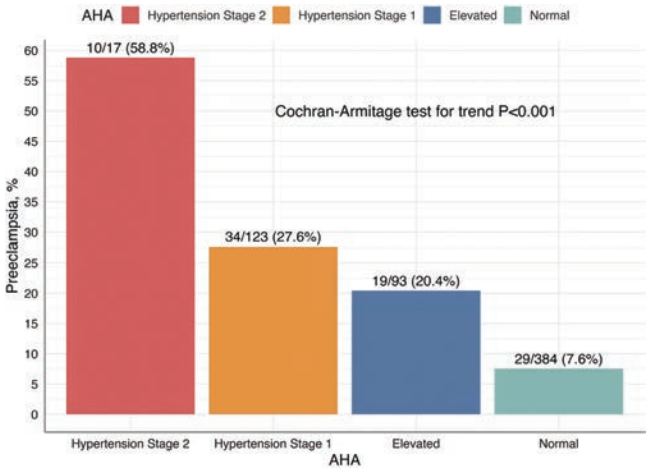
Objective: To assess the relationship between 1st trimester blood pressure (BP) classified according to American Heart Association (AHA) guidelines and risk of preeclampsia.

Study Design: This was a prospective longitudinal cohort study which enrolled patients at ≤ 13+6 weeks' gestation. Data was obtained by trained research coordinators. At the 1st trimester study visit, baseline BP was classified per AHA guidelines (normal, elevated, stage I hypertension (HTN), stage II HTN). The primary outcome was the incidence of preeclampsia, defined per ACOG criteria. Cox-proportional hazard model was used to investigate the association between HTN categories and development of preeclampsia.

Results: 617 patients were included. 92 developed the primary outcome. In the first trimester, 62.2% of patients had normal BP, 15.1% had elevated BP, 20.0% had stage I HTN, and 2.8% had stage II HTN. The incidence of preeclampsia increased based on AHA classification (7.6%, 20.4%, 27.6%, 58.8%, P< 0.001, Figure 1). Compared to AHA normal BP in the 1st trimester, elevated (aHR: 2.55, 95% CI: 1.42- 4.56, P = 0.002), stage I (aHR: 3.52, 95% CI: 2.10-5.89, P< 0.001) and stage II HTN (aHR: 7.58, 95% CI: 3.48-16.5, P< 0.001) had significant association with preeclampsia after adjusting for risk factors, race, and body-mass index. The Cox-regression model using AHA classification had a significantly higher concordance index compared to the model using the current classification of a singular 140mm/Hg systolic and 90mm/Hg diastolic cut-off (0.71±0.028 vs. 0.56±0.019, P< 0.001). The significant associations remained in sensitivity analyses excluding pregnancies with pre-gestational hypertension (7.4%, 20.2%, 26.2%, 33.3%, P< 0.001; 0.67±0.031 vs. 0.51±0.011, P< 0.001).

Conclusion: First trimester BP per AHA guidelines had significant independent association with preeclampsia. AHA classi-

fication outperformed HTN diagnosis based on 140/90 mm/Hg cut-off, with all categories having more than the 10% risk of preeclampsia that was used by the USPSTF to recommend low dose aspirin.



331 | Adjustment of Uta-pi for Maternal Baseline Characteristics Does not Improve Predictive Performance for Preeclampsia

Rebecca Horgan[1]; Erkan Kalafat[2]; Elena Sinkovskaya[1]; Alfred Z. Abuhamad[1]; George R. Saade[1]
[1]Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA; [2]Koc University Hospital, Istanbul, Istanbul

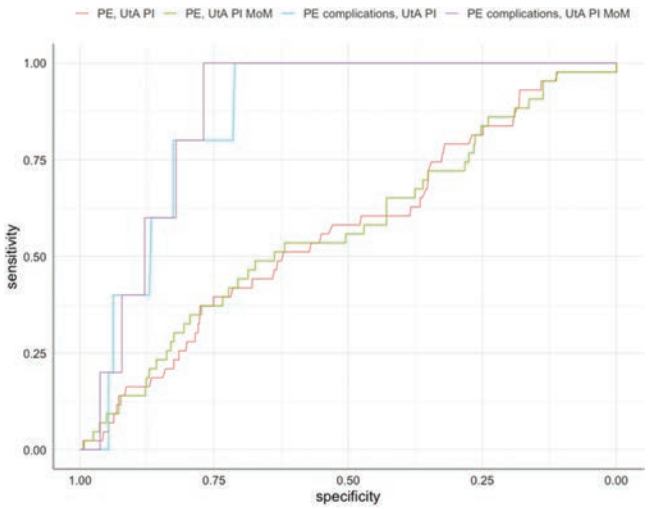
10:30 AM - 12:30 PM

Objective: The evidence regarding first trimester uterine artery (UtA) Doppler as a predictor of preeclampsia (PE) is contradictory. UtA perfusion is sensitive to various factors which were not considered previously. Our objective was to determine whether first trimester UtA Doppler measurements, adjusted for maternal baseline characteristics, predict PE.

Study Design: This was a prospective cohort study which enrolled patients at ≤ 13+6 weeks' gestation. Patients were followed throughout pregnancy and data obtained by trained research coordinators. At the 1st trimester study visit, UtA Doppler pulsatility index (UtA-PI) was obtained. Generalized Additive Models for Location, Scale and Shape were used for modelling UtA-PI, which was found to have distributional properties fitting gamma distribution. Predictive capabilities of raw and maternal characteristics adjusted multiple of median UtA-PI values were tested with area-under the curve values and concordance index. The primary outcome was PE and complicated PE defined as placental abruption, delivery < 34 weeks or HELLP syndrome.

Results: 571 pregnant patients without chronic hypertension were included in the study. Regression analyses showed increasing gestational age at measurement (P = 0.03) and increasing maternal age (P = 0.003) were both associated with lower UtA-PI values. There were no associations with body-mass index (P = 0.36), race (P = 0.7), mean arterial pressure (P = 0.25) and parity (P = 0.4). UtA-PI had poor predictive performance for PE, and there was no improvement after adjusting for gestational age and maternal age (AUC: 0.567 vs. 0.570, P = 0.56, Concordance index: 0.582±0.04 vs. 0.583±0.04, P = 0.98). UtA-PI was a strong predictor of complicated PE, and there was no improvement following adjustment (AUC: 0.871 vs. 0.858, P = 0.56, Concordance index: 0.866±0.03 vs. 0.848±0.03, P = 0.65).

Conclusion: UtA-PI is a strong predictor of complicated preeclampsia but not overall preeclampsia. Adjustment of UtA-PI for maternal baseline characteristics does not improve predictive performance.



332 | Disparities in Prenatal Care Initiation Among Medicaid and Commercially Insured Pregnant Women

Reetam Ganguli[1]; Maguire Anuszewski[2]; Srishti Ganguli[3]; Stephen Wagner[4]
[1]Elythea, San Jose, CA; [2]Warren Alpert Medical School, Brown University, Providence, RI; [3]Brown University, Providence, RI; [4]Beth Israel Deaconess Medical Center, Boston, MA

10:30 AM - 12:30 PM

Objective: Access to prenatal care is critical to improving pregnancy outcomes, yet disparities in its timing and quality persist. Our objective is to elucidate how insurance type is associated with the timing of prenatal care initiation and maternal and neonatal outcomes.

Study Design: A retrospective cohort study was conducted using CDC National Vital Statistics System data from 2018 to 2022. Pregnant women were categorized based on their insurance status: Medicaid or commercially insured. We analyzed variables related to maternal demographics, health behaviors, and birth outcomes. The primary outcome was prenatal care within the 1st trimester. Adjusted odds ratios (aORs) and 95% confidence intervals (CIs) were calculated using logistic regression to account for potential confounders. Chi-squared test for independence to compare the proportions of prenatal care initiation times. Statistical significance was determined with a p-value threshold of < 0.001.

Results: Of 16,828,197 total patients, 9,235,696 were commercially insured and 7,592,501 were on Medicaid. Prenatal care initiation showed significant differences, with 68.05% of Medicaid recipients starting care in the 1st trimester, compared to 86.23% of those commercially insured. A larger proportion of Medicaid recipients initiated care in the 2nd trimester (21.99% vs. 10.11%), the 3rd

trimester (6.26% vs. 2.22%), or had no prenatal care at all (2.77% vs. 0.75%) ($p < 0.001$).

Women on Medicaid are over twice as likely [aOR: 2.118 (95% CI: 2.107-2.130, $p < 0.001$)] to receive prenatal care after the 1st trimester compared to commercial insurance after controlling for maternal age, marital status, ethnicity, and education level. Significant differences ($p < 0.001$) were also observed in: number of prenatal visits, smoking status before pregnancy, NICU admission, maternal ICU admission, postpartum hemorrhage, and preterm labor.

Conclusion: Disparities in the timing of prenatal care initiation between Medicaid and commercially insured pregnant women exist. Innovative engagement strategies may mitigate these disparities, ensuring timely and equitable prenatal care.

333 | Generalizing NICU Admission Predictions for Medicaid Patients Using Machine Learning

Reetam Ganguli[1]; Julia Sroda Agudogo[2]; Stephen Wagner[2]
[1]Elythea, San Jose, CA; [2]Beth Israel Deaconess Medical Center, Boston, MA

10:30 AM - 12:30 PM

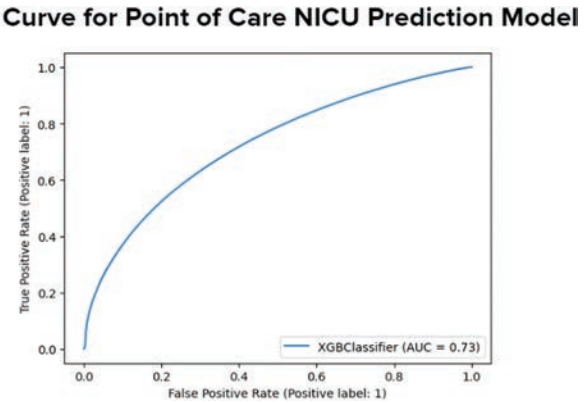
Objective: Medicaid patients have higher rates of maternal and neonatal complications. No models have been designed to specifically examine this patient population. We evaluated the generalizability of a NICU admission prediction model trained on a mixed population of insured patients (commercial, Medicaid, self-pay) when applied specifically to Medicaid patients.

Study Design: An extreme gradient boosting model was trained on data from years 2014-2021 of the Vital Statistics System of mixed insurance coverage with the exclusion of year 2015 due to unavailable data. The model was tested on a mixed insurance and solely Medicaid-covered cohort. Inclusion criteria for the Medicaid testing set were deliveries covered by Medicaid in the year 2022 with available NICU admission data. Inclusion for mixed testing cohort were 2022 deliveries with available NICU admission data. Cases with missing NICU admission data and those from hospitals not reporting NICU admissions were excluded. The primary outcome of interest was NICU admission immediately post-delivery.

Results: 38 clinical variables for 15,782,488 obstetric patients were included in the training data. The testing set consisted of 1,500,152 Medicaid patients, with 157,871 (10.5%) experiencing NICU admissions. The model demonstrated a strong performance on the Medicaid cohort with an AUC of 0.73, 80.3% accuracy, and a 0.80 F1 score.

When tested on the 2022 mixed cohort (self pay, commercially insured, Medicaid, and other) of 3,666,784 patients, of which 347,586 (9.5%) patients had a NICU admission, the model had an AUC of 0.73, 83.3% accuracy, and F1 score of 0.83. The analysis revealed that the most influential factor in predicting NICU admissions was the interval since the last live birth.

Conclusion: The NICU prediction model, initially trained on a mixed population of insured patients, demonstrated strong generalizability and robust performance when applied to Medicaid patients in 2022. By leveraging routinely collected data, the model can aid in reducing NICU admissions and associated healthcare costs, ultimately improving outcomes for Medicaid patients.



334 | Effects of Preconception Weight Loss on Gestational Weight Gain and Obesity-Associated Maternal Morbidities

Richard S. Legro[1]; Karl R. Hansen[2]; Michael P. Diamond[3]; Anne Steiner[4]; Christos Coutifaris[5]; Marcelle I. Cedars[6]; Nanette Santoro[7]; Heping Zhang[8]; Alllen Kunselman[1]; Christina Stetter[1]; On behalf of the Reproductive Medicine Network (RMN)
[1]Penn State College of Medicine, Hershey, PA; [2]University of Oklahoma Health Sciences Center, Oklahoma City, OK; [3]Augusta University/ Medical College of Georgia, Augusta, GA; [4]UNC School of Medicine, Chapel Hill, NC; [5]U Penn School of Medicine, Philadelphia, PA; [6]UCSF School of Medicine, UCSF/San Francisco, CA; [7]U Colorado School of Medicine, U Colorado/Denver, CO; [8]Yale School of Public Health, New Haven, CT

10:30 AM - 12:30 PM

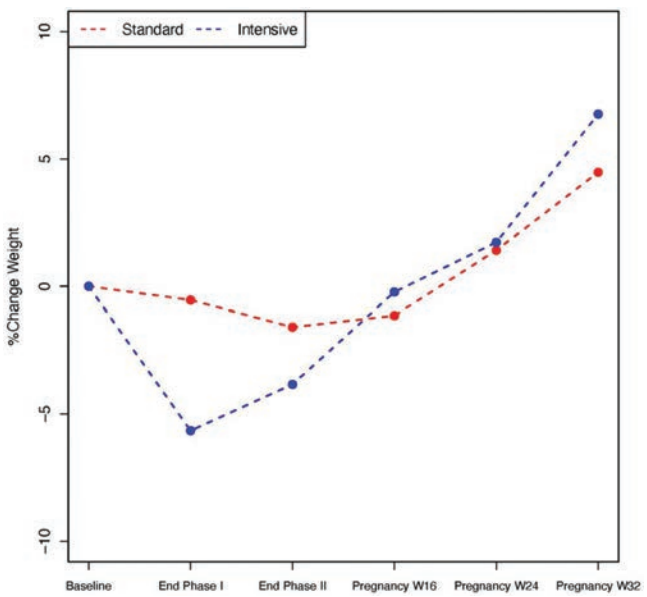
Objective: Preconception Weight Loss(PWL) is recommended in women with obesity (OW), but the effects of PWL on gestational weight gain(GWG) and associated obesity-related maternal morbidities are poorly studied. We examined these parameters in a previous multicenter RCT(FIT-PLESE, NCT02432209) of two types of preconception lifestyle intervention(16 weeks duration) in a population of OW with unexplained infertility($N = 379$)

Study Design: Secondary and subgroup analysis of singleton live birth gestations from FIT-PLESE. Preconception(Phase 1), the intensive lifestyle group($N = 32$) underwent increased physical activity and weight loss(target 7%) through meal replacements and medication(Orlistat) compared to a standard group($N = 39$) with increased physical activity alone without weight loss. Both groups then received standardized infertility therapy consisting of CC/IUI(Phase 2). Singleton pregnancies including GWG were tracked to live birth. The post hoc composite outcome was the prevalence of adverse obesity-related maternal events: PTL, PET, GDM and PROM

Results: The standardized group of singleton pregnancies had no significant mean weight loss from baseline after the lifestyle intervention[-0.5%, 95% CI(-2.4, 1.3)] while the intensive group approached the target with significant weight loss[-5.6% (-7.6, -3.7) P< .001], and significant decreases in waist circumference. However weight in the intensive group rebounded during Phase 2 and was equivalent to the standard group by 16 wks gestation(Fig 1) and continued to have similar weights up to 32 weeks gestation. Despite the rebound weight gain and equivalent maternal weights by this time point, there was a trend towards

decreased obesity-related maternal morbidity in the intensive weight loss group(Tab 1)

Conclusion: Weight rebound is inevitable after weight loss treatment. Pregnancy may further exacerbate weight rebound after PWL. However, there may be maternal pregnancy benefits after PWL despite weight rebound. These data provide trends towards powering a larger study and incorporating pregnancy interventions after PWL to achieve better GWG and obstetric outcomes



Complication	Intensive N/32 (%)	Standard N/39 (%)	P value

335 | Effect of Pre-Pregnancy BMI Vs. Total Pregnancy Weight Gain on Trial of Labor After Cesarean

Logan McClure; Riley Short; Patricia Goedecke; Alexa Swailes
University of Tennessee Health Science Center, Memphis, TN

10:30 AM - 12:30 PM

Objective: To examine whether pre-pregnancy BMI or total pregnancy weight gain is more closely associated with successful vaginal birth after Cesarean delivery (VBAC) in patients with term gestations with no prior history of vaginal delivery.

Study Design: IRB approval was obtained for the study (24-09915-NHSR). The CDC National Center for Health Statistics birth certificate database was utilized to obtain relevant birth information from 2016-2022 in the United States. Inclusion criteria were term, singleton gestations in patients who underwent TOLAC with the following characteristics: second pregnancy with history of one prior Cesarean delivery, BMI >/ = 18.5, and no pre-existing diagnosis of hypertensive disorders (either pre-gestational or gestational). Odds ratios and confidence intervals indicating likelihood of successful VBAC were developed both by (1) pre-pregnancy BMI alone, (2) total pregnancy weight gain alone, and (3) pre-pregnancy BMI stratified by total pregnancy weight gain.

Results: 12,164 patients met inclusion criteria for analysis, of whom 11,919 had data reported for both BMI and weight gain. Of these, 6,096 (51.1%) experienced a successful VBAC and 5,823 (48.9%) were delivered via repeat Cesarean section after TOLAC. Increasing pre-pregnancy BMI was associated with a lower likelihood of successful VBAC when compared to patients with a normal BMI (BMI 25-29.9: OR 0.75 [0.691, 0.825] vs. BMI 30-34.9: 0.56 [0.506, 0.624] vs. BMI 35.0-39.9: 0.56 [0.492, 0.645] vs. BMI >40: 0.36 [0.311, 0.433]) (All p values < 0.001). Among individuals with obesity, increased total pregnancy weight gain was significantly associated with decreased likelihood of VBAC success for those gaining greater than 20 pounds (21-30lbs: OR 0.76 [0.633, 0.909]; >30lbs: 0.75 [0.626, 0.887], p values < 0.001). However, when stratified by total pregnancy weight gain within each BMI category, no consistent significant differences in VBAC success were observed.

Conclusion: Our data suggest that pre-pregnancy BMI is more closely associated with likelihood of successful VBAC than total pregnancy weight gain within each BMI category.

336 | Breastfeeding Intention, Initiation, and Continuation in Pregnant Patients with Sickle Cell Disease

Roselyn Oyenuga[1]; Kaitlin Farias[2]; Caroline J. Berberian[2]; Andrea D. Shields[3]
[1]University of Connecticut, Rocky Hill, CT; [2]University of Connecticut, Farmington, CT; [3]University of Connecticut Health, Avon, CT

10:30 AM - 12:30 PM

Objective: Mothers with sickle cell disease have more barriers that may either prevent them from breast feeding or discontinue early. The aim of this study is to compare the rates of breastfeeding intention, initiation, and discontinuation at 6 weeks in patients with sickle cell disease (SCD) versus patients without SCD.

Study Design: A retrospective matched cohort study was performed between January 1, 2018 to July 31, 2023 to examine the risk of SMM with SCD in the first year postpartum. Inclusion criteria were pregnant patients with SCD who received their prenatal and postpartum care at a single tertiary academic center. We randomly selected two non-exposed patients for every SCD patients, matched for age and year of delivery. Baseline characteristics were summarized using frequencies and percentages for categorical variables and mean and standard deviation for continuous variables overall. Chi square analysis and a two-population proportion test was used to compare breastfeeding rates between SCD and non-exposed cohorts.

Results: We identified 25 eligible patients with SCD with singleton pregnancies who received their pregnancy and postpartum care up to one year at our institution. Baseline demographics were similar between both SCD and non-SCD groups including age, parity, and insurance. There were differences however in race and ethnicity. SCD patients were more likely to be non-Hispanic Black. Intention to breastfeed was similar in patients with SCD versus non-SCD (96% (24/25) versus 94% (47/50), P = 0.9523). Similarly, breastfeeding initiation less than 7 days postpartum was 88% (22/25) in patients with SCD compared to 90% (45/50) in non-SCD patients (P = 0.9045). Only 48% (12/25) of SCD patients and 70% (35/50) of non-SCD patients continued to breast feed after 6 weeks postpartum (P = 0.0629).

Conclusion: While we did not find a difference in breastfeeding intention, initiation or discontinuation rates between mothers with sickle cell disease and those without sickle cell disease, there was a trend in discontinuation of breastfeeding at 6 weeks in SCD patients that should be explored with a larger population.

337 | Late Preterm Steroids for those with Pregestational/ Early Gestational Diabetes and Risk of Neonatal Hypoglycemia

Ruby Lin; Cande V. Ananth; Todd J. Rosen; On behalf of the MOMPOD Consortium
Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ

10:30 AM - 12:30 PM

Objective: The ALPS trial showed reduced rate of neonatal respiratory complications with the use of late preterm steroids but excluded those with pregestational diabetes. We hypothesize that late preterm steroids given to those with pregestational and early gestational diabetes are associated with a higher risk of neonatal hypoglycemia (NNH) and lower risk of respiratory complications.

Study Design: This is a secondary analysis of MOMPOD, a multicenter, randomized controlled trial of 831 pregnant patients with preexisting type 2 diabetes or diabetes diagnosed prior to 23 weeks' gestation that were treated with insulin alone or insulin and metformin. Patients who delivered 34-36 6/7 weeks were included. Those who received late preterm steroids were compared to those who did not have any exposure to antenatal steroids in pregnancy. The primary outcome was NNH (blood glucose < 40 mg/dl or need for IV dextrose treatment). Secondary outcomes included respiratory support in the NICU/ intermediate nursery, transient tachypnea of the newborn, and respiratory distress syndrome. Modified Poisson regression was performed to calculate the relative risk, adjusting for confounding variables.

Results: Of the patients that delivered late preterm, 20 received late preterm steroids and 136 did not have any antenatal steroid exposure. NNH was present in 16 (80%) and 73 (54%) of those exposed to steroids vs no steroids. The adjusted relative risk for NNH was 1.63 (95% CI 1.23-2.16). 9 (45%) and 62 (46%) required respiratory support in the NICU during the first 30 days of life in the steroid and no steroid group, respectively. The adjusted relative risk for respiratory support in the NICU was 1.08 (95% CI 0.63-1.86).

Conclusion: Administration of late preterm antenatal steroids in pregnancies complicated by pregestational diabetes and early gestational diabetes is associated with a 1.6 increased risk for neonatal hypoglycemia. However, the secondary analysis was not powered to evaluate for respiratory complications. Further studies are needed to understand the full spectrum of neonatal outcomes associated with this practice.

Table 1
Neonatal Hypoglycemia in Pregnancies Complicated by Diabetes with Late Preterm Deliveries

Adverse Outcomes	Steroids (n=20)	No Steroids (n=136)	Adjusted Relative Risk (95% CI)*
Neonatal Hypoglycemia	16 (80%)	73 (54%)	1.63 (1.23-2.16)
Treated with IV dextrose	13 (65%)	49 (46%)	
BG<40	11 (55%)	60 (44%)	

*Adjusted for age, BMI, treatment with insulin with or without metformin, pregestational vs early gestational diabetes, HgbA1c early in pregnancy, and total daily insulin dose at the end of pregnancy

Table 2
Neonatal Respiratory Complications in Pregnancies Complicated by Diabetes with Late Preterm Deliveries

Adverse Outcomes	Steroids (n=20)	No Steroids (n=136)	Adjusted Relative Risk (95% CI)*
Respiratory Support in first 30 days**	9 (45%)	62 (46%)	1.08 (0.63-1.86)
Transient Tachypnea of newborn	2 (11%)	12 (9%)	1.11 (0.26-4.68)
Respiratory distress syndrome	3 (15%)	32 (23%)	0.71 (0.24-2.13)

*Adjusted for age, BMI, treatment with insulin with or without metformin, pregestational vs early gestational diabetes, HgbA1c early in pregnancy, and total daily insulin dose at the end of pregnancy

338 | Leptin Alters Myometrial Contractility-Related Gene Expression in a Human Myometrial Cell Line

Ruchira Sharma[1]; Xiangying Xue[2]; Prodyot Chatterjee[2]; Burton Rochelson[3]; Christine Metz[2]
[1]Rutgers Robert Wood Johnson Medical School, New Brunswick, New Jersey, Rutgers Robert Wood Johnson Medical School, NJ; [2]Feinstein Institutes for Medical Research, Manhasset, NY; [3]Northwell, New Hyde Park, NY

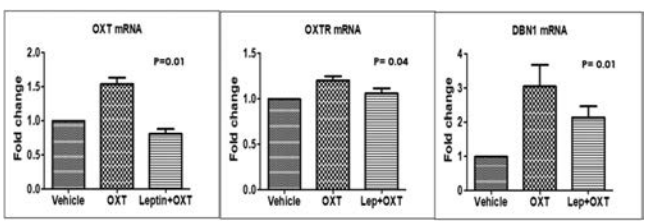
10:30 AM - 12:30 PM

Objective: Obesity is linked with poor labor progression and increased cesarean deliveries. Dysfunctional labor in the setting of obesity is hypothesized to result from reduced myometrial contractility. Leptin levels rise with obesity and are reported to inhibit spontaneous and oxytocin-induced myometrial contractility (Moynihan et al., 2006). However, the underlying biologic mechanisms by which leptin produces this effect is unknown. We investigated the effects of leptin on the expression of genes associated with uterine contractility in a myometrial cell line treated ±oxytocin.

Study Design: Immortalized human myometrial (PHM1-41) cells were treated with vehicle or leptin (1μM) for 24 hours. Cytotoxicity assays confirmed non-cytotoxicity of this dose. The expression of mRNAs encoding oxytocin (OXT), oxytocin receptor (OXTR) and gap junction-related Debrin-1 (DBN1) were analyzed by real time qRT-PCR. Cells pretreated with either vehicle or leptin (1μM) were subsequently exposed to oxytocin for 2 hours, and gene expression was re-assessed. Vehicle vs. leptin data were analyzed using unpaired t tests with Welch's correction and combination treatment data were analyzed using non-parametric Kruskal-Wallis test, followed by Dunn's multiple comparisons. $P< 0.05$ was considered significant.

Results: Leptin treatment alone did not alter OXT mRNA or OXTR mRNA expression but significantly increased DBN1 mRNA expression ($p = 0.04$). Oxytocin treatment increased OXT, OXTR and DBN1 mRNA expression compared to vehicle. Leptin significantly inhibited oxytocin-induced OXT mRNA expression ($p < 0.01$) and showed a non-significant trend towards reducing oxytocin-induced OXTR and DBN1 mRNA expression when compared to vehicle+oxytocin treated cells (Figure 1).

Conclusion: Leptin alone did not affect OXT or OXTR mRNA expression in human myometrial cells but suppressed oxytocin-induced contractility-related gene expression. These novel findings suggest leptin's role in modulating myometrial expression of contractility-related genes, offering insights into possible pathways contributing towards parturition dysfunction in obese individuals.



339 | Association Between Obstetric Care Provider Density and Maternal and Perinatal Outcomes: A Cross-Sectional Analysis

Rula Atwani; Lindsay S. Robbins; George R. Saade; Tetsuya Kawakita

Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA

10:30 AM - 12:30 PM

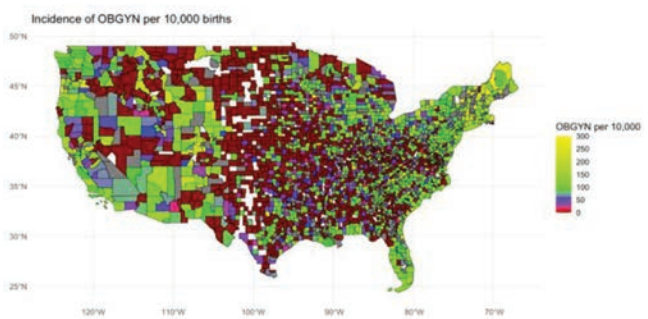
Objective: To examine the association between obstetric care provider density and maternal and perinatal outcomes at the county level.

Study Design: This was a cross-sectional analysis of publicly available Health Resources & Services Administration and limited-use county-level birth certificate data. The primary exposure was the number of obstetric care providers (obstetrician/gynecologist or midwives) per 10,000 births in the county, categorized according to the March of Dimes as full coverage (60 or more providers), moderate coverage (1-59 providers), and desert areas (no providers). Our primary outcome was maternal mortality during pregnancy and up to 42 days postpartum (deaths per 100,000 live births). Our secondary outcomes were maternal mortality up to 365 days post-delivery (deaths per 100,000 live births), stillbirth, preterm birth (PTB), and cesarean delivery (CD) rates. We calculated relative risks (RR) with 95% confidence intervals (95%CI) using Bayesian conditional autoregressive models with Poisson distribution, accounting for spatial autocorrelation and potential confounders.

Results: Of 14,802,676 births included in this analysis, 137,023 (0.9%) births were in desert counties, 1,131,211 (7.6%) births were in counties with moderate coverage and 13,534,442 (91.4%) births were in counties with full coverage (Figure 1). Compared with desert counties, moderate coverage counties had significantly lower maternal mortality up to 42 days postpartum and mortality up to 365 days post-delivery along with higher stillbirth, PTB, and CD rates. Compared with desert counties, full-coverage counties had significantly lower maternal mortality up to 42 days postpartum and mortality up to 365 days postpartum; along with higher stillbirth, PTB, and CD rates (Table 1).

Conclusion: Increased maternal mortality at the county level is associated with decreased obstetrical provider coverage, with counties that have no providers having the highest mortality rates despite having lower stillbirth, preterm birth, and cesarean rates.

Figure 1. Density of obstetrician/gynecologist or midwives per 10,000 live births.



OBGYN includes obstetricians, gynecologists, and midwives.

Colors indicate the density of OBGYN per 10,000 live births.

340 | Mid-trimester Cervical Length in Patients with a History-Indicated Cerclage and the Risk of Preterm Delivery

Rula Atwani; Rebecca Horgan; Jerri A. Waller; Mackenzi Mchugh; Tetsuya Kawakita; George R. Saade; Alfred Z. Abuhamad; Marwan Ma'Ayeh
Macon & Joan Brock Virginia Health Sciences Eastern Virginia Medical School at Old Dominion University, Norfolk, VA

10:30 AM - 12:30 PM

Objective: To investigate the predictive value of cervical length (CL) in patients with a history-indicated cerclage on preterm delivery (PTB) < 37 weeks.

Study Design: This was a retrospective cohort study of individuals who had history-indicated cerclage during pregnancy and who delivered at a tertiary referral center between 2014 and 2022. Individuals who did not have cervical length measurement post-cerclage were excluded. Post-cerclage CL was categorized into < 2.5 cm and ≥ 2.5 cm. The primary outcome was preterm birth (PTB) < 37 weeks. Secondary outcomes included PTB < 34 weeks, mode of delivery, chorioamnionitis, postpartum hemorrhage, transfusion, and endometritis. Categorical variables were compared using Chi-squared or Fisher's exact test. Continuous variables were tested for normality using the Shapiro-Wilk test and compared using Student's t-test or Mann-Whitney-U test as applicable.

Results: A total of 65 patients were included in the study, with 50 having a post-cerclage CL < 2.5 cm and 15 having a post-cerclage CL ≥ 2.5 cm. There was no significant difference in the rates of PTB < 37 weeks between the two groups (32%vs. 46.7%, p = 0.36). Similarly, there were no significant difference in the rates of PTB < 34 weeks (p = 0.08), mode of delivery (p = 1.00), postpartum hemorrhage (p = 0.71), transfusion (p = 1.00), or endometritis (p = 0.23). Significant differences were noted in rates of chorioamnionitis (94.00% for CL < 2.5 cm vs. 73.33% for CL ≥2.5 cm, p = 0.04) (Table 1).

Conclusion: Post-cerclage CL appears to have limited predictive value for PTB and other pregnancy outcomes in the setting of history indicated cerclage. Further research with larger sample sizes is needed to confirm these findings and explore potential clinical implications.

341 | The Relationship Between In-Hospital Opioid use After Cesarean Delivery and Opioid use After Discharge

Ruth Landau; Uma M. Reddy; On behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD) Maternal-Fetal Medicine Units (MFMU) Network
Columbia University, New York, NY

10:30 AM - 12:30 PM

Objective: To evaluate opioid use after cesarean delivery (CD) and assess our hypothesis that no in-hospital opioid use is associated with no post-discharge opioid use, and to evaluate the association between no opioid use and post-discharge pain.

Study Design: Secondary analysis of a multicenter trial in patients who underwent CD at 31 U.S. hospitals (2020-22) and were randomized to individualized or fixed quantity of opioid tablets at discharge. The exposure was no in-hospital opioid use (morphine milligram equivalents [MME] = 0). Primary outcome was post-discharge MME = 0 up to 90 days. Secondary outcomes were moderate to severe pain (Brief Pain Inventory [BPI] score; BPI worst pain ^{3} 4 at 1-, 2- and 6-weeks post-discharge), opioid prescriptions filled, and refills within 90 days. MMEs included all routes of administration. Univariable modeling estimated the association between in-hospital MME = 0 and outpatient opioid use, as well as pain.

Results: Of 5515 eligible participants, in-hospital MME = 0 rate was 19% (N = 1023) and post-discharge MME = 0 rate was 34% (N = 1752). Overall, 710 of the 1,023 of the participants (76%) who did not use opioids in-hospital used none post-discharge, though 54% filled a prescription for opioids at or after discharge. In-hospital MME = 0 was associated with lower post-discharge opioid use, higher odds of MME = 0 (OR 9.8, CI 8.3, 11.5) and lower median MME dose (0 vs 7) (Table 1). With post-discharge MME = 0, the proportion of participants with moderate to severe pain was significantly lower at 1 week (42% vs. 70%), 2 weeks (20% vs. 38%), and 6 weeks (6% vs. 14%, all p < 0.001).

Conclusion: Consistent with our hypothesis, in-hospital opioid use was associated with post-discharge opioid use. Though one-third of participants did not use any opioids post-discharge, this was not associated with higher pain scores at any time point up to

90 days post-discharge. Further efforts are needed to align opioid prescriptions with actual post-discharge opioid use.

Table 1. In-hospital vs. post-discharge MME and opioid prescription

Outcome	In-hospital MME=0 (N= 1,023)	In-hospital MME > 0 (N= 4,492)	Unadjusted Odds Ratio (95% CI) or p-value
Post-discharge MME=0 – n (%)	710 (76.3)	1042 (24.8)	9.8 (8.3, 11.5)
Median post-discharge MME – median [IQR]	0 [0, 0]	7 [1,16]	<0.001
Filled opioid prescription at or after discharge – n (%)	521 (53.7)	3774 (86.2)	0.18 (0.16, 0.22)
Filled an opioid prescription post-discharge – n (%)	28 (2.9)	338 (7.7)	0.35 (0.24, 0.52)

MME, morphine milliequivalent;
In-hospital MME: any opioids, from surgery until discharge
Post-discharge MME: opioids used from discharge to 90 days post-discharge

342 | Factors Associated with no In-Hospital Opioid use After Cesarean Delivery

Ruth Landau; Uma M. Reddy; On behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD) Maternal-Fetal Medicine Units (MFMU) Network
Columbia University, New York, NY

10:30 AM - 12:30 PM

Objective: Improving pain trajectories after cesarean delivery (CD) with minimal to no opioid use is a challenging goal: opioid reduction may result in uncontrolled pain, yet in-hospital opioid use may be associated with persistent opioid use after discharge. Our objective was to evaluate factors associated with opioid use after CD, with 2 aims: characterize patients with no in-hospital opioid use after CD, and identify pre/peri-delivery factors associated with no opioid use.

Study Design: Secondary analysis of a controlled trial in patients who underwent CD at 31 U.S. hospitals (2020-22) and were randomized to individualized or fixed quantity of opioid tablets at discharge. For this analysis, participants were categorized into one of 2 groups based on opioid use (morphine milligram equivalents [MME]), with MME = 0 indicating no in-hospital opioid use. Secondary outcomes were worst pain on the (Brief Pain Inventory [BPI] score) and Pain Catastrophizing Score (PCS) assessed within 24 hours of discharge. Univariable and multivariable logistic regression analyses with backward selection were performed to identify factors associated with no in-hospital opioid use.

Results: Of 5515 eligible participants, 1023 (19%) had MME = 0. On multivariable analysis, Black race, government insurance, anxiety/depression, and preterm birth were associated with decreased odds for MME = 0 (Table 1). In contrast, Hispanic ethnicity, spinal or combined spinal-epidural (CSE) anesthesia, and neuraxial morphine administration were associated with increased odds for MME = 0. Participants with BPI ^{3} 4 or PCS $\geq$ 13 were more likely to use opioids (Table 2).

Conclusion: Patient-specific factors, including anxiety/depression and preterm birth were associated with increased in-hospital opioid use after CD, while anesthesia technique (spinal and CSE) and neuraxial morphine administration were associated with reduced opioid use. No opioid use was not associated with higher in-hospital pain scores or pain catastrophizing.

*p-value from chi-square test comparing factors to no in-hospital opioid use (MME=0)
**Adjusted OR from a multivariate logistic regression model including all of the factors in this column and with the outcome of no in-hospital opioid use (MME=0).
Sum of anesthetic is higher than total of participants, because some patients received more than one anesthetic (e.g., general anesthesia might occur in addition to spinal/epidural/CSE).
General anesthesia, epidural anesthesia and opioids given intraoperatively were not associated with a reduction in aOR for MME=0

Table 2. Relationship between baseline pain and inpatient MME use

	MME > 0 Inpatient (N=4488)	MME=0 Inpatient (N=1023)	Unadjusted OR (95% CI)	Adjusted* OR (95% CI)
Worst BPI				
≥ 4	4217 (85.3)	728 (14.7)	6.3 (5.3, 7.6)	6.7 (5.4, 8.3)
< 4	271 (47.9)	295 (52.1)		
Pain catastrophizing score				
Median (IQR)	8 [4,13]	5 [2,9]		
≥ 13	1172 (89.3)	140 (10.7)	2.2 (1.8, 2.7)	2.1 (1.7, 2.7)
< 13	3314 (79.0)	883 (21.0)		

*Adjusted models included black race, Hispanic ethnicity, government insurance, anxiety or depression, spinal or combined spinal anesthesia, and neuraxial morphine administration, and preterm birth.
BPI and PCS were assessed within 24 hours of discharge from the hospital

343 | Cost Effectiveness of Zuranolone for Treatment of Postpartum Depression

Ryan Duggal[1]; Casey Tak[2]; Marcela C. Smid[3]
[1]Indian Health Service, Salt Lake City, UT; [2]University of Utah, Salt Lake City, UT; [3]University of Utah Health, Salt Lake City, UT

10:30 AM - 12:30 PM

Objective: Zuranolone is a novel GABA-A agonist approved to treat postpartum depression (PPD), however its cost effectiveness (CE) is unknown. We sought to estimate the CE of Zuranolone for PPD treatment when compared to selective serotonin receptor inhibitors (SSRIs).

Study Design: We constructed a decision-analytic model to estimate the CE of treating postpartum depression with Zuranolone as compared to SSRIs and placebo over one year among a cohort of 10,000 postpartum individuals with depression from a perspective of a third-party payer. The direct medical costs of PPD and medication-related costs over one year were gathered from existing literature and incorporated into the model. We defined effectiveness in two ways: treatment response defined

as >50% decrease in symptoms from baseline and remission of PPD. Using first order Monte Carlo simulations, we calculated the incremental cost-effectiveness ratio (ICER). We also explored parameter uncertainty with probabilistic sensitivity analyses.

Results: Across the hypothetical cohort, SSRIs returned the lowest average cost for both effectiveness outcomes (response: $18880; remission: $18876) across the three strategies. The proportion of the cohort experiencing treatment response and remission in the SSRI group were 0.33 and 0.15, respectively. Zuranolone showed the highest average cost across both outcomes (response: $33986; remission: $15085) but also yielded the highest effectiveness (response: 0.72; remission: 0.37). The ICER of Zuranolone compared to SSRIs was $105635 for treatment response and $271799 for remission. The probabilistic sensitivity analysis showed that Zuranolone was the preferred strategy at willingness-to-pay thresholds at or above approximately $105000 for treatment response whereas SSRIs were the preferred strategy across all explored thresholds.

Conclusion: Zuranolone is cost effective for treatment response of PPD when compared to SSRIs, however it is not cost effective at the given thresholds for full remission

344 | Impact of Comorbid Chronic Hypertension on Perinatal Outcomes among Pregnant Persons with Pregestational Diabetes

Samantha E. Howell[1]; Yuanfan Ye[2]; Lily Wiedmer[1]; Abigayle Kraus[1]; Ayodeji Sanusi[2]; Ashley N. Battarbee[2]

[1]University of Alabama at Birmingham, Birmingham, AL; [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL

10:30 AM - 12:30 PM

Objective: Pregnant persons with either pregestational diabetes (DM) or chronic hypertension (cHTN) are at increased risk for adverse outcomes; however, the additive effect of comorbid cHTN among patients with DM is not well studied in contemporary cohorts. Our objective was to quantify the association between DM+cHTN and adverse outcomes, compared to DM only.

Study Design: Retrospective cohort study of pregnant persons with pregestational DM who delivered a non-anomalous singleton or twin gestation ≥22 weeks' at a tertiary care center (2012-2023). The primary outcome was a composite of neonatal morbidity and mortality (Table). Secondary outcomes included composite components and other pregnancy outcomes. Baseline characteristics and outcomes were compared between persons with DM+cHTN vs DM only. Multivariable logistic regression estimated the association between DM+cHTN and outcomes, adjusting for covariates that differed between groups. Results were stratified by DM type when there was evidence of interaction.

Results: Of 1,656 neonates, 498 (30.1%) were born to persons with DM+cHTN and 1158 (69.9%) with DM only. DM+cHTN was associated with higher odds of composite neonatal morbidity and mortality (65.3% vs 58.5%; aOR 1.88, 95% CI 1.33-2.67) compared with DM only. Among the composite components, DM+cHTN was associated with higher odds of hyperbilirubinemia, IVH, and perinatal death (Table). DM+cHTN was also associated with higher odds of preterm birth (PTB), NICU admission, and preeclampsia (PreE). The association between DM+cHTN and PTB and PreE was only significant for those with T2D (Figure).

Conclusion: Preconception and early pregnancy counseling for pregnant persons with DM and comorbid cHTN should emphasize the nearly two- to three-fold higher risk of adverse outcomes including composite neonatal morbidity/mortality, hyperbilirubinemia, IVH, perinatal death, PTB, NICU admission, and PreE, compared to DM alone. Future studies should focus on interventions that improve outcomes for this particularly high-risk population as 2 out of 3 persons with DM+cHTN experienced neonatal morbidity and mortality.

Table. Association between diabetes with comorbid chronic hypertension and perinatal outcomes, compared to diabetes only

	DM & cHTN (n=498)	DM only (n=1158)	aOR (95% CI)
Neonatal morbidity composite	325 (65.3)	677 (58.5)	1.88 (1.33-2.67)

345 | Small for Gestational Age Neonates and Neonatal Adverse Outcomes Among Pregnant Persons with Pregestational Diabetes

Samantha E. Howell[1]; Yuanfan Ye[2]; Ashley E. Shea[2]; Abbey Thornton[1]; Abigayle Kraus[1]; Ashley N. Battarbee[2]
[1]University of Alabama at Birmingham, Birmingham, AL; [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL

10:30 AM - 12:30 PM

Objective: Pregnant persons with pregestational diabetes are at increased risk for having SGA infants; however, this is often overlooked compared to the risk of LGA. Additionally, the risk of adverse outcomes is typically generalized for all pregestational diabetes. We aimed to evaluate the risk of SGA and other adverse outcomes among persons with type 2 diabetes (T2D) versus type 1 diabetes (T1D). Additionally, we aimed to identify risk factors for SGA.

Study Design: Retrospective cohort study of pregnant persons with T2D or T1D who delivered at a tertiary care center (2012-2023). Persons with fetal anomalies, delivery < 22 weeks' gestation, multiple gestation, and missing birthweight or diabetes type were excluded. The primary outcome was SGA, defined as birthweight < 10th percentile for gestational age. Secondary outcomes included composite neonatal morbidity/mortality and other adverse outcomes (Table). Baseline characteristics and outcomes were compared between T2D and T1D. Multivariable logistic regression estimated the association between T2D and outcomes, adjusting for covariates that differed between groups. Multivariable regression with step-wise backward selection was used to identify factors associated with SGA.

Results: Of 1,255 persons included, 872 (69.5%) had T2D and 383 (30.5%) had T1D. Pregnant persons with T2D differed from those with T1D by multiple sociodemographic and medical factors. SGA was more common with T2D (12.2%, vs 4.7%; aOR 3.48, 95% CI 1.48-8.34) compared with T1D. Secondary neonatal outcomes were similar between groups, but preeclampsia was more common with T1D (Table). Factors associated with higher odds of SGA were T2D, government insurance, nulliparity, tobacco use, aspirin use, chronic kidney disease, neonatal male sex, and less gestational weight gain (Figure).

Conclusion: In this cohort, pregnant persons with T2D were 3.5 times more likely to have an SGA infant than those with T1D. Pregnant persons with T2D and other risk factors such as tobacco use and chronic kidney disease among others, should be specifically counseled about the risk of SGA and monitored closely.

Table. Association of diabetes type with adverse outcomes

	Type 2 Diabetes (n=872)	Type 1 Diabetes (n=383)	aOR (95% CI)*
SGA	106 (12.2)	18 (4.7)	3.48 (1.45-8.34)
LGA	178 (20.4)	139 (36.3)	0.61 (0.36-1.05)
Composite neonatal morbidity and mortality	502 (57.6)	279 (72.9)	0.73 (0.45-1.17)
Hypoglycemia	280 (33.0)	165 (44.0)	0.64 (0.40-1.02)
Hyperbilirubinemia	294 (34.7)	166 (44.3)	0.94 (0.57-1.54)

346 | Effects of Antiretroviral Therapy on Fetal Biometric Measurements and Neonatal Weight

Sara E. Edwards[1]; Nicola F. Tavella[2]; Raina Kishan[2]; Sarriyah Hanif[2]; Allison Perelman[2]; Henri M. Rosenberg[3]; Daniel L. Kuhr[1]; Sara M. Hachey[2]; Leslie J. Warren[2]; Victoria Ly[2]; Samsiya Ona[2]; Noel Strong[2]; Angela T. Bianco[2]; Chelsea A. DeBolt[2]

[1]*Division of Maternal-Fetal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY;* [2]*Icahn School of Medicine at Mount Sinai, New York, NY;* [3]*Icahn School of Medicine at Mount Sinai, Division of Maternal-Fetal Medicine, Icahn School of Medicine at Mount Sinai, NY*

10:30 AM - 12:30 PM

Objective: Several types of antiretroviral therapy used in the treatment of HIV, such as integrase inhibitors, have been linked to increased risk of metabolic syndrome in adults. This study assessed if these antiretroviral medications that cause metabolic syndrome in adults have similar effects on fetal weight and abdominal circumference when taken by HIV patients during pregnancy.

Study Design: Retrospective cohort study of HIV-positive pregnant patients at a single academic institution in New York City who delivered from 2014-2023. Patients were included if they had at least one ultrasound assessing fetal growth. Demographics, medical co-morbidities, antiretroviral medications, intrapartum complications, and birthweight were extracted from the electronic medical record. We extracted estimated fetal weight and abdominal circumference from the last ultrasound for each pregnancy. Bivariate analysis was performed to assess the difference between neonatal birthweight and estimated fetal abdominal circumference between those on antiretroviral therapy associated with metabolic syndrome (integrase inhibitors) and those on other antiretrovirals.

Results: Among 155 patients meeting inclusion criteria, 106 (68%) were taking integrase inhibitors and 49 (32%) were on other antiretrovirals. There was no significant difference in neonatal birthweight (p = 0.3), birthweight percentile (p = 0.4), or sonographic estimate of fetal abdominal circumference percentile (p = 0.57, Table 1) despite increased rates of gestational diabetes and obesity. Additionally, there were no significant differences in obstetric outcomes associated with macrosomia, including postpartum hemorrhage or cesarean delivery for labor abnormalities.

Conclusion: Although specific antiretroviral medications are associated with metabolic syndrome in adults, these regimens do not appear to be associated with increased birthweight or abnormal fetal biometric measurements, such as elevated abdominal circumference, when taken in pregnancy. Further examination among larger datasets is needed, as well as comparison with HIV negative patients.

347 | Probiotics Perinatal Vertical Transmission from Mother to Neonate

Jean-Charles Pasquier[1]; Amélie Têtu[2]; Marie-Pier Houde[2]; Marie-Laure Oula[3]; Saly El Salti[4]; Sarah Bilodeau[5]; Jean-François Beaulieu[6]

[1]*Research Centre of Centre hospitalier de l'Université de Montréal, Montreal, PQ;* [2]*Research Centre of Centre hospitalier de l'Université de Sherbrooke, Sherbrooke, PQ;* [3]*Lallemand Health Solutions, Montreal, PI;* [4]*Lallemand Health Solutions, Montreal, PQ;* [5]*Research Center Of Centre Hospitalier De L'Université De Montréal, Montreal, PQ;* [6]*Université de Sherbrooke, Sherbrooke, PQ*

10:30 AM - 12:30 PM

Objective: Probiotics given to preterm babies can reduce the risk of perinatal complications such as necrotising enterocolitis. The primary objective was to determine if *in utero* vertical probiotics transmission is possible.

Study Design: A randomized double-blinded crossover pilot study was proposed to women aged 18-42 years, with a single pregnancy, considered at low risk. Probiotics (powder for dilution) containing 5 bacterial strains (FlorababyÒ) vs Placebo were offered. At 32-33 weeks of gestation (WG), women were randomized in: Group A: probiotics from the 34 WG until delivery and placebo from delivery to 10 days post-partum (D PP) or group B: placebo from the 34 WG until delivery then probiotics from delivery to 10D PP. All women completed questionnaires and a logbook to assess compliance and side effects. Samples were collected at baseline and at 37 WG (stools, vaginal secretions), at birth (meconium, colostrum) and at 10D PP (maternal stools, breastmilk, neonate stools). Detection of the probiotic strains was performed using single nucleotide variants method to confirm engraftment.

Results: 52 women were recruited and 45 of them were analysed. There were no statistical differences between groups' characteristics at baseline. All mothers (100%) were breastfeeding from delivery to 10D PP. Probiotic strains in mother's stools were detected in 91% of cases at 37 WG (group A) and 87% of cases at 10D PP (group B)). Strains were only marginally detected in the vaginal samples. No probiotic strains were detected in meconium or colostrum (group A). Only one strain was found in 2 samples of breastmilk at 10D PP (group B). In the babies' stools at 10D PP, probiotics were detected in 17% (group A) and 61% (group B) respectively. The *B. Infantis* strain HA116 was the most detected

strain in babies' stools. No severe adverse events were reported during the study.
Conclusion: Vertical transmission was evidenced by the presence of probiotic strains in babies' stools to a greater extent in the neonatal period than in the ante-natal period. However, probiotic strains were not detected in meconium or breastmilk.

348 | Comparing Perinatal Outcomes in Gestational and Cystic Fibrosis Related Diabetes

Briana Clifton[1]; Basra Osman[2]; Katelyn M. Tessier[3]; Amir Moheet[3]; Sarah A. Wernimont[3]
[1]University of Minnesota Medical School, Falcon Heights, MN; [2]University of Minnesota Medical School, Fridley, MN; [3]University of Minnesota, Minneapolis, MN

10:30 AM - 12:30 PM
Objective: Gestational Diabetes (GDM) and pre-existing cystic fibrosis-related diabetes (CFRD) impact 18-62% of pregnancies in individuals with cystic fibrosis (CF). While GDM and CFRD can alter maternal metabolism and contribute to hyperglycemia, it is unknown if there are specific differences in clinical outcomes related to GDM compared to CFRD.
Study Design: This is a retrospective cohort study from 2011-2023 of all singleton, non-anomalous pregnancies affected by cystic fibrosis within a multi-institution health system obstetric outcome database. Individuals with CFRD were diagnosed prior to pregnancy, and GDM was diagnosed by glucose tolerance testing during the second or third trimester in those without evidence of CFRD before pregnancy. Metabolic, pregnancy, and neonatal outcomes between individuals with CFRD and GDM were statistically compared using Wilcoxon rank-sum tests or Fisher's exact test as indicated.
Results: 31 individuals with CF were identified: 16 with CFRD, 6 with GDM, and 9 without diabetes. While no one with GDM required insulin, those with CFRD used 15 units (range 5.9, 31.9) of insulin daily in the third trimester, with an average increase of 0.5 units from pre-pregnancy dosing. As expected, those with CFRD had higher median hemoglobin A1c (HbA1c) compared to those with GDM during preconception (6.3 vs. 5.3, $p = 0.005$), 3rd trimester (6.0 vs. 5.1, $p = 0.033$), as well as postpartum (6.2 vs. 5.7, $p = 0.047$). HbA1c decreased 0.4% for GDM and 0.7% for CFRD throughout gestation. No differences in pregnancy-induced hypertensive disorders or gestational age at birth were observed. Additionally, there were no significant differences in median birth weights, rates of large for gestational-age neonates, or neonatal hypoglycemia.
Conclusion: We find that individuals with CFRD have higher insulin needs and HbA1c than those with GDM though both groups have similar maternal and neonatal outcomes.

349 | Impact of CFTR Modulators for Cystic Fibrosis on Perinatal Outcomes

Briana Clifton[1]; Basra Osman[2]; Katelyn M. Tessier[3]; Sabrina C. Burn[3]; Cresta W. Jones[4]; Amir Moheet[3]; Sarah A. Wernimont[3]
[1]University of Minnesota Medical School, Falcon Heights, MN; [2]University of Minnesota Medical School, Fridley, MN; [3]University of Minnesota, Minneapolis, MN; [4]University of Minnesota Medical School, Minneapolis, MN

10:30 AM - 12:30 PM
Objective: Pregnancy in individuals with cystic fibrosis (CF) has been associated with acute deterioration of pulmonary function, leading to higher perinatal morbidity and mortality. Combination cystic fibrosis transmembrane conductance regulator (CFTR) modulators have been shown to improve outcomes in non-pregnant patients, but data on their use in pregnancy are limited. Here, we examine the CFTR modulator, Trikafta (Elexacaftor/Tezacaftor/Ivacaftor), and its impact on perinatal outcomes.
Study Design: In a retrospective cohort study, we identified individuals with CF and singleton, non-anomalous pregnancies within a multi-institution health system obstetric outcomes database between 2011-2023. We compared maternal and neonatal outcomes by perinatal Trikafta exposure using the Wilcoxon rank-sum test and Fisher's exact test as indicated.
Results: 31 individuals with CF were identified, including 10 with Trikafta exposure in pregnancy. Baseline characteristics were similar between the two groups. There was no difference in the development of pregnancy complications such as diabetes or hypertensive disorders of pregnancy. Although there was no identified difference in acute pulmonary exacerbations, there was a trend toward improved FEV (Forced Expiratory Volume) during the third trimester in the Trikafta-exposed group. The Trikafta-exposed had a 5% improvement in FEV from their pre-pregnancy baseline to the third trimester, while the non-exposed had a 2% *decline* in FEV during the same time interval ($p = 0.10$). Trikafta-exposed had a higher third trimester weight (75 kg vs. 64 kg, $p = 0.03$) and experienced increased weight gain from pre-pregnancy to the third trimester than the non-exposed (13 kg vs. 9 kg, $p = 0.06$). These results suggest that Trikafta may improve pulmonary function and nutritional status in pregnancy. There was no significant difference in gestational age at birth, birth weight, or NICU admission between groups.
Conclusion: The use of Trikafta in pregnancy tends to improve respiratory function and maternal weight gain without clearly increasing maternal or neonatal complications.

350 | Methamphetamine use and Mental Health Disorders: What are the Effects on Maternal and Neonatal Outcomes?

Sarena Hayer; Erin Nacev; Bharti Garg; Jamie O. Lo; Aaron B. Caughey
Oregon Health & Science University, Portland, OR

10:30 AM - 12:30 PM
Objective: The objective of this study is to examine the association of methamphetamine use and mental health disorders with perinatal outcomes.
Study Design: This is a retrospective cohort study using California linked vital statistics and hospital discharge data from 2008 to 2020. We included singleton, non-anomalous gestations delivered between 23 and 42 weeks and excluded polysubstance use. Methamphetamine use and mental health disorders (depression, anxiety, bipolar disorder, schizophrenia) were identified using ICD-9 and ICD-10 codes. Chi-square tests and multivariable Poisson regression models were used.
Results: 4,602,896 individuals were included, 0.34% had methamphetamine use, 2.79% had mental health disorders,

and 0.04% had both methamphetamine use and mental health disorders. Compared to individuals without methamphetamine use or a mental health disorder, individuals with both methamphetamine use and a mental health disorder had significantly higher risk of all maternal outcomes, including non-severe hypertensive disorders (8.4% vs 4.7%; aRR = 1.93; 95% CI 1.67, 2.22) and cardiovascular morbidity (1.8% vs 0.3%; aRR = 4.09; 95% CI 2.82, 5.93). The increased risk of these outcomes however, was similar to individuals with methamphetamine use alone. Likewise, individuals with both methamphetamine use and a mental health disorder had a higher risk of all neonatal outcomes, including preterm birth < 37 weeks (17.8% vs 6.1%; aRR = 2.29; 95% CI 2.08, 2.54) and infant death (0.8% vs 0.2%; aRR = 3.43; 95% CI 2.03, 5.81). While this risk was increased compared to individuals with mental health disorders alone, the risk of adverse neonatal outcomes was similar or decreased compared to individuals with methamphetamine use alone.

Conclusion: Individuals with methamphetamine use and mental health disorders have increased risk of maternal and neonatal morbidity. The occurrence of both of these risk factors for adverse outcomes however did not appear to be synergistic.

Table 1: Comparison of maternal and neonatal outcomes among pregnant individuals with and without methamphetamine use and/or mental health disorders (2008-2020)

	No methamphetamine use or mental health disorders	Methamphetamine use	Mental health disorders	Methamphetamine use and mental health disorders	p-value*
	n=4,457,231 (96.84%)	n=15,483 (0.34%)	n=128,238 (2.79%)	n=1,984 (0.04%)	
Maternal outcomes					
Non-severe hypertensive disorder	207,907 (4.7%)	1,175 (7.6%)	10,423 (8.1%)	166 (8.4%)	<0.001
Preeclampsia with severe features	49,814 (1.1%)	587 (3.8%)	2,853 (2.2%)	65 (3.3%)	<0.001

351 | Association of Cord Serum Insulin-like Growth Factor-1 and Fetal Fractional Limb Volume

Satoru Ikenoue[1]; Junko Tamai[1]; Keisuke Akita[1]; Naotsugu Ishikawa[1]; Yasuhiko Ogata[1]; Kaoru Kajikawa[1]; Yuka Fukuma[1]; Yuya Tanaka[1]; Toshimitsu Otani[2]; Yoshifumi Kasuga[1]; Mamoru Tanaka[1]
[1]Keio University School of Medicine, Shinjuku-ku, Tokyo; [2]Keio University School of Medicine, Nakano-ku, Tokyo

10:30 AM - 12:30 PM

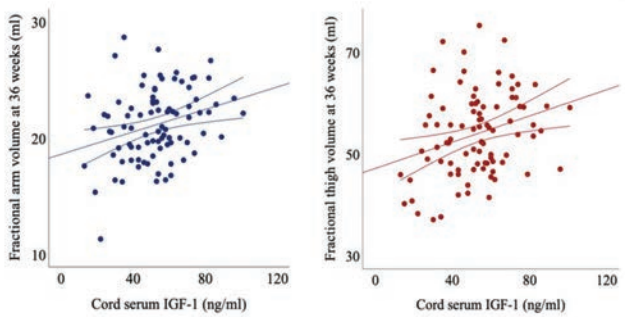
Objective: Insulin-like growth factor-1 (IGF-1) is one of the growth factors that promote protein and carbohydrate metabolism, and consequently affects birth weight. Fetal fractional limb volume has been proposed as a useful parameter for predicting birth weight and quantifying fetal soft tissue development. However, the association between umbilical cord serum IGF-1 level and fetal fractional limb volume remains unclear. This study aimed to investigate the association between cord serum IGF-1 level with longitudinal change of fetal fractional limb volume in uncomplicated pregnancies.

Study Design: A prospective study was conducted in a cohort of 91 singleton pregnancies. Fetal ultrasonography was performed at 24, 30, and 36 weeks' gestation. Fractional arm volume and thigh volume were assessed as cylindrical limb volumes based on 50% of the fetal total diaphysis length using 3D ultrasonography. Cord serum IGF-1 level was measured using Electrochemiluminescence immunoassay.

The association between cord blood IGF-1 level and fetal fractional limb volume was determined by multiple linear regression adjusted for potential confounding factors including maternal age, parity, pre-pregnancy body mass index, gestational weight gain, fetal sex, and gestational age at assessments.

Results: Cord serum IGF-1 was 52.8 ± 18.4 ng/ml (mean ± S.D.). IGF-1 was not associated with fetal fractional limb volume at 24 and 30 weeks. IGF-1 significantly correlated with fractional arm volume ($r = 0.290$, $p = 0.006$) and fractional thigh volume ($r = 0.289$, $p = 0.006$) at 36 weeks. After accounting for the effects of covariates, cord serum IGF-1 explained 8.0% and 10.0% of the variation in fractional arm volume and fractional thigh volume at 36 weeks, respectively.

Conclusion: Cord serum IGF-1 level significantly correlated with fetal fractional limb volume in late gestation. IGF-1 could be one of the serum markers for predicting fetal growth and soft tissue development in late gestation.



352 | Disparities in Non-Invasive Prenatal Testing (NIPT) in the Medicaid and Private Insurance Populations

Saundra Albers[1]; Sarah J. Weingarten[2]; Brittany Roser[3]; Stephen T. Chasen[4]

10:30 AM - 12:30 PM

Objective: Effective screening involves not only the test's availability but also its timing and the coordination of follow-up care. We evaluated the use of NIPT in patients with Medicaid versus private insurance to identify disparities in screening practices.

Study Design: This is a retrospective cohort study of those with abnormal NIPT who underwent diagnostic testing from 2015-2022. We recorded demographic information, NIPT abnormality, type of invasive testing (CVS vs amniocentesis) and pregnancy outcomes. We excluded low fetal fraction results on NIPT. We compared gestational ages at first prenatal visit, NIPT, genetic counseling, invasive testing and abortion between the Medicaid and private insurance populations. Wilcoxon rank sum test was used to compare continuous data. Fisher's exact test and Pearson's Chi-squared test were used for categorical comparisons.

Results: We identified 206 patients with abnormal NIPT, including 179 with private insurance and 27 with Medicaid. Results are in Table 1. Medicaid patients initiated prenatal care and underwent NIPT at later gestational ages and were less likely to have CVS than private insurance patients. Invasive testing had similar normal result rates and distribution of abnormalities. Abortion rates were comparable; however, Medicaid patients underwent abortion at later gestational ages. Intervals between NIPT, disclosure of results, invasive testing, and abortion are in Table 2. While Medicaid patients underwent NIPT at a later gestational age, there were no significant differences in the intervals for post-NIPT care between the groups.

Conclusion: In patients with abnormal NIPT, those with Medicaid underwent screening, prenatal diagnosis, and abortion at later gestational ages. These disparities appear to arise from the later gestational age at first prenatal visit. The availability of early genetic screening, which can greatly affect the timing of prenatal diagnosis and abortion, identifies a clear benefit of earlier prenatal care. Redoubling efforts to initiate prenatal care earlier can alleviate disparities in pregnancies affected by genetic conditions.

Table 1: Demographics and Characteristics

Characteristic	Private Insurance N = 179	Public Insurance N = 27	p-value
Age (years)	37.0 (34.0, 40.0)	37.0 (31.0, 39.0)	0.6

353 | Pregnancy Outcomes in the Setting of Overt Hypothyroidism

Shakeela J. Faulkner[1]; Christopher Pham[2]; April R. Alcantara[2]; Intira Sriprasert[3]; Zoey W. Agle[4]; Caroline T. Nguyen[5]
[1]University of Southern California/Los Angeles General Medical Center, Los Angeles, CA; [2]Los Angeles General Medical Center, Los Angeles, CA; [3]Department of Obstetrics & Gynecology Keck School of Medicine, University of Southern California, Los Angeles, CA; [4]Keck School of Medicine, Los Angles, CA; [5]University of Southern California, Los Angeles, CA

10:30 AM - 12:30 PM

Objective: This study aimed to evaluate whether patients with uncontrolled overt hypothyroidism at initial presentation in pregnancy (thyroid stimulating hormone(TSH) >10) had differences in pregnancy outcomes in comparison to those with controlled hypothyroidism (TSH < 2.5μU/mL), and whether degree of control by gestational week(GW) 28 affected results.

Study Design: This was a retrospective cohort study of patients with hypothyroidism in pregnancy comparing patients with a TSH less than 2.5 to patients with TSH levels greater than 10 at the initiation of prenatal care. Patients with a TSH > 10 were separated based on whether control was obtained by GW 28 weeks (TSH < 2.5), to evaluate potential effects of controlling overt hypothyroidism during pregnancy.

Results: There was a significant difference in rates of gestational hypertension and preeclampsia. For patients with controlled hypothyroidism, overt hypothyroidism that became controlled, and overt hypothyroidism that remained uncontrolled the rates of gestational hypertension were 2.7%, 5.56%, and 21.4%(p 0.03), respectively. The rates of preeclampsia followed a similar pattern with the rates of preeclampsia increasing as the control of hypothyroidism worsened, 6.85%, 22.2%, and 35.7%(p 0.01). There were no significant differences in miscarriage, preterm delivery, NICU admission, gestational diabetes, stillbirth or postpartum hemorrhage. When considering the past medical history, there was a significant difference in the rates of a history of gestational hypertension/preeclampsia across the groups; no differences in the rates of chronic hypertension. There were no significant differences between a history of gestational hypertension/preeclampsia and preeclampsia or gestational hypertension in the current pregnancy.

Conclusion: We observed a dose response with the degree of hypothyroidism control by GW 28 and rates of preeclampsia and gestational hypertension, suggesting that controlling overt hypothyroidism may reduce risk of complication of preeclampsia and gestational hypertension, but risks remain elevated compared to those who are euthyroid initially.

354 | Implementation and Outcomes of an Intrauterine, Vacuum-Induced Hemorrhage-Control Device at a Community Hospital

Shane P. Farrell[1]; Sierra Camburn[2]; Rachel O'Connell[3]
[1]St. Luke's University Health Network, Easton, PA; [2]St. Luke's University Health Network/Lewis Katz School of Medicine at Temple University, Bethlehem, PA; [3]St. Luke's University Health Network, Bethlehem, PA

10:30 AM - 12:30 PM

Objective: Our study examined the real-world implementation and outcomes of an intrauterine vacuum-induced postpartum hemorrhage (PPH) control device (Jada) versus a balloon tamponade device (Bakri) in a community hospital setting. We aimed to determine the frequency of Jada use over Bakri and its impact on quantitative blood loss, need for blood transfusion, and further surgical intervention.

Study Design: This single-institution, retrospective, observational study analyzed PPH cases from January 2019 to July 2023. We identified cases using the electronic medical record with keywords "Jada" and "Bakri" to track mechanical device use. Primary outcomes included device failure, estimated or quantitative blood loss (EBL, QBL), need for blood transfusion, and further surgical intervention. Device failure was defined as a device that was placed but expelled or needed removal due to malfunction or inefficacy. Additional data included subject characteristics, number of uterotonics used, and type of surgical intervention.

Results: Over 4.5 years, 741 PPH cases were identified, with 88 managed using mechanical devices: 29 (32.9%) with Bakri and 57 (64.7%) with Jada. Within 18 months of the Jada device introduction, it was more frequently chosen over Bakri (p = 0.0001). Subject characteristics between the Jada and Bakri groups were not significantly different. Bakri device was more likely to fail than Jada when adjusting for gestational age, BMI, and ethnicity (RR 4.11, 95% CI 1.53-11.02). The Jada group experienced lower blood loss, fewer blood transfusions, and fewer surgical interventions and uterotonics (Table 2).

Conclusion: Our study showed that within 18 months of introducing the intrauterine vacuum device, it was preferred over balloon tamponade for PPH management, resulting in fewer device failures and better outcomes in terms of blood loss, uterotonic use, blood transfusions, and further surgical intervention.

Table 1: Subject Characteristics Across Device Type

Characteristic	Device JADA (n=57)	Bakri (n=29)	p- value

355 | Impact of Continuous Glucose Monitoring and Insulin Pump use on Type 1 Diabetes in Pregnancy

Shannon McCloskey[1]; Joseph R. Biggio, Jr[2]; James D. Toppin[2]; Talia Suner[3]; Kali M. Juracek[4]; Sarah Sternlieb[1]; Frank B. Williams[1]

[1]Ochsner Clinic Foundation, New Orleans, LA; [2]Ochsner Health, New Orleans, LA; [3]Ochsner Clinic, New Orleans, LA; [4]Ochsner Clinical School, New Orleans, LA

10:30 AM - 12:30 PM

Objective: Type 1 diabetes (T1DM) is strongly associated with adverse pregnancy outcomes. Technological advancements, including insulin pumps and continuous glucose monitors (CGM), may improve glycemic control in pregnancy but have not been consistently associated with improved clinical outcomes. We hypothesize that patients utilizing both an insulin pump and CGM will have improved outcomes.

Study Design: This was a retrospective cohort study of patients with T1DM receiving pregnancy care in a large health system from 2016 to 2023. Patients were compared by utilization of insulin pumps versus multi daily insulin injections (MDI). Patients were excluded if missing delivery information, care was established after 20 weeks, or if unable to determine CGM status in pregnancy. Primary outcome was on-target glycemic control, defined as a second trimester Hb A1c < 6.5%. Secondary outcomes included additional glycemic and clinical outcomes. A sub-analysis limited to pump patients compared CGM versus traditional blood glucose monitoring (TBGM). Adjusted odds ratios were calculated using multivariable logistic regression to adjust for potential confounding variables.

Results: Among 288 patients with T1DM, there were 155 deliveries in the insulin pump group and 133 in the MDI group. Patients using insulin pumps were more likely to be of non-Black race, nulliparous, utilize CGM, and have commercial insurance (Table 1). On-target glycemic control was unchanged in the pump group when compared to MDI (36.1% vs 21.1%, aOR 0.97, 95% CI 0.47-1.98). There was no difference in clinical outcomes. In contrast, when examining the pump group by CGM status, glycemic control was improved in those utilizing CGM as compared to TBGM (43.8% vs 16.3%, aOR 3.38, 95% CI 1.24-9.23). There was also improvement in DKA admission and rates of antenatal stillbirth (Table 2). Other non-glycemic outcomes remained unchanged.

Conclusion: When used in conjunction with insulin pump therapy, CGM use in T1DM is predictive of glycemic control in pregnancy and associated with improvement in certain clinical outcomes.

356 | The Relationship between the Plasminogen Activator Inhibitor-1 (PAI-1) Polymorphism and Adverse Obstetrical Outcomes

Sharon Galperin[1]; Sarah Baker[2]; Abdulla Al-Khan[3]; Jesus Alvarez-Perez[1]

[1]Hackensack University Medical Center, Hackensack, NJ; [2]Hackensack Meridian School of Medicine, Hackensack University Medical Center, NJ; [3]Hackensack Meridian School of Medicine, Hackensack Meridian Health, NJ

10:30 AM - 12:30 PM

Objective: The purpose of this study is to investigate the characteristic differences in PAI-1 polymorphism status in a population of patients with RPL and/or adverse obstetrical outcomes.

Study Design: An IRB-approved retrospective chart review of patients who sought care at the Hackensack University Medical Center MFM Division and underwent testing for the PAI-1 polymorphism between January 1, 2019 and January 1, 2024 was performed. Included patients were those that had a history of 2 or more pregnancy losses, and/or adverse obstetrical outcomes, such as fetal growth restriction, intrauterine fetal demise,

postpartum hemorrhage, placental abruption, preterm labor / PPROM associated with the thrombin pathway, or preeclampsia with severe features. Patient characteristics and pregnancy outcomes were recorded in REDCap. Chi-square goodness-of-fit test was performed.

Results: 132 patients who met inclusion criteria were identified. 18 patients (13.6%) had the PAI-1 4G/4G polymorphism present, 69 patients (52.3%) had the 4G/5G polymorphism present, and 45 patients (34.1%) had the 5G/5G polymorphism present. There was no significant difference between the observed and expected distribution of PAI-1 polymorphisms in patients with recurrent pregnancy loss, nor was there a significant difference in patients who had second trimester pregnancy losses. In patients with placental abruption, there was a statistically significant difference in the observed distribution of PAI-1 polymorphisms compared to expected (X^2 (2, $N = 13$) = 6.286, $p < 0.0432$), with the PAI-1 5G/5G polymorphism occurring in 61.5% of patients with placental abruption. However, there was no statistically significant difference in PAI-1 polymorphism status in patients with any of the other studied adverse obstetrical outcomes.

Conclusion: In patients with placental abruption, there was a higher distribution of patients with the PAI-1 5G/5G polymorphism than expected. However no significant difference in distribution was noted in patients with recurrent pregnancy loss or other studied adverse obstetrical outcomes.

357 | Self-Assessment of Complexity and Risk for Pregnant Adults with Congenital Heart Disease

Sherrill "Charlie" J. Rose[1]; Brianna E. Balansay[1]; Catherine M. Albright[1]; Yonatan Buber[2]; Jill M. Steiner[1]
[1]University of Washington, Seattle, WA; [2]University of Washington Medical Center, Redmond, WA

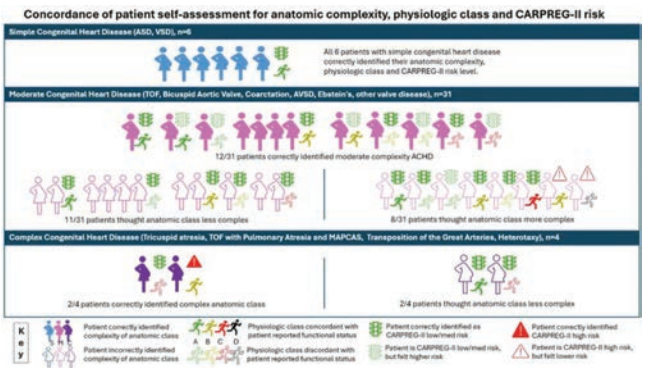
10:30 AM - 12:30 PM

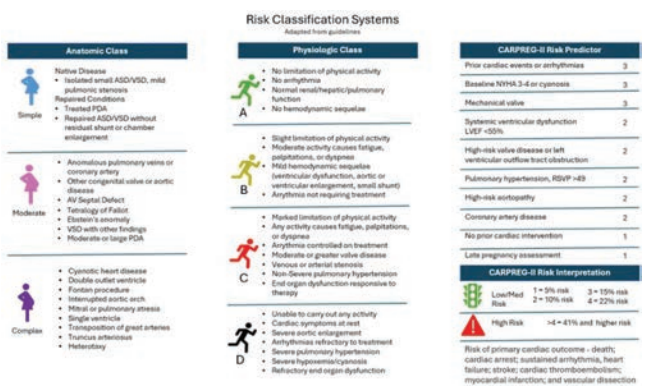
Objective: Elucidate the degree to which patient risk self-assessment correlates with anatomic and physiologic class and CARPREG-II score in the setting of pregnancy and adult congenital heart disease (ACHD).

Study Design: Patients with ACHD with new Cardio-Obstetric consultation were invited to complete a pre-visit self-assessment. The survey queried ACHD complexity, physical activity limitations, rating of overall health, and prior counseling. Patients selected factors that increase pregnancy risk for people with ACHD and identified their level of risk for outcomes like heart failure, arrhythmia, stroke, cardiac arrest, or death. Basic demographic information was collected. Correlation of self-assessed risk was compared to ACHD anatomic and physiologic class and CARPREG-II scores.

Results: 41 patients were reviewed. Only 26% had entirely concordant self-assessment of ACHD complexity, functional status, and ACHD-related pregnancy risk. 31% felt their ACHD was less complex than their anatomic class, 14% more complex. Patient self-assessment of functional status correlated with ACHD physiologic class in only 56%. 84% of patients with a low/medium risk of complications based on CARPREG-II correctly identified this level. Of the 3 patients with a CARPREG-II score >4, only one correctly identified that they were at high risk for cardiac complications.

Conclusion: Only 1 in 4 pregnant patients' pre-visit self-assessment of ACHD complexity, functional status, and risk for complications matched physician assessment. When patients misestimated anatomic class, they tended to think disease was less complex. Physiologic class, which is partially based on imaging findings, was a poor predictor of self-assessed functional status. We anticipate NYHA class would more closely match patient self-assessment. Of the highest risk patients in our cohort, 2/3 were unaware they were at high risk for complication, highlighting the critical nature of preconception counseling for patients with ACHD. Further analysis will identify factors associated with inaccurate patient risk assessment and examine pregnancy outcomes.





358 | Examining Maternal Medication Administration Prior to Urine Drug Screening

Siera Lunn; Adwoa A. Baffoe-Bonnie; Janea Cato; Lena Fried; Leyi Sun; Tracy Truong; Sarahn M. Wheeler; Jennifer J. M. Cate
Duke University School of Medicine, Durham, NC

10:30 AM - 12:30 PM

Objective: Urine drug screening (UDS) is prevalent on many labor and delivery (L&D) units. However, several common medications can cause a false positive UDS. We assessed how often pregnant patients received medications associated with false positive results and whether patient characteristics were associated with receipt of these medications.

Study Design: Retrospective cohort study of patients presenting to L&D at a single academic center between June 10, 2021, and May 31, 2022, who had UDS following implementation of a maternal substance use screening protocol. Primary outcomes included the proportion of patients who received medications

associated with false positives prior to UDS and the proportion of patients with a positive UDS after receipt of these medications (Table 1). Additionally, we examined whether patient age, race, ethnicity, or insurance status differed between those who received these medications and those who did not. Kruskal Wallis and Chi square tests were used to compare categorical variables.

Results: 140 patients underwent UDS. Of those, 30 (21.4%) received medications associated with false positives, and 12 (8.6%) subsequently tested positive (Table 2). Among these 12 patients, the most commonly detected substance was THC (n = 7, 58.3%). The majority of patients tested negative and did not receive any associated medications beforehand. We found no significant differences in age, race, ethnicity, or insurance status, or primary language between those who received these medications and those who did not.

Conclusion: Few patients were administered medications associated with false positives prior to UDS. Given the screening nature and potential for false positives in UDS, iatrogenic false positive results should be considered in instances of confounding administration. Patient characteristics were not associated with receiving medications that can cause false positives. Future research should explore the frequency of confirmatory testing in pregnant patients, the steps taken after a potentially confounded positive result, and whether these vary based on patient demographics.

Table 1. Medications that can cause a false positive UDS

Medication	False Positive
Bupropion (Wellbutrin)	Amphetamines, Methamphetamines
Dextromethorphan (Robafen, Robitussin)	PCP, Opioids
Diphenhydramine (Benadryl)	Opioids, PCP
Doxylamine (Unisom)	Barbiturates
Labetalol (Trandate)	Amphetamines, Methamphetamines
NSAIDs (e.g. Ibuprofen (Advil), Naproxen (Aleve), Toradol (Ketorolac))	THC, PCP, Barbiturates, Benzodiazepines
Phentermine	Amphetamines
Promethazine (Phenergan)	Amphetamines, Methamphetamines
PPIs (e.g. Pantoprazole (Protonix))	THC
Pseudoephedrine (Sudafed)	Amphetamines, Methamphetamines
Quetiapine (Seroquel)	Opioids
SSRIs (e.g. Sertraline (Zoloft))	Benzodiazepines, LSD
Trazodone (Desyrel)	Amphetamines, Methamphetamines
Venlafaxine (Effexor)	PCP

Table 2. UDS results stratified by medication intake

Substance tested	(1) Positive and received associated medications (n, %)	(2) Positive and did not receive associated medications (n, %)	(3) Negative and received associated medications (n, %)	(4) Negative and did not receive associated medications (n, %)
Amphetamine	2(1.4%)	4(2.9%)	8(5.7%)	126(90.0%)
Barbiturate	0(0.0%)	0(0.0%)	23(16.4%)	117(83.6%)
Benzodiazepine	2(1.4%)	3(2.1%)	19(13.6%)	116(82.9%)

359 | Expanding Obstetric Carrier Screening: Patient Knowledge of Genes Tested and Interest in Adding Cancer-Associated Genes

Sonali Iyer[1]; Alex Raghunandan[1]; Christina Pardo[1]; Jessica Scholl[1]; Robin B. Kalish[2]; Melissa Frey[1]
[1]Weill Cornell Medical College, New York, NY; [2]New York Presbyterian- Weill Cornell, New York, NY

10:30 AM - 12:30 PM

Objective: The American College of Obstetricians and Gynecologists recommends that all pregnant women receive information regarding expanded carrier screening (ECS), with up to 40% of patients completing ECS. ECS can include hundreds of genes but has, traditionally, excluded genes implicated in hereditary cancer. Our objective is to assess patient knowledge of ECS and interest in concurrent cancer multigene panel testing (CMPT).

Study Design: In a mixed-methods, quality improvement study, patients were called 2-6 following ECS results. Patients were queried about their understanding of ECS and interest in CMPT. Descriptive statistics were used for quantitative data and grounded theory to perform thematic analysis for qualitative data.

Results: 155 patients were called and 73 reached, among who 67 (43%) agreed to complete the survey (Table 1, demographics). When asked if a provider had explained ECS during a prenatal visit, 63 (94%) said yes, 2 (3%) no, and 2 (3%) unsure. When asked if patients know what ECS evaluates, 34 (50%) said yes, 23 (34%) no, and 10 (15%) unsure. When asked if they believed testing for cancer-related genes was included in ECS, 13 (19%) said yes, 31 (46%) said no, and 23 (34%) were unsure. When asked if they would have opted for testing for cancer-associated genes with ECS if offered, 50 (75%) said yes, 13 (19%) no, and 4 (6%) were unsure. 48 participants provided additional comments, with the themes of increased knowledge, increased anxiety, and cost concerns being the most common (Table 2).

Conclusion: More than half of patients were unsure or believed that cancer-related genes were included on ECS panels, suggesting a potentially dangerous misunderstanding of the scope of this test and meaning of "negative" results. Furthermore, 75% of patients stated that if offered, they would accept CMPT at time of ECS. As the majority of individuals with hereditary cancer syndromes remain unidentified, pregnancy and ECS may offer a unique window of opportunity for women to engage in discussions around genetic testing and complete potentially lifesaving CMPT.

Table 1. Patient Demographics (n = 67)		
	Median	Range
Patient Age (years)	34	18 – 43
Gestational Age (weeks)	20.1	10.0 – 34.7
Gravida	2	0 – 7
Para	0	0 – 3
Race	n	%
White	30	44
Black	11	16
Asian	9	13
Other	6	9
Declined to answer	11	16

Table 2. Themes regarding testing for cancer-related genes with ECS		
Theme	N of participants contributing (n=48)	Example quote
Knowledge - Better to know test results - Option to take preventative measures - Desire for increased medical counseling	11	"I want to know if I will pass [cancer] onto my baby. Knowledge is power and I want to have that information up front… It's important to educate patients so they know what they can do with these test results."
Anxiety and fear - Fear of abnormal results - Guilt of increasing child's risk of cancer - Anxiety of not being able to do anything about results during pregnancy	10	"Cancer is anxiety producing. I'd get tested if it was protocol, but the feelings I got before when doing tests when I know I couldn't fix anything was not a good feeling."
Factors that affect feelings on including cancer-related genes - Cost - Family history - Medical comorbidities - Joint decision making with providers and family members - Using information to plan future pregnancies	24	"It really depends on if insurance covered the test or if you have a family history of cancer."

360 | Cerebroplacental Doppler Ratio for the Prediction of Adverse Perinatal Outcomes in Late-Onset Fetal Growth Restriction

Sonia Sajja[1]; Onur Turkoglu[2]; Torey Asao[1]; Perry Friedman[3]; Ray Bahado-Singh[4]
[1]Corewell Health William Beaumont University Hospital, Royal Oak, MI; [2]Baylor College of Medicine, Houston, TX; [3]Memorial Healthcare System, Memorial Healthcare System, FL; [4]Corewell Health William Beaumont University Hospital, Oakland University William Beaumont School of Medicine, Royal Oak, MI

10:30 AM - 12:30 PM

Objective: Late-onset fetal growth restriction (LO-FGR), defined as onset ³ 32 weeks gestation, is the more common subgroup of FGR. The umbilical artery Doppler is usually unaffected. There are no subgroup-specific guidelines for monitoring pregnancies affected by LO-FGR. We compared the utility of the cerebroplacental Doppler ratio (CPR) to the Biophysical Profile (BPP), a widely endorsed FGR monitoring tool, for the prediction of adverse perinatal outcomes (APO).

Study Design: This is a retrospective cohort study of LO-FGR, defined as estimated fetal weight < 10th%, from 2013-2018. Using logistic regression analysis, we determined whether low CPR < 5th% and BPP score £ 6 significantly independently predicted the composite APO defined as one or more complications: cord pH < 7.20, 5-minute Apgar score of < 5, operative or cesarean delivery secondary to non-reassuring fetal heart tracing, assisted respiration at birth, NICU admission, and/ or perinatal death. Secondarily, we also evaluated prediction of severe neonatal morbidity (SNM) defined in Table 1 (legend).

Results: There were 233 cases of LO-FGR of which 76 (34%) had a low CPR percentile and 28 (13%) had a low BPP score. There were 22 (9.9%) cases with SNM of which 5 (2.1%) had a low CPR percentile and 4 (1.8%) had a low BPP score. A low CPR was associated with a significantly higher rate of individual and composite APO than cases with normal CPR percentile (p < 0.001) [Table 1]. Both a low CPR percentile and a low BPP score significantly predicted APO overall. CPR appeared to be a better predictor of the APO, controlling for gestational age at testing [Table 2]. Only BPP significantly predicted SNM: CPR (OR = 4.64, p = 0.13) and BPP (OR = 4.11, p = 0.038).

Conclusion: A low CPR percentile was a significant independent predictor of perinatal complications in LO-FGR, including abnormal fetal heart rate tracing, smaller birthweight percentile, and NICU admission. CPR appeared superior to BPP overall. CPR should be considered as a fetal surveillance tool in LO-FGR.

Table 1: Characteristics and outcomes in late-onset fetal growth restriction: abnormal CPR <5th% or BPP score ≤ 6.

	Abnormal CPR (n=76)	Normal CPR (n=147)	*P*-value	BPP score ≤ 6 (n=28)	BPP score 8 (n=195)	*P* -value

361 | Dual Positivity for Down Syndrome and Neural Tube Defects: Indicator of Adverse Pregnancy Outcomes

Sooji Ham; Youri Lee; Ji-Hee Sung; Sukjoo Choi; Cheongrae Roh; Sooyoung Oh
Samsung Medical Center, Sungkyunkwan University of Medicine., Seoul, Seoul-t'ukpyolsi

10:30 AM - 12:30 PM

Objective: 'Dual positivity' refers to screen-positive for both Down syndrome (DS) and neural tube defect (NTD) in second-trimester screening tests (Fetal Diagn Ther 1998;13:106–110). Given that alpha-fetoprotein (AFP) level is usually low in DS, the concurrence of high risk for both DS and NTD does not match each other. Herein, we aim to check the clinical significance of dual positivity associated with adverse pregnancy outcomes, including preeclampsia and fetal growth restriction (FGR).

Study Design: This retrospective study included 445 pregnant women whose serum marker tests indicated a high risk for DS (N = 315), NTD (N = 81), or both (N = 49), who delivered at our institution between January 2014 and March 2024. Additionally, one hundred consecutive women with low-risk results for both DS and NTD during the study period were selected as a control group. We compared the rate of preeclampsia and FGR among four groups: control, high risk for DS, high risk for NTD, and dual positivity. We also examined the gestational age of delivery and neonatal birth weight. Statistical analyszes were performed using linear-by-linear analysis and ANOVA.

Results: Among the dual positivity group, no fetus was diagnosed as DS by amniocentesis nor NTD by level II ultrasonography. The rate of preeclampsia was highest in dual positivity (57.1%), followed by high risk for NTD (18.5%), high risk for DS (14.9%), and control (4%). Similarly, the rate of FGR was highest in dual positivity (79.6%), followed by high risk for NTD (40.7%), high risk for DS (17.1%), and control (6%). The median gestational age at delivery and neonatal birth weight of dual positivity group were 29+5 (interquartile range, 25+6-35+5) weeks and 0.94 (interquartile range, 0.45-1.96) kg, respectively, which was significantly lower compared with other three groups (Figure 1).
Conclusion: Our data indicate that dual positivity is strongly associated with preeclampsia or FGR. This suggests that women with dual positivity require enhanced prenatal care, including regular monitoring of maternal blood pressure and fetal growth assessments.

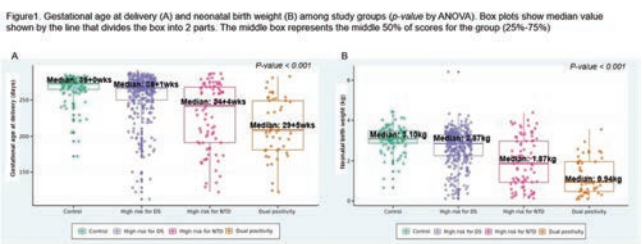

Figure1. Gestational age at delivery (A) and neonatal birth weight (B) among study groups (*p-value* by ANOVA). Box plots show median value shown by the line that divides the box into 2 parts. The middle box represents the middle 50% of scores for the group (25%-75%)

362 | Variable Expression of sFlt-1 Splice Variants in Distinct Placental Cells in Normal and Preeclamptic Pregnancies

Sri Padma Ravali Kanigalpula[1]; Gracy Rosario[2]; Hruda Malik[2]; Sabita Dhal[2]; Shilpa Babbar[3]; Thajasvarie Naicker[4]; Nihar Nayak[2]
[1]University of Missouri Kansas City School of Medicine, Overland Park, KS; [2]University of Missouri Kansas City School of Medicine, Kansas City, MO; [3]University of Missouri Kansas City, Kansas City, MO; [4]University of KwaZulu-Natal, Durban, KwaZulu-Natal

10:30 AM - 12:30 PM
Objective:
Elevated levels of soluble fms-like tyrosine kinase-1 (sFlt-1) have been associated with placental disorders, such as preeclampsia. However, the precise expression patterns and regulation of the main placental sFlt1 splice variants, e15a and i13, within the intricate placental tissue remain poorly understood. The aim of our study is to investigate how these splice variants are differentially expressed and regulated across pregnancy and in preeclampsia, providing insights into their roles in placental pathology.
Study Design: We used 16 placental samples for this study. First-trimester samples were obtained from women undergoing pregnancy terminations, while samples from individuals with preeclampsia and gestational age-matched controls were collected at the time of delivery. Cellular localization of sFlt-1 e15a and sFlt-1 i13 transcripts was analyzed by RNA in situ hybridization using a custom-designed BaseScope probe for e15a and a 35S-labeled probe for i13.
Results: In the first-trimester placentas, e15a and i13 mRNAs were highly expressed in the intermediate trophoblasts and invading cytotrophoblast columns. In term placentas (controls), the signal was primarily detected in the extravillous trophoblasts located in the basal plate/decidua. In preeclamptic placentas, the expression of both e15a and i13 was markedly elevated in the extravillous trophoblasts and also observed in some villi near the basal plate. Notably, the signals for both e15a and i13 were highly focal within the villi but more widespread in the extravillous trophoblasts. Furthermore, the e15a signal was stronger in the villi, while the i13 signal was more intense in the extravillous trophoblasts.
Conclusion: Our findings reveal that sFlt-1 e15a and i13 expression in the placenta is highly localized and confined to specific cell types, challenging the previous notion of their widespread and uniform distribution. This localized expression highlights the importance of understanding the cell-specific regulatory mechanisms of sFlt-1 in unraveling the pathophysiology of pregnancy complications.

363 | Hospital Birth Volume and Rural/Urban Location: Associations with Perinatal Outcomes Among Individuals with Chronic Hypertension

Stephanie A. Leonard[1]; Elliott K. Main[2]; Brielle L. Formanowski[3]; Scott Lorch[3]; Ciaran S. Phibbs[2]; Sara Handley[4]; Molly Passarella[3]; Brian T. Bateman[2]; Katy Backes Kozhimannil[5]
[1]Stanford University, Palo Alto, CA; [2]Stanford University, Stanford, CA; [3]Children's Hospital of Philadelphia, Philadelphia, PA; [4]Children's Hospital of Pennsylvania, Philadelphia, PA; [5]University of Minnesota, Minneapolis, MN

10:30 AM - 12:30 PM
Objective: Chronic hypertension (cHTN) in pregnancy is increasing, but little is known about perinatal outcomes at birth hospitals with different characteristics. We evaluated the association between hospital birth volume and rural/urban location with risk of adverse perinatal outcomes among individuals with cHTN.
Study Design: We conducted a population-based study using linked vital statistics and birth hospitalization discharge data from Michigan, Oregon, Pennsylvania, and South Carolina (2008-2020). We classified hospitals based on federal rural-urban county classifications and annual birth volume. The primary outcome was a composite of obstetric and fetal/neonatal outcomes, with components as secondary outcomes (Table 1). We used multivariable modified Poisson regression models with hospital fixed effects and robust standard errors to estimate the relative risk (RR) of the outcomes for each hospital group compared with high-volume urban hospitals.
Results: Among 102,787 births to individuals with cHTN, the crude incidence of the primary outcome was highest in high-volume urban hospitals (47.2%) and lowest in low-volume rural hospitals (32.0%Table 2). Additionally, a higher proportion of individuals giving birth at high-volume urban hospitals had a high (≥10) obstetric comorbidity score (44% vs 24-26% at rural and low-volume urban hospitals). After robust adjustment in regression models, however, no differences between hospital groups were evident. Among primary outcome components, only risk of superimposed preeclampsia/eclampsia was higher in low-volume urban (RR: 1.14; 95% CI: 1.02-1.28) and medium-volume rural (RR: 1.33; 95% CI: 1.08-1.62) hospitals, with imprecise results in low-volume rural hospitals.

Conclusion: Lower rates of adverse outcomes among individuals with cHTN giving birth at lower volume and rural hospitals were observed and our results suggest these differences were largely explained by hospital case mix. Higher risk-adjusted rates of superimposed preeclampsia/eclampsia at medium-volume rural and low-volume urban hospitals suggest potential opportunities for prevention.

*Covariates in adjusted models: delivery year, state, age, payment method, education level, parity, race-ethnicity, and obstetric comorbidity index. Hospital fixed effects were used to control for unobservable differences between hospitals.

364 | Forward Weight Prediction Among Sga, Aga, and Lga Neonates

Stephanie Masters[1]; Chloe Lessard[1]; Nneoma Edokobi[1]; Monica Ahrens[2]; Ryan Bradley[1]; Benny Antony[3]; Megan Whitham[4]

[1]Virginia Tech Carilion, Roanoke, VA; [2]Virginia Tech Carilion School of Medicine, Roanoke, VA; [3]Virginia Tech, Roanoke, VA; [4]Carilion Clinic, Waynesboro, VA

10:30 AM - 12:30 PM

Objective: The Gestation-Adjusted Projection (GAP) forward projection model extrapolates birth weight at delivery from third-trimester growth ultrasounds. This method relies on the observation that the ratio of the weight of the normal fetus to the population median remains constant in the third trimester. This study aims to evaluate weight prediction accuracy using GAP forward projection from 3rd trimester growth assessments from neonates ultimately with LGA, SGA, and AGA birthweights at delivery and examine the effect of elevated maternal body habitus on accuracy of these estimates.

Study Design: We conducted a retrospective analysis of pregnancy records from 2016 to 2023 of patients cared for and delivered in our hospital system. We included singleton, liveborn, and non-anomalous pregnancies delivered after 28 weeks GA. Exclusions were multiple gestation, major fetal anomalies, stillbirth, and absence of third trimester growth assessments or mid-gestational anatomic surveys. We identified 1559 records that resulted in review of 554 records with final growth ultrasounds. Accuracy of GAP prediction was defined as an estimation of birth weight within 10% of actual birth weight. Percent error and absolute value of percent error of estimation were also examined.

Results: We observed an overall median absolute value of accuracy of 8.56 (IQR 3.9, 15.19). Across all pregnancies, 57.2% of fetal weight estimates were accurate. Respective groups showed a 51.4% accuracy in women with appropriate BMI (n = 185), 61.4% accuracy in the overweight category (n = 145), and 58% in the obese category (n = 224). Rates of accuracy, overestimation, and underestimation were significantly different between weight classifications (p = 0.031).

Conclusion: The GAP forward projection method can be used as an alternative method to estimating fetal weight rather than extrapolation by adding stagnant estimates of grams per day or by using Leopold's maneuvers which can be challenging on patients of higher maternal BMI.

365 | Burden of Placental Pathology is Associated with Severity of Clinical Outcomes

Stephanie Schreiber[1]; Sunitha Suresh[1]; Ann EB Borders[2]; Alexa A. Freedman[3]; Linda M. Ernst[1]; Greg E. Miller[3]

[1]Endeavor Health, Evanston, IL; [2]Endeavor Health, Evanston Hospital, Evanston, IL; [3]Northwestern University, Chicago, IL

10:30 AM - 12:30 PM

Objective: Hypertensive disorders of pregnancy (HDP) and Small for Gestational Age (SGA) neonates have both been previously associated with placental pathology. Here we evaluate the association of placental disease burden with severity of clinical disease - either HDP or SGA alone compared to the combination of both HDP and SGA.

Study Design: Placentas were prospectively collected and examined by a perinatal pathologist in the Stress, Pregnancy, and Health study. We compared placentas from patients with neither HDP nor SGA, HDP or SGA, and both HDP+SGA by four categories of placental pathology: acute inflammation (AI), chronic

inflammation (CI), maternal vascular malperfusion (MVM), and fetal vascular malperfusion (FVM). Univariate analysis was performed using chi^2 tests, ANOVA, and Kruskal-Wallis as appropriate. Multivariate analysis was conducted with logistic regression adjusted for BMI, mode of conception, diabetes, and socioeconomic status. We additionally examined the number of MVM related lesions.

Results: Of 571 placentas, 421 (74%) served as the control with neither HDP nor SGA, 138 (24%) had either HDP or SGA, and 12 (2%) had both HDP+SGA. Prevalence of MVM was higher with increasing clinical disease (22.1% control, 45.7% HDP or SGA, 75% HDP+SGA, p< .001). After adjustment, odds of MVM increased more than 3-fold from just HDP or SGA (aOR 3.34 [95%CI 2.08,5.34]) to both HDP+SGA (aOR12.3 [95%CI 3.17,47.5]) compared to the control group. There was no significant difference in prevalence of AI (p = 0.09), FVM (p = 0.78), and CI (p = 0.6) between the three groups. In examining placental disease burden, increasing MVM was seen with increasing amount of clinical disease (median [IQR] MVM score 0[0,1] for control, 1[0,3]for HDP or SGA, 3.5[1.5,5] for HDP+SGA, p = .0001).

Conclusion: A combination of both HDP and SGA, compared to either alone, is associated with greater prevalence of placental MVM lesions as well as higher MVM score. Future research should focus on further understanding this relationship and potential opportunities for intervention for patients with HDP and suspected SGA.

366 | Neonatal Inflammatory Profiles Associated with Perinatally Acquired HCV Infection

Stephanie A. Fisher; On behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD) Maternal-Fetal Medicine Units (MFMU) Network
Northwestern University Feinberg School of Medicine, Chicago, IL

10:30 AM - 12:30 PM

Objective:

To identify plasma inflammatory cytokine and chemokine profiles associated with hepatitis C virus (HCV) infection among infants with perinatal HCV exposure.

Study Design: Nested case-control study of infants born to pregnant people with HCV viremia enrolled in a prospective, multisite, observational cohort study of perinatal HCV transmission (2012-21). Cases were infants with perinatally acquired HCV infection (positive HCV RNA PCR at 2 months of life). Negative controls were matched on center, term vs. preterm birth, and peak maternal viral load (HCV RNA >10^6 IU/ml vs. HCV RNA ≤10^6 IU/ml) during pregnancy. We assessed pro-inflammatory cytokine and chemokine (TNF-α, IL-1RA, IL-18, FGF-basic, PD-L1, CXCL10/IP-10) concentrations in infant plasma drawn at 2 months of life. Quantile regression was used to compare the distribution of cytokine and chemokine concentrations between cases and controls; box plots depicting their log-transformed concentrations were generated.

Results: Perinatal transmission occurred in 26 infants (8%) born to 314 individuals. Of infants without exposure to HIV (N = 24), 11 had had 2-month samples available for analysis. In 11 cases and 11 controls, the mean gestational age at birth was 38 ± 2 weeks (3 cases and 2 controls were born preterm). Median PD-L1 concentration was higher in cases than controls (79 vs. 58 pg/ml; difference in medians, 95 % CI 22 pg/ml, 3 - 41; p = 0.03). Median CXCL10/IP-10 concentration was higher in cases than controls, but not statistically significantly (100 vs 57, p > 0.05). The distributions of other detectable cytokine concentrations were similar between groups (Table, Figure).

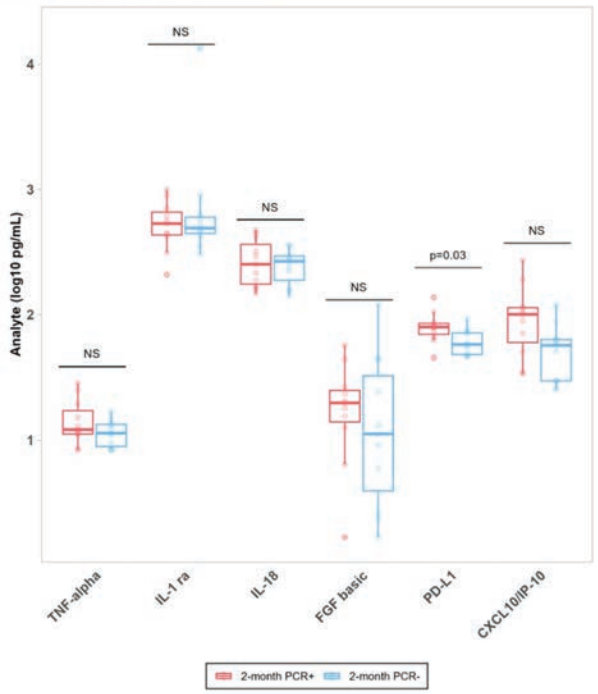
Conclusion: Compared to HCV-exposed uninfected infants at 2 months of life, infants with perinatal HCV infection demonstrate upregulation of PD-L1, a signature of functional CD8 T-cell exhaustion. Understanding the role of the PD-1/PD-L pathway and regulation of cytotoxic T-cell responses requires further investigation in infants exposed to HCV viremia *in utero*.

Table. Distribution of cytokine and chemokine concentrations in infants with versus without perinatal HCV infection at 2 months of life

Analyte	2 month HCV PCR+ *Median (IQR)* N=11	2 month HCV PCR- *Median (IQR)* N=11	Difference in medians (95% CI)
TNF-α	12 (11, 20)	11 (8, 14)	1 (-4, 5)
IL-1RA	533 (422, 706)	491 (422, 629)	42 (-164, 248)
IL-18	252 (164, 414)	267 (159, 295)	-14 (-153, 125)
FGF-basic	20 (13, 27)	11 (3, 44)	9 (-10, 27)
PD-L1	79 (66, 86)	58 (47,73)	22 (3, 41)
CXCL10/IP-10	100 (50, 115)	57 (30, 63)	44 (-1, 88)

All analyte concentrations, assessed at 2 months of life, are reported as pg/mL.
HCV: hepatitis C virus, PCR: polymerase chain reaction, IQR: interquartile range, CI: confidence interval, TNF-α: tumor necrosis factor-alpha, IL-1RA: interleukin-1 receptor antagonist, IL-18: interleukin-18, FGF-basic: basic fibroblast growth factor, PD-L1: programmed death-ligand 1, CXCL10/IP-10: C-X-C motif chemokine ligand 10, also known as Interferon gamma-induced protein 10

Figure. Distribution of cytokine and chemokine concentrations in HCV PCR+ vs. PCR- neonates



HCV: hepatitis C virus, PCR: polymerase chain reaction, NS: not statistically significant

367 | Area-Based Socioeconomic Deprivation Indices to Predict Glycemic Control in Pregnant Patients with Type 1 Diabetes

Talia Suner[1]; Kali M. Juracek[2]; James D. Toppin[3]; Joseph R. Biggio, Jr[3]; Shannon McCloskey[4]; Frank B. Williams[4]
[1]Ochsner Clinic, New Orleans, LA; [2]Ochsner Clinical School, New Orleans, LA; [3]Ochsner Health, New Orleans, LA; [4]Ochsner Clinic Foundation, New Orleans, LA

10:30 AM - 12:30 PM

Objective: Area Deprivation Index (ADI) and Social Vulnerability Index (SVI), indicators of socioeconomic disadvantage, have been associated with adverse outcomes. The inclusion of demographic and economic variables differs between the two indices, potentially affecting the strength of the association with some conditions. We sought to determine if Area Deprivation Index (ADI) or Social Vulnerability Index (SVI) better predicts glycemic control in pregnant patients with type one diabetes mellitus (T1DM).

Study Design: We performed a retrospective cohort study of pregnant patients with singleton gestations and T1DM receiving care at a large regional health system from January 2016 to January 2023. Patients establishing care after 20 weeks and those with missing delivery information were excluded. Primary outcome was optimal baseline glycemic control, defined as HbA1c < 6.5%. Area under the curve (AUC) was calculated to examine the ability of each index to predict optimal glycemic control. Secondary outcomes included midtrimester HbA1c < 6.0%, delivery < 34 weeks and non-transfusion severe maternal morbidity (SMM). Outcomes were compared via regression analyses controlling for individual level deprivation as indicated by public insurance.

Results: Among 288 patients, 144 (50%) had public insurance, with those patients more likely to be younger (median age 26 vs 31, p < 0.001) and Black (52% vs 17%, p < 0.001, Table). Public insurance was associated with lower odds of optimal HbA1c (5.6% vs 29.2%, p < 0.001). Controlling for payor status, ADI was associated with baseline glycemic control (p = 0.006) while SVI was not (p = 0.36). The AUC for prediction of optimal baseline HbA1c was similar for ADI and SVI when paired with payor status (Figure). ADI, but not SVI, was predictive of midtrimester glycemic control (ADI p = 0.013, SVI p = 0.098). Neither ADI nor SVI was associated with SMM or delivery < 34 weeks after controlling for payor.

Conclusion: Neighborhood deprivation defined by ADI, but not SVI, was associated with glycemic control after controlling for individual-level income status in pregnant patients with T1DM.

Table 1. Baseline characteristics of pregnant patients with type I diabetes mellitus by insurance payor status.

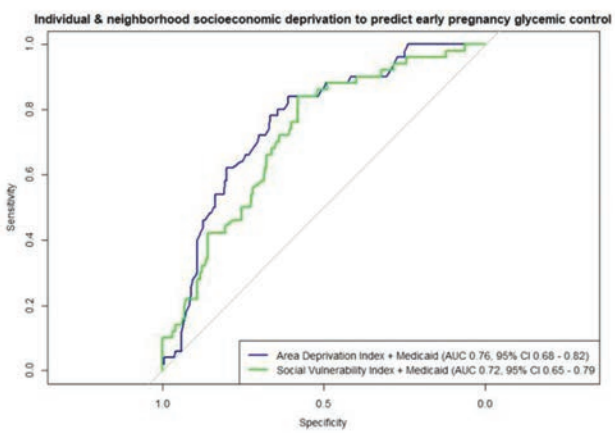

Figure 1: Receiver operator characteristic (ROC) produced comparable area under the curve (AUC) for ADI and SVI in prediction of optimal glycemic control. ADI shows AUC 0.76 (95% CI 0.68-0.82) while SVI shows AUC 0.72 (95% CI 0.65-0.79).

368 | The Intersectionality of Social Determinants on Preterm Birth Risk

Taylor Drazan[1]; Angela Campbell[1]; Elissa Faro[2]; Namrata Singh[3]; Kelli K. Ryckman[1]
[1]Indiana University - Bloomington, Indianapolis, IN; [2]University of Iowa, Iowa City, IA; [3]University of Washington, Seattle, WA

10:30 AM - 12:30 PM

Objective: There is a significant gap in the understanding of what causes women with rheumatic disorders to be at increased risk for preterm birth (PTB). This study aimed to identify social determinants that influence the relationship between immune-mediated inflammatory arthritis (IMIA), including rheumatoid arthritis, psoriatic arthritis, and axial spondyloarthritis, and PTB in a large multi-racial/ethnic cohort of women. In line with the intersectionality framework, we quantified the relationship between IMIA and PTB and how it is impacted by race, insurance type, and mother's age.

Study Design: We utilized data from electronic medical records from Indiana University Health curated by the Regenstrief Institute, Inc. on births from 2018 to 2022 to create a retrospective cohort of 72,264 unique deliveries. A stratified logistic regression analysis was conducted to assess the associations between maternal age, race, and insurance type with preterm birth, separately for women with and without IMIA. Interaction terms were included to explore the multiplicative effects of these variables.

Results: Among women with IMIA (n = 294), Non-Hispanic (NH) Black women were at significantly increased risk of PTB (OR = 1.50, p = 0.006), and advanced maternal age (35-49yrs) was also associated with higher risk (OR = 0.94, p = 0.031). However, the interaction between age and NH Black women, though suggestive, did not reach statistical significance. For non-IMIA women (n = 71,970), similar patterns were observed with significant associations for maternal age (OR = 0.23, p < 0.001) and NH Black women (OR = 0.19, p < 0.001). Importantly, the interaction between age and NH Black women was statistically significant (OR = 0.32, p < 0.001), indicating that the combined effect of these factors may amplify PTB risk.

Conclusion: These findings suggest intersectional factors, particularly race and maternal age, interact complexly to influence PTB irrespective of IMIA. Future exploration of intersectional identities and their impact on perinatal health is warranted.

369 | Assessing Racial Disparities in the Initiation of Prenatal Care in Women after Emergency Department Visits

Temiloluwa O. Oladeji[1]; Cydni Akesson[2]; Sokhna Seck[2]; Stacie Jhaveri[2]

[1]Cleveland Clinic Lerner College of Medicine, Cleveland Heights, OH; [2]Cleveland Clinic, Cleveland, OH

10:30 AM - 12:30 PM

Objective: Colloquially, we have seen emergency departments (ED) become the first line of prenatal care for persons early in their pregnancy. Still, there is insufficient data on how this prenatal care is performed, who utilizes the ED prior to initiation of prenatal care, and how quickly and often this leads to long-term follow-up by an obstetrician for initiation of prenatal care. This study aimed to assess the demographics of women who presented with pregnancy for the first time in the emergency department before initiating prenatal care to identify demographics and risk factors associated with this presentation.

Study Design: A retrospective cohort analysis was conducted on women who presented at Fairview Hospital Emergency Department (ED) with a positive hCG test between January 2, 2019, and December 31, 2019, without prior established obstetric care in their current pregnancy.

Results: The analysis included 347 patients who presented to the ED before establishing obstetric care in their pregnancy, with 87% of patients seeking care for obstetric-related complaints during their ED visit. Our study found notable differences between non-Hispanic white (140 patients) and minority patients (Black, Hispanic, and Multiracial ~ 197 patients) populations, with minority patients being more likely to be on public insurance or uninsured (p = 0.0148) and to establish care after 12 weeks gestational age (23.5% vs 11.6%, p = 0.0141). Minority patients were less likely to have an established OB/GYN (44.4% vs 62.2%, p = 0.0013) or to have an OB/GYN for their current pregnancy than Non-Hispanic White patients (p = 0.0193).

Conclusion: Although there are racial disparities evident in the time taken to establish prenatal care between minority to non-Hispanic white patients who present to the ED prior to establishing care, this study revealed how differences in insurance status between racial and ethnic groups may also be contributing to this disparity in the initiation of prenatal care.

Characteristic	Total Population	White (N = 140)	Minority (N = 199)	P value
BMI median, kg/m2	27.3 (7.84)	26.61 (8.01)	27.98 (7.72)	0.0826

370 | Application of a Multiscale Model of Heart Growth in Pregnancy to Patient-Specific Echocardiographic Data

Tiffany Corlin; Molly S. Kaissar; Kyoko Yoshida

University of Minnesota, Minneapolis, MN

10:30 AM - 12:30 PM

Objective: Computational models are a useful tool in predicting changes during pregnancy, as real-time monitoring can be invasive or not practically feasible. Here, we apply a multiscale model

of left ventricular (LV) growth throughout pregnancy. The model was scaled to patient masses and mean arterial pressures (MAP) to assess how the model represents individual pregnant patients.
Study Design: The MATLAB code for the previously developed model in the rat is publicly available and allometric scaling was used to adapt the rat model's hemodynamics to human physiology. Hormone levels (estrogen, progesterone, and angiotensin II) were adapted to human concentrations reported by the literature. Then, using an obstetric outcomes database, we identified 663 pregnant patients without comorbidities and at least one normal echocardiogram during pregnancy. The model was executed for 18 patients, which was scaled to the patient's pre-pregnancy mass and matched to MAP. Hormones were considered the same for all patients.
Results: The model demonstrates an increase in LV mass by approximately 60-70% through pregnancy. The allometric scaling between patients did not significantly affect the model's growth, as each patient's LV mass growth curve was nearly the same (Figure 1). The model overpredicted LV mass in patients with a pre-pregnancy mass of < 60 kg, but was nearly all within a 20% error range of the patient's LV mass in patients > 60 kg (Table 1). The model's predictions for end-diastolic diameter (EDD) and cardiac output
(CO) were overestimated in the patients weighing > 60 kg prior to pregnancy (Table 1).
Conclusion: A multiscale model demonstrating heart growth during pregnancy has been scaled from rats to humans. It is a novel use of this model to compare to human echocardiographic data that makes reasonable predictions, especially in normal-weight patients. Future directions include comparison of the model's accuracy to longitudinal data for specific patients to determine which factors are most instrumental in predictions and how to make determinations about those at risk for pregnancy-associated cardiac morbidity.

371 | One Key Question Ascertainment of Pregnancy Intention and Participation in Genetic Testing/Research Among Puerto Ricans

Timothy D. Dye[1]; Zahira Quiñones Tavarez[2]; Ivelisse Rivera[2]; Nancy Cardona Cordero[3]
[1]University of Rochester Medical Center, Rochester, NY; [2]University of Rochester School of Medicine and Dentistry, Rochester, NY; [3]University of Puerto Rico, San Juan, Puerto Rico

10:30 AM - 12:30 PM
Objective: Peri-pregnancy is a unique opportunity for genetic testing (GT) in clinical care and for inclusion of pregnant people in genetic research (GR). Equitable inclusion of people self-identifying as Puerto Rican (PR) in GT/GR is complicated by historical scientific abuses, mistrust, and minoritization, placing PR at risk of distributional injustice in being excluded from GT/GR from which they could benefit. We aimed to ascertain likelihood of participation in GT/GR among non-pregnant PR women of reproductive age who hope to become pregnant in the next year.
Study Design: We conducted a nested analytical cross-sectional study of social determinants of GR/GT participation among people who self-identified as non-pregnant PR women age 21-49. We used *One Key Question* to ascertain pregnancy intention in the next year. We used two beliefs scores (GT and GR), and participation in GT/GR using 5-point Likert scales.
Results: Among 321 eligible people, 13.9% (n = 49) hoped to become pregnant in the next year, 79.0% (256) did not want to become pregnant, and 6.2% (20) were ambiguous. Those living in Puerto Rico were 50% more likely than those in the USA to participate in GR ($p < 0.001$). In the USA, those intending pregnancy were significantly more likely to participate in GR than those not intending pregnancy. In Puerto Rico, GT/GR participation rates for both intent groups were high and not significantly different. In Puerto Rico, women intending pregnancy within the next year had similarly high levels of positive GR beliefs and GT beliefs as others, while in the USA, only women intending pregnancy within the next year had significantly more positive levels of both.
Conclusion: PR hoping to become pregnant in the next year have high rates of intending to participate in GT/GR, with GR interest higher in Puerto Rico. This interest provides a unique opportunity to engage people intending pregnancy in efforts toward participating in GT/GR, aiming to improve PR inclusion in GT clinical benefits while contributing to GR involving unique tissues of pregnancy (e.g., placenta, cord blood), and reducing distributional injustice.

Table 1: Likelihood of participating in genetic research and genetic testing, among self-identified Puerto Rican women of reproductive age (21-49), by pregnancy intention status and country of residence

One Key Question* Would you like to become pregnant or have a child in the next year?	We would like you to now answer some questions about genetic research. Genetic research is when researchers collect your DNA (through saliva, blood, or other tissues) to explore a link between people's genetic makeup and their risk for certain health outcomes. Please use the options provided to share how likely or unlikely you are to participate in genetic research. I would participate in research that used my DNA.		Genetic testing, also known as DNA testing, allows individuals and medical professionals to determine how vulnerable a person is to certain diseases. For example, individuals with a certain gene in their DNA may be more likely to get certain types of cancer. DNA testing could be used for other many reasons, such as determining a child's biological mother or father or identifying where your biological ancestors are from. If a genetic test was available to you at a minimum cost, how likely are you to have it done?		Belief Scales (Higher score = more positive beliefs)

372 | Implementation of a Novel Blood Distribution System in an Obstetrics Service

Tobias Cohen[1]; Jaclyn Spinelli[2]; Dennis Chen[2]; Wei Zeng[2]; Natali Valderrama[2]; Priscilla Parra[2]; Hillary Shaw[2]; Robin B. Kalish[3]; Sharon E. Abramovitz[4]; Corrina M. Oxford-Horrey[4]; Christine Lennon[4]; Denden Benabdessadek[2]; Alexandra Jimenez[4]; Melissa Cushing[4]; Robert DeSimone[4]
[1]Weill Cornell Medicine, NEW YORK, NY; [2]New York-Presbyterian/Weill Cornell Medical Center, New York, NY; [3]New York Presbyterian- Weill Cornell, New York, NY; [4]Weill Cornell Medicine, New York, NY

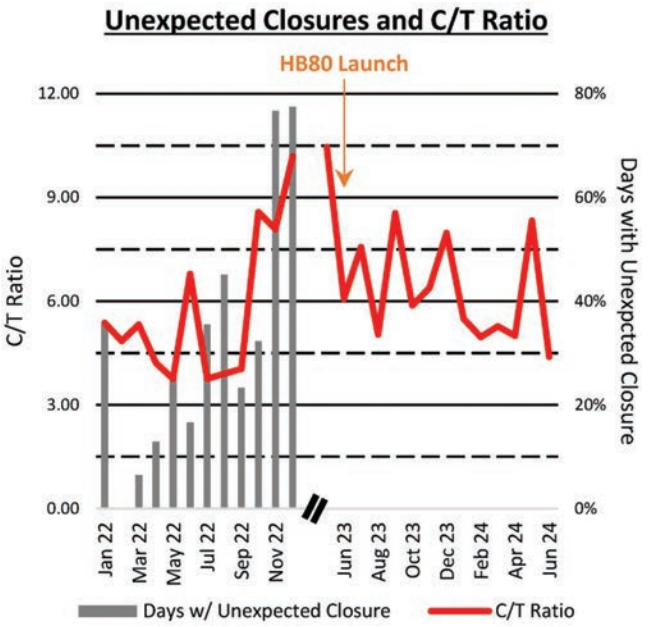
10:30 AM - 12:30 PM

Objective: Obstetric hemorrhage, a leading cause of maternal morbidity and mortality, complicates up to 10% of births. Our institution opened an obstetric hospital with a satellite blood bank (SBB), 0.25 miles from the main hospital. Due to national licensed blood bank technologist shortages, the SBB could not remain open consistently, requiring blood to be obtained from the main blood bank (MBB). This presented a significant patient safety issue and increased unnecessary blood orders indicated by crossmatch-to-transfusion (C/T) ratio. Our objective was to assess the impact of implementing a novel blood distribution system using non-licensed personnel on blood product availability, ordering, and utilization.

Study Design: The BloodTrack Haemobank 80 (HB80) is an FDA-cleared smart refrigerator with 80 compartments that can perform electronic crossmatches and issue blood products (RBCs, plasma, fibrinogen concentrate, RhIG) for specific patients in a rapid and controlled manner. We developed workflows to provide 24/7 blood product dispensing and massive hemorrhage support from the HB80 using lab assistants in the SBB starting in June 2023. The SBB closure rates and C/T ratio were assessed before and after installation of the HB80.

Results: Prior to HB80 rollout, SBB experienced a high closure rate and an increasing C/T ratio (Figure 1). Post HB80, there were no unplanned SBB closures and the C/T ratio decreased from a peak 10.5 before the HB80 to a recent nadir of 4.4 after implementation (Figure 1).

Conclusion: Implementation of a novel blood distribution system utilizing an HB80 within an obstetric unit eliminated SBB closures and improved blood product utilization. The HB80, which can be embedded within an obstetric unit, is a valuable resource to provide safe and effective blood product support for an obstetric service.



373 | Allostatic Load Score is Associated with Gestational Age at Delivery in a Dose Dependent Manner

Sarah Heerboth[1]; Maura Jones Pullins[1]; Emily Gascoigne[2]; Rebecca Fry[1]; Tracy A. Manuck[1]
[1]University of North Carolina, Chapel Hill, NC; [2]UNC Chapel Hill School of Medicine, Carrboro, NC

10:30 AM - 12:30 PM

Objective: Allostatic load (AL) is a multidimensional construct that encompasses cumulative stressors, and is associated with a multitude of adverse health outcomes outside of pregnancy. Despite this, there is no 'standard' definition of AL, and the relationship between AL and preterm birth (PTB) remains poorly defined.

Study Design: Secondary analysis of a prospective cohort enriched for those at high *a priori* risk of PTB. Participants identifying as Black, White, and/or Hispanic, with singleton, non-anomalous gestations were recruited < 22 weeks, 2017-2022. At enrollment, baseline health data and blood samples collected. We considered 6 markers previously considered in other AL indices: CV domain factors (initial prenatal systolic BP, initial prenatal diastolic BP), a metabolic factor (pre-pregnancy BMI), and inflammation (plasma IL-6, IL-10, and IL-1β levels). Each marker was classified as 'high' ($\geq 75^{th}$ centile; 1 point) or 'low' ($< 75^{th}$ centile; 0 points). The total AL score was calculated by summing these 6 factors for a max AL score = 6. The primary outcome was GA at delivery (continuous). Secondary outcomes were PTB < 37, < 35, and < 28 wks. Data were analyzed by t-test, chi-square, Cox regression, and Kaplan-Meier survival.

Results: 493 participants were included, delivering at a median 38.3 (IQR 36.9, 39.3) weeks'. The median AL was 1 (IQR 0, 2).

Clinical characteristics are shown in Table 1. In Cox regression models, an AL score of 0 was associated with pregnancy prolongation [adjusted Hazard Ratio (aHR) 0.81, 95% CI 0.67, 0.99]; in contrast, AL scores ≥1 were associated with an increased aHR of delivery in a dose dependent manner (Figure 1A). In survival analyses, those with a high AL scores [≥75th centile (≥2)] delivered earlier (Figure 1B, log-rank p = 0.0014).

Conclusion: A multidimensional AL score calculated early pregnancy is associated with delivery gestational age in a dose-dependent manner. Several of these AL components are potentially modifiable; future studies should evaluate whether optimization of health / improvement in these metrics is associated with improved perinatal outcomes.

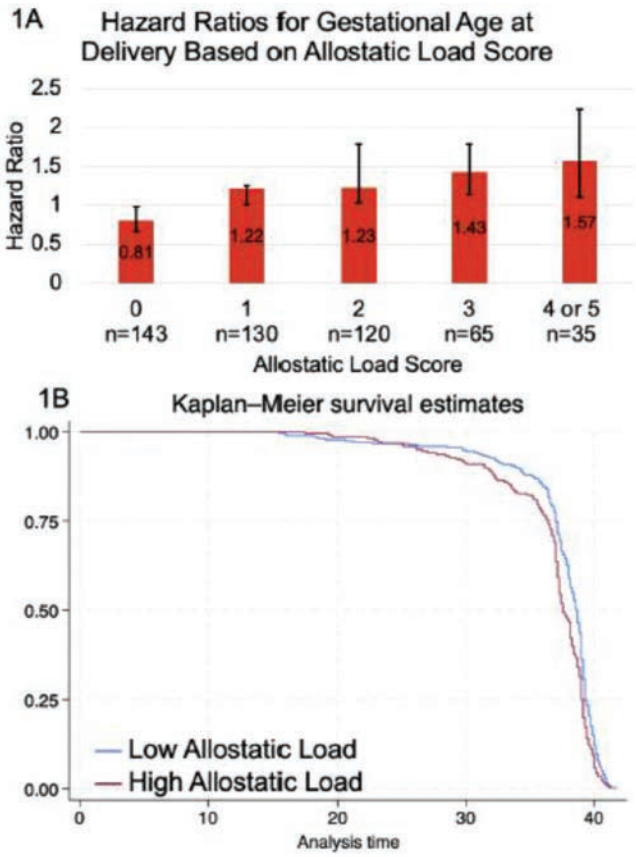

Figure 1A: Cox Regression model results. Shown are adjusted Hazard Ratios for gestational age at delivery based on Allostatic Load Score. Other factors considered in regression models included short sonographic mid-trimester cervical length (<25mm), public insurance, and cigarette smoking during pregnancy.
Figure 1B: Kaplan-Meier survival curve, adjusted for short trimester cervical length (<25mm), public insurance, and cigarette smoking during pregnancy. Those with a high allostatic load score (≥ 75th centile, ≥ 2) were compared to those with lower scores.

374 | Community Features Incorporating Multiple Domains Outperforms Composite Indices in Predicting NC County-Level Perinatal Outcomes

Megan Ragusa[1]; Emily Gascoigne[2]; Sarah Heerboth[1]; Annie Dude[1]; Lauren Eaves[1]; Rebecca Fry[1]; Tracy A. Manuck[1]
[1]University of North Carolina, Chapel Hill, NC; [2]UNC Chapel Hill School of Medicine, Carrboro, NC

10:30 AM - 12:30 PM

Objective: Community features influence health outcomes; these data are increasingly available and commonly incorporated into research and clinical care. However, it is unknown if multiple individual community domains or composite community indices better predict perinatal outcomes.

Study Design: NC county-level data were obtained online. Primary perinatal outcomes = county-level PTB < 37 wks, LBW, infant mortality, breastfeeding (BF) initiation, and short IPI (< 6 mo). We adapted an established community framework to create models with 6 community domains (health behaviors, clinical care & quality, SES factors, physical environment, length of life, quality of life), Figure 1A. For each outcome, we selected the most predictive factor from each domain using linear regression;

the relative contribution of each domain to each outcome was calculated using general dominance analysis. Next, we selected the most predictive composite index (evaluating the social vulnerability index, childhood opportunity index, and reproductive maternal vulnerability index) for each outcome. Logistic regression was used to evaluate which model best predicted the highest (e.g., worst) quartile for each outcome.

Results: The median rates of PTB (11.5%, IQR 10.1-12.8%), LBW (9.2%, IQR 8.4-10.2%), infant mortality (6.0%, IQR 0.0-8.0%), BF initiation (78.5%, IQR 68.7, 83.5), and short IPI (13.7%, IQR 11.8-15.2%) varied widely across the 100 NC counties. The optimal county-level domain predictor and the relative contribution of each domain to each outcome differed by perinatal outcome (Figure 1B). For all outcomes, the multiple domain models outperformed composite index models (higher AUCs), and the AUC was statistically significantly higher for infant mortality ($p < 0.001$) and BF-initiation models ($p < 0.001$), Table 2.

Conclusion: A range of non-conventional community features in multiple domains are associated with perinatal outcomes; these vary by perinatal outcome. These data underscore the importance of considering individual community factors in multiple domains (vs. composite community indices) when quantifying neighborhood exposures.

Figure 1A. Community Health Framework used to construct the multiple exposure models, adapted from the UWPHI County Health Rankings model. For each perinatal outcome, the most predictive health behavior, clinical care & quality, SES factor, physical environment, length of life, and quality of life factor was selected for model inclusion.

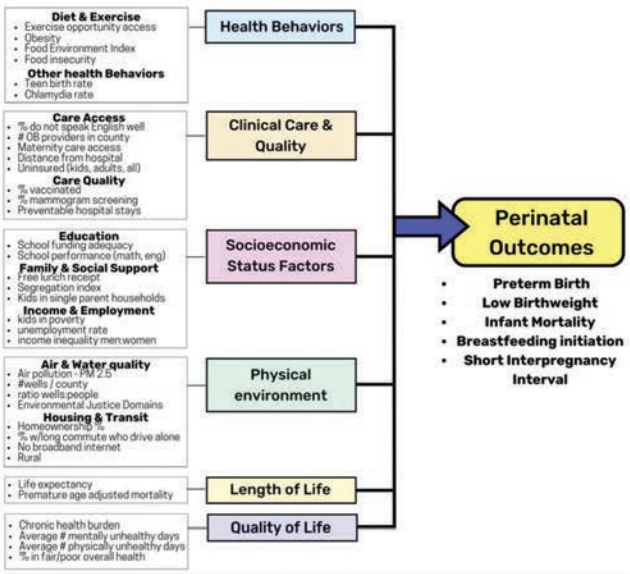

Figure 1B. Factors included in multiple domains models. The factors most predictive of each outcome and included in regression models are listed. The relative dominance (importance) of each domain for each perinatal outcome is shown in the bar graph.

	Health behaviors	Clinical Care & Quality	SES	Physical environment	Length of life	Quality of life
PTB	obesity	Uninsured kids	School funding	#wells/ county	Life expectancy	# in fair/poor health
LBW	Teen birth rate	Uninsured kids	Free lunch receipt	Home-ownership %	Adjusted death rate	Avg. # phys. unhealthy days
Infant mortality	Chlamydia rate	Maternity care access	Segregation index	Ratio wells:people	Life expectancy	Avg. # phys. unhealthy days
Breast feeding	Food environ. index	% vaccinated	Single parent hh	Long commute, drive alone	Life expectancy	Avg. # mental unhealthy days
Short IPI	Food insecurity	Preventable hospital stays	% Kids in poverty	Envir. Justice Domain #3	Life expectancy	Chronic health burden

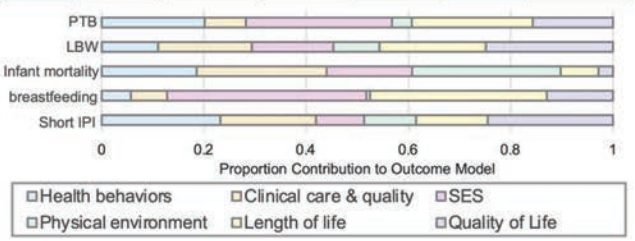

Table. Logistic regression results. Shown are the Multiple Predictors Models (included 6 independent variables: the best county-level predictor in each of the 6 main domains as described in the methods) and the Composite Predictors Model (included the single best composite predictor, as listed in the table, as the independent variable). The AUC (95% CI) for the highest quartile of each outcome are shown. The p-value reflects the comparison of the AUCs of the Multiple Predictor and Composite Predictor models.

Outcome	Multiple Domains Model	Composite Index Model		p-value
	AUC (95% CI)	Best composite index	AUC (95% CI)	
Preterm birth <37 weeks	0.8336 (0.744, 0.923)	Childhood Opportunity Index	0.784 (0.69, 0.877)	0.273
Low birth weight	0.937 (0.887, 0.987)	Childhood Opportunity Index	0.874 (0.793, 0.954)	0.097
Infant mortality	0.9371 (0.886, 0.987)	Social vulnerability index	0.785 (0.695, 0.874)	<0.001
Breast-feeding initiation	0.962 (0.929, 0.994)	Social vulnerability index	0.694 (0.564, 0.824)	<0.001
Short inter pregnancy interval	0.688 (0.571, 0.806)	Childhood Opportunity Index	0.595 (0.471, 0.718)	0.092

375 | Opioid Use Disorder and Severe Maternal Morbidity

Valeria Mantilla[1]; Alexis Cates[2]; Mariella Gastanaduy[2]; Elizabeth Howard[2]; Frank B. Williams[3]
[1]Ochsner Clinic Foundation, Ochsner/New Orleans, LA; [2]Ochsner Clinic, New Orleans, LA; [3]Ochsner Clinic Foundation, New Orleans, LA

10:30 AM - 12:30 PM

Objective: Opioid use disorder (OUD) in pregnancy increased nationally more than four-fold from 1999-2014. OUD has been associated with adverse perinatal outcomes, including preterm labor, growth restriction, and low birth weight. We hypothesize that OUD is likewise associated with severe maternal morbidity (SMM).

Study Design: We performed a retrospective cohort study of delivery admissions at a large regional health system from May 2018 to April 2023. Patients with multiple delivery admissions were limited to only the first pregnancy. Those without delivery outcome information and prenatal care in the system were excluded. OUD was defined by ICD-10 code documentation in the electronic medical record. The primary outcome was the Centers for Disease Control-defined SMM. Baseline characteristics were compared via chi-square test or t-test. Outcomes were compared with regression analysis controlling for age, obesity, nulliparity, pre-gestational diabetes, chronic hypertension and public insurance. Secondary outcomes included cesarean delivery, preterm delivery, and low birth weight.

Results: Among 57,023 deliveries, OUD was diagnosed in 534 (0.9%) patients. OUD was more prevalent among patients with age > 35 years, multiparity, chronic hypertension, and public insurance (Table 1). Obesity was less common among patients with OUD (Table 1). SMM was more common in OUD patients compared to those without the diagnosis (11.6% vs 4.0%); difference persisted when controlling for age, obesity, nulliparity, pre-gestational diabetes, chronic hypertension and public insurance (aOR 3.10, 95% CI 1.84–5.21, Figure). OUD was also associated with an increase in cesarean (aOR 1.44, 95% CI 1.03–2.02) and low birth weight (aOR 1.61, 1.02–2.54). Preterm delivery outcomes did not differ.

Conclusion: OUD is associated with three-fold increased odds of SMM, as well as increased in cesarean and low birth weight.

Table 1. Baseline characteristics of pregnant patients by opiod use disorder status

376 | Late Preterm Corticosteroid Treatment in Twin Pregnancies and Neonatal Outcomes

Victor A. Olafusi[1]; Elizabeth Roy[1]; Enaja Sambatur[2]; Faezeh Aghajani[3]; Moti Gulersen[4]; Asma Khalil[5]; Vincenzo Berghella[4]; Hiba J. Mustafa[6]
[1]Indiana University School of Medicine, Indianapolis, IN; [2]Fetal Care and Surgery Center, Division of Fetal Medicine and Surgery, Boston Children's Hospital and Harvard School of Medicine, Boston, MA; [3]Maternal Fetal Care Center, Division of Fetal Medicine and Surgery, Boston Children's Hospital and Harvard School of Medicine, Boston, MA; [4]Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA; [5]Fetal Medicine Unit, St George's Hospital, St George's University of London, London, England; [6]Indiana University and Riley Children's Hospital, Indianapolis, IN

10:30 AM - 12:30 PM

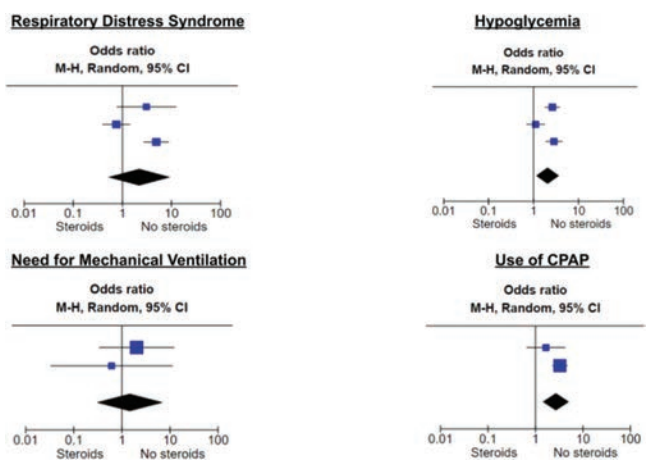
Objective: To examine the impact of administering late preterm corticosteroids on neonatal outcomes in twin pregnancies.

Study Design: A systematic review of the literature was conducted in four electronic databases between 2000 and 2024. Studies reporting on neonatal outcomes in twin pregnancies exposed to corticosteroid (ACS) treatment vs no treatment for fetal lung maturity at the gestational age (GA) of 34 0/7-36 6/7 weeks were included. Studies involving participants with specific conditions (twin-to-twin transfusion syndrome and

intrauterine fetal demise of one fetus) were excluded. The primary outcome was the incidence of respiratory distress syndrome (RDS). Secondary outcomes included the need for mechanical ventilation, continuous positive airway pressure (CPAP), and neonatal hypoglycemia. The random effect model was used to generate weighted mean differences (MD) and odds ratio (OR) along with their 95% confidence intervals (CI). Heterogeneity was assessed using the I^2 value.

Results: 267 abstracts were screened, of which 15 full-texts were fully reviewed. Three studies were included in the final analysis which comprised 489 twin pregnancies receiving steroids and 2807 not receiving steroids. There were no significant differences in baseline characteristics compared between groups including maternal age, body mass index, rate of preeclampsia or diabetes, and type of twin chorionicity. GA at delivery was significantly earlier in the steroids group (MD -0.91, 95% CI -1.50 to -0.32). For neonatal outcomes, no significant differences in RDS and the need for mechanical ventilation between groups. There were higher chances for CPAP use (OR 2.69, 95% CI, 1.47 to 4.92) and neonatal hypoglycemia (OR 2.05, 95% CI, 1.18 to 3.56) in the steroids group.

Conclusion: This study found that antenatal corticosteroid treatment during the late-preterm period in twin pregnancies was not associated with a reduced risk of neonatal respiratory complications.



377 | Cesarean Delivery Rate Among Pregnancies with Fetal Growth Restriction

Virali Patel[1]; Madeline V. Smith[2]; Mariella F. Toro[1]; Brooke E. Ciampaglio[2]; Zarin Mohsenin[3]; Rodney A. McLaren, Jr., Jr.[4]; Huda B. Al-Kouatly[4]; Amanda Roman[5]

[1]Sidney Kimmel Medical College at Thomas Jefferson University, Philadelphia, PA; [2]Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA; [3]Sidney Kimmel Medical College at Thomas Jefferson Univeristy, Philadelphia, PA; [4]Thomas Jefferson University Hospital, Philadelphia, PA; [5]Department of Maternal-Fetal Medicine, Thomas Jefferson University Hospital, Philadelphia, PA

10:30 AM - 12:30 PM

Objective: To determine the incidence of cesarean section (CS) in patients diagnosed with fetal growth restriction (FGR)

Study Design: This is a retrospective cohort study conducted at a single, urban institution of all singleton, nonanomalous pregnancies with no known genetic disorder that had a diagnosis of FGR (defined as estimated fetal weight (EFW) < 10th% or abdominal circumference (AC) < 10th%). All included patients were candidates for vaginal delivery. The severity of FGR was classified into 2 groups: < 3rd% and/or abnormal umbilical artery (UA) Doppler and EFW 4-9th% or AC < 10th% and normal UA Doppler. Maternal demographics, gestational age at delivery, and indication for delivery were collected. Outcomes were analyzed using t-test and Chi-square.

Results: Of the 179 patients meeting inclusion criteria, a total of 24 patients (13.4%) underwent CS. Overall, 36/179 (20.1%) patients had EFW < 3rd% and/or abnormal UA Doppler and 143/179 (79.9%) had EFW 4-9th% and normal UA Doppler, with no significant difference between delivery modes (Table 1). Non reassuring fetal status was the indication for cesarean in 14/24 (58%) of patients. Successful vaginal delivery after CS was noted in 8/13 (61.5%). Compared to patients who delivered vaginally, patients who delivered via CS were more likely to have pre-eclampsia (25% vs. 5.2%, p = 0.001), a prior CS (20.8% vs. 5.2%, p = 0.006) or be induced before 37 weeks (20.8% vs.7.8%, p = 0.042) (Table 1). The nulliparous, term, singleton, vertex CS rate was 11/56 (19.6%) and the preterm rate was 22/179 (12.3%), which are comparable to the national general population rate of 25%.

Conclusion: Patients with an antenatal diagnosis of FGR have similar CS rates when compared to the general population. This information will assist in counseling patients with FGR when discussing mode of delivery.

378 | Episiotomy in the US: Have We Got it Right?

Vivienne Souter[1]; Ian Painter[1]; Kristin Sitcov[1]; Asma Khalil[2]; Aaron B. Caughey[3]
[1]*Foundation for Health Care Quality, Seattle, WA;* [2]*Fetal Medicine Unit, St George's Hospital, St George's University of London, London, England;* [3]*Oregon Health & Science University, Portland, OR*

10:30 AM - 12:30 PM

Objective: A recent randomized controlled trial (Bergendahl et al., BMJ June 2024) reported a 50% reduction in obstetric anal sphincter injury (OASI) in nulliparous patients undergoing vacuum delivery who were assigned to lateral episiotomy versus no episiotomy. Our objective was to evaluate OASI in a similar US population.

Study Design: This retrospective study included births at 17 US hospitals (2022-2023). The analysis was restricted to singleton nulliparous, pregnancies undergoing vacuum delivery at > = 34 weeks' gestation. The outcome was 3rd or 4th degree laceration (OASI). The comparator groups were mediolateral episiotomy (ML) and midline episiotomy (M) and the reference group was no episiotomy (N). The incidence of OASI was compared among the ML, M, and N groups. Unadjusted odds ratios (OR) for OASI were calculated for each of ML and M groups compared to the N group. Adjusted ORs controlled for maternal age, BMI, and birthweight.

Results: Of 926 vacuum deliveries that met eligibility criteria, 775 (83.7%) were in the N, 80 (8.6%) in the M, and 71 (7.7%) in the ML episiotomy group. OASI was reported in 8.4% of the ML, 14.6% of the N, and 26.2% of the M episiotomy group (Table 1). Compared to the N group, the adjusted odds of OASI were significantly higher in the M group (2.25; 95% CI 1.28, 3.93) and lower in the ML group but the latter did not meet statistical significance (0.54; 95% CI 0.23, 1.30). Compared to ML, M episiotomy was associated with a significantly increased risk for OASI: adjusted OR 4.41 (95% CI; 1.55, 12.49).

Conclusion: Our study showed increased risk for OASI with midline episiotomy and a trend towards decreased OASI with mediolateral episiotomy, compared to no episiotomy in nulliparous patients undergoing vacuum delivery. Additionally, midline episiotomy was associated with a significantly increased risk for OASI compared to a mediolateral approach. Given this and the recent RCT results, reflection on episiotomy technique and more research into operative vaginal delivery are needed in the US.

Table 1 Episiotomy and 3rd or 4th degree laceration (OASI).

	3rd or 4th degree laceration n (%)	Unadjusted odds for 3rd or 4th degree laceration OR (95% CI)	Adjusted odds* for 3rd or 4th degree laceration aOR (95% CI)
No episiotomy (N=775)	113 (14.6)	Ref	Ref
Right mediolateral (N=71)	6 (8.4)	0.54 (0.23, 1.28)	0.54 (0.23, 1.30)
Midline (N=80)	21 (26.2)	2.09 (1.22, 3.57)	2.25 (1.28, 3.93)

379 | Placenta Accreta Spectrum Disorder and Vasa Previa: is There a Connection?

Yadira L. Bribiesca Leon[1]; Zaira Chavez Jimenez[1]; Fay Pon[1]; Shinya Matsuzaki[2]; Jennifer Yao[3]; Rachel S. Mandelbaum[1]; Joseph G. Ouzounian[1]; Koji Matsuo[1]
[1]*University of Southern California/Los Angeles General Medical Center, Los Angeles, CA;* [2]*Osaka University Graduate School of Medicine, Osaka, Osaka;* [3]*Keck School of Medicine, University of Southern California, Los Angeles, CA*

10:30 AM - 12:30 PM

Objective: This study assessed the association between placental accreta spectrum (PAS) disorder and vasa previa.

Study Design: This serial cross-sectional study queried the Healthcare Cost and Utilization Project's National Inpatient Sample in the United States. The study population was 21,517,317 in-hospital deliveries from 2016 to 2021. The exposure status was a diagnosis of PAS. The outcome measure was a diagnosis of vasa previa. Log-Poisson generalized linear model was created to assess the independent exposure-outcome association, adjusted for prior selected clinico-obstetrics characteristics. Sensitivity analysis included PAS subtype-specific evaluation (accreta, increta, and percreta).

Results: Vasa previa was diagnosed in 11,830 patients, corresponding to an incidence of 5.5 per 10,000 deliveries or one in 1,819 deliveries. The prevalence of vasa previa was 180.0 per 10,000 deliveries in patients with PAS and 5.3 per 10,000 deliveries for patients without PAS ($P < .001$). After controlling for maternal age, race and ethnicity, hypertensive disorder, diabetes mellitus, obesity, prior uterine scar, placenta previa, and multifetal gestation, the diagnosis of PAS was associated with nearly a five-fold increased risk for vasa previa (adjusted-prevalence ratio 4.46, 95% confidence interval 4.02-4.95, $P < .001$). When assessed by PAS subtypes, placenta increta had the highest prevalence rate of vasa previa (5.3, 171.2, 366.1, and 111.1 per 10,000 deliveries, for absence of PAS, accreta, increta, and percreta, respectively, $P < .001$).

Conclusion: The results of this study suggest that PAS is associated with an increased risk of vasa previa. Careful sonographic examination assessing for vasa previa may be necessary when evaluating patients with high suspicion for PAS. This hypothesis-generating observation is clinically compelling and warrants further investigation prospectively. Furthermore, it is possible that maternal neovascularization secondary to PAS may also occur in the fetoplacental unit vasculature.

380 | Glycoprotein Olfactomedin 4 is Preferentially Expressed in Cervical Epithelia of Patients with Preterm Birth

Yevgenia Y. Fomina[1]; ShanmugaPriyaa Madhukaran[2]; Sarah K. England[3]; Mala Mahendroo[2]
[1]*University of Texas Southwestern, Dallas, TX;* [2]*University of Texas Southwestern Medical Center, Dallas, TX;* [3]*Washington University, St. Louis, MO*

10:30 AM - 12:30 PM

Objective: Cervical epithelium is protected by a mucous layer that serves as an essential barrier against genitourinary

pathogens. Despite the central role of mucins in immune defense, we do not understand the regulatory pathways that drive mucus composition. We hypothesize that specialized secretory cells called goblet cells secrete the glycoprotein olfactomedin 4 (OLFM4) which plays an important role in mucosal defense during infection mediated preterm birth.

Study Design: Cervicovaginal fluid (CVF) samples (n = 183) were obtained from patients in the first, second, and third trimester of pregnancy who had term (n = 20) or preterm (n = 30) birth. Of the patients with a preterm delivery, 14 had a genitourinary infection diagnosed during the pregnancy. OLFM4 expression in CVF samples was measured by enzyme-linked immunosorbent assays and normalized to the total protein concentration of each sample. Protein concentration between cohorts were compared using the Wilcoxon rank-sum test. Next, OLFM4 expression was analyzed in mouse cervical epithelium using RNA in situ hybridization. Finally, histologic studies were performed in OLFM4 deficient mice to characterize OLFM4 deficiency on cervical structure in pregnancy.

Results: Expression of OLFM4 is higher in preterm as compared to term CVF samples across all three trimesters, with the highest concentrations in the preterm patients who had a reproductive tract infection in pregnancy ($p < 0.05$) **(Figure 1)**. In mice, OLFM4 is preferentially expressed in the pregnant state. Histologically, OLFM4 deficient mice had fewer goblet cells with secretory vacuoles and reduced mucin in the endocervical canal as compared to wild type controls (**Figure 2).**

Conclusion: In humans, while OLFM4 synthesis and secretion occurs throughout gestation, it is highest in patients with a preterm delivery and a reproductive tract infection. In mice, OLFM4 is preferentially expressed during pregnancy. The cervix of OLFM4 deficient mice has a distinct morphologic signature. Insights into such secretory proteins as OLFM4 can serve as biomarkers for infection-mediated preterm birth.

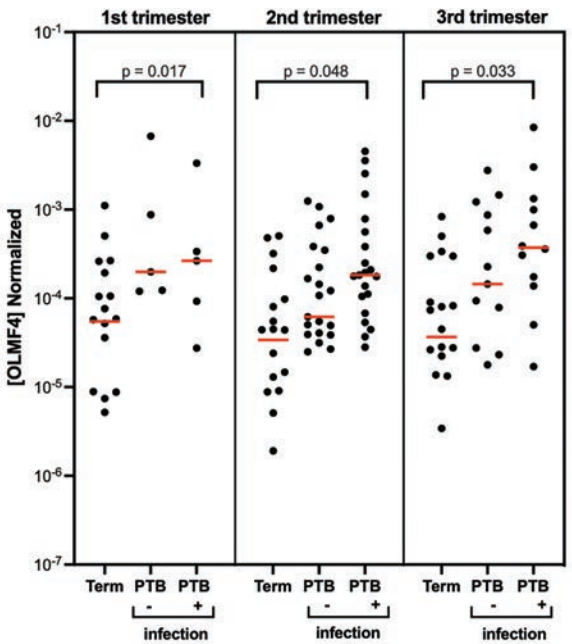

Figure 1: Expression of OLFM4 in cervicovaginal fluid is elevated in patients with an infection-mediated PTB relative to term pregnancies. (n= 20 term, 14 PTB + inf, 16 PTB - inf). Each black dot is a patient sample, red lines are medians. Protein expression between cohorts is compared using the Wilcoxon rank-sum test, with a p-value < 0.05 considered significant. P-values presented are not adjusted for multiple comparisons.

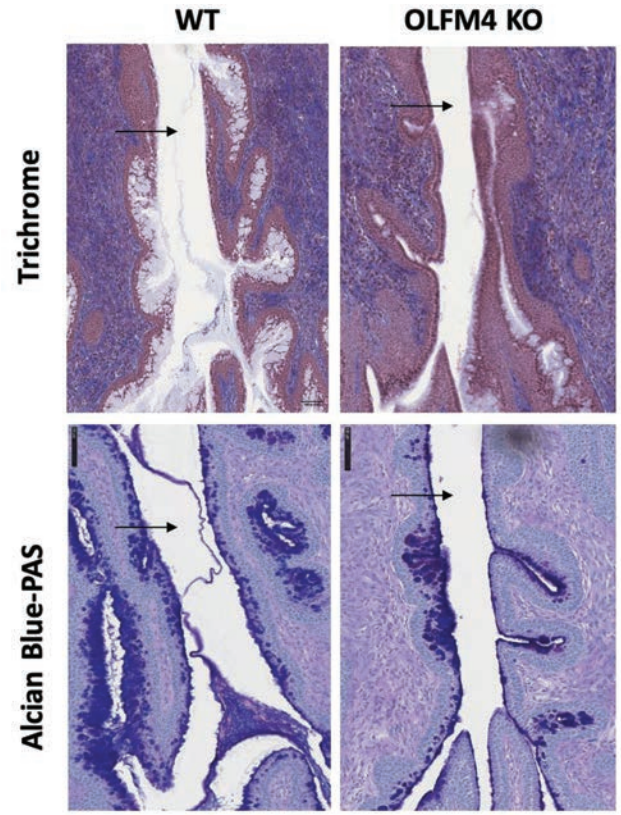

Figure 2: Reduction in goblet cells and mucins in endocervix (arrow) of OLFM4 deficient pregnant mice as seen by trichrome and Alcian Blue-PAS mucin staining respectively.

381 | Beta-Defensin is Preferentially Expressed in Cervical Epithelia of Patients with Preterm Birth

Yevgenia Y. Fomina[1]; Sarah K. England[2]; Mala Mahendroo[3]
[1]University of Texas Southwestern, Dallas, TX; [2]Washington University, St. Louis, MO; [3]University of Texas Southwestern Medical Center, Dallas, TX

10:30 AM - 12:30 PM

Objective: Human beta-defensin 2 is a cysteine-rich antimicrobial peptide that is expressed by cervical epithelial cells. This peptide is a critical mediator of the innate immune system and is an important contributor to maintaining a healthy cervical mucosal barrier. Disruption of this immune barrier allows microorganisms to penetrate fetal membranes and cause preterm labor. We hypothesize that cervical secretory cells increase the expression of beta-defensin 2 after exposure to genitourinary infections in an effort to maintain a sterile intrauterine environment during pregnancy.

Study Design: Cervicovaginal fluid samples (n = 183) were obtained from patients in the first, second, and third trimester of pregnancy who had term (n = 20) or preterm (n = 30) birth outcomes. Of the patients with a preterm delivery, 14 had a genitourinary infection diagnosed during the pregnancy. Cervicovaginal fluid samples were used for measurements of human beta-defensin 2 by enzyme-linked immunosorbent assay (ELISA). Beta-defensin concentration was normalized to the total protein concentration of each sample. Levels of beta-defensin were compared between the term and preterm study groups using

the Wilcoxon rank-sum test, with a p-value < 0.05 considered significant. P-values presented are not adjusted for multiple comparisons.

Results: Beta-defensin 2 is expressed in the cervicovaginal fluid across all three trimesters of gestation in term and preterm birth cohorts. Beta-defensin 2 is expressed at a higher concentration in the preterm as compared to the term cohort during all trimesters. In the third trimester of pregnancy, there is a statistically significant ($p < 0.01$) increase beta-defensin expression between patients with term (median: 1.1×10^{-6}) as compared to preterm (median: 9.6×10^{-6}) delivery outcomes **(Figure 1)**.

Conclusion: Beta-defensin 2 synthesis and secretion occurs throughout gestation and is highest in patients with a preterm delivery in the third trimester. Insights into such secretory proteins as beta-defensin 2 can serve as potential biomarkers for preterm birth outcomes.

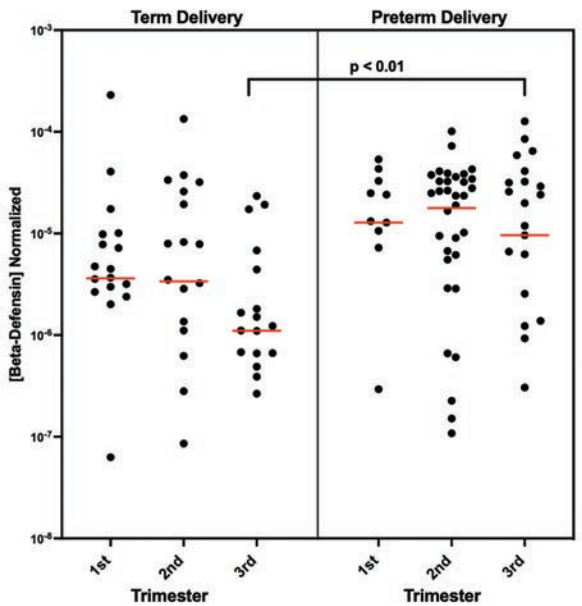

Figure 1: Expression of beta-defensin is elevated in cervicovaginal fluid samples of patients with preterm as compared to term delivery outcomes. Each black dot is a patient sample, red lines are medians. Protein expression between cohorts is compared using the Wilcoxon rank-sum test, with a p-value < 0.05 considered significant. P-values presented are not adjusted for multiple comparisons.

382 | Intrapartum Cesarean Delivery in Different Phases of Labor and Maternal Morbidity

Yossi Bart[1]; Hector M. Mendez-Figueroa[2]; Farah H. Amro[1]; Sean C. Blackwell[1]; Baha M. Sibai[1]

[1]*McGovern Medical School at UTHealth Houston, Houston, TX;*
[2]*McGovern Medical School at UTHealth, Houston, TX*

10:30 AM - 12:30 PM

Objective: Intrapartum cesarean delivery (CD) is associated with maternal morbidity. We aimed to examine if the phase of labor when the decision was made to proceed with intrapartum CD is associated with adverse maternal outcomes.

Study Design: We conducted a secondary analysis of the Assessment of Perinatal Excellence (APEX) database. We included all nulliparous singletons that underwent labor and delivered via CD at term (≥ 37 weeks). Individuals with fetal malformations and absent documentation of vaginal exam prior to delivery were excluded. We divided the cohort into three groups according to their labor stage/phase when the decision to proceed with CD was made: latent phase, 0-5 cm; active phase, 6-9 cm; and 2nd stage, 10 cm. The primary outcome was defined as a composite of maternal outcomes, including estimated blood loss ≥ 1,500 mL, blood transfusion, surgical tamponade, hysterectomy, wound infection or separation, endometritis, sepsis, and venous thromboembolism. Poisson regression was applied to adjust for confounders.

Results: Overall, inclusion criteria were met by 4,738 individuals; of those, 2,090 (44%) underwent CD during the latent phase, 1,811 (38%) during the active phase, and 837 (18%) during the 2nd stage. Intrapartum CD at later phases of labor was associated with higher rates of the composite outcome, driven mainly by higher rates of hemorrhage, transfusion, and surgical tamponade (Table). The adjusted relative risk for composite maternal outcome was 1.54 (95% CI 1.21-1.95) for CD during the active phase and 1.90 (95% CI 1.45-2.51) for CD during the 2nd stage. A subgroup analysis of the active phase demonstrated that individuals with 8-9 cm dilation at the decision to proceed with CD had higher composite outcome rates than 6-7 cm dilation (Figure).

Conclusion: Compared to the latent phase, CD in a more advanced phase of labor was associated with higher rates of maternal morbidity.

Table – Intrapartum cesarean delivery in different phases of labor and the association with maternal adverse outcomes

Outcomes	Group [a]	N (%)	Adjusted RR [b] (95% CI)
Composite maternal outcome [c]	Latent phase	122 (5.8)	1.00
	Active phase	153 (8.4)	**1.54 (1.21-1.95)**
	2nd stage	89 (10.6)	**1.90 (1.45-2.51)**
Estimated blood loss ≥ 1,500 mL	Latent phase	35 (1.7)	1.00
	Active phase	54 (3.0)	**1.85 (1.18-2.90)**
	2nd stage	37 (4.4)	**2.68 (1.63-4.40)**
Blood transfusion ≥ 1 unit	Latent phase	41 (2.0)	1.00
	Active phase	52 (2.9)	**1.66 (1.10-2.53)**
	2nd stage	26 (3.1)	**1.95 (1.19-3.21)**
Surgical tamponade [d]	Latent phase	12 (1.1)	1.00
	Active phase	23 (2.3)	**2.17 (1.07-4.39)**
	2nd stage	12 (2.3)	1.77 (.076-4.11)
Hysterectomy	Latent phase	0	1.00
	Active phase	1 (0.1)	-
	2nd stage	0	-
Wound infection or separation	Latent phase	16 (1.5)	1.00
	Active phase	9 (0.9)	0.56 (0.23-1.34)
	2nd stage	8 (1.6)	0.92 (0.37-2.28)
Endometritis	Latent phase	41 (3.9)	1.00
	Active phase	56 (5.7)	1.45 (0.98-2.16)
	2nd stage	30 (5.8)	1.53 (0.96-2.44)
Sepsis	Latent phase	1 (0.1)	1.00
	Active phase	2 (0.2)	-
	2nd stage	3 (0.6)	-
Venous thromboembolism	Latent phase	1 (0.0)	1.00
	Active phase	0	-
	2nd stage	1 (0.1)	-

Bolded if significant.
[a] The groups were defined by cervical dilation: latent phase, 0-5 cm; active phase, 6-9 cm; and 2nd stage, 10 cm.
[b] Adjusted to obesity (defined as pre-delivery body-mass index ≥ 30 kg/m²), chronic hypertension, diabetes mellitus, and a pre-delivery hematocrit < 30%.
[c] The primary outcome included estimated blood loss ≥ 1,500 mL, blood transfusion, surgical tamponade, hysterectomy, wound infection or separation, endometritis, sepsis, and venous thromboembolism.
[d] Any of the following: B-Lynch suture, uterine artery ligation, hypogastric artery ligation.
* No maternal deaths were reported in this cohort.

383 | DNA Methylation Analysis of Imprinting Control Regions and Copy Number Variation Sequencing in Early Miscarriage

ZhongJie Guo[1]; Jingwen Mai[2]; Qing Li[3]; Fang Wang[4]; Xuan Lin[1]; Jianping Zhang[5]

[1]Chengdu Xinhua Hospital, North Sichuan Medical College, Chengdu, Sichuan; [2]IbnSinaHealth Diagnostics, Guangzhou, Guangdong; [3]Independent Researcher, Denver, CO; [4]Lanzhou University Second Hospital, Lanzhou University Second Hospital, Gansu; [5]SUN YAT-SEN MEMORIAL HOSPITAL, SUN YAT-SEN University, Guangzhou, Guangdong

10:30 AM - 12:30 PM

Objective: To characterize DNA methylation of imprinting control regions (ICR) and copy number variation sequencing (CNV-seq) among early miscarriages in China. CNV-seq detects chromosomal abnormalities in embryos, but the full genetic basis remains unclear. ICR methylation analysis offers insights into gene expression regulation crucial for embryonic development.

Study Design: We conducted a cross-sectional study of 80 patients with early miscarriages (6-8 weeks gestation) in 3 provinces, China from November 2022 to Jun 2024. Chorionic villi of embryonic arrest were collected using hysteroscopy. Specialized in technologies in molecular genetics and reproductive immunology, our centralized lab performed CNV-seq and ICR methylation analysis of 19 loci. These loci include PLAGL1, GRB10, H19/IGF2(IC1), KvDMR1(IC2), SNURF(IC), GNAS-XL, MEST, ZNF331, PEG3, IGF1R, PEG10, DNMT1, DIRAS3, NAP1L5, FAM50B, TRAPPC9 (PEG13), MCTS2P/HM13, and L3MBTL1.

Results: Among these 80 cases (Table 1), chromosomal abnormalities (45%, 36) were detected and ICR methylation abnormalities 28% (22). NESP-AS/GNAS-AS1 was detected in 5 cases (Table 2). PLAGL1 was in 2 cases with transient neonatal diabetes mellitus and KvDMR1(IC2) in 2 with Bechwith-Wiedemann syndrome. Methylation abnormalities were detected in 30% (13/44) of early miscarriages with normal CNV-seq. This ratio varied across maternal age groups [≤ 30 years 18% (2/11), 31-40 years 31% (9/29), and ≥ 41 years 50% (2/4)] and conception methods [PGT-A 20% (2/10), natural 27% (7/26), ICSI 40% (2/5), and IVF 67% (2/3)] (Table 2).

Conclusion: ICR methylation abnormalities among early miscarriages with normal CNV-seq were prevalent across maternal ages and conception methods, indicating epigenetic causes. Study findings inform future cohort studies in our multi-center consortium with 90,000 annual live births in 16 provinces, China.

384 | Environmental Endocrine Disrupting Chemicals and Chromosomal Abnormalities in Recurrent Pregnancy Loss in 5 provinces China

ZhongJie Guo[1]; Jingwen Mai[2]; Qing Li[3]; Fang Wang[4]; Xuan Lin[1]; Jianping Zhang[5]

[1]Chengdu Xinhua Hospital, North Sichuan Medical College, Chengdu, Sichuan; [2]IbnSinaHealth Diagnostics, Guangzhou, Guangdong; [3]Independent Researcher, Denver, CO; [4]Lanzhou University Second Hospital, Lanzhou University Second Hospital,

Gansu; [5]SUN YAT-SEN MEMORIAL HOSPITAL, SUN YAT-SEN University, Guangzhou, Guangdong

10:30 AM - 12:30 PM

Objective: To examine the association between environmental endocrine disrupting chemicals (EDCs) and abnormal chromosomal karyotypes among cases of recurrent pregnancy loss. EDCs could induce mitochondrial dysfunction in pregnant mice then cell death which could cause miscarriage and developmental toxicity. Strict regulations were set up to ban the application of Bisphenol A in baby bottles in countries including China in 2011.

Study Design: We designed a cross-sectional study of 106 recurrent pregnancy loss patients recruited in 5 provinces, China from December 2022 to June 2024. Our centralized molecular genetic lab has specialized technologies in environmental EDCs and reproductive immunology. We assessed chromosomal karyotype in chorionic villi through copy number variation sequencing (CNV-seq) and urine samples using liquidchromatography-mass spectrometry to detect EDCs such as monomethyl phthalate (MMP), monoethyl phthalate (MEP), monobutyl phthalate (MBP), mono-2-ethylhexyl phthalate (MEHP), bisphenol A, and parabens. We performed McNemar's tests.

Results: We identified and ranked the most commonly detectable EDCs (e.g., Methyl paraben 23.58%, MMP 21.70%, Bisphenol A 16.04%, Propyl Paraben 13.21%) (Table 1). Of 106 recurrent pregnancy loss patients, 50 were detected chromosomal abnormalities whereas 56 were not (Table 2). The association between CNV-seq abnormalities and EDCs was significant ($\chi^2 = 6.12$, $p = 0.01$) (Table 2).

Conclusion: The significant association between EDCs and embryonic chromosomal abnormalities suggests that EDC exposure may contribute to recurrent pregnancy loss. Future research should investigate mechanisms and explore prevention and intervention strategies. Study findings inform the registered prospective cohort studies in our multi-center consortium with 90,000 annual live births in 16 provinces, China.

Table 1. Environmental Endocrine Disrupting Chemicals among 106 patients with Recurrent Pregnancy Loss in 5 Provinces, China, 2022 to 2024

Endocrine Disrupting Chemicals	n	Percentage	Min	Max	Median	Reference Range
Methyl Monoester of Phthalic Acid (MMP)	23	21.70%	37.47	347.3	81.63	below 37.32ug/g-cr

385 | "Keep Transfusing Until the Bleeding Stops"-Massive Transfusion and Circulatory Overload in Obstetric Hemorrhage

Aaron W. Roberts[1]; Ghamar Bitar[1]; Ahmed Zaki Moustafa[2]; Carly Shahbazian[3]; Kate Drone[3]; Kendra Folh[3]; Sean C. Blackwell[1]

[1]*McGovern Medical School at UTHealth Houston, Houston, TX;* [2]*Division of Maternal-Fetal Medicine, Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern Medical School at UTHealth Houston, University of Texas - Houston, TX;* [3]*Children's Memorial Hermann Hospital, Houston, TX*

4:00 PM - 6:00 PM

Objective: Hemodynamic support and blood replacement during massive hemorrhage is critical to survival, but high-volume massive transfusion (MTP) increases risk of transfusion associated circulatory overload (TACO). When faced with cardiac arrest from hemorrhagic shock restriction of fluid resuscitation may not be an option, and management of MTP goes beyond the moment bleeding is finally controlled. We aim to assess the risk and morbidity of TACO due obstetric hemorrhage managed with MTP.

Study Design: This retrospective cohort quality improvement study of parturients who suffered obstetric hemorrhage requiring large volume transfusion of blood products with more than four units of PRBC transfused as part of a MTP from June 2023 to July 2024 at our level IV center. Those cases with TACO were compared to those without.

Results: There were 5690 deliveries, 176 (3.1%) had PPH/MTP activation, of which 51 (28.9%) had > 4U MTP blood products transfused. The rate of TACO with MTP was 40% (N = 20/51). Placenta accreta spectrum alone was not a risk factor for TACO, neither was average estimated blood loss. Those with TACO had significantly more blood component volume/units transfused (Table 2). Patients with TACO had more diffuse intravascular coagulation (DIC) (75% vs 6%; $p < 0.001$), hemolysis (35% vs 3%; $p = 0.002$), ICU admission (75% vs 35%; $p = 0.006$), and acute kidney injury (50% vs 9%; $p = 0.001$). Post-transfusion hemoglobin and nadir fibrinogen were similar between groups, despite more baseline anemia in the TACO group. The only maternal death in this study occurred in the TACO group.

Conclusion: High volume MTP in obstetric patients shows increased rates of TACO and other serious morbidity, mostly related to transfusion volume and development of DIC. There are few reliable predictors of morbidity. Those with TACO were not grossly more medically complicated at baseline, which underscores that TACO can happen to any parturient. Future investigation of techniques to limit hemorrhage, improve resuscitation quality, reduce volume administered, and mitigate sequalae of massive transfusion is warranted.

386 | Neighborhood Deprivation Impacted COVID-19 Vaccination and Infection Rates Among Pregnant Patients

Abigail Bell[1]; Megan Foeller[1]; Candice Woolfolk[1]; Emily Dively, BSN[2]; Daniel Jackson[3]; Nandini Raghuraman[4]; Indira U. Mysorekar[5]; Jeannie C. Kelly[4]
[1]Washington University School of Medicine in Saint Louis, St. Louis, MO; [2]Washington University School of Medicine, St. Louis,

MO; [3]Mercy Hospital, St Louis, MO; [4]Washington University School of Medicine in St. Louis, St. Louis, MO; [5]Baylor College of Medicine, Houston, TX

4:00 PM - 6:00 PM

Objective: Area Deprivation Index (ADI) is strongly associated with obstetric outcomes but understudied during the COVID-19 pandemic. We sought to evaluate the relationship between ADI and COVID-19 outcomes among pregnant patients during the early pandemic.

Study Design: We performed a secondary analysis of a prospective longitudinal cohort study investigating the impact of COVID-19 exposure in pregnancy on perinatal outcomes. Patients were recruited if they were pregnant between 12/23/20-7/18/22 and serially evaluated for exposure to SARS-CoV-2 infection using serum antibody testing throughout pregnancy. Address of residence at time of delivery was used to categorize patients into a low ADI group ($\leq 50^{th}$ percentile, indicating low levels of deprivation) and a high ADI group ($\geq 75^{th}$ percentile, indicating high levels of deprivation). Our primary outcome was COVID-19 vaccination and infection during pregnancy.

Results: 306 patients were included. Those with higher ADI were younger (28 vs 32, p< 0.01), were less likely to be nulliparous (18% vs 38%, p = 0.02), had a higher average body mass index (35 vs 28, p = 0.01), and had higher rates of tobacco use (7% vs 2%, p = 0.03), asthma (17% vs 9%, p< 0.01), and depression (21% vs 17%, p = 0.01). There were notable differences in insurance type, race, and household income between groups (Table 1). Importantly, the high ADI group was less likely to receive COVID-19 vaccination (24.2% vs 54%, p< 0.01), more likely to develop SARS-CoV-2 infection (59.3% vs 41.9%, p< 0.01), and more likely to be hospitalized due to COVID-19 (3.9% vs 0%, p = 0.04, Table 2).

Conclusion: ADI differences were associated with vaccine hesitancy and COVID-19 infection and severity. Overall, these findings highlight the complex interplay of factors impacting perinatal outcomes during the COVID-19 pandemic, leading to two disparate perinatal experiences. Modifiable characteristics for both individuals and communities–such as tobacco use, obesity, and lack of vaccination–could serve as targets for interventions to improve perinatal outcomes.

387 | Evaluating Indicators of Severe Maternal Morbidity based on Maternal OBCMI Score

Adina R. Kern-Goldberger[1]; Megan R. Ansbro[2]; Antonio Bajan[2]; Elizabeth Raiff[3]; Justin R. Lappen[4]

[1]Cleveland Clinic Lerner College of Medicine, Cleveland, OH; [2]Cleveland Clinic Foundation, Cleveland, OH; [3]Cleveland Clinic Ob/Gyn & Women's Health Institute, Cleveland, OH; [4]Cleveland Clinic, Cleveland, OH

4:00 PM - 6:00 PM

Objective: Severe maternal morbidity (SMM) encompasses a diversity of adverse maternal medical outcomes that may be differentially triggered in patients with different risk profiles. This study evaluates incidence of component indicators of SMM by OBCMI level.

Study Design: This is a retrospective study of all deliveries $\geq$ 20 weeks across a multi-hospital academic health system from 1/1/2022-6/30/2024. Patient clinical information was extracted from the electronic health record and OBCMI scores were constructed based on risk factors present at delivery and divided into brackets of low risk (0-2), medium risk (3-5), and high risk ($\geq$6) based on score distribution. Patient characteristics including

OBCMI components and delivery admission SMM indicator variables were compared across brackets in univariable analysis using chi^2.

Results: 28,812 deliveries were included: 67.4% with scores 0-2, 21.0% with scores 3-5, and 11.5% with scores $\geq$ 6. There were significant differences in the incidence of each OBCMI component by score bracket (Table 1). Cardiomyopathy and pulmonary hypertension were the only comorbidities present exclusively in the highest risk bracket. Table 2 demonstrates the overall incidence of SMM by group: 0.5% in the lowest, 2.5% in the medium, and 8.1% in the highest risk bracket. Renal failure was the most common SMM indicator for all brackets, followed by disseminated intravascular coagulation in the 2 highest risk brackets and sepsis in the lowest risk bracket. Eclampsia co-ranked as second most frequent SMM indicator in the highest risk bracket. Incidence of each SMM indicator across brackets was significantly different for all except ruptured aneurysm and vaso-occlusive crisis.

Conclusion: SMM sub-types occur at different relative frequencies across patient groups with different co-morbidity-based risk. Understanding these differences can shape patient counseling as well as target specific interventions to prevent sub-types of SMM.

Table 1. Frequency of OBCMI* Components by OBCMI Score Bracket

N (%)	Low Risk OBCMI 0 – 2 N = 19,431	Medium Risk OBCMI 3 – 5 N = 6,061	High Risk OBCMI ≥ 6 N = 3,320	P-value
Maternal age 35 - 39	2,714 (14.0%)	1,649 (27.2%)	141 (4.2%)	< 0.01
Maternal age 40 - 44	235 (1.2%)	411 (6.8%)	408 (12.3%)	< 0.01
Maternal age > 44	0 (0%)	51 (0.8%)	877 (26.4%)	< 0.01
BMI ≥ 40	136 (0.7%)	456 (7.5%)	286 (8.6%)	< 0.01
BMI ≥ 50	0 (0%)	60 (1.0%)	44 (1.3%)	< 0.01

388 | Characterizing Sub-Types of Severe Maternal Morbidity in Patients with Hypertensive Disorders of Pregnancy

Adina R. Kern-Goldberger[1]; Megan R. Ansbro[2]; Antonio Bajan[2]; Elizabeth Raiff[3]; Justin R. Lappen[4]

[1]Cleveland Clinic Lerner College of Medicine, Cleveland, OH; [2]Cleveland Clinic Foundation, Cleveland, OH; [3]Cleveland Clinic Ob/Gyn & Women's Health Institute, Cleveland, OH; [4]Cleveland Clinic, Cleveland, OH

4:00 PM - 6:00 PM

Objective: Patients with preeclampsia are at increased risk for severe maternal morbidity (SMM). Elucidating risk for specific sub-types of SMM can inform interventions to improve maternal outcomes. This study describes the incidence of SMM indicators in patients with hypertensive disorders of pregnancy (HDP).

Study Design: This retrospective cohort study included all deliveries $\geq$ 20 weeks across a multi-hospital academic health system from 1/1/2022-6/30/2024. Patient clinical information was extracted from the electronic health record and patients were classified as having gestational hypertension/mild preeclampsia (gHTN), severe preeclampsia (SPEC, inclusive of superimposed preeclampsia), or no HDP during the delivery admission. Patient characteristics classified according to OBCMI components and outcomes, including SMM sub-types, were compared in univariable analyses using chi^2 by hypertensive disorder of pregnancy status.

Results: 28,812 patients were included: 5,495 with gHTN (19.1%) and 2,432 with SPEC (8.4%). Patient co-morbidities classified according to OB-CMI components were different across groups for every condition except coronary artery disease, congenital heart disease, and autoimmune disease (Table 1). There were significant differences in incidence of preterm birth, cesarean delivery, ICU admission, extended postpartum length of stay ($\geq$5 days), and readmission, as well as non-transfusion SMM, which ranged from 1.0% in patients without HDP to 1.8% in patients with gHTN and 9.1% in patients with SPEC (Table 2). Renal failure was the most frequent SMM indicator for all groups, occurring in 4.7% of patients with SPEC. Eclampsia was the second most common indicator in patients with SPEC, followed by disseminated intravascular coagulation (Table 2).

Conclusion: SMM sub-types have differential incidence based on HDP status. The high rate of renal failure in patients with SPEC could be an important target for care improvement or may reflect over-coding of mild kidney injury, correction of which is an equally important quality target to accurately capture SMM.

Table 1. Clinical Characteristics of Included Patients with and without Hypertensive Disorders of Pregnancy

N (%)	No hypertensive disorders of pregnancy N = 20,885	Gestational hypertension/Mild Preeclampsia N = 5,495	Severe preeclampsia N = 2,432	P-value

389 | Antenatal Risk Stratification Using the Obstetric Co-Morbidity Index (OBCMI) during Prenatal Care

Adina R. Kern-Goldberger[1]; Megan R. Ansbro[2]; Antonio Bajan[2]; Elizabeth Raiff[3]; Justin R. Lappen[4]
[1]Cleveland Clinic Lerner College of Medicine, Cleveland, OH; [2]Cleveland Clinic Foundation, Cleveland, OH; [3]Cleveland Clinic Ob/Gyn & Women's Health Institute, Cleveland, OH; [4]Cleveland Clinic, Cleveland, OH

4:00 PM - 6:00 PM

Objective: The obstetric comorbidity index (OBCMI) predicts risk for severe maternal morbidity (SMM) based on chronic and pregnancy-specific conditions and was devised from comorbidities present at the time of delivery admission. This study assesses the ability of an OBCMI calculated during antenatal care to predict risk of SMM.

Study Design: This is an observational study of all deliveries ≥ 20 weeks at 3 delivery hospitals within a large health system from 1/1/2022-6/30/2024. Patient demographic and clinical information was extracted from the electronic health record (EHR) and OBCMI scores were calculated at 3 time points based on the clinical conditions identified from the EHR during that encounter: (1) initial prenatal visit, (2) 32-week visit, and (3) delivery admission. Patient characteristics were evaluated in univariable analysis based on the presence of an OBCMI ≥3 at any of the 3 time points. Receiver-operator characteristic (ROC) curves were constructed and compared for OBCMIs calculated at the initial and 32-week visits versus the delivery admission OBCMI in terms of SMM prediction.

Results: 28,812 deliveries were included and 9,625 patients (33.4%) had an OBCMI ≥ 3 at any point in pregnancy, with significant differences in all examined patient characteristics based on OBCMI score [Table]. The incidence of SMM was 1.8% (N = 525). The prediction of SMM by OBCMI scores calculated during antenatal care at both time points was significantly inferior, with area-under-the-curve (AUC) of 0.59 (95% CI 0.57–0.61) for initial prenatal visit and 0.58 (95% CI 0.55–0.610) for the 32-week visit, compared to AUC of 0.81 (95% CI 0.79–0.83) for delivery admission OBCMI ($p < 0.01$ for all comparisons) [Figure].

Conclusion: While the OBCMI reliably predicts SMM when calculated based on conditions documented at delivery, it performs poorly as a tool for antenatal risk stratification. This is likely multifactorial due to both EHR under-coding at antenatal visits and the development of clinically significant risk factors late in pregnancy. Better tools for maternal risk prediction prior to delivery are essential.

Table. Patient Characteristics Based on OBCMI* Score Throughout Pregnancy

	OBCMI Always <3 N = 19,187	OBCMI ≥3 at Initial Prenatal Visit N = 2,640	New Cases of OBCMI ≥3 at 32 Week Visit N = 557	New Cases of OBCMI ≥3 at Delivery Admission N = 6,438	P-value
Maternal age (median, IQR)	30 (26, 33)	34 (30, 38)	33 (29, 36)	31 (27, 35)	< 0.01
Pre-gravid BMI (median, IQR)	25.5 (22.5, 29.9)	36.4 (26.9, 43.6)	28.2 (24.2, 35.2)	27.8 (23.8, 33.2)	< 0.01

390 | Employment Experiences of High-Risk Obstetric Patients: A Post-Pregnant Worker's Fairness and PUMP Act Cohort Study

Adwoa A. Baffoe-Bonnie[1]; Shakthi Unnithan[1]; Tracy Truong[1]; Thelma Fitzgerald[1]; Barvina Toledo[1]; Danielle Lanpher[1]; Kelley E. C. Massangele[2]; Maya Jackson[3]; Sarahn M. Wheeler[1]
[1]Duke University School of Medicine, Durham, NC; [2]National Diaper Bank Network, Diaper Bank of North Carolina, Hillsborough, NC; [3]Mobilizing African American Mothers Through Empowerment , Inc, Durham, NC

4:00 PM - 6:00 PM

Objective: The 2022 Providing Urgent Maternal Protections (PUMP) Act and the 2023 Pregnant Workers Fairness Act have recently changed employment laws in pregnancy. We evaluated employment benefits, knowledge of employment laws, and racial differences among hourly wage and salaried workers receiving high-risk obstetric care.

Study Design: Self-identified non-Hispanic Black (NHB) and White (NHW) patients at a single high-risk OB clinic within a Southeastern tertiary academic medical center were surveyed. We excluded major fetal anomalies, stillbirth or fetal demise. Participants completed surveys on work hours and duties, employment benefits at a single timepoint between 28 weeks' gestation to 12 weeks postpartum. Participants also reported if they received any information about employments laws or employment discrimination resources and the source of that information. Results were analyzed using descriptive statistics with SAS 9.4 (SAS Institute Inc., Cary, NC).

Results: 50/86 participated including 26 NHB and 24 NHW. Of these, 28 (56%) had hourly wage jobs, and 22 (44%) held salaried positions (Table 1). Thirty-seven (74%) had health insurance, and 31 (62%) had paid maternity leave. NHB patients were more often hourly wage earners compared to NHW patients (19/26, 73% vs. 9/24, 37.5%). Although mandated by the PUMP Act, only 13 (26%)

patients in the total cohort and 2 (7.1%) hourly workers reported having private lactation facilities in their workplaces. 33 (66%) received information about Family Medical Leave Act (FMLA), while fewer knew about the Pregnant Worker's Fairness Act (8, 16%) and the PUMP Act (8, 16%). Some participants who did not receive information expressed a desire for more information on these laws (Table 2).

Conclusion: While most participants had health insurance and paid maternity leave, a significant gap existed in workplace lactation support and knowledge of employment laws. These results highlight need for patient education about employment laws in pregnancy.

Table 1. Demographic and employment characteristics of the cohort stratified by race (N=50)

PARTICIPANT CHARACTERISTICS		
Characteristic (n,% unless otherwise noted)	**Black (n=26)**	**White (n=24)**
Age at consent (median, IQR years)	30.4 (29.0, 36.0)	33.0 (28.9, 36.4)
Pay type		
Hourly	19 (73.1%)	7 (26.9%)
Salaried	7 (26.9%)	15 (62.5%)

391 | Maternal and Neonatal Substance Screening Discordance After Implementation of an Obstetric Substance use Screening Protocol

Adwoa A. Baffoe-Bonnie; Siera Lunn; Janea Cato; Lena Fried; Leyi Sun; Tracy Truong; Sarahn M. Wheeler; Jennifer J. M. Cate
Duke University School of Medicine, Durham, NC

4:00 PM - 6:00 PM

Objective: To evaluate cases of discordance between maternal and neonatal drug screening before and after implementing an obstetric substance use screening protocol.

Study Design: This was a retrospective cohort study performed at a single tertiary care center using electronic health record data with pre- (July 1, 2020-June 9, 2021) and post-intervention (June 10, 2021-May 31, 2022) design after implementation of an obstetric substance use screening protocol incorporating pre-specified indications for maternal biologic testing and universal maternal consent. Concordances and discordances in neonatal and maternal drug screening were reported as frequency (percentage) in each time period. and compared by time period using test of two proportions. In the cohort of neonates with drug test and no maternal drug test, race, ethnicity, payor status, admission to the NICU, readmission, and neonate UDS results were compared by time period using Fisher's exact tests.

Results: 6552 neonates were born in the study period with 3163 (48.3%) pre and 3389 (51.7%) post implementation. 349/6552 (5.3%) neonates were drug screened (195/3163 [6.2%] pre vs. 154/3389 [4.5%] post, p = 0.004). 172 were ordered in the absence of a maternal test (63/195 [32.3%] pre, 109/154 [70.8%] post; p< 0.001) (Figure). Among 172 drug screens ordered in the absence of maternal tests, 80 were positive (24/63 [38.1%] pre, 56/109 [51.4%] post, p = 0.093). The number of neonates testing positive for specific substances did not significantly differ between the pre- and post-periods (Table).

Conclusion: After implementing the obstetric substance use screening protocol, neonatal substance use screening in the absence of maternal screening occurred more frequently post-intervention than pre-intervention despite similar rates of positive tests and substances for which neonates tested positive. These findings suggest a need for further investigation into the factors driving this increase in discordant testing and the potential implications for both neonatal and maternal care and support strategies in the future.

392 | Prior Delivery History and Risk of Placenta Accreta Spectrum

Alesha M. White[1]; Ariana Weiss[1]; Jessica E. Pruszynski[2]; Christina L. Herrera[1]
[1]*University of Texas Southwestern Medical Center, Dallas, TX;* [2]*University of Texas Southwestern, Dallas, TX*

4:00 PM - 6:00 PM

Objective: Previous cesarean delivery, prior uterine procedures, in vitro fertilization and placenta previa are known risk factors for placenta accreta spectrum (PAS). Further studies investigating prior delivery characteristics and risk of PAS are limited. The objective of this study was to describe additional risk factors in prior deliveries associated with the development of PAS.

Study Design: This was a case-control study at a single institution from June 2009 through June 2022 that included patients with prenatal suspicion of PAS based on imaging and confirmed at the time of delivery. Cases were matched to controls based on age, race, number of cesarean deliveries and prior vaginal birth. Prior delivery characteristics included preterm prelabor rupture of membranes, preterm birth, chorioamnionitis, delivery stage, uterine incision, bladder flap closure, peritoneal closure and manual placental extraction. Location of placenta in relation to the internal os on second trimester sonogram in the prior pregnancy was also analyzed. A conditional logistic regression model was used, that accounted for 3:1 matching, to compare cases to controls. A p-value less than 0.05 was significant.

Results: 55 cases were matched to 165 controls. There were no differences in maternal characteristics or comorbidities. Cases were more likely to have experienced preterm birth (OR 3.00 95% CI 1.37-6.57) and have had a manual placenta extraction (OR 5.25 95% CI 1.54-17.93) in a prior delivery. Placental location in a prior pregnancy was not significantly different between cases and controls (Table).

Conclusion: Preterm birth and manual extraction of the placenta in a prior pregnancy appear to be additional risk factors for development of PAS in future pregnancies. Further multicentered studies with a larger population are needed to further understand other risk factors for PAS.

Table. Maternal and delivery characteristics from prior pregnancies of matched patients presenting with (case) and without PAS (control) in subsequent pregnancies.

	Case N = 55	Control N = 165	P-value	Odds Ratio (95% CI)

393 | Postpartum EPDS Scores in Prenatally Suspected Placenta Accreta Spectrum

Alesha M. White[1]; Ellery R. Cohn[1]; Mishel Malik[1]; Jessica E. Pruszynski[2]; Catherine Y. Spong[1]; Christina L. Herrera[1]
[1]*University of Texas Southwestern Medical Center, Dallas, TX;* [2]*University of Texas Southwestern, Dallas, TX*

4:00 PM - 6:00 PM

Objective: Placenta accreta spectrum (PAS) is a life-threatening condition and may impact mental health. Peripartum hysterectomy is also independently associated. This study's objective was to assess the association of prenatally suspected PAS and Edinburgh Postnatal Depression Scale (EPDS) scores.

Study Design: This was a case-control study of singleton pregnancies from 2010 to 2024. Cases with prenatal suspicion of PAS based on imaging were matched to controls by age, parity, cesarean delivery and whether the cesarean was scheduled. Those with fetal anomalies or stillbirth after 24 weeks gestation were excluded. Postpartum EPDS scores were compared with patients with prenatal suspicion of PAS by hysterectomy status using the Kruskal-Wallis test and to matched controls using the Wilcoxon signed rank test.

Results: Of 184 cases matched 101 had available EPDS scores. This was significantly different from matched controls where 150 scores were available (55% vs 82% %, p< 0.001). Sixty-two (61.4%) of cases with EPDS scores underwent hysterectomy. Median EPDS scores were not statistically higher (3 (1-7) vs 3 (1-4), p = 0.114) comparing cases to matched controls. Among cases, patients that underwent hysterectomy had significantly higher median EPDS scores (4 (2-8) vs 2 (0-5), p = 0.049). The percentage of EPDS scores that would require intervention and referral (score of ≥13) were not significantly different between cases and controls

(p = 0.206), however all five cases with EPDS score ≥13 had a hysterectomy compared to none in the controls (p = 0.048).
Conclusion: Patients with prenatal suspicion of PAS were less likely to attend their routine postpartum visit. Compared to matched controls, these patients did not have higher postpartum EPDS scores following delivery but performance of hysterectomy increased EPDS score significantly. Providing counseling services in pregnancy and enhanced postpartum interventions may be of benefit.

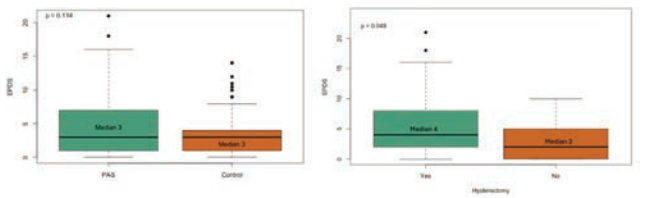

Figure. *Left* Median EPDS scores in patients with prenatal suspicion of placenta accreta spectrum. *Right* Median EPDS scores within the cases of prenatal suspicion of placenta accreta spectrum stratified by outcome of hysterectomy.

394 | Impact of Antenatally Suspected Uterine Window on Maternal and Neonatal Outcomes

Alexa L. Cohen[1]; Carly Pickett[2]; Taylor Douglas[2]; Grace M. Lee[2]; Chloe Porigow[2]; Pe'er Dar[2]; Georgios Doulaveris[2]
[1]University of Miami Health System, Miami, FL; [2]Montefiore Medical Center, Albert Einstein College of Medicine, New York, NY

4:00 PM - 6:00 PM
Objective: Prenatal sonographic suspicion for uterine window at a prior cesarean scar niche may impact mode and timing of delivery. We aimed to investigate maternal and neonatal outcomes in patients with prenatal suspicion of uterine window.
Study Design: Retrospective cohort study of all patients with a sonographic diagnosis of a uterine window at a tertiary referral academic institution from 2014-2024. Uterine window was defined as lower uterine myometrial segment >10mm in length and thickness < 2mm on 2nd trimester transvaginal ultrasound. Patients were compared to controls with a history of cesarean delivery (CD) without a uterine window, electing a repeat CD. All study patients were planned for repeat CD at early term (37 weeks). Primary outcome was a composite adverse maternal outcome (uterine rupture, blood loss >1.5L, transfusion, intensive care unit (ICU) admission, need for vasopressors and hysterectomy). Secondary outcomes included APGAR < 7, NICU admission and a composite neonatal morbidity outcome (sepsis, respiratory distress, and IVH or NEC). Multivariable logistic regression analysis was performed.
Results: Study included 103 patients with mid-gestation suspicion of uterine window and 103 matched controls. There was no significant difference in age, race/ethnicity, BMI, or parity between groups. Uterine rupture occurred in two (1.94%) study patients and one (0.9%) control. Delivery on the planned date was similar between groups (67.0% vs 69.9%, p = 0.6). Actual delivery occurred earlier for study patients (36.3 ±0.2 weeks vs 38.2 ±0.2 weeks, p< 0.01). Maternal composite adverse outcome was higher in study patients (22.3% vs 11.7%, p = 0.04). Study neonates had similar APGAR scores, but were more likely to be admitted to NICU (20.4% vs 9.7%, p = 0.03) and had higher morbidity (16.5% vs 6.8%, p = 0.02), compared with controls.
Conclusion: Patients with 2nd trimester sonographic suspicion for uterine window are at increased risk for iatrogenic earlier delivery, and higher maternal and neonatal morbidity. Possible benefits of earlier scheduled repeat CD should be weighed against the increased neonatal risks.

395 | Isolated Large Fetal Abdominal Circumference is Associated with Adverse Perinatal Outcomes in Non-Diabetic Pregnancies

Alexa L. Cohen[1]; Eliane Shinder[2]; Grace M. Lee[2]; Chloe Porigow[2]; Pe'er Dar[2]; Georgios Doulaveris[2]
[1]University of Miami Health System, Miami, FL; [2]Montefiore Medical Center, Albert Einstein College of Medicine, New York, NY

4:00 PM - 6:00 PM
Objective: The Society of Maternal Fetal Medicine currently recognizes an association between large for gestational age (LGA), defined as estimated fetal weight (EFW) >90%, and adverse perinatal outcomes. Our study aimed to assess the impact of isolated large fetal abdominal circumference (AC) on maternal and neonatal outcomes in non-diabetic pregnancies.
Study Design: Retrospective cohort analysis of patients at an urban academic institution who had ultrasonography between 35-36 weeks to estimate fetal weight. Those with multiple gestation, pregestational or gestational diabetes, prior cesarean delivery (CD) and contraindication to vaginal delivery were excluded. Outcomes were compared between three groups: a) appropriate for gestational age (AGA): AC and EFW between 10-90%, b) Isolated large AC: AC >90% and c) LGA: EFW >90%. Groups were matched by parity and gestational age by ultrasound. Primary outcome was primary CD. Secondary outcomes included shoulder dystocia, hemorrhage >1.5L, composite adverse maternal outcome (transfusion, infection, ICU admission, intubation, and mortality) and composite adverse neonatal outcome (APGAR < 7 at 5 min, NICU admission, neonatal morbidity and mortality). Analysis was performed using multivariate logistic regression.
Results: 765 patients were included: 255 in each group. There was no difference in age, parity, body mass index and hypertension among groups. Macrosomia (>4000 grams) at birth was confirmed in 2.4% of AGA, 12.5% of large AC and 38.0% of LGA group (p< 0.01). Patients with isolated large AC were more likely to have primary CD (aOR 2.41, 95%CI 1.56-3.71, p< 0.01), hemorrhage (aOR 2.76, 95%CI 1.19-6.45, p = 0.01) and composite adverse neonatal outcome (aOR 2.98, 95%CI 1.71-5.21, p< 0.01), when compared to AGA group. Outcomes were similar between large AC and LGA groups.
Conclusion: Isolated large AC with normal EFW is associated with an increased risk of primary CD and adverse perinatal outcomes in non-diabetic pregnancies. Including isolated large AC in the definition of LGA may improve counseling, delivery planning, and perinatal management.

396 | Accuracy of Point of Care Urine Drug Screen Testing in Pregnancies Complicated by Opioid Use

Alexander M. Harrison, Sr.[1]; Cynthia Cockerham[2]; Nancy Hendrix[3]; Asmita Shrestha[2]; Wendy Whitley[2]; Barbara V. Parilla[2]
[1]University Of Kentucky, Lexington, KY; [2]University of Kentucky, Lexington, KY; [3]University of Kentucky, University of Kentucky, KY

4:00 PM - 6:00 PM

Objective: To evaluate the accuracy of point of care (POC) versus the gold standard quantitative urine drug screen in a comprehensive perinatal substance treatment program.

Study Design: This study was from a longitudinal cohort of women receiving prenatal care through a comprehensive perinatal substance use treatment program between 2014 and 2024. We assessed participants who had both a POC and a quantitative urine drug screen (UDS) result during the same prenatal visit. Postpartum visits were excluded.

Results: Data was available for 2079 samples collected for a POC analysis and a quantitative drug screen, and the results were compared. We looked specifically at the accuracy of identifying opioids as most of our patients are on medication for opioid use disorder (MOUD). A true positive was defined as the POC matching the gold standard urine quantitative result. 78.2% (76.3, 79.9%) of the time the POC test yielded results matching the quantitative assessment. 21.8% of the time the POC was positive for an opiate when the quantitative was negative either for an opiate or for that specific opiate. The test yielded a positive predictive value of 79.5% (78.7, 80.2%) and a negative predictive value of 64.9% (58.2, 71.0%).

Conclusion: POC is not an accurate tool for use in pregnancy when evaluating compliance with MOUD. False positive and false negative results can adversely affect decisions that impact the patient and fetus. This can result in loss of trust in the medical system, decreased likelihood to engage in care, and poorer outcomes. More accurate quantitative tests should be utilized for evaluating compliance with treatment.

397 | Increased Buprenorphine Dosing Frequency Was Not Associated With An Increase In Neonatal Opioid Withdrawal Syndrome

Alexander M. Harrison, Sr.[1]; Cynthia Cockerham[2]; Katherine Vignes[3]; Asmita Shrestha[2]; Ronald Clarkson[2]; Gregory Hawk[2]; John O'Brien[2]; Barbara V. Parilla[2]

[1]University Of Kentucky, Lexington, KY; [2]University of Kentucky, Lexington, KY; [3]Oschner, New Orleans, LA

4:00 PM - 6:00 PM

Objective: Pregnancy alters the pharmacokinetics of buprenorphine with the need for increased dosing frequency to stay in the therapeutic range. We sought to evaluate whether increased dosing frequency is associated with an increased risk of Neonatal Opioid Withdrawal Syndrome (NOWS).

Study Design: This study was from a longitudinal cohort of pregnant persons receiving prenatal care through a multidisciplinary program for substance use disorder (SUD) between 2015 and 2024. We compared outcomes between patients prescribed once-a-day (QD) dosing verses twice a day (BID) or greater dosing of buprenorphine. Women not taking buprenorphine at delivery were excluded as well as those with less than 6 visits. Fisher's exact and two-sample t-tests were used for our statistical analysis.

Results: 367 patients were included, with 266 (72.5%) receiving QD dosing versus 101 (27.5%) dosed BID or more. Demographics were similar between groups including tobacco use. There was no significant difference in gestational age at delivery (38.4 +/- 2.2, 38.1 +/- 1.9;, p = 0.25), rate of preterm birth (9.4%, 12.9%, p = 0.34), birthweight percentile (37.6 +/- 25.5, 32.5 +/- 22.7, p = 0.08), rate of NOWS (48.9%, 45.5%, p = 0.68), length of hospital days (11 [6 to 20.2], 13 [6 to 20.0], p = 0.37) or NOWS treatment days (15 [10 to 20], 14 [11 to 24], p = 0.28).

Conclusion: An increase in dosing frequency was not associated with an increased risk of NOWS. Our data suggests that providers may be able to dose buprenorphine based on patient's needs (cravings and withdrawal symptoms) without concern of increasing the risk of NOWS.

398 | Unplanned Cesarean Delivery is Associated with Higher Risk of Postpartum Depression and Engagement in Care

Alexandra N. Mills[1]; Nicola F. Tavella[2]; Rachel Meislin[2]; Chelsea A. DeBolt[2]

[1]Division of Maternal-Fetal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY

4:00 PM - 6:00 PM

Objective: Postpartum depression (PPD) is a serious pregnancy complication, affecting 10-15% of postpartum people. Studies suggest an association between method of delivery (MOD) and PPD. Intrapartum experiences may contribute to PPD development and affect patient engagement in healthcare after birth through attendance at the six week postpartum visit (PPV). This study aims to interrogate the associations between MOD and PPD as well as PPV attendance in a large national pregnancy dataset.

Study Design: This was a retrospective study using the Pregnancy Assistance Monitoring Systems (PRAMS) national dataset by the United States Centers for Disease Control and Prevention (CDC). The cohort includes patients for whom MOD, demographic, and outcome data was available. The outcome of interest was PPD (via survey-administered PHQ-2 and patient-reported via survey), and attendance at the 6-week PPV (patient-reported via survey). The predictor variable was MOD: vaginal delivery (VD), planned cesarean delivery (CD), or unplanned CD. Chi-squared tests examined differences between groups and logistic regression models adjusting for maternal factors estimated adjusted odds ratios (aOR) of outcomes given MOD.

Results: This study included 6078 pregnancies: 3481 VDs (57.3%), and 2597 CDs (42.7%). Of the CDs, 1066 were planned CDs while 1531 were unplanned CDs. These groups differed significantly by maternal age, years of education, and household income. While those who delivered by planned CD did not have increased odds of PPD compared to VD, those who delivered by unplanned CD had increased odds of PPD as compared to VD (aOR 1.19 (1.04, 1.44)), and were significantly more likely to attend a postpartum visit (aOR 1.22 (1.05, 1.56)).

Conclusion: This study found that participants who delivered by unplanned CD but not planned CD are at increased odds of developing PPD and attending PPV compared to VD. Future work should focus on the physical and psychosocial stressors of an unplanned CD that may contribute to PPD development and postpartum care engagement.

399 | Risks Factors of Perinatal Morbidity After Instrumental Delivery Among Nulliparous Women

Alexiane LOUIS[1]; Paul BERVEILLER[2]; Bertrand GACHON[3]; PATRICK ROZENBERG[4]; ANNE ROUSSEAU[5]
[1]CH Poissy Saint Germain en laye, Poissy, Poissy, Ile-de-France; [2]CH Poissy Saint Germain en Laye, Poissy, Ile-de-France; [3]CH Poitiers, Poitiers, Poitou-Charentes; [4]UVSQ, Neuilly sur seine, Ile-de-France; [5]UVSQ, Poissy, Ile-de-France

4:00 PM - 6:00 PM

Objective: Instrumental vaginal delivery is a common practice, especially among nulliparous women, and may increase the risk of neonatal morbidity. However, there is a paucity of recent data regarding the risk factors for neonatal morbidity in this context. The goal is to identify risk factors of neonatal morbidity during instrumental vaginal deliveries among nulliparous women.
Study Design: This is an ancillary study of the prospective cohort study INSTRUMODA, the aim of which was to evaluate the protective effect of episiotomy on anal sphincter injury among nulliparous women during instrumental vaginal delivery. This study was conducted in 111 maternity units in France between April 2021 and March 2022. Instrumental deliveries were included from 34 weeks of gestation. Our primary outcome was a composite criterion of neonatal morbidity, including: Apgar score < 7 at 5 minutes, pH < 7.10, neonatal intensive care unit admission, hypothermia therapy, peripartum death, and cephalic or upper-limb trauma. The association between potential risk factors and perinatal morbidity was assessed using logistic regression, accounting for a center effect. Imputation was performed for missing data.
Results: A total of 11,938 instrumental deliveries were included. The primary outcome was observed in 16.9% of deliveries (table 1). Increased perinatal morbidity was associated with sequential instrument use (aOR = 1.50, 95% CI = 1.26–1.76), occiput posterior position (a OR = 1.30, 95% CI = 1.07–1.58), and delivery between 8 PM and 8 AM (aOR = 1.16, 95% CI = 1.05–1.29) (table 2). There was no significant difference in neonatal morbidity related to the type of instrument used (vacuum or forceps) or associated obstetric pathology (macrosomia, preeclampsia, IUGR).
Conclusion: Sequential use of instruments, occiput posterior fetal position, and deliveries occurring during night shifts are risk factors of neonatal morbidity in case of instrumental vaginal births among nulliparous women. However, neither the type of instrument nor associated obstetric pathology influence neonatal morbidity.

400 | Maternal and Neonatal Outcomes Following Maternal Cardiac Arrest

Allison Kurzeja[1]; Lindsay Yeh[1]; Anna Buford[2]; Yevgenia Y. Fomina[2]; Jessica E. Pruszynski[2]; C. Edward Wells[1]
[1]University of Texas Southwestern Medical Center, Dallas, TX; [2]University of Texas Southwestern, Dallas, TX

4:00 PM - 6:00 PM

Objective: Maternal cardiac arrest is an uncommon but catastrophic event. We sought to define the maternal and neonatal outcomes associated with maternal code at our public tertiary care center.

Study Design: This is a single-institution retrospective cohort study of cases of maternal cardiac arrest from 2010 through 2024 at a large county hospital. Demographics and data regarding maternal code events, delivery, and neonatal outcomes were obtained from the medical record. All cases of maternal codes in the setting of pregnancy or within six months postpartum were included. A descriptive statistical analysis was completed.

Results: Thirty-eight maternal codes were identified during the study timeframe, with 169,848 deliveries, this is consistent with 2 per 10,000 births. Of the 38 cases, 6 occurred at a gestational age of less than 20 weeks. Thirty-five codes occurred in the hospital with 25 (71%) resulting in return of spontaneous circulation (ROSC). Of the 3 cases of cardiac arrest outside of the hospital, only one patient survived. Overall, 23 individuals (61%) survived until discharge with an average length of stay of 18.2 days. For survivors, ROSC was achieved within 5 minutes in 74%. Eleven of the 38 individuals had a live fetus at 24 weeks or greater at the time of code. A resuscitative hysterotomy occurred in 9 out of 11 (82%) with a median time from code to delivery of 4 minutes. All of the neonates who underwent resuscitative hysterotomy survived until discharge. NICU admission occurred in the majority (78%), with 44% requiring mechanical ventilation and 33% complicated by hypoxic-ischemic encephalopathy. An additional 13 patients experienced a code in the immediate peripartum period with a median time from delivery to maternal code of 22 minutes.

Conclusion: Despite the infrequent and high acuity nature of maternal codes, achievement of ROSC and survival remains high, especially in the event of in-hospital cardiac arrest. Rapid delivery of the neonate, within four minutes of maternal code, was associated with a high likelihood of neonatal survival in the setting of viability.

401 | Increasing Antimicrobial Resistance Among Post-Cesarean Surgical Site Infections at a Large Public Hospital from 2009-2019

Allison Kurzeja[1]; Isabelle Mulder[1]; Amanda C. Zofkie[1]; Dena Taherzadeh[2]; Darlene Madriz[2]; April R. Gorman[1]; Scott W. Roberts[1]; Emily H. Adhikari[1]
[1]*University of Texas Southwestern Medical Center, Dallas, TX;* [2]*Parkland Health, Dallas, TX*

4:00 PM - 6:00 PM

Objective: To evaluate trends of bacterial composition and antimicrobial resistance among post cesarean surgical site infections (SSIs) in a cohort exposed to contemporary antibiotic prophylaxis.

Study Design: This is a single-institution retrospective cohort study of post-cesarean SSIs for whom culture data was available between 2009-2019 at a large county hospital. Medical records were reviewed to examine microbes isolated, and antimicrobial susceptibility data over time and by wound class. Wounds were clinically classified as superficial, deep, or organ space SSIs according to National Healthcare Safety Network guidelines. Logistic regression was completed to look at trends over time for antimicrobial resistance and bacterial composition.

Results: Of 41,338 cesarean sections, 484 cultured wounds were identified. 104 individuals (21.5%) had chorioamnionitis preceding delivery. SSI incidence remained below 2% consistently; however, positive cultures increased during the study ($p = 0.005$). For all organisms isolated, resistance to any antibiotic increased at a rate of 0.65 per year ($p = 0.13$ for trend). Escherichia coli (E.coli) was the most prevalent microbe identified in 67(13.8%), including 55(11.4%) superficial and 12(2.5%) deep or organ space infections. Significant increases in both the frequency of E. coli isolates among superficial SSIs (0.75 per year, $p = 0.005$) and antibiotic resistance of E.coli (0.49 per year, $p = 0.014$) were seen. Of E. coli isolates with susceptibility testing, 9/23 (37.5%) were resistant to ampicillin, 25/58 (49.1%) to ampicillin-sulbactam, 13/63 (23%) to gentamicin, and 23/66 (34.8%) to Bactrim.

Conclusion: While post-operative cesarean SSI rates have remained relatively constant at a single center over the past decade, antibiotic resistance is increasing, particularly among E. coli isolates. The impact of increasing antimicrobial resistance on maternal and neonatal morbidity and infection-associated healthcare costs warrants further study, and safety data for newer antimicrobial agents in pregnancy and lactation are urgently needed.

402 | Polyhydramnios is Associated with Worse Perinatal Outcomes Among Non-Anomalous Births Complicated by Diabetes

Alyssa R. Hersh; Bharti Garg; Wendy Tian; Kristin C. Prewitt; Amy M. Valent; Aaron B. Caughey
Oregon Health & Science University, Portland, OR

4:00 PM - 6:00 PM

Objective: Pre-existing diabetes mellitus (DM) is associated with adverse perinatal outcomes. Polyhydramnios is more common among pregnant persons with DM, particularly those with suboptimal glycemic control. Our study examined perinatal outcomes in patients with DM in pregnancy with co-occurring polyhydramnios.

Study Design: This was a retrospective cohort study of births in California complicated by pre-existing DM between 2008-2020. We included singleton, non-anomalous births between 32 and 42 weeks of gestation. We assessed numerous maternal and neonatal outcomes among births complicated by polyhydramnios compared to those without polyhydramnios. We performed bivariate and multivariable logistic regression analyses adjusting for significant confounders with a p-value of 0.05.

Results: There were 56,106 people with DM included in this study, of which 1,767 (3.1%) had polyhydramnios. Polyhydramnios was associated with worse outcomes for both pregnant persons and their neonates. There were strong associations observed between polyhydramnios and cesarean delivery despite stratification by history of cesarean delivery, and there were also strong associations with concurrent macrosomia (46.3% vs 19.4%, $p< 0.001$; aOR 3.41, 95% CI 3.07-3.78) and infant death (0.7% vs 0.2%, $p< 0.001$; aOR 2.48, 95% CI 1.28-4.81). Additionally, hypertensive disorders, severe maternal morbidity, lower APGAR at 5 minutes, neonatal ICU admission, and respiratory distress syndrome were more common among people with DM and polyhydramnios.

Conclusion: Polyhydramnios was associated with significantly worse outcomes among pregnant people with pre-pregnancy DM. These results highlight the importance of strategies to mitigate the risk of development of polyhydramnios and optimize glycemic control in patients with DM to improve perinatal outcomes.

Table 1. Outcomes of pregnant people with pre-existing diabetes mellitus with polyhydramnios versus no polyhydramnios

	Polyhydramnios	No polyhydramnios	p	aOR (95% CI)*
Hypertensive disorder of pregnancy	25.8%	20.3%	<0.001	1.17 (1.04-1.32)
Cesarean delivery				
Nulliparous	81.7%	58.2%	<0.001	3.06 (2.34-4.00)
Multiparous without prior CD	57.1%	23.1%	<0.001	3.92 (3.28-4.67)
Multiparous with prior CD	98.5%	94.9%	<0.001	3.16 (1.78-5.62)

403 | Perinatal Outcomes Pre- and Post-Arrive Trial Publication Among Low-Risk Term Nulliparous Births in California

Alyssa R. Hersh; Bharti Garg; Megha Arora; Aaron B. Caughey
Oregon Health & Science University, Portland, OR

4:00 PM - 6:00 PM

Objective: Following publication of the ARRIVE trial in 2018, there were notable changes to pregnancy management of low-risk nulliparous patients at term, particularly in rates of induction of labor. Therefore, we sought to assess the differences in management and outcomes pre- and post-ARRIVE trial publication.

Study Design: This was a retrospective cohort study of singleton, non-anomalous, nulliparas between 39-42 weeks of gestation in California. To assess only low-risk pregnant persons, we excluded births complicated by chronic hypertension, diabetes, breech presentation, advanced maternal age, oligohydramnios, polyhydramnios, and placental conditions requiring cesarean delivery. We assessed births in the two years before and after publication of the ARRIVE trial, 2016-2017 and 2019-2020, respectively. We assessed overall outcomes among the entire cohort, then stratified by week of gestation. Chi squared and multivariable logistic regression were used for statistical analyses.

Results: There were 151,779 births in 2016-2017 and 126,829 births in 2019-2020 that met our inclusion criteria. Compared with pre-ARRIVE trial publication, induction of labor increased (31.8% vs. 39.1%, p< 0.001) and the rate of cesarean delivery decreased (22.7% vs. 21.3%, p< 0.001). There was a lower rate of adverse neonatal outcomes post-ARRIVE trial publication, including NICU admission (7.4% vs. 6.4%, p< 0.001), respiratory distress syndrome (0.49% vs. 0.44%, p = 0.041), and stillbirth (0.09% vs. 0.06%, p = 0.002). Outcomes remained similar upon stratification by week of gestation.

Conclusion: In this study, we found that maternal and neonatal outcomes were improved on a state level after publication of the ARRIVE trial in 2019-2020 when compared to 2016-2017. As management of low-risk nulliparas at term continues to evolve, it is critical to continue to assess outcomes on a population level.

Table 1. Perinatal outcomes pre- and post-ARRIVE trial publication among low-risk, nulliparous patients.

404 | Circadian Variations of Glucose Challenge Test Results In Pregnancy: Examining Non-Linear Trends

Amanda Makol[1]; Luke Keating[2]; R. Jonathan Robitsek[1]; Tristen Tang[1]; Bailey Lien[1]; Lena Woo[1]; Ivan Ngai[1]
[1]Flushing Hospital Medical Center, Queens, NY; [2]Flushing Hsopital Medical Center, Queens, NY

4:00 PM - 6:00 PM

Objective: Research has documented circadian variations in glucose challenge test (GCT) results by comparing morning to afternoon collection. Variations by collection time have implications for the performance of potentially unnecessary glucose tolerance tests (GTTs). However, more detailed examination of the complex non-linear trends in GCT results across collection times has yet to be conducted. Therefore, we aim to examine non-linear relations between collection time and GCT values using polynomial regression.

Study Design: This is a retrospective cohort study of all pregnancies 2017-2023 for which GCT was collected after 24 weeks in a community hospital in New York. Patients with pregestational diabetes mellitus (DM), or early diagnosis of DM in the 1st or 2nd trimester were excluded. To examine non-linear trends in GCT values, we used polynomial regression with a stepwise approach to adding polynomial terms to the initial linear model, assessing model fit with each inclusion.

Results: Our sample included 5341 pregnancies for which GCT was collected. The sample was highly racially/ethnically diverse (Asian: 23.62%, Hispanic/Latino: 66.39%, Other: 10.99%). In the final model, we found significant linear (B = .47, p = .034), quadratic (B = -.18, p< .001), and cubic terms (B = -.02, p< .001), indicating a non-linear relationship of GCT values with collection time. Evaluation of inflection points showed that GCT values reached a local maximum at approximately 1:30pm.

Conclusion: GCT values vary with diurnal rhythms, such that observed values appear to increase throughout the AM, peak in the early afternoon, and then trend downwards. These findings have clinical implications, as GCTs collected in the afternoon may lead to more false positives and potentially unnecessary further testing by GTT. Overall, these data suggest that GDM screening

protocols that include the GCT should be refined to account for the effect of time of day on test performance.

405 | Adherence to Antiseizure Medications in Pregnancy

Amelie Pham[1]; Andrew D. Wiese[1]; Andrew J. Spieker[1]; Chad You[2]; Ashley A. Leech[1]; Margaret A. Adgent[1]; Carlos G. Grijalva[1]; Sarah S. Osmundson[1]
[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University Medical Center, Nasvhille, TN

4:00 PM - 6:00 PM

Objective: To evaluate antiseizure medication (ASM) adherence in pregnancy.

Study Design: We constructed a retrospective cohort of births (2007-2019) among patients ≥ 20 weeks' gestation with continuous Tennessee Medicaid enrollment 90 days before conception through delivery, using linked healthcare claims, prescription fills, hospital discharge, and birth certificate data. We included births to patients aged 15-44 with evidence of ASM use before and during pregnancy, defined by ≥ 2 prescription fills in the 90 days before conception and ≥ 1 prescription fill between conception and delivery, for a single ASM (monotherapy for newer (levetiracetam, lamotrigine, oxcarbazepine, zonisamide) or older (carbamazepine, phenytoin, and valproate) ASM). We excluded births where patients switched to an alternative ASM or used > 1 ASM (polytherapy). We categorized timing of ASM discontinuation and calculated adherence as the percentage of days covered by filled ASM prescriptions from conception through delivery, accounting for hospitalizations. We evaluated ASM use and adherence by medication, class, and associated epilepsy diagnosis.

Results: Among 2,135 eligible births with ASM monotherapy, 30% had an epilepsy diagnosis and 41% had no diagnosis traditionally associated with ASMs (Table 1). Overall median adherence was low (23%, IQR 12-67%) with 58% discontinuing ASMs before the third trimester (Table 2). Adherence did not significantly differ by ASM class, but was higher among levetiracetam and phenytoin users and significantly higher among births with an epilepsy diagnosis compared to those without (Table 2). Most common ASMs used, by class, were lamotrigine and carbamazepine in all users compared to levetiracetam and phenytoin in those with epilepsy.

Conclusion: The American Academy of Neurology recommends continued use of most ASMs in pregnancy when clinically indicated. In our cohort of births with regular ASM use preceding pregnancy, ASM adherence in pregnancy was poor. These findings emphasize the need for improved patient counseling on ASM use in pregnancy.

407 | is Timing of Onset of Early Fetal Growth Restriction Associated with Worse Outcomes?

Anam Farooqui[1]; Emily K. Guernsey[2]; Vanya Manthena[2]; Kelly Nelson Kelly[2]; Andrew Rausch[2]; Ryan E. Longman[2]; Ashish Premkumar[2]
[1]University of Chicago, Chicago, IL; [2]Pritzker School of Medicine, University of Chicago, Chicago, IL

4:00 PM - 6:00 PM

Objective: Fetal growth restriction (FGR) is associated with significant neonatal morbidity and mortality, which can especially be impacted by timing of onset. Limited data are available to assess whether timing of diagnosis among the high-risk cohort of

early-onset FGR (i.e., diagnosis at < 32 weeks) is associated with adverse outcomes.

Study Design: We conducted a single-site retrospective study of singleton gestations with early-onset FGR, diagnosed between 2020-2023. The exposure was gestational age (GA) at time of diagnosis, dichotomized into 20-27 weeks (group 1) and 28-31 weeks (group 2). The primary outcome was a composite of adverse neonatal outcomes (i.e., neonatal intensive care unit admission, respiratory distress syndrome, need for intubation, sepsis, necrotizing enterocolitis, intraventricular hemorrhage, periventricular leukomalacia, retinopathy of prematurity, death). Secondary outcomes were GA at delivery, route of delivery, diagnosis of small-for-gestational age, neonatal length of stay, and all components of the primary outcome. Bi- and multivariate analyses were performed.

Results: 94 participants were eligible; 52% (n = 49) were in group 1 and 48% (n = 45) were in group 2. Individuals with earlier onset of FGR were more likely to have public payor insurance, be nulliparous and have hypertensive disorders (Table 1). The frequency of the composite outcome was not significantly different between the two groups (45 v. 29%, RR 1.55, 95% CI 0.89-2.70), even after controlling for receipt of antenatal steroids (aRR 1.29, 95% CI 0.82-2.04). Furthermore, there were no differences in any of the secondary outcomes (Table 2).

Conclusion: GA at diagnosis of early-onset FGR is not associated with worse maternal or perinatal outcomes, though the directionality of the findings warrants further investigation with a larger sample size.

408 | Impact of Health-Related Social Needs on Postpartum Anxiety in an Underserved Urban Community

Andrea Rizkallah[1]; Ashlyn K. Lafferty[2]; Robert B. Martin[2]; Elaine L. Duryea[2]; Kristie R. Wilburn-Wren[2]; Donald D. McIntire[2]; Catherine Y. Spong[2]; David B. Nelson[2]
[1]UT Southwestern, Dallas, TX; [2]University of Texas Southwestern Medical Center, Dallas, TX

4:00 PM - 6:00 PM

Objective: The aim of this study was to determine the association of health-related social needs (HRSNs) with postpartum anxiety for individuals living in underserved communities. We hypothesized that individuals with greater social needs would have increased rates of anxiety after birth.

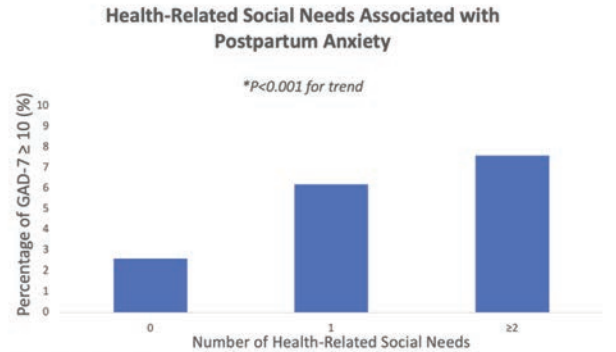
Study Design: This was a prospective observational study of patients delivered from 1 Oct 2020 through 31 Dec 2022 with subsequent 1-year follow-up postpartum. Participants living in underserved areas identified through a community-health needs assessment were enrolled in a dedicated, multidisciplinary postpartum care program. HRSNs were assessed upon enrollment using a standardized assessment modeled from the HealthyPeople2030 framework, and medical services were provided for 12 months. Patients were screened for anxiety using Generalized Anxiety Disorder-7 (GAD-7), at 1, 3, 6, and 9 months with positive scores ≥ 10 prompting mental health referral. Cochran-Armitage trend test was used to examine the association between number of HRSN and GAD-7 and the number of visits completed in relation to the type of HRSN.

Results: Of 1647 enrolled, 64.5% (N = 1063) reported at least one HRSN with 28% (N = 468), 16% (N = 257), and 21% (N = 338) of individuals reporting one, two, or more than two HRSN, respectively. The most prevalent HRSNs were poor WiFi (23.6%), access to childcare (21%), and missed electric or gas bill (15.3%). There was a significant association between increasing number of reported HRSN and screening positive for anxiety using GAD-7 instrument (P < 0.001, Figure). Individually, a reported need for transportation to medical appointments (N = 158) and access

to childcare (N = 364) were significantly associated with fewer number of follow-up visits (both P < 0.01).

Conclusion: Among patients living in an underserved urban community, increasing number of HRSN was significantly associated with higher GAD scores, and specific HRSNs were associated with lower rates of postpartum follow-up. Addressing HRSN provides the opportunity to impact maternal wellbeing and postpartum follow-up.

Figure. Trend of GAD-7 positive screening tests (≥ 10) by number of reported health-related social needs (P < 0.001 for trend).



Health-related social needs include mental health disorder, homelessness, housing instability, incarceration, missed electric or gas bill, missed water bill, poor phone plan, poor WiFi, need for clothes, lack of access to childcare, need for transportation for medical and non-medical reasons, alcohol use, drug use, domestic violence.

409 | Development of Common Data Elements for Maternal Health Research: Results from a Delphi Consensus Process

Elizabeth Stierman[1]; Carrie Wolfson[2]; Sarah Clifford[1]; Meighan Mary[1]; Amanda Burgess[1]; Khyzer Aziz[3]; Sean O'Reilly[1]; Jessica L. Gleason[4]; Diane Gumina[5]; Paul Nagy[3]; Andreea A. Creanga[1]
[1]Johns Hopkins University, Baltimore, MD; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [3]JHU, Baltimore, MD; [4]Epidemiology Branch, NICHD-NIH, Bethesda, MD; [5]NIH, Bethesda, MD

4:00 PM - 6:00 PM

Objective: Common data elements (CDEs, i.e., standardized questions paired with allowable responses) are critical for providing consistency in data collection and promoting research collaborations. This study aims to determine a *minimum reporting set of CDEs* by NICHD grantees conducting maternal health (MH) research.

Study Design: NICHD convened a 64-expert panel including representatives from large research networks, ACOG, SMFM, CDC, HRSA, and NIH. Experts formed 2 working groups supporting development of biomedical and psychosocial CDEs. Two modified Delphi processes, each with 2 voting rounds, were undertaken. In Delphi 1 (03/24-05/24; 84% response rate), experts voted on MH constructs for standardized data collection categorized as: Tier 1 (all MH research), Tier 2 (thematic MH research areas), or neither. Constructs for which >80% of experts affirmed the importance of standardization were retained for categorization to Tier 1 or 2 based on majority vote. The Tier 1 list was restricted to constructs with >75% of experts identifying the construct as Tier 1, forming the *minimum set of constructs* for all MH research. For measuring these constructs, in Delphi 2 (07/24-08/24; 70% response rate), experts used 5-point Likert scales to rate the feasibility and validity of specific CDEs identified via landscape analysis and literature searches.

Results: Experts voted on 267 biomedical and 194 psychosocial constructs; 202 biomedical (146 Tier 1; 56 Tier 2) and 144 psychosocial (90 Tier 1; 54 Tier 2) constructs were retained. Restriction to constructs with >75% Tier 1 votes yielded 35 biomedical and 22 psychosocial constructs in the *minimum set of constructs* for all MH researchers (Table). A total of 89 biomedical and 115 psychosocial CDEs were rated by experts during Delphi 2. Of these, depending on available data source (EHR, survey, other), the *minimum reporting set* includes 50-60 CDEs/CDE bundles.

Conclusion: Reporting of CDEs across MH research is expected to improve data quality, study consistency, data interoperability, and our understanding of how to improve MH.

Table. Minimum set of Tier 1 maternal health constructs

Biomedical Constructs (n=35)	Psychosocial Constructs (n=22)

410 | Does Fetal Growth Restriction Actually Resolve? Maternal and Neonatal Risks with Resolved Fetal Growth Restriction

Angela Nakahara[1]; Olivia Feltner[1]; William Fesmire[2]; Victoria Schlesinger[1]; Grace Anne Holladay[1]; Anna Belk[3]; Patricia Goedecke[1]; Jim Wan[2]; Kerri Brackney[1]
[1]University of Tennessee Health Science Center, Memphis, TN; [2]University of Tennessee–Department of Preventative Medicine, Memphis, TN; [3]Regional One Health, Memphis, TN

4:00 PM - 6:00 PM

Objective: Little guidance exists on the management of FGR that resolves, and potential neonatal outcomes including birth weight and NICU admission are unknown. We compared the likelihood of identifying small for gestational age (SGA) infants in fetuses with resolved FGR (based on estimated fetal weight (EFW) and abdominal circumference (AC) >10th percentile) compared to those without history of FGR.

Study Design: A retrospective case control study of fetal growth ultrasounds (US) performed at our institution from 01/2019-04/2024 was conducted. US evaluating biometric parameters for singleton pregnancies originally meeting criteria for FGR

based on EFW or AC < 10th percentile, with resolution of both EFW and AC parameters, were included. Controls were matched based on year of birth, gestational age (GA) and maternal age at delivery. Primary outcome was prevalence of SGA neonate at birth; secondary outcomes were need for NICU admission, GA at birth and mode of delivery. We applied a mixed effects logistic regression model comparing cases and controls.

Results: A total of 140 infants were evaluated. Cases with resolved FGR had a 2.26 RR (95% CI 1.44-3.24) for SGA. When controlling for hypertensive disorders of pregnancy, the RR was 2.31 (95% CI 1.46-3.32). The mean GA of delivery was 37 weeks for both groups (p >0.9) and NICU admission rates were similar (24% vs 24%, p >0.9). Cesarean section (CS) was more likely in pregnancies with resolved FGR (37% vs 26%, p = 0.039) and more likely to be performed for non reassuring fetal heart tones (NRFHT) than those without history of FGR (10% vs 2.9%, p = 0.025).

Conclusion: Neonates with history of FGR are more likely to be SGA compared to those with normal growth profile in antenatal period and are more likely to need CS for NRFHT.

411 | Time is Money: Comparing Costs in 12 Vs 24 Hours of Postpartum Magnesium

Angela Nakahara[1]; Bailey Huggins[1]; Claire Sorenson[1]; Elise Sickle[1]; Victoria Schlesinger[1]; Zach Berry[1]; Patricia Goedecke[1]; Jim Wan[2]; Paul J. Wendel[1]; Kerri Brackney[1]

[1]University of Tennessee Health Science Center, Memphis, TN; [2]University of Tennessee–Department of Preventative Medicine, Memphis, TN

4:00 PM - 6:00 PM

Objective: This study evaluates the implementation of a protocol for shortened magnesium sulfate (MAG) duration in postpartum seizure prophylaxis for preeclampsia (preE). We compared MAG administration of 12 vs 24 hours, assessing cost-effectiveness, patient safety, and postpartum length of stay (LOS), utilizing clinical parameters to identify suitable candidates.

Study Design: This interrupted time series and retrospective cohort study evaluated all patients with preE who received MAG and delivered at a tertiary academic center from 04/2022-04/2024. Patients meeting clinical criteria were considered for shortened 12 (G1) vs traditional 24 hour (G2) MAG administration. Primary outcome was difference in mean total hospital cost (MTHC) after delivery pre vs post protocol; secondary outcomes were number of patients with G1 course, rates of postpartum preE readmissions (PPRA), severe maternal morbidity (SMM) and LOS between groups. Wilcoxon rank sum test was applied to compare variables between G1 vs G2, with alpha = 0.05 as statistically significant.

Results: A total of 656 patients were evaluated; 53% (n = 349) were post protocol, of which 23% (n = 80) met criteria for G1. There were no statistically significant differences in gestational age at delivery, delivery for preE, or mode of delivery between pre vs post protocol groups. The MTHC was not significantly different after protocol initiation ($9158 vs $9514, p = 0.4) however LOS was shorter post protocol (2.72 vs 3.02 days, p = 0.004). Post protocol, G1 had less MTHC ($6840 vs $9850, p = 0.001) and shorter LOS (2.23 vs 2.87 days, p < 0.001). PPRA rates were not significantly different pre protocol (10 vs 6.9%) with RR 0.7 (95% CI 0.4-1.1). Overall SMM was decreased post protocol (7.2% vs 14%, p = 0.004) with G1 having lower SMM vs G2 (0% vs 9.3%, p = 0.005).

Conclusion: Shortened MAG course is a cost effective consideration with shortened LOS and decreased PPRA, but likely requires a larger study group to detect overall differences in MTHC. SMM may be decreased with shortened MAG however, direct causation cannot be established.

412 | Previable Premature Rupture of the Membranes and Neonatal Mortality/Morbidity in a National Retrospective Cohort

Anja Gojic[1]; Yanchen Wang[1]; Eleanor Pullenayegum[2]; Amit Mukerji[1]; Swati Agrawal[1]; Eugene Ng[3]; Miroslav Stavel[4]; Yun-Yi Cui[1]; Sarah D. McDonald[1]

[1]McMaster University, Hamilton, ON; [2]Hospital for Sick Children and University of Toronto, Toronto, ON; [3]University of Toronto, Toronto, ON; [4]Royal Columbian Hospital, New Westminster, BC

4:00 PM - 6:00 PM

Objective: Counselling after previable preterm premature rupture of the membranes (PPROM) is challenging due to older previable PPROM cutoffs and small studies. Our objective was to assess neonatal mortality/morbidity after previable PPROM < 22 weeks versus no PPROM to assist in counselling at viability and decision making.

Study Design: We conducted a retrospective cohort study of liveborn singletons born < 32 wk' gestation from 2018-2022, who received active resuscitation (including delivery room deaths), or did not need it, and were admitted to a neonatal intensive care unit within the Canadian Neonatal/Preterm Birth Network database. Among previable PPROM infants, gestational age at birth and latency period were determined. Our primary outcome was a composite of neonatal mortality or severe morbidity consisting of any one or more of severe respiratory distress syndrome, severe intraventricular hemorrhage, severe necrotizing enterocolitis, severe retinopathy of prematurity, moderate/severe bronchopulmonary dysplasia, cystic periventricular leukomalacia or sepsis. Outcomes were compared between infants with and without previable PPROM < 22 wk, using generalized estimating equations to account for hospital effect and adjusting for confounders and covariates.

Results: As onset of previable PPROM (n = 225) increased from ≤16 to 21 wk' gestation, median gestational age at birth decreased from 27.5 wk (IQR 24.5, 29.0) to 25.0 (IQR 23.0, 28.0) and latency period decreased from 86.5 days (IQR 63.5, 98.0) to 30.0 (IQR 15.0, 49.0, Table 1). Infants with previable PPROM had increased odds of neonatal mortality/severe morbidity (90%), compared to those without (66%, n = 7846, adj OR 1.71, 95% CI 1.14 to 2.56, Table 2).

There was a trend toward more sepsis with previable PPROM at 21 wk than earlier.

Conclusion: In a large, contemporary cohort of previable PPROM (< 22 wk) reaching viability, an inverse relationship was seen between timing of rupture and gestational age at birth, decreasing from a median of 27.5 to 25 wk. Almost all previable PPROM infants experienced mortality/morbidity, almost double the odds without PPROM.

Table 1: Decreasing gestational age at birth and latency period with later onset of previable PPROM in a national retrospective cohort of infants reaching viability

GA at rupture of membranes	GA at birth Median (IQR)	Latency period Median (IQR)

Legend:
PPROM - preterm premature rupture of membranes; OR - odds ratio; CI - confidence interval
[a] Crude logistic regression with generalized estimating equations applied to account for the hospital effect.
[b] Multivariable logistic regression with generalized estimating equations applied to account for the hospital effect. Adjusted for the following confounders and covariates: age of pregnant person, nulliparity, assisted reproductive technology, diabetes, hypertension, infant sex, small for gestational age < 10th percentile for gestational age at birth and infant sex, deferred cord clamping ≥ 60 seconds, admission temperature and SNAP-II score.

413 | Induction Compared with Expectant Management at Term for Individuals with a Prior Cesarean

Ann M. Bruno; On behalf of the Eunice Kennedy Shriver National Institute of Child Health and Human Development Maternal-Fetal Medicine Units Network
University of Utah Health, Salt Lake City, UT

4:00 PM - 6:00 PM

Objective: It is common to await spontaneous labor in individuals undertaking a trial of labor after cesarean (TOLAC) over concern of uterine rupture and its associated harms. We evaluated whether this concern is warranted.

Study Design: Secondary analysis of a multicenter cohort of patients delivering on randomly selected days at 17 U.S. hospitals (2019-20). Data were manually abstracted from the medical record by trained staff. Term individuals with a prior cesarean delivery (CD) were included while those with a contraindication to TOLAC, planned repeat CD, multifetal gestation, stillbirth, or fetal anomaly were excluded. The primary outcome was vaginal birth after cesarean (VBAC). Secondary outcomes included uterine rupture, maternal morbidity, neonatal morbidity, and NICU admission. Multivariable modeling estimated the association between induction compared with expectant management and outcomes by gestational week. Adjusted Desirability Of Outcome Ranking (DOOR) analyses calculated the probability that induction leads to more desirable dyadic (paired maternal-neonatal) outcomes. The ordinal DOOR outcome ranged from VBAC without uterine rupture or morbidity (most desirable) to CD with uterine rupture and maternal and neonatal morbidity (least desirable).

Results: Of the 935 individuals included, mean maternal age was 31 years (± 5), median body mass index 31.8 kg/m^2 (interquartile range 27.7-36.7), and 89% had one prior CD. In adjusted multivariable models, there was no association between induction and odds of VBAC in week 37, 38 or 40; in week 39, induction was associated with increased odds of VBAC (Table). Induction and expectant management had similar odds of maternal morbidity at all weeks, while induction was associated with neonatal morbidity and NICU admission only at week 37. In DOOR analyses, induction in week 39 resulted in a higher probability of a desirable outcome for the dyad (adjusted DOOR probability 55%, 95% CI 51-59%; Figure).

Conclusion: For those undertaking TOLAC, induction compared with expectant management in gestational week 39 optimized outcomes for the maternal-neonatal dyad.

Table. Vaginal birth after cesarean (VBAC) success and perinatal outcomes following induction of labor compared with expectant management among those with prior cesarean delivery (CD) by gestational age week

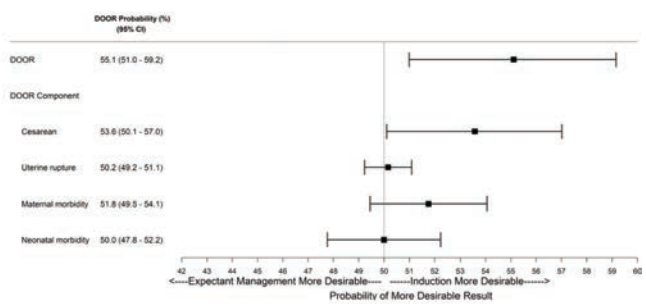
Data are n (%). Odds ratio, OR; confidence interval, CI; Adjusted odds ratio, aOR; vaginal birth after cesarean delivery, VBAC; Neonatal intensive care unit, NICU. *Induction group included individuals with an induction of labor from 37w0d to 37w3d (or subsequent gestational age week, e.g., 38w0d to 38w3d). †Adjusted for body mass index, maternal co-morbidity (any: cancer, autoimmune disease, pre-gestational diabetes, cardiovascular disease, pulmonary disease, chronic hypertension, renal disease, liver disease, personal history of thromboembolism), gestational diabetes mellitus, and hypertensive disorders of pregnancy. ‡Maternal morbidity composite including: blood transfusion, peripartum infection, hysterectomy, intensive care unit (ICU) admission during delivery hospitalization. §Neonatal morbidity composite including: perinatal death, need for respiratory support within 72 hours of birth, Apgar score ≤3 at 5 minutes, hypoxic ischemic encephalopathy (HIE), seizure, infection (confirmed sepsis or pneumonia), meconium aspiration syndrome, intracranial hemorrhage, hypotension requiring vasopressor support. ¶Not applicable for multivariable modeling secondary to small cell size. Data for gestational age week 40 and 41 weeks not shown secondary to small numbers.

Figure. Desirability Of Outcome Ranking (DOOR) analyses estimating the probability of having a more desirable outcome with induction of labor compared with expectant management at 39 weeks' gestation



The DOOR probability is the estimated probability with accompanying 95% confidence interval (CI) that a dyad undergoing induction of labor has a more desirable dyadic (paired maternal-neonatal) outcome than a dyad undergoing expectant management. A DOOR probability of 50% equates to chance. A DOOR probability >50% (with the lower bound of the CI >50%) demonstrates an advantage or higher likelihood of a desirable outcome, while a DOOR probability <50% (with the upper bound of the CI <50%) demonstrates a disadvantage or a higher likelihood of an undesirable outcome. DOOR probabilities were adjusted using inverse probability weighting accounting for body mass index, maternal co-morbidity (any: cancer, autoimmune disease, pre-gestational diabetes, cardiovascular disease, pulmonary disease, chronic hypertension, renal disease, liver disease, personal history of thromboembolism), gestational diabetes mellitus, and hypertensive disorders of pregnancy.

414 | Maternal and Obstetric Factors Associated with Successful Cerclage Treatment: A Prediction Model

Annabelle L. van Gils[1]; Jasper T. Lamens[1]; Flip W. W. van der made[2]; Sanne J. Gordijn[3]; Brenda J. Hermsen[4]; Brenda M. M. Kazemier[1]; Martijn A. Oudijk[5]; Eva Pajkrt[1]
[1]Amsterdam UMC, Amsterdam, Noord-Holland; [2]St. Franciscus Hospital, Rotterdam, Zuid-Holland; [3]University Medical Center Groningen, Groningen, Groningen; [4]Onze Lieve Vrouwe Gasthuis, Amsterdam, Noord-Holland; [5]Amsterdam UMC, location University of Amsterdam, Amsterdam, Noord-Holland

4:00 PM - 6:00 PM

Objective: Cervical cerclage treatment effectively reduces the risk of recurrent preterm birth (PTB) in specific subgroups. This study aimed to identify maternal and obstetric factors influencing success of cerclage treatment (i.e. no PTB < 32 weeks) to develop a prediction model.

Study Design: This multicenter prospective cohort study analyzed data of the PC-study (NTR4415) and associated observational cohort. We included patients with prior sPTB < 34 weeks and a singleton pregnancy who received a history-based (HB) or an ultrasound-indicated (UI) cerclage. Primary outcome was PTB < 32 weeks. Maternal and obstetric factors were included in multivariate logistic regression (MLR) and a risk model was composed for the HB- and UI group. Subsequently, outcomes were stratified by risk scores (high, medium and low).

Results: In total, 222 patients received cerclage treatment. PTB < 32 weeks occurred in 43/222 cases (19.4%), of which 13/85 in the HB group (15.3%) and 30/137 (21.9%) in the UI group. In the total group, MLR showed that higher maternal age (p = 0.04), non-Caucasian ethnicity (p = 0.02) and smoking (p = 0.045) were associated with decreased cerclage success (i.e. higher PTB < 32 weeks). In the HB group, event rates were considered too low for proper MLR. In the UI group, higher maternal age (p = 0.008), smoking (p = 0.005), lower gestational age at placement (p< 0.001) and lower CL (p = 0.004) were associated with decreased cerclage success. Individual risk scores in this group were calculated using the composed risk model. Scores < -1.7 were considered low-risk, -1.7 to 0 medium-risk and > 0 high risk. For high-risk patients, the UI-model had a positive predictive value (PV) of 81.3% for occurrence of PTB < 32 weeks. Low-risk patients had a PV of 91.2% for no PTB < 32 weeks. The AUC of the ROC-curve was 0.81 (95% CI 0.72–0.90).

Conclusion: Several maternal and obstetric risk factors significantly influence the success rate of cerclage treatment. The developed risk model effectively stratifies patients with an UI cerclage into high, medium, and low risk categories and can be a valuable tool in counseling patients.

415 | Defining Specific Bile Acid Profiles in Intrahepatic Cholestasis of Pregnancy

Anne M. Ambia[1]; Jeffrey McDonald[2]; Yevgenia Y. Fomina[1]; Andrea Rizkallah[2]; C. Edward Wells[3]; Catherine Y. Spong[3]; Donald D. McIntire[3]; David B. Nelson[3]
[1]University of Texas Southwestern, Dallas, TX; [2]UT Southwestern, Dallas, TX; [3]University of Texas Southwestern Medical Center, Dallas, TX

4:00 PM - 6:00 PM

Objective: Although intrahepatic cholestasis of pregnancy (ICP) is often diagnosed using total serum bile acid (BA) measurements, there is a paucity of information on the individual bile acid profiles in this enigmatic condition. Thus, our aim was to define the specific BA profiles among a cohort of pregnant individuals with ICP.

Study Design: This was a prospective, observational cohort study of pregnant individuals evaluated for ICP from February 2022 to July 2023 a single academic center. Patients were characterized into pruritis of pregnancy (total BA < 10 mmol/L, referent), ICP (BA 10-39 mmol/L), and severe ICP (BA >40 mmol/L) using a quantitative enzymatic assay. At the time of initial evaluation for ICP, an additional blood sample was collected to evaluate for a selection of primary (cholic, chenodeoxycholic), secondary (deoxycholic), glycol-conjugated (glycocholic, glycodeoxycholic,

glycolithocholic), and tauro-conjugated (taurocholic, taurochenodeoxycholic, taurodeoxycholic, taurolithocholic) forms of BA. These measurements were conducted using liquid chromatography and mass spectrometry methods.

Results: There were 39 patients evaluated: 5 with pruritis, 24 with ICP, and 10 with severe ICP. Levels of glycocholic, taurocholic, and taurochenodeoxycholic acids were significantly increased in those with ICP. When comparing patients with ICP to severe ICP, there was an increase in both glycol and tauro-conjugated BA (Figure).

Conclusion: Beyond total BA, patients with ICP have significantly elevated levels of specific BA profiles that offer an important opportunity to better understand the pathophysiology and treatment targets for this enigmatic condition.

416 | Intrapartum Glycemic Control with IV Insulin Infusion in Pregestational and Gestational Diabetes

Annkay Alexander[1]; Yuanfan Ye[2]; Victoria C. Jauk[1]; Frances Burgan[1]; Carolyn Webster[1]; Ashley N. Battarbee[2]

[1]University of Alabama at Birmingham, Birmingham, AL; [2]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL

4:00 PM - 6:00 PM

Objective: ACOG recommends maintaining maternal glucose < 110mg/dL in labor, often managed with IV insulin infusion. Our objective was to describe the degree of intrapartum glycemic control achieved with IV insulin infusion and identify factors associated with intrapartum glycemic control.

Study Design: A retrospective cohort study of pregnant persons with pregestational or gestational diabetes who received IV insulin infusion during labor at a tertiary center was conducted (2015-2024). Antepartum fetal demise and deliveries < 22 weeks were excluded. At our center, IV insulin titration is individualized by clinicians based on hourly glucose values and response to prior adjustments. The primary outcome was percentage of intrapartum glucose values within target range of 65-110mg/dL (TIR_{Labor}). We compared TIR_L and other glycemic measures by diabetes type. Multivariable linear regression with backward stepwise selection was used to identify sociodemographic and clinical factors associated with TIR_L.

Results: Of 896 included persons, 49 (5%) had A1GDM, 305 (34%) had A2GDM, 365 (41%) had T2DM, and 177 (20%) had T1DM. Overall, 52% were non-Hispanic Black, 32% non-Hispanic White, 14% Hispanic; 65% had government insurance; mean BMI was 40±9 kg/m2; mean delivery GA was 35.8±3.2 weeks; and 72% had labor induction. The mean TIRL was 51±33% with differences in glycemic control by diabetes type (Table 1). A2GDM (vs T1D), labor induction, use of SMBG (vs CGM) for monitoring, greater number of intrapartum glucose measurements and later delivery year were associated with higher TIR_L, whereas higher HbA1c and corticosteroids < 7 days before delivery were associated with lower TIR_L (Table 2).

Conclusion: Strict intrapartum glycemic control (65-110 mg/dL) is difficult to achieve with clinician-managed IV insulin infusion. Future interventions to improve intrapartum control including alternatives to clinician-managed IV insulin should address potential barriers such as diabetes type, suboptimal glycemic control before admission, recent antenatal corticosteroids, and short labor duration with fewer intrapartum glucose measurements.

Table 1. Intrapartum glycemic control of overall study cohort and compared by maternal diabetes type

	Overall study cohort (N=896)	A1GDM (n=49)	A2GDM (n=305)	T2DM (n=365)	T1DM (n=177)
TIR_{Labor} (% glucose values 65-110mg/dL)	51 ± 33	52 ± 35	57 ± 35	49 ± 34	48 ± 28
% glucose values ≥110 mg/dL	47 ± 34	47 ± 35	43 ± 35	50 ± 35	49 ± 29
% glucose values ≥140 mg/dL	15 ± 23	12 ± 22	10 ± 15	17 ± 25	20 ± 24
% glucose values <65 mg/dL	1 ± 5	0.3 ± 1	0.5 ± 3	1 ± 6	4 ± 8
Mean glucose (mg/dL)	113.2 ± 23.1	112.4 ± 20.1	109.6 ± 18.4	115.4 ± 25.5	115.0 ± 25.1
Max glucose (mg/dL)	150.1 ± 45.4	142.4 ± 36.8	138.5 ± 39.1	150.4 ± 43.6	171.6 ± 53.1

Table 2. Sociodemographic and medical factors associated with percentage of intrapartum glucose values in target range (65-110 mg/dL)

	TIR_{Labor} Adjusted mean difference (95% CI)
Diabetes type	
A1GDM	-9.48 (-31.60 to 12.65)
A2GDM	8.81 (0.70 to 16.93)
T2DM	1.29 (-5.14 to 7.72)
T1DM	Ref
Last HbA1c before delivery (per 1%)	-2.23 (-4.17 to -0.28)
Steroids <7 days before delivery	-19.02 (-24.51 to -13.53)
Labor induction	9.87 (3.30 to 16.44)
SMBG for intrapartum monitoring	11.58 (2.90 to 20.26)
Number of intrapartum glucose values (per 1 value)	0.43 (0.12 to 0.74)
Delivery year (per 1 year)	1.39 (0.28 to 2.50)

Factors considered in initial models included maternal age, race/ethnicity, insurance, nulliparous, multiple gestation, delivery BMI, delivery gestational age, last HbA1c before delivery, diabetes type, metformin use, insulin use, chronic hypertension, preeclampsia, creatinine before delivery, antenatal corticosteroids within 7 days before delivery, fetal anomaly, labor induction, used POCT glucose for monitoring, number of intrapartum glucose values, time from insulin infusion to delivery, year of delivery

417 | Time in Range and Barriers to Achieving Continuous Glucose Monitoring Targets in Type 2 Diabetes

Annkay Alexander[1]; Amber Sanders[2]; Claire A. McIlwraith[1]; Brian E. Brocato[1]; Ashley N. Battarbee[3]
[1]University of Alabama at Birmingham, Birmingham, AL; [2]Lincoln Memorial University DeBusk College of Osteopathic Medicine, Harrogate, TN; [3]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL

4:00 PM - 6:00 PM

Objective: For pregnant persons with type 1 diabetes (T1D) using CGM, the recommended time in target range (TIR, 63-140 mg/dL) is > 70%. However, TIR recommendations for pregnant persons with type 2 diabetes (T2D) are uncertain. Our objectives were to evaluate TIR achieved before delivery among pregnant persons with T2D and identify barriers to achieving TIR > 70%.

Study Design: Retrospective cohort study of gravidae with T2D who used CGM and received care at a single, tertiary center (2019-2024). Timed CGM data was downloaded, and TIR in 30 days pre-delivery was calculated. Factors were compared between persons with TIR > 70% vs £ 70%. Multivariable logistic regression with backward selection identified the factors independently associated with TIR > 70%. Sensitivity analyses evaluated factors associated with TIR > 70% in 2 weeks and %TIR 30 days pre-delivery.

Results: Of 134 pregnant persons included, the average TIR during 30 days pre-delivery was 59.5±19.2% with 43 (32%) achieving TIR > 70% pre-delivery. Of 22 sociodemographic and clinical factors, only pre-pregnancy HbA1c and baseline insulin dose differed between TIR > 70% vs £ 70% (Table 1) and were independently associated with TIR > 70% in regression models (Table 2). For every 1% increase in pre-pregnancy HbA1c, there was 26% lower odds of TIR > 70% (aOR 0.74, 95% CI 0.60-0.94). For every 10 unit increase in baseline insulin dose, there was 16% lower odds of TIR > 70% (aOR 0.84, 95% CI 0.74-0.94). These findings were unchanged in sensitivity analyses evaluating TIR > 70% in 2 weeks and %TIR in 30 days pre-delivery.

Conclusion: In this cohort of gravidae with T2D, the average TIR in 30 days pre-delivery was 60% with only 1/3 achieving the T1D-recommendation of TIR > 70%. Barriers to achieving TIR > 70% that should be addressed include improving glycemic control before pregnancy and identifying effective interventions for gravidae with high insulin requirements. The lack of association with other factors suggests that patients may be able to achieve TIR > 70% pre-delivery despite unfavorable social determinants or later access to prenatal care and CGM.

Table 1. Sociodemographic and clinical factors compared by TIR>70% versus TIR ≤70% in 30 days before delivery

418 | Postpartum Gastroenterology Referrals and Follow Up in Pregnant Patients with Viral Hepatitis

Anthony Chartier[1]; Kaitlyn Stark[2]; Han-Yang M. Chen[3]; Irene A. Stafford[3]
[1]Department of Obstetrics, Gynecology and Reproductive Sciences, McGovern Medical School at UTHealth, Houston, TX; [2]University of Texas Health Science Center at Houston - McGovern Medical School, Houston, TX; [3]McGovern Medical School at UTHealth Houston, Houston, TX

4:00 PM - 6:00 PM

Objective: The objective of this study was to determine rates of appropriate postpartum gastroenterology (GI) referral and follow up in pregnant patients with hepatitis B and C.

Study Design: After institutional review board approval, we performed a retrospective cohort study among 19,974 pregnant patients who delivered at a safety net hospital system between 1/2019 and 12/2022. The primary outcomes were referrals to GI and postpartum follow-up with GI. All baseline demographics and obstetrical variables were collected, including viral hepatitis status. Differences in the baseline characteristics and outcomes were examined using chi-square or Fisher's exact test for categorical variables. A P value of < 0.05 was considered significant. Multivariable Poisson regression models with robust error variance were used to examine the association, and an adjusted relative risk (aRR) with 95% CIs was calculated.

Results: Out of the 19,974 pregnant patients in this cohort, 82 (0.4%) had hepatitis B and 49 (0.2%) had hepatitis C. Hepatitis B was more prevalent in Black women, limited prenatal care, and lack of substance abuse, $p = < 0.001$, for each. (Table 1). Patients with hepatitis B were significantly more likely to be referred to GI than hepatitis C patients, with 62 (75.6%) of hepatitis B patients referred and 22 (44.9%) of hepatitis C patients referred ($p < 0.001$). Furthermore, patients with hepatitis B were significantly more likely to attend a follow-up appointment with GI during the postpartum period. 23 (28.1%) of hepatitis B patients attended a GI appointment postpartum, compared to 5 (10.2%) of hepatitis C patients ($p = 0.016$). After adjustment, hepatitis B patients were 2.60 times more likely to be referred or seen by GI (CI: 1.54-4.38), compared to hepatitis C patients.

Conclusion: This study demonstrates low rates of indicated GI referrals for pregnant women with viral hepatitis, despite screening recommendations to test all pregnant women to prevent mother-to-child transmission and to link them to care services for treatment. Further studies are needed to evaluate the reasons for these gaps.

419 | Sociodemographic Differences in Perinatal Outcomes Following Publication of the Chap Trial

Anthony E. Melendez Torres[1]; Sarah K. Dotters-Katz[1]; Sarahn M. Wheeler[1]; Rachel L. Wood[2]
[1]Duke University School of Medicine, Durham, NC; [2]Duke University, Durham, NC

4:00 PM - 6:00 PM

Objective: The April 2022 CHAP trial showed that tight chronic hypertension (cHTN) control decreased preterm birth (PTB) and low birthweight (BW) < 2500g. We conducted a difference in differences (DID) analysis to assess population-level sociodemographic disparities in these outcomes before and after publication and dissemination of the CHAP trial.

Study Design: Population level DID analysis from February 2021 to August 2023 using US Natality data including patients with a singleton, non-anomalous gestation, cHTN, and who initiated prenatal care at $\leq$ 6 months gestation. Pre- and post-CHAP periods were defined *a priori* as February 2021-January 2022 and September 2022-August 2023 respectively with a dissemination period from February-August 2022. Primary outcomes were PTB< 35 weeks, PTB< 37 weeks, and BW< 2500g. Differences in outcomes were compared between Black and White race, Hispanic and non-Hispanic ethnicity, and privately and publicly insured patients during pre- and post-CHAP trial periods. The difference in differences was then calculated. Average treatment effect differences were obtained using linear regression with Stata18 SE.

Results: Black, Hispanic, and publicly insured patients had higher rates of PTB and low BW during the study period compared to their White, non-Hispanic, and privately insured counterparts (Table 1). Rate differences between subgroup categories were significant during the pre- and post-CHAP periods for PTB< 35 weeks, PTB< 37 weeks, and BW< 2500g, except for BW< 2500g during the pre-CHAP period in the ethnicity subgroup.

Treatment effect differences in differences were not significant for any primary outcome across subgroups (Table 1).

Conclusion: Sociodemographic disparities in PTB and low BW in patients with cHTN were identified across racial, ethnic, and payor status subgroups both prior to and after the CHAP trial. However, existing disparities were unchanged by dissemination of CHAP trial. Future research should assess in more granular detail if application of CHAP trial interventions can improve these disparities.

420 | Maternal Placental Vascular Pathology Association with Aspirin Response Among High-Risk Singleton Pregnancies

Ariana Spiegel[1]; Joanna Chan[1]; Walter Kraft[1]; Steven McKenzie[1]; Rupsa C. Boelig[2]
[1]Thomas Jefferson University Hospital, Philadelphia, PA; [2]Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA

4:00 PM - 6:00 PM

Objective: Placental vascular pathologies are noted in pregnancies complicated by preeclampsia and preterm birth. Aspirin initiation in high-risk pregnancies reduces the risk of these outcomes. However, it is unclear how aspirin response affects placental histopathology. Our objective is to evaluate the relationship between aspirin response and placental vascular pathology in high-risk pregnancies taking 81mg aspirin daily.

Study Design: This is a secondary analysis of a prospective cohort of high-risk singletons taking aspirin daily. Placental maternal vascular pathology was categorized according to Amsterdam classification system. The primary outcome was maternal vascular malperfusion (MVM). Aspirin response was assessed by Platelet Function Assay-100 epinephrine closure time (PFA-100) at baseline (before aspirin, < 16 weeks), 2-4 weeks after aspirin initiation (follow up-1), and at 28-32 weeks gestation (follow up-2). The exposure was PFA-100 assessed as a continuous and categorical variable (<150 seconds, inadequate response) in those with and without placental MVM. The Mann-Whitney-U test and Chi-squared test were used.

Results: Of the original cohort (n = 130), 91 participants took 81mg aspirin daily, completed requisite follow-up, and had placental histopathology available. 38 (42%) exhibited placental MVM; baseline characteristics were similar in those with and without MVM (Table 1). There was no significant difference in aspirin response in those with and without placental MVM (Table 2), although there was a higher rate of inadequate aspirin response at 28-32 weeks in those who developed MVM. However, this was not statistically significant (p = 0.14).

Conclusion: We found a high rate of placental MVM in high-risk singletons taking aspirin daily, and a strong association between placental MVM and preterm birth. We did not find a significant association between aspirin response and placental MVM, although a larger study should be done to evaluate the relationship between aspirin response and placental vascular pathology especially when assessed in the 3rd trimester.

421 | Reducing Bias in AI Models for Fetal Heart Ultrasound: Assessing Annotation Quality

Aris T. Papageorghiou[1]; J Alison Noble[1]; Olga Patey[1]; Mostafa Sarker[1]; Netzahualcoyotl Hernandez-Cruz[1]; Divyanshu Mishra[1]; Beverly Tsai-Goodman[2]
[1]University of Oxford, Oxford, England; [2]Royal Brompton Hospital, London, England

4:00 PM - 6:00 PM

Objective: When building machine learning algorithms in a collaborative manner, annotating ultrasound videos of fetal heart "sweeps" is important prerequisite. These annotations are undertaken by experts following standard guidelines and criteria. To

ensure these data for training machine learning algorithms are reliable, we aimed to create a system to quantify inter and intra-annotation variation. The ultimate aim is to create quality assurance systems of video annotations to reduce annotator bias.
Study Design: Two experienced cardiologists (A1 and A2) each annotated 4,539 individual ultrasound frames from ten fetal heart ultrasound videos (transverse sweep). Individual frames received one of five fetal cardiac labels through manual annotation. Pairwise comparisons were made between annotations conducted two weeks apart by A1 (intra-annotator agreement) and between cardiologists A1 and A2 (inter-annotator agreement). Inter- and intra-annotator agreements were quantified on a frame-by-frame basis using Intra-Class Correlation Coefficient [ICC] and Kappa score values.
Results: Successful labelling of all frames were carried out. Intra-annotator reproducibility showed correlation strong agreement (ICC = 74.9 %, Kappa score of 81%). Inter-annotator agreement between A1 and A2 was moderate (ICC = 66.6, Kappa score of 60%).
Conclusion: The results show high reproducibility of annotations of frames of the fetal heart from ultrasound sweeps for a single annotator. However, when comparing annotations between different annotators, the results are less consistent, indicating only moderate agreement. These variations have implications for quality assurance and what constitutes "ground truth" when using fetal heart annotations in ultrasound videos for training machine learning algorithms.

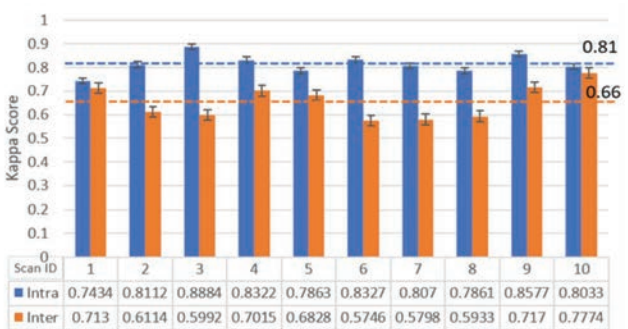

Figure: Visualizing intra and inter-annotator agreement between A1 and A2 by Kappa scores for the 10 (scan ID) fetal heart transverse sweep ultrasound videos.

422 | Impact of Fetal Sex on Adverse Pregnancy and Neonatal Outcomes in Individuals with Pre-Existing Diabetes

Arlin Delgado; Kaitlyn E. James; Andrea G. Edlow; Camille E. Powe; Lydia L. Shook
Massachusetts General Hospital, Boston, MA

4:00 PM - 6:00 PM
Objective: Pre-existing diabetes mellitus (DM)–diabetes identified prior to pregnancy - is increasing in prevalence among pregnant individuals and is associated with adverse maternal and neonatal outcomes. Prior work suggests that fetal sex impacts underlying placental dysfunction leading to differential pregnancy risks. The objective of this study is to assess the impact of fetal sex on placentally-mediated adverse pregnancy outcomes in individuals with DM.
Study Design: This was a retrospective cohort study of 503 pregnant individuals with pre-existing DM and known fetal sex receiving care at a major urban academic center between 1998-2016. The exposure of interest was fetal/infant sex. The primary outcome was a composite of preterm birth, hypertensive disorder of pregnancy (HDP), small for gestational age (SGA), and stillbirth, and the secondary outcome was NICU admission. A composite of large for gestational age (LGA), hypoglycemia, hyperbilirubinemia, shoulder dystocia, and respiratory distress syndrome (RDS) was assessed. Mixed effects logistic regression models were built to assess the relationship between fetal sex and the pregnancy/neonatal outcomes, accounting for multiple pregnancies and adjusting for 1st Trimester BMI, parity, and race/ethnicity.
Results: Of the 503 pregnant individuals included, 258 pregnancies had a female fetus (51%) and 245 pregnancies had a male fetus (49%)–Table 1; no significant differences in sociodemographic or clinical characteristics were observed between groups. No significant differences in either composite outcome was identified, however there was a significantly higher likelihood of NICU admissions for males (adjusted odds ratio 1.83 [1.14, 2.94], p = 0.012, Table 2).
Conclusion: Although we did not identify differences in composite adverse pregnancy or neonatal outcomes in individuals with DM by offspring sex, the significantly higher rate of NICU admission suggests male neonatal vulnerability to the impact of maternal DM and warrants further investigation.

423 | Self-Perceptions and Decision-Making Factors regarding CBD Use Among Pregnant People

Mia Hodges[1]; Sarah Bader[2]; Emily Hardisty[3]; Neeta L. Vora[3]; Asha N. Talati[3]
[1]University of North Carolina, Chapel Hill, NC; [2]University of North Carolina at Greensboro, Greensboro, NC; [3]University of North Carolina at Chapel Hill, Chapel Hill, NC

4:00 PM - 6:00 PM

Objective: To understand perceptions of risks and benefits, and factors influencing CBD use among pregnant people given limited data regarding CBD use during pregnancy.

Study Design: Participants were drawn from a parent study at UNC-CH on CBD use and reproductive genetics. Eligible participants were pregnant within the last 3 years, had a history of CBD use, or were willing to discuss hypothetical scenarios of CBD use during pregnancy. One on one semi structured interviews were conducted by a single interviewer, recorded, coded, and transcribed. Domains of the interview guide included experience with CBD or other substances, decision making influences, and information seeking behaviors. Interviews were coded using grounded theory methods by three coders (MH, SHB, AT) using Dedoose software. Sampling for interviews was completed once thematic saturation was achieved.

Results: Ten participants were interviewed (Table 1), including one who used CBD during pregnancy and five who used CBD when not pregnant and chose not to continue during pregnancy. Five major themes emerged: (1) Risk and benefit perceptions, (2) identifying trustworthy resources, (3) disclosure, (4) suggestions for practice, and (5) differences between pregnancies (Table 2). Importantly, participants reported frequently receiving discordant opinions when seeking information from various sources, identifying a gap in available data given the prevalence of CBD use. Additionally, participants revealed how relationship with an obstetric provider and perceptions of how a provider will receive information about CBD use, determined revealing use.

Conclusion: This study highlights the myriad of factors influencing pregnant patients' decisions on CBD use. These findings underscore the need for more research on CBD safety during pregnancy given the prevalence of use around gestation and first trimester exposure and can inform the development of educational tools for obstetric providers to better discuss CBD use with reproductive-aged patients.

Theme	Subtheme	Exemplary Quotations
Risk and benefit perception	Unknown risk to fetus Fear of legal repercussions Alternative to traditional medications or to marijuana Use of CBD to address common pregnancy symptoms	*"I would have probably done [CBD] instead of Zoloft, if it was something that's natural."* *"I wouldn't put my baby in danger of being taken by the state or anything like that because some of the restrictions."*
Trust in resources	Based on education level, personal or provider experience Anxiety navigating various sources and conflicting information Difficulty ascertaining which resources are trustworthy Association between trust with provider and honesty Difficulty repairing trust after negative interactions with the healthcare system	*"There's way too much information, and conflicting information."* *"I talked to my husband quite a bit, like, should I be doing this? And he did some research, and I did some research, and I talked to the midwives, and it seems like everybody was kind of just like, it's no big deal. But then if you go to the internet, it's like, this is a big deal."* *"You hear different things from different doctors, and then that's confusing too."*
Disclosure	Importance of trusting relationship with obstetrician Influence of past experiences Safety in group settings Power of suggestion/prompted communication	*"I would have worried a little bit if I spoke to my OB, then they would report me or judge me or treat me differently."* *"Creating the space to bring up those taboo topics grouped with other things can help open the doors."* *"I loved the group aspect of it, the community, and every week was, like, a different topic about taking care of yourself, nutrition, exercise, all the things we have questions about."*
Suggestions for practice	Potentially beneficial resources (pamphlets, apps, hotlines, group classes) Recommendations for providers to increase patient disclosure Empowering patient-driven questions through increased accessibility Desire for more research on CBD use in pregnancy	*"…make sure that they seem like I'm not a burden to their time. That is a really big thing"* *it would be nice if they had like an app, but like more built out thing for pregnant women to go to for different stuff because I was fortunate to have a great doctor, but maybe for women who don't feel like they have that resource."* *"…Zooms, fine emails, fine calls, texts, anything. I would love to call [the clinic] and just be like, hey, I need advice today."*
Differences between pregnancies	Differences in approach to disclosure and research Familiarity with resources Confidence with pregnancy and personal intuition Increased willingness to ask sensitive questions	*"The first time was a little different. Everything was new… The second time, I was way less conservative."* *"I had way more questions with the first, but with the second, I don't know if I was tired or just felt more comfortable because I had been through it before."*

424 | Implementation Challenges for Prenatal Genetic Screening (PGS) at Federally Qualified Health Centers

Asha N. Talati[1]; Maura Jones Pullins[2]; Mia Hodges[2]; Emily Hardisty[1]; Madeline Dyke[1]; Neeta L. Vora[1]
[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]University of North Carolina, Chapel Hill, NC

4:00 PM - 6:00 PM

Objective: To identify implementation challenges for prenatal genetic services (PGS) (aneuploidy and carrier) at federally qualified health centers (FQHCs).

Study Design: Qualitative interview study of maternity care providers (MCPs) at FQHCs in NC. Eligible participants were those that see pregnant patients, order and provide counseling for prenatal genetic screening, and follow up results. One-on-one semi-structured interviews were conducted by a single interviewer using an audio-video platform, were recorded, and transcribed. Interviews focused on the following domains based on the Consolidated Framework for Implementation Research (CFIR) constructs: (1) perceived value of genetic screening; (2) perceptions of advancing prenatal genetic technologies; (3) individuals and structural barriers to PGS in public health settings; and (4) recommendations for improved implementation. Interviews were completed after categorical saturation was reached. Interviews were immediately analyzed after interview using a rapid qualitative analytic process.

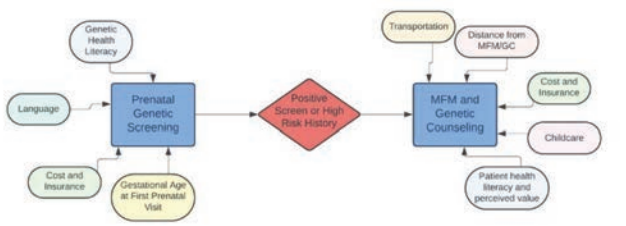
Results: Twelve MCPs were interviewed across FQHCs in 12 counties in NC. 9 providers identified as maternal health program coordinators or managers (RN), and 3 providers identified as advanced practice providers (NP). Mean number of years in practice among the cohort was 6.6 (SD 2.4). In describing their patient populations, all providers reported seeing patients who have Medicaid, presumptive Medicaid, or uninsured. Patient languages in all clinical settings were described as English and Spanish, with one clinic reporting a large Haitian Creole population. Several key themes were identified: (1) MCPs value PGS and describe inequities in access, informed consent, and types of testing between public and private healthcare settings; (2) health literacy and cost are the most cited barriers to PGS implementation; (3) resources for education and expert consultation are needed in rural areas.

Conclusion: Resources to address health literacy, cost, and access to genetics expertise are necessary to improve implementation of PGS at FQHCs.

Matrix 1. Key Findings and Exemplary Quotations

Theme	Exemplary Quotations
Value of PGS	"I think carrier screening is a good tool to have so we can best access where they may need to deliver, what resources we may need to get in place prior to the delivery." *Participant 2* "...especially in North Carolina now, with the abortion limit age...it really comes more into play as far as knowing sooner, having all the information that way you can to make a decision and to make it in time." *Participant 1*
Inequities in PGS in Public versus Private Spaces	"You know for yourself, if you were pregnant, you would go to another private practice clinic and have other test options. It's not right." *Participant 3* "...it doesn't sit very well....I don't think it's fair or equitable that patients receive care or options based on where they go to receive their care." *Participant 7* "I feel like every week I'm seeing emails, but something else is being offered...I don't it's just it's hard to keep up with all of it." *Participant 8*
Barriers to PGS	"I do find that it can be challenging to describe the genetic testing and explain exactly what it is for patients...I think there's limited understanding of the testing. Most of the time, [patients] agree to have it done, but they don't fully understand what they are agreeing to. And so when something comes back abnormal, or we need to do some some follow up testing... I think that's where, things get more complex for our patient population." *Participant 9* "The first question most of the time about genetic testing is, how much does it cost, or will my insurance cover it? And I think that's a huge barrier if, if they're present, if they don't have presumptive or, you know, we explain that you may have to pay out of pocket if there aren't funds through the company that we use. And most of the time, people you know decide not to go through with it because of the potential of the cost." *Participant 7*
Resources Needed for PGS	Participants described resources that they felt would facilitate genetic testing in public settings: • Visual aids or counseling aids in English/Spanish written at a 6th grade reading level • More availability of laboratory genetic counseling services • Genetic counseling or MFM hotline for rural coverage • Webinars, 'lunch and learn' for providers about advances in genetic screening and testing

Figure 1. Model of Multilevel Barriers to PGS at FQHCs



[a]Model demonstrates barriers to initial prenatal genetic screening and additional barriers faced by those with high risk history or positive screens that require MFM/Genetic Counseling Care with transition from public to private healthcare settings.

425 | Duration of High-Dose Postpartum Oxytocin Infusion and Postpartum Bleeding Outcomes in Individuals Undergoing Vaginal Delivery

Ashley E. Shea[1]; Christina T. Blanchard[1]; Alan T. Tita[2]; Ashley N. Battarbee[1]; Akila Subramaniam[1]
[1]Center for Women's Reproductive Health, University of Alabama at Birmingham, Birmingham, AL; [2]University of Alabama at Birmingham, Birmingham, AL

4:00 PM - 6:00 PM

Objective: High-dose prophylactic postpartum (PP) oxytocin (80 IU) has been suggested to reduce postpartum hemorrhage (PPH); however the optimal infusion duration is unknown. We sought to compare rates of PPH and other bleeding outcomes between high-dose (80 IU) oxytocin infused over 1 versus 4 hours.

Study Design: Secondary analysis of a database of all vaginal deliveries >22 weeks at a large academic referral center (1/1/2013-12/31/2018). Our institution's protocol for PP oxytocin infusion was altered on 10/15/2015 for vaginal deliveries only from 80 IU/500 mL over 1 hour to 80 IU/500 mL over 4 hours with initial 100 mL bolus prior to 4 hour infusion. All vaginal deliveries with

available outcomes were included. Patients were categorized as receiving oxytocin over 1 versus 4 hours, individually confirmed in the medication administration record. Primary outcome was a composite of estimated blood loss (EBL) >1000 mL, 2nd line uterotonic use, and any blood transfusion (secondary outcomes in Figure). Generalized estimating equation models were used to estimate adjusted odds ratios (aORs) and 95% confidence intervals (CI) using the 4 hour group as referent.

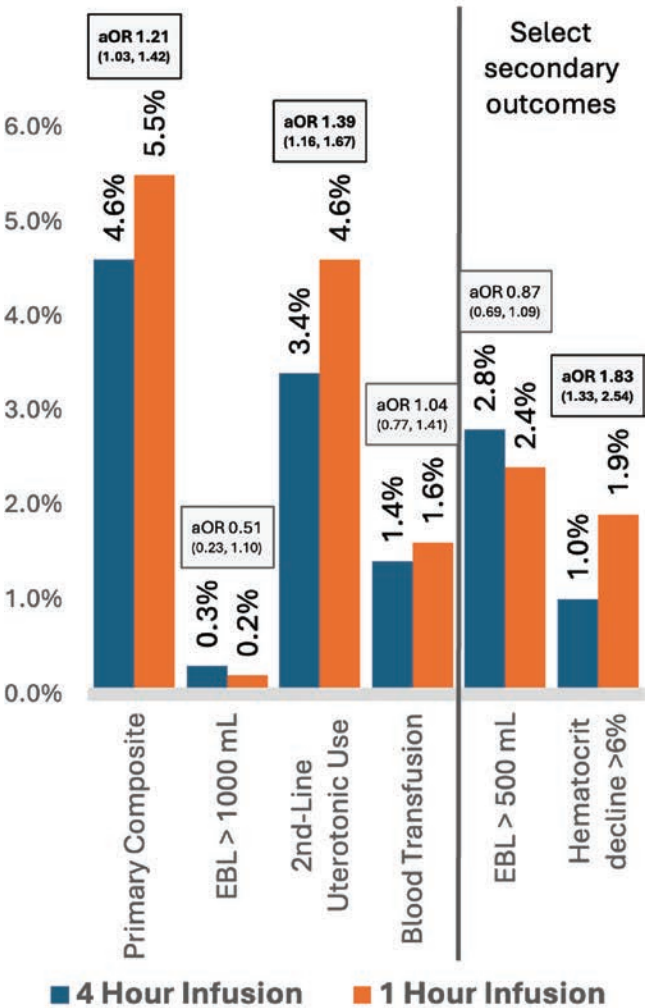
Results: Of 16,793 deliveries, 12,092 met inclusion criteria: 5,675 received 80U oxytocin for 1-hour (47%), 6,417 (53%) for 4-hours. There were multiple differences in baseline characteristics between groups (Table). Compared to the 4-hour group, the 1-hour group had increased odds of the primary composite (aOR 1.21, 95% CI 1.03-1.42), driven by an increase in 2nd line uterotonic use (aOR 1.39,1.16-1.67) (Figure). While there was no difference in EBL >1000 mL or blood transfusion, the 1-hour group had increased odds of HCT decline >6% (aOR 1.83, 1.33-2.54).

Conclusion: Infusion of PP high-dose oxytocin over 1 hour compared to 4 hours is associated with increased odds of postpartum bleeding–mainly 2nd-line uterotonic use and HCT decline > 6%. Given that 2nd line uterotonic use is clinician dependent, further investigation, utilizing less subjective outcomes such as transfusion, is needed to further define optimal high-dose oxytocin duration.

Table. Baseline characteristics of our population (data presented as % or mean± standard deviation)

	4 Hour Infusion Group (n=6417)	1 Hour Infusion Group (n=5675)	P-value
Maternal age	26.9 ± 5.8	26.4 ± 5.7	<0.001
BMI >30	32.8	34.5	0.51
Medicaid/Self pay	69.0	72.8	<0.001
Term delivery	86.6	83.5	<0.001
Diabetes	1.3	1.8	0.004
Chronic hypertension	3.5	3.8	0.82
Admission hematocrit	34.8 ± 4.1	34.6 ± 4.1	0.08
Intrapartum magnesium	3.3	4.5	<0.001
Type of labor			<0.001
Induction	37.2	31.2	
Augmentation	39.5	42.3	
SROM	23.4	26.5	
Neuraxial Anesthesia	78.0	75.7	0.048
Operative Delivery	5.4	4.3	0.006

Figure. Primary composite outcome and its individual components plus select secondary outcomes



*Odds ratios are adjusted for maternal age, insurance, term delivery, diabetes, intrapartum magnesium, labor type, neuraxial anesthesia, and operative vaginal delivery. 4 hour infusion as referent. Significant outcomes are in bold.

‡There was no difference in mean hematocrit change, blood transfusion >4 units, transfusion of products other than blood, hysterectomy, ICU admission, or maternal death.

426 | Impact of Nicu Length of Stay on Outcomes of Birthing People with Opioid use Disorder

Ashley Boerrigter; Cynthia Cockerham; Julie Bowers-Pryor; Ronald Clarkson; Gregory Hawk; Barbara V. Parilla
University of Kentucky, Lexington, KY

4:00 PM - 6:00 PM

Objective: To determine the impact of NICU length of stay on health outcomes of birthing people with opioid use disorder (OUD). Primary outcome was EDPS and GAD-7 scores.

Study Design: Longitudinal prospective cohort of pregnant persons receiving care through a comprehensive perinatal substance use treatment program between 2014 and June 2024. Characteristics of every patient who participated in the program were analyzed regardless of prenatal program participation or complete delivery outcome information; a minimum of postpartum program participation and neonatal outcomes were required for inclusion in the study. Participants were divided into groups based on whether their infant stayed more or fewer than 15 days in the NICU. Fisher's exact and two-sample t-tests were utilized for statistical analysis.

Results: There was no significant difference in postpartum EDPS and GAD-7 scores when groups were analyzed by infant's duration of stay in the NICU (<15 days, n = 183 or 15+ days, n = 106). However, EPDS score >13 at weeks 11–15 postpartum was observed in 33% of patients with infant NICU stays >15 days as compared to 0% with shorter stays, though this was not statistically significant (p = 0.4667). Birthing parents of infants who stayed < 15 days in the NICU were more likely to be exclusively breastfeeding at time of discharge (38.1% vs 32.6%, p = 0.0331) and room in with their infant (70.6% vs 47.1%, p = 0.001). There was no significant difference in attendance at postpartum visits (74% vs 72%, p = 0.6106).

Conclusion: When stratified at the 15-day mark, duration of infant's NICU stay did not appear to be associated with any significant difference in birthing parents' EDPS or GAD-7 scores. However, 33% of parents experienced an EPDS score suggestive of depression as compared to 0% in the shorter stay group. Further studies are needed to evaluate the mental health of parents when their neonate has an extended hospital stay for neonatal opioid withdrawal syndrome (NOWS). Breastfeeding and rooming-in are strategies associated with shorter stays for NOWS, which our study also found.

Table 1. Demographics.

	NICU admission < 15 days (n=183)	NICU admission 15+ days (n=106)	P-value

427 | Personalized Infant Birth Weight Percentile Charts for Accurate Assessment of Neonatal Growth using Machine Learning

Natalie Suder[1]; Ashley Zimmermann[2]; Rachel Kim[3]; Karen Huang[3]; Maria Teresa Benedetto[1]; Mio Sawai[1]; Teresa Cheon[1]; Yuzuru Anzai[1]

[1]Lenox Hill Hospital, NY; [2]Northwell Lenox Hill Hospital, New York, NY; [3]University of Chicago, Chicago, IL

4:00 PM - 6:00 PM

Objective: Identifying small for gestational age (SGA) and large for gestational age (LGA) neonates is imperative to manage potential neonatal complications. The Hadlock growth curve, the most widely used standardized growth curve in the United States, overlooks maternal factors such as race, height, BMI, and pregnancy weight gain, which are known to impact fetal weight. This study aims to create a personalized birth weight percentile chart to improve accuracy of diagnosing SGA and LGA neonates.

Study Design: Using the 2022 CDC natality dataset, a least squares quantile regression model was developed using Python to predict the 10th and 90th percentile birth weights based on maternal factors. To improve model accuracy, gestational diabetes, gestational hypertension, plurality, tobacco use, infant sex, and gestational age (GA) were included. Polynomial regressions determined the best-fit degrees. The model focused on pregnancies from 27 to 42 weeks GA, excluding extreme birth weights (< 200 grams or > 5000 grams) and unknown parameters (n = 3,428,570). Validity of the model was confirmed using an 80:20 split for testing and training, respectively.

Results: Among the factors in the model, plurality had the strongest effect on determining the fetal weight, followed by

GA, maternal race, cigarette smoking, fetal gender, and maternal height, even though GA should not alter the percentile. Pre-pregnancy maternal BMI and pregnancy weight gain showed much smaller effects in this model. The quantile loss at the 10th percentile was 66 grams and 90th percentile was 72 grams.

Conclusion: The model was trained using a large, national dataset and shows high accuracy with low quantile losses; therefore, this model can supplement physicians' diagnoses of SGA and LGA and aid in appropriate delivery preparations. However, the model results should be interpreted with caution because medical complications and tobacco smoking status used for the model are known factors that can affect fetal growth. In the next model, we aim to determine the SGA threshold that is associated with adverse fetal outcomes.

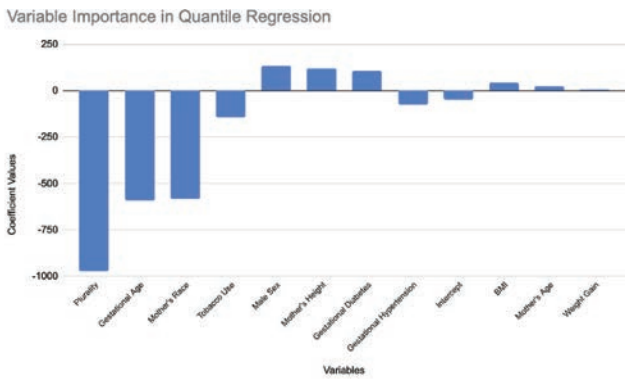

Figure 1: Variables Shown by Coefficient Importance

Input
Mother's BMI: 20 **Mother's Age**: 30 years **Mother's Height**: 65 inches **Mother's Race**: White **Weight Gain During Pregnancy**: 20 lbs **Gestational Diabetes**: No **Gestational Hypertension**: No **Plurality**: 1 **Tobacco Use**: No **Infant Sex**: Female **Gestational Age**: 37 weeks

428 | Interactive Lecture Improves Resident Knowledge and Comfort with Periviable Delivery Counseling

Ashli Gibb; Carolyn Chatterton; Fatima Ali; Kara Patek
Detroit Medical Center/Wayne State University, Detroit, MI

4:00 PM - 6:00 PM

Objective: Counseling patients at risk for periviable delivery (PVD) is a challenging part of obstetrics. Available resources for PVD counseling (PVDC) include previously published best practices and the National Institute for Child Health and Human Development (NICHD) Calculator for Extremely Preterm Birth Outcomes. Given the necessary nuanced provider knowledge, ethical complexity, and emotional environment of a PVD, we assessed ObGyn resident PVD knowledge and comfort with counseling before and after an educational intervention.

Study Design: ObGyn residents at a large urban center were given a pre-survey to assess experience, knowledge, and comfort with PVDC. An interactive lecture was given, with case review and group discussion. Those unable to attend lecture were given a reading for comparison. A post-survey was distributed. Paired t-test was used for statistical analysis.

Results: 39 residents participated, and 32 (82.1%) completed the pre-survey. Collectively, residents reported counseling 100 patients a year on PVD, and receiving 1.6 hours of PVD education a year. A majority (87.5%) felt that patients poorly understood after counseling. 21 residents completed the post-survey: 18/26 post-lecture and 3/13 post-reading. Post-lecture, comfort with PVDC significantly improved for all residents (mean 1.9 vs 3.6 on a 5-point Likert Scale; $p< 0.01$) and PGY1s (mean 1.5 vs 3.2; $p = 0.01$). Knowledge also improved as 50% of residents named all 5 NICHD calculator factors post-lecture, versus 12.5% pre-survey. 100% of residents felt the lecture was very or extremely valuable, and 94.4% plan to implement changes in their practice. Residents post-reading had minimal improvement in PVDC comfort, felt it was slightly or moderately valuable, and none would implement changes.

Conclusion: At centers with a high incidence of PVD, resident education is crucial to counseling and patient care. Interactive lectures with an opportunity to practice counseling significantly improved comfort and knowledge. These findings highlight a need for high-quality resident education and resources to improve care for patients at risk for PVD.

429 | Cost-Effectiveness of Antepartum Versus Postpartum Treatment of Latent Tuberculosis Infection

Ava D. Mandelbaum; Megha Arora; Sarah K. Dzubay; Aaron B. Caughey
Oregon Health & Science University, Portland, OR

4:00 PM - 6:00 PM

Objective: Treatment of latent tuberculosis infection (LTBI) during pregnancy is typically reserved for high-risk cases due to concerns about potential side effects. However, pregnancy provides a unique interaction with the healthcare system, offering an opportunity to treat LTBI and prevent future progression to active tuberculosis (TB). This study aimed to evaluate the health outcomes and cost-effectiveness of antepartum versus postpartum treatment among pregnant individuals with LTBI.

Study Design: A decision-analytic model using TreeAge software was constructed to compare the outcomes and cost-effectiveness of antepartum versus postpartum treatment of LTBI. The theoretical cohort included 20,000 individuals with LTBI based on the number of annual pregnancies and prevalence of LTBI in the United States. Outcomes included the number of complete treatments, drug-induced hepatotoxicity, progression to active TB, fatality from active TB, and cases of untreated latent TB based on data demonstrating lower adherence and follow-up in the postpartum period. Model inputs were derived from the literature. The threshold for cost-effectiveness was $100,000/ quality-adjusted life year (QALY). Sensitivity analyses were performed to assess the robustness of the results.

Results: Compared to postpartum treatment, the antepartum treatment strategy resulted in 4,217 additional treatment completions, 239 fewer cases of progression to active TB, and 17 fewer fatalities from active TB (Table 1). Additionally, the postpartum group had 4,520 cases of untreated LTBI related to the rate of lower follow-up postpartum. Antepartum treatment was the cost-effective and dominant strategy, resulting in cost savings of $8,555,587 and an increase in 4,266 QALYs relative to postpartum treatment.

Conclusion: The antepartum treatment strategy for LTBI was cost-effective and resulted in better health outcomes compared to postpartum treatment. These findings may inform future policies that integrate LTBI treatment into prenatal care to potentially improve outcomes and enhance resource allocation.

Table 1: Outcomes, cost, and effectiveness associated with antepartum versus postpartum treatment of latent tuberculosis infection

	Antepartum Treatment	Postpartum Treatment	Difference
LTBI Treatment Completed	16,326	12,109	↑4,217
Drug-induced Hepatotoxicity	30	17	↑13
Progression to Active TB	243	482	↓239
Fatality from Active TB	17	34	↓17
Untreated LTBI	0	4520	↓4,520
Cost (USD)	$8,708,029	$537,783	↓$8,555,587
Effectiveness (QALYs)	17,263,616	533,517	↑4,266
Strategy	Dominant	Dominated	

LTBI – latent tuberculosis infection, TB – tuberculosis

430 | Management of Placenta Accreta Spectrum with Cesarean Hysterectomy Versus Conservative Management: a Cost-Effectiveness Analysis

Ava D. Mandelbaum[1]; Binh Luu[2]; Andrew H. Chon[1]; Tania F. Esakoff[3]; Deirdre J. Lyell[4]; Aaron B. Caughey[1]
[1]Oregon Health & Science University, Portland, OR; [2]Oregon Health and Science University, Vancouver, WA; [3]Cedars Sinai Medical Center, Los Angeles, CA; [4]Stanford University, Palo Alto, CA

4:00 PM - 6:00 PM

Objective: Cesarean hysterectomy is the standard treatment for placenta accreta spectrum (PAS), but alternative conservative management strategies (e.g., leaving the placenta in situ), have been proposed to preserve fertility. This study aimed to evaluate the cost-effectiveness of conservative management for PAS.

Study Design: A decision-analytic model was built using TreeAge software to compare the outcomes and cost-effectiveness of cesarean hysterectomy versus conservative management. The theoretical cohort included 5,000 individuals in the U.S. with PAS. Maternal outcomes included severe postpartum hemorrhage (>3000 mL estimated blood loss), adjacent organ injury, severe maternal morbidity (including intensive care unit admission, sepsis, and disseminated intravascular coagulation), endometritis, maternal death, and readmission. The number of hysterectomies performed within and after 24 hours of delivery (primary and delayed, respectively) was calculated for the conservative management group. Model inputs were derived from the literature. The threshold for cost-effectiveness was set at $100,000 per quality-adjusted life year (QALY). Sensitivity analyses were performed to assess the robustness of the results.

Results: Cesarean hysterectomy resulted in 2,137 more severe postpartum hemorrhages, 413 more adjacent organ injuries, and 516 more cases of non-hemorrhage SMM, and 8 more maternal deaths compared to conservative management. Conversely, conservative management led to 542 more cases of endometritis and 1,268 more readmissions. Additionally, 347 primary and 202 delayed hysterectomies were performed in the conservative management group. Conservative management resulted in a $64 million cost reduction and an increase of 7,609 QALYs relative to cesarean hysterectomy.

Conclusion: Compared to cesarean hysterectomy, conservative management was cost-effective, with distinct trade-offs in maternal outcomes, such as reduced severe hemorrhage and increased endometritis and readmission. Additional studies are needed to refine the selection of patients undergoing conservative management for fertility preservation.

Table 1: Maternal outcomes, cost, and effectiveness associated with cesarean hysterectomy versus conservative management for PAS

	Cesarean Hysterectomy	Conservative Management	Difference
Severe Postpartum Hemorrhage* (cases)	2,951	814	2,137
Adjacent Organ Injury (cases)	645	233	413
Endometritis (cases)	0	542	-542
Severe Maternal Morbidity** (cases)	806	291	516
Maternal Death (cases)	39	31	8
Readmission within 6 months (cases)	169	1,437	-1,268
Primary Hysterectomy (cases)	0	347	-347
Delayed Hysterectomy (cases)	0	202	-202
Cost ($USD)	178,748,367	115,002,669	63,745,698
Effectiveness (QALYs)	125,587	133,195	-7,609

431 | Patient-Similarity Tool Enhancing Decision-Making on Whether to Place Cervical Cerclage

Avihu Krieger[1]; Rakefet Yoeli-Ullman[2]; Abraham Tsur[3]
[1]Sheba Medical Center, Tel Aviv, Tel Aviv; [2]Sheba Medical Center, Ramat Gan, HaMerkaz; [3]Sheba Medical Center, Ramat Gan, Tel Hashomer, Israel, Ramat Gan, HaMerkaz

4:00 PM - 6:00 PM

Objective: Decision-making for cervical cerclage placement is complex and requires consideration of specific patient characteristics. We sought to develop a *patient similarity tool* to augment clinical decision-making and enhance shared decision-making based on the clinical course of similar patients. Patient similarity identifies patients with similar clinical characteristics to predict outcomes and personalize treatment plans.

Study Design: We used a retrospective cohort of all pregnancies at a tertiary center from 2010-24, including all individuals with discussions considering cervical cerclage. The list of patients and their clinical variables served as the analytic DATABASE for the patient similarity tool. We defined 16 variables for similarity assessment that were available in the electronic health record. An additional seven variables will require manual collection: cervical dilation, membranes bulging, cervical length, amniotic fluid sludge, uterine activity, WBC, and CRP. Based on the index patient's similarity parameters, the tool detects similar patients and describes their maternal and neonatal outcomes with and without cerclage.

Results: Among 138,439 deliveries during the study period, 684 clinical scenarios considering cervical cerclage were captured. Cerclage was performed in 343 (50.1%) of these cases. Table 1 compares individuals with and without cerclage based on the

variables selected for similarity assessment. Significant differences were observed in maternal age, gravidity, previous painless dilation, previous cerclage, last pregnancy gestational age (GA) at delivery, spontaneous conception, multifetal pregnancy, and GA at decision time. Figure 1 illustrates an index patient and presents similar patients and their outcomes with and without cerclage.

Conclusion: Developing a patient similarity tool to augment decision-making and decision sharing regarding cervical cerclage placement is feasible. We speculate that our proposed tool may improve data-driven decision-making and empower patient participation in shared decision-making.

Table 1: Similarity Assessment Variables

432 | Early Pregnancy Levels of Cholesterol in Maternal Serum and Pregnancy Outcomes

Ayal Haimov[1]; Eyal Sheiner[2]; Tamar Wainstock[2]
[1]*Ben Gurion University of the Negev, Ramat Gan, HaMerkaz;* [2]*Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom*

4:00 PM - 6:00 PM

Objective: Elevated maternal serum lipid concentrations during late pregnancy are associated with pregnancy complications. The goal of this study was to investigate the association between early pregnancy maternal serum levels of cholesterol and selected pregnancy outcomes.

Study Design: A prospective cohort study was conducted, including pregnant women with a singleton pregnancy, recruited between 11-13 gestational weeks. The independent variable was maternal serum level of cholesterol (high cholesterol was defined as >200 mg/dL). The incidence of the following pregnancy outcomes was compared between women with high and low cholesterol: abortion, gestational hypertension, gestational diabetes mellitus, gestational length, preterm birth, birth weight, low birthweight, macrosomia, cesarean delivery and low 5 minutes Apgar score.

Results: The study included 201 women. The incidence of high cholesterol was 35% (n = 70). Mean birthweight was higher among women with high cholesterol (Table 2, 3392.71 ± 426 versus 3220.78 ± 448 grams, p-value = 0.01). Similarly, women with high cholesterol were more likely to deliver a macrosomic newborn (10.1% versus 3.2%, p-value = 0.057). Multivariable linear model, adjusted for gender and maternal diseases, found that an increase in one unit of cholesterol was significantly related with an increase of 2.85 grams in birthweight (95% CI = 0.98 - 4.73, p-value = 0.003). Multivariable logistic model which adjusted for gender and maternal BMI, found that every unit increase of cholesterol was significantly related with an increased risk for macrosomia (OR = 1.025, 95% CI = 1.003–1.047, p-value =

0.025). No association was found between cholesterol and others pregnancy outcomes.

Conclusion: Higher birthweight and a risk for macrosomia were found among women with high early pregnancy cholesterol levels, even after controlling for maternal BMI. Lowering maternal cholesterol levels may aid in prevention of pregnancy complications associated with high birthweight.

Table 2 – The association between cholesterol and pregnancy outcomes

	Cholesterol ≤ 200 mg/dL n= 128, 65%	Cholesterol > 200 mg/dL n= 70, 35%	p-value
Abortion (n, %)	6, 4.8%	1, 1.4%	0.219

433 | Early Pregnancy Levels of Acute Phase Reactants in Maternal Serum and Pregnancy Outcomes

Ayal Haimov[1]; Eyal Sheiner[2]; Tamar Wainstock[2]
[1]*Ben Gurion University of the Negev, Ramat Gan, HaMerkaz;* [2]*Department of Obstetrics and Gynecology, Soroka University Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom*

4:00 PM - 6:00 PM

Objective: Inflammation and infection within the fetoplacental unit have been suggested as a mechanism involved in pregnancy complications. The goal of this study was to investigate the association between early pregnancy maternal serum levels of the following acute phase reactants (ARPs): CRP (C- reactive protein), albumin, triglyceride, HDL and selected pregnancy outcomes.

Study Design: A prospective cohort study was conducted, including pregnant women with a singleton pregnancy, recruited between 11-13 gestational weeks. The independents variables were serum levels of the following ARPs: CRP, Albumin, Triglyceride, and HDL. The incidence of the following pregnancy outcomes was compared between women with high and low levels of the measures APRs: abortion, hypertensive disorders, gestational diabetes mellitus, gestational length, preterm birth (PTB), birth weight, low birthweight, macrosomia, cesarean delivery and low 5 minutes Apgar score.

Results: The study included 201 women. No association was found between the ARPs and pregnancy outcomes (Table 2), for instance, the incidence of PTB were 5.8% (n = 8) versus 5.5% (n = 3), among women with high and low HDL, respectively (p = 0.917), and 5.3% (n = 6) versus 6.6% (n = 5) among women with high and low Albumin, respectively (p = 0.704). Birth weight was 3220.75 ± 403 versus 3317.51 ± 467 grams among women with low and high CRP, respectively (p = 0.160), and 3296.39 ± 433.26 versus 2676.05 ± 464.76 grams among women with high and low Albumin, respectively (p = 0.758). These findings were supported by multivariable logistic and linear models, which adjusted for maternal BMI and maternal age.

Conclusion: Based on the current study, early pregnancy levels of ARPs are not associated with an increased risk for adverse pregnancy outcomes.

4:00 PM - 6:00 PM

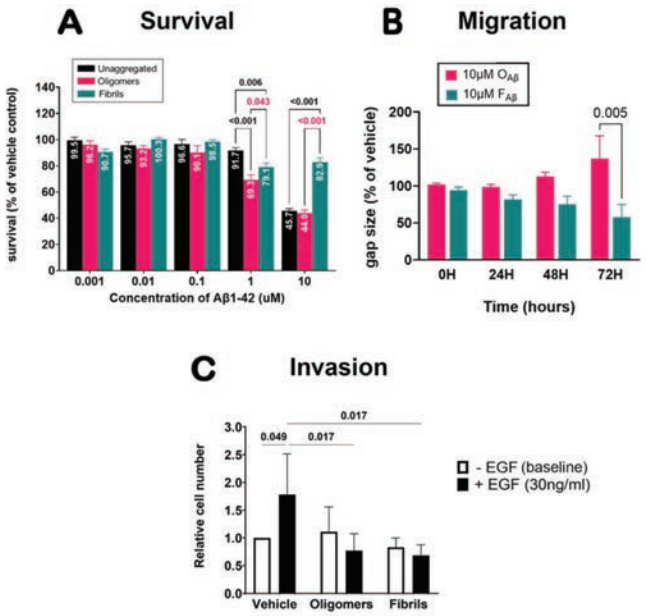
Objective: Misfolding of proteins and their subsequent assembly into supramolecular aggregates are key mechanisms involved in neurodegenerative diseases such as Alzheimer's disease (AD). These aggregates range from small prefibrillar cytotoxic oligomers to large β-sheet rich fibrils that accumulate in tissues and disrupt normal function. In AD, the accumulation of amyloid-β (Aβ) oligomers ($O_{A\beta}$) and fibrils ($F_{A\beta}$) in the brain is a disease hallmark. Excess Aβ aggregates were recently detected in the serum, urine, and placenta of patients with preeclampsia, which is now considered a protein misfolding disease of pregnancy. Whether Aβ aggregates directly impact placental function thereby contributing to pathogenesis of preeclampsia has yet to be elucidated. We aimed to characterize the effect of different Aβ proteoforms on trophoblast cell survival and function.

Study Design: We exposed an immortalized human extravillous trophoblast (EVT) cell line (HTR8/SVNeo) to exogenous unaggregated ($U_{A\beta}$), $O_{A\beta}$, or $F_{A\beta}$ preparations (0.001-10μM) and assessed their effect on cell survival by measuring cytotoxicity (MTT assay), migration (scratch assay) and invasion (Transwell assay ± epidermal growth factor [EGF], an essential regulator of placental development). Data from n = 3-5 independent experiments was analyzed. A dual apoptosis/necrosis assay was used to determine the mechanism of cell death.

Results: **1)** Both $O_{A\beta}$ and $F_{A\beta}$ decreased EVT survival with $O_{A\beta}$ having a more profound effect (p< 0.001); at higher concentrations, $U_{A\beta}$ also decreased cell viability likely due to spontaneous oligomerization (Fig. **A**). **2)** EVT death occurred primarily via apoptosis (not shown). **3)** While $O_{A\beta}$ decreased EVT migration (increased gap size), $F_{A\beta}$ increased cell migration compared to vehicle control (Fig. **B**). **4)** Both $O_{A\beta}$ and $F_{A\beta}$ inhibited EGF-

mediated invasion (p = 0.017) without affecting baseline invasion (Fig. **C**).

Conclusion: Presence of excess Aβ aggregates during placental development has the potential to contribute to preeclampsia pathogenesis by disrupting key cellular processes such as EVT survival, migration and invasion.



435 | APOE4 Genotype Increases Susceptibility to Fetal Growth Restriction in the Context of Preeclampsia

Bani Medegan Fagla[1]; Cielo Dela Rosa[1]; Savita Sundar[1]; Erykah Walton[1]; Jason York[1]; Guomao Zhao[1]; Aswathi Jayaram[1]; Leon M. Tai[1]; Mert Ozan Bahtiyar[2]; Catalin S. Buhimschi[1]; Irina A. Buhimschi[1]

[1]University of Illinois at Chicago, College of Medicine, Chicago, IL; [2]Yale University, New Haven, CT

4:00 PM - 6:00 PM

Objective: *APOE4,* one of three alleles of the lipid regulating gene *APOE,* is the greatest genetic risk factor for sporadic Alzheimer's disease (AD) particularly in females. Preeclampsia (PE), a pregnancy-specific disorder, is characterized by abnormal deposition of misfolded proteins in the placenta, analogous to the hallmark protein aggregates in AD brain. We sought to investigate in a human cohort the association between *APOE* genotype and risk of PE with or without fetal growth restriction (FGR; EFW < 10%). Additionally, the effect of *APOE4* was investigated mechanistically in a transgenic mouse model where the mouse *ApoE* gene was substituted by either human *APOE4* or *APOE3* (the common allele).

Study Design: We genotyped 181 consecutively enrolled maternal-fetal dyads divided by pregnancy phenotype in three clinical groups: **1)** PE without FGR (n = 56), **2)** PE with FGR (n = 21), and **3)** non-PE pregnancies (n = 104). DNA was extracted from maternal or cord blood and subjected to PCR. Risk association was determined by logistic regression. For mechanistic studies, we induced a PE-like syndrome in pregnant $APOE4^{+/+}$ and $APOE3^{+/+}$ mice using the reduced uteroplacental perfusion pressure (RUPP) procedure. Control mice underwent sham surgeries (n = 6-7/group/genotype). Endpoints consisted of kidney morphology (glomerular size), fetal weights, placental efficiency, and placental ApoE mRNA expression by RT-qPCR.

Results: **1)** In the human cohort, fetal carriage of at least one *APOE4* allele was associated with increased odds of PE with FGR (p = 0.043, Fig. 1); **2)** An interaction of *APOE4* with female fetal sex was further identified (p = 0.024); **3)** In mice, placental efficiency was reduced post-RUPP in both genotypes (Fig. 2A) but only $APOE4^{+/+}$ had decreased fetal weights (Fig. 2B) and kidney injury (p = 0.014, Fig. 2C); **4)** RT-qPCR of mouse placenta indicated significantly upregulated ApoE mRNA in response to RUPP in both genotypes.

Conclusion: ApoE participates to placental homeostasis during pregnancy. *APOE4* may have a reduced capacity to maintain optimal fetal growth in the context of PE-associated placental dysfunction compared to *APOE3*.

436 | Changes in Uterine, Placental Metrics, and Vascularization in Placenta Left In Situ for PAS Management

Barouyr Ajemian[1]; Donatella Gerulewicz Vannini[1]; Eleazar E. Soto[2]; Farah H. Amro[2]; Baha M. Sibai[2]; Edgar A. Hernandez-Andrade[2]

[1]University of Texas Health Science Center in Houston, McGovern Medical School, Houston, TX; [2]McGovern Medical School at UTHealth Houston, Houston, TX

4:00 PM - 6:00 PM

Objective: In our center, one of our placenta accreta spectrum (PAS) management approaches is leaving the placenta left in situ (LIS) for either delayed hysterectomy (6-7 weeks later), or uterine preservation. We aim to describe changes in uterine and placental metrics and vascularization in individuals with placenta LIS after delivery. We compared those with planned delayed hysterectomy or uterine preservation, to those with unscheduled hysterectomy (UH).

Study Design: In this retrospective cohort, 32 individuals with placenta LIS were evaluated. Our management approach includes postpartum ultrasound biweekly until hysterectomy or passage of placental tissue. The individuals were divided into two groups, group I: successful planned procedure (scheduled hysterectomy or uterine preservation), group II: UH (defined as that occurring prior the scheduled date mainly due to vaginal bleeding). Measurements included: uterus length and height, and placental thickness. Directional color Doppler ultrasound was applied to evaluate the lower uterine segment using the following settings PRF = 22-25 cm/sec, medium filter, and 1.4 dB gain. Images were analyzed using Image J software. Quantitative vascularization (QV) was defined as the percentage of pixels containing color information over the total number of pixels in the studied area. Average change per week of the mentioned parameters were calculated. Differences in metrics and QV between UH and successful conservative management were calculated.

Results: Of 32 patients, 17 (53%) had a successful planned procedure (10 scheduled hysterectomy and 7 retained their uterus) and 15 (47%) had an UH. Differences between the two groups are presented in table 1. The reduction in uterine metrics and QV in those with successful conservative management was more pronounced, but not statistically significant.

Conclusion: This is the first report showing longitudinal change in uterine, placental metrics and QV in those with the placenta LIS. More studies are needed to identify clinical variables which may predict successful conservative management of PAS.

437 | The Impact of Weight Gain on Pregnancy Outcomes in Patients with Low BMI

Taha Elfarra[1]; Leah M. Hefelfinger[2]; Jessica Lin[3]; Braxton Forde[2]
[1]University of Cincinnati, Cincinnati, OH; [2]University of Cincinnati College of Medicine, Cincinnati, OH; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH

4:00 PM - 6:00 PM

Objective: The association between adverse pregnancy outcomes and obesity is established, however the impact of low maternal weight upon outcomes is much less studied. We sought to evaluate the odds of adverse pregnancy outcomes in the setting of low pre-pregnancy BMI as well as if these risks are mitigated with adequate weight gain in pregnancy.

Study Design: Retrospective cohort study of all United States births in 2021 using National Vital Statistics US birth certificate data. Pregnancy demographics, as well as maternal and neonatal outcomes were compared between a referent group of normal pre-pregnancy BMI with adequate pregnancy weight gain and 3 investigational cohorts: low pre-pregnancy BMI with either adequate, inadequate, or greater than recommended pregnancy weight gain. Multivariate logistical regression models were used to calculate the odds of adverse maternal and neonatal outcomes.

Results: During study period, 520,552 patients had normal pre-pregnancy BMI and adequate weight gain, compared to 40,144 patients 36,650 patients, and 26,155 patients with low pre-pregnancy BMI and adequate, inadequate, or greater than recommended weight gain, respectively. Demographical data was significantly different amongst groups (Table 1). Interestingly, after adjustment for differences in demographics, low pre-pregnancy BMI was associated with adverse neonatal outcomes only when weight gain was inadequate (aOR of composite adverse neonatal outcomes 1.6, 95% CI 1.6-1.7, Figure 1), whereas low pre-pregnancy BMI with either adequate or greater than recommended weight gain has similar neonatal outcomes (aOR 1.0, 1.0-1.0, aOR 1.0, 0.9-1.0, respectively). Of equal interest, low pre-pregnancy BMI was associated with adverse maternal outcomes regardless of weight gain in the pregnancy (Figure 1).

Conclusion: Low pre-pregnancy BMI is associated with adverse neonatal outcomes only in the setting of inadequate pregnancy weight gain, whereas low pre-pregnancy BMI is associated with adverse maternal outcomes regardless of weight gain in the pregnancy.

Table 1. Demographics of Low pre-pregnancy BMI with either adequate, inadequate, or more than recommended weight gain compared to pregnancies with normal pre-pregnancy BMI and adequate weight gain. Data is presented as mean and standard deviation or N (%).

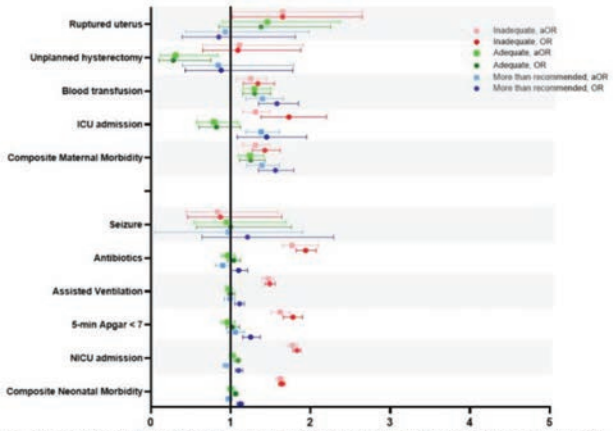

Figure 1. Association of low BMI, stratified by pregnancy weight gain, and adverse maternal and neonatal outcomes. Data presented as odds ratio (OR) with 95% CI. Only inadequate weight gain was associated adverse neonatal outcomes, indicating that appropriate weight gain is protective from a neonatal perspective. Interestingly, weight gain did not affect the risk of adverse maternal outcomes. Composite maternal morbidity is considered positive by the presence of any maternal morbidity in a pregnancy. Composite neonatal morbidity is considered positive by the presence of any neonatal morbidity in a pregnancy.

438 | The Importance of the Number of Prenatal Visits on Pregnancy Outcomes

Anna Gehret[1]; Braxton Forde[2]
[1]Ohio University College of Medicine, Athens, OH; [2]University of Cincinnati College of Medicine, Cincinnati, OH

4:00 PM - 6:00 PM

Objective: Most guidelines recommend roughly 11-15 prenatal visits in each pregnancy, with possibly more for high-risk pregnancies. While no prenatal care is associated with adverse outcomes, the true risk of limited prenatal care is unknown. Thus, we sought to evaluate the association of the number of prenatal visits with pregnancy outcomes.

Study Design: Retrospective cohort of all United States births in 2022 using National Vital Statistics US birth certificate data. Pregnancy demographics, as well as maternal and neonatal outcomes were compared between a referent group of patients that attended 11-15 prenatal visits with 3 investigational cohorts: patients with < 5 prenatal visits, 5-10 prenatal visits, and > 15 prenatal visits. Linear regression models were used to calculate the attributable effect of prenatal visit number upon delivery gestational age, and multivariate logistic regression was used to calculate the odds of adverse maternal and neonatal outcomes.

Results: During study period, 232,616 patients had < 5 prenatal visits, while 1,341,990 had 5-10, 1,702,481 had 11-15, and 320,008 had > 15 visits. Demographics were significantly different amongst groups (Table 1). While all study groups had increased rates of adverse outcomes, the findings were strongest with < 5 visits, which was attributable to a 1.5 week (95% CI 1.44-1.54) decrease in gestational age at delivery, even after adjustment for known risk factors of preterm birth. Conversely, attending 5-10 visits attributed to only 0.66 week (95% CI 0.64-0.68) decrease, and attending > 15 visits attributed to a clinically irrelevant 0.19 week decrease in delivery gestational age. Similar trends were identified when evaluating maternal and neonatal outcomes, in which < 5 prenatal visits significantly increased the odds of adverse maternal and neonatal outcomes (Figure 1).

Conclusion: Attending < 5 prenatal visits is strongly associated with adverse pregnancy outcomes. As patients attend more visits, the odds of adverse outcomes decrease. This highlights the extremely important role of routine prenatal care upon maternal and child health.

Table 1. Demographics, gestational age, and birthweight across various groups of prenatal care visits. Data is presented as N(%) or mean (95% CI) unless noted elsewhere.
*Adjusted for maternal race, chronic hypertension, gestational hypertension, gestational diabetes, pre-existing diabetes, maternal age, BMI, medical usage, smoking, and parity.

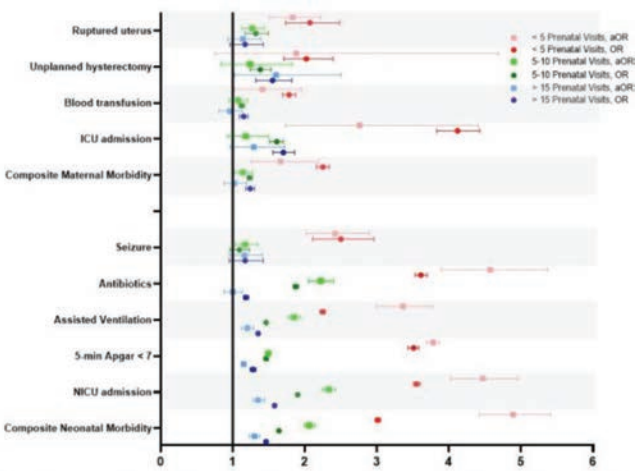

Figure 1. Association of number of prenatal visits and adverse maternal and neonatal outcomes. Data presented as odds ratio (OR) with 95% CI. The highest odds of adverse outcomes in all categories was in the setting of < 5 prenatal visits. OR adjusted for age, race, education, parity, chronic hypertension, gestational hypertension, pregestational diabetes, gestational diabetes, cigarette use, and Medicaid status.

439 | Birth Experiences of Discrimination on Labor and Delivery

Bridget C. Huysman[1]; Paige Wilder[1]; Maya Bussey[2]; Lori Atwood[1]; Mia Malcolm[2]; Monique Gill[2]; Rachel Witt[3]; Ebony B. Carter[4]; Eve Colson[2]; Candice Woolfolk[5]
[1]Washington University in St. Louis, St. Louis, MO; [2]Washington University in St. Louis/Barnes-Jewish Hospital, St. Louis, MO; [3]University of Minnesota, Minneapolis, MN; [4]University of North Carolina, Chapel Hill, NC; [5]Washington University School of Medicine in Saint Louis, St. Louis, MO

4:00 PM - 6:00 PM

Objective: Discrimination and racism impact obstetric care and approximately 1 in 5 birthing people will report mistreatment during maternity care. We sought to assess perceived discrimination experienced by birthing persons at the time of their delivery admission.

Study Design: This is a prospective survey of 129 birth people presenting for delivery from 03/2024 to 05/2024 using the Discrimination in Medical Settings Scale (DMSS) administered prior to discharge. Birthing people admitted for an indication not related to delivery, who delivered off L&D or precipitously, or unable to speak English were excluded. DMSS scores were compared between people of color (BIPOC) and White and assessed by reports of any discrimination, and DMSS scores >75th percentile (score 8) and ≥90th percentile (score 11). Survey responses were compared between groups using the Mann Whitney U test and multivariable logistic regression was used to estimate adjusted odds ratios(aOR) and 95% confidence intervals (CI) after adjusting for relevant confounders.

Results: Prior to discharge, 176 birthing people were approached to complete the survey and 47 declined to participate. Over 60% of the cohort identified as a person of color. Comparing by race, BIPOC and White birthing people differed by highest educational level achieved and insurance and employment status. In bivariate analysis, there was a statistically significant difference in reported DMSS scores ≥90th percentile between BIPOC and White birthing people with 5 times higher likelihood of reporting discrimination (14 (17%) vs. 2 (4%), p = 0.03, OR 5.42 [95% CI 1.18, 25.00])(Table 1). There was a statistically significant difference in security calls while in medical care between Black and White birthing people, respectively (13 (20%) vs. 5 (7%), p = 0.04)(Table 2).

Conclusion: Discrimination is experienced more by people of color on labor and delivery. Calls made to security calls by staff were more commonly experienced by Black birthing people. Future work is needed to explore how experiences of discrimination contribute to obstetric outcomes and care seeking.

Open Responses:

Participant #1: "*Nurses racial profiling me I feel like getting pain management a nurse told me not to go sell my pain meds on [street] another one would not even give me my pain meds after my c section.*"

Participant #2: "*There was initially a concern of being sent home again with a 45-minute drive. 2 prior pregnancies both went from barely progressing to immediately needing to push. I feel like it's hard to get this concern across successfully without feeling like I'm pushing to stay unnecessarily.*"

Participant #3: "*Lactation consultant on made me feel like trash. Less than human.*"

440 | Association of Transversus Abdominus Plane Block and Postoperative Opioid Consumption Following Planned Cesarean Hysterectomy

Brittany M. Hood; Jessica C. Ehrig; Michael Hofkamp
Baylor Scott and White Health, Temple, TX

4:00 PM - 6:00 PM

Objective: The rate of placenta accreta spectrum is 1 in 272. To combat the opioid epidemic, alternative pain management strategies including multimodal analgesia have been investigated. We hypothesized that patients who underwent planned cesarean hysterectomy (C-HYST) who received a transversus abdominus plane (TAP) block would have lower 24-hour postoperative opioid consumption compared to patients who did not.

Study Design: Our IRB approved the study and waived informed consent. Patients with C-HYST who did not require postoperative mechanical ventilation at our hospital from July 1, 2014 to December 31, 2022 were eligible for inclusion. Our primary outcome was 24-hour postoperative opioid consumption. We converted opioid use to morphine milligram equivalents (MME). For patients with patient-controlled analgesia (PCA), the closest documented entry to 24 hours was used to calculate opioid consumption. Demographic, physical, and clinical data were recorded.

Results: Demographic and physical characteristics of patients with TAP block following C-HYST with (n = 23) and without TAP block (n = 26) were no different. Patients with TAP block following C-HYST had a 24-hour opioid consumption of 30.8 + 29.8 mg compared to 80.4 + 59.4 mg for patients without a TAP block (p< 0.001). Patients with PCA (n = 12) had an average deviation in documentation from the 24-hour period of 41 minutes. For patients with TAP block, the average time from wound closure to TAP block was 69 minutes.

Conclusion: Patients with TAP block following C-HYST had statistically significant reductions in 24-hour opioid consumption compared to patients without TAP block. A limitation of this study was that patients without TAP block had statistically significant lower acetaminophen consumption compared to patients with TAP block. Increased acetaminophen administration may explain a modest decrease in opioid consumption but is unlikely to fully explain the magnitude of reduction observed in our study. Another limitation was imprecise data for patients with intravenous PCA. TAP blocks should be considered for patients who undergo C-HYST procedures.

Table 1. Demographic, physical, and clinical characteristics

441 | Pregnancy Under Fire: Disparities in Firearm-Related Injuries During Pregnancy in the United States, 2017-2021

Brittany Arditi[1]; Rachel Herz-Roiphe[2]; Alexander M. Friedman[1]; Adina R. Kern-Goldberger[3]; Cynthia Gyamfi-Bannerman[4]; Kartik K. Venkatesh[5]; Timothy Wen[6]
[1]Columbia University Irving Medical Center, New York, NY; [2]Columbia University Medical Center, New York, NY; [3]Cleveland Clinic Lerner College of Medicine, Cleveland, OH; [4]University of California, San Diego, San Diego, CA; [5]The Ohio State University, Columbus, OH; [6]University of California, San Diego, Irvine, CA

4:00 PM - 6:00 PM

Objective: Firearm violence is a preventable public health crisis in the US, and pregnant patients are not immune from this epidemic. Studies have shown that pregnant individuals are more likely to die due to homicide than the three leading obstetric causes of maternal mortality. Our objective was to evaluate disparities in firearm-related injuries (FRI) during pregnancy.

Study Design: A cross-sectional analysis of delivery hospitalizations with FRI was conducted using the Nationwide Inpatient Sample from 2017-2021. We analyzed trends of FRI stratified by self-reported race, payor, hospital region, and location/teaching status. Trend significance was determined using the Cochran-Armitage test. Multivariate logistic regression analyses, adjusting for patient and hospital factors, were performed to evaluate the effects of payor, self-reported maternal race, hospital region, and hospital teaching status on the incidence of FRI.

Results: Of 17.5 million deliveries, 6,365 were complicated by FRI (3.6 per 10,000 delivery hospitalizations). In unadjusted analysis, Black patients (OR 1.35, 95% CI 1.15-1.58) and patients delivering at urban teaching hospitals (OR 1.44, 95% CI 1.1-1.88) experienced higher rates of FRI; this finding did not hold after adjustment for patient and hospital factors. In both univariable and adjusted analyses, patients with public insurance were at increased risk of FRI (Medicare aOR: 3.10, 95% CI 2.07-4.66; Medicaid aOR 1.33, 95% CI 1.12-1.59 vs. private insurance). Rates of FRI were lower in the Midwest (aOR 0.53, 95% CI 0.43-0.65) and South (aOR 0.68, 95% CI 0.58-0.81) compared to the Northeast [Table 1]. Rates of FRI increased over time for non-Hispanic Black, non-Hispanic White, and Hispanic patients, as well as for those with public insurance. Rates of FRI also increased over time at urban teaching hospitals, and in all regions except the Midwest ($p < 0.01$) [Figure 1].

Conclusion: There are disparities in firearm related injuries by geographic location and payor status in the United States. Knowledge of such disparities can help to guide public policy aimed at preventing gun violence.

Table 1: Demographic and hospital-level factors and unadjusted and adjusted risk for firearm related injury

442 | Pregnancy Outcomes in Gestational Diabetes Based on Method of Diagnosis: GCT ≥ 200 Versus OGTT

Candace Levian[1]; Mariam Naqvi[2]; Alexandra Navarrete[1]; Mona Garcia[1]; Tania F. Esakoff[2]
[1]Cedars-Sinai Medical Center, Los Angeles, CA; [2]Cedars Sinai Medical Center, Los Angeles, CA

4:00 PM - 6:00 PM

Objective: Gestational diabetes mellitus (GDM) can be diagnosed based on 1-hour glucose challenge test (GCT) ≥ 200 mg/dL or ≥ 2 abnormal values on 3-hour oral glucose tolerance testing (OGTT). We sought to investigate medication needs and pregnancy outcomes among patients with GDM by method of diagnosis.

Study Design: This is a retrospective cohort study of patients with GDM who delivered at a single institution from 2020-2023.

Comparisons were made between two groups based on abnormal diagnostic test: 1-hour GCT result ≥ 200 mg/dL versus 1-hour GCT < 200 mg/dL and abnormal OGTT. Data were obtained by chart abstraction. The primary outcome was need for insulin initiation. Secondary adverse pregnancy outcomes were also described. Comparisons were performed using χ^2 and t-test, with multivariable logistic regression to adjust for confounders.

Results: We identified 587 patients with GDM during the study period, of whom 111 (19%) were diagnosed by 1-hour GCT ≥ 200 mg/dL and 476 (81%) had a glucose of 140-199 mg/dL and subsequently met Carpenter-Coustan criteria on 3-hour OGTT. Background characteristics were similar between cohorts, though the ≥ 200 mg/dL group was more likely to be Black and was diagnosed at an earlier gestational age (Table 1). Patients with a 1-hour GCT ≥ 200 mg/dL were more likely to require insulin during their pregnancy (53% vs 30%, $P < 0.01$) and to develop poor glycemic control (28% vs 15%, $P < 0.01$), defined as failure to meet recommended glycemic targets > 50% of the time despite medical therapy. A 1-hour GCT ≥ 200 mg/dL was associated with higher likelihood of a large for gestational age (LGA) neonate (17% vs 8%, $P < 0.01$) and neonatal intensive care unit (NICU) admission (28% vs 18%, $P = 0.02$). After adjustment for potential confounders, these associations remained significant (Table 2).

Conclusion: Patients diagnosed with GDM based on 1-hour GCT ≥ 200 mg/dL were more likely to require insulin and have poor glycemic control. LGA and NICU admission were more frequent in this population compared to those diagnosed with abnormal 3-hour OGTT.

443 | Pregnancy Outcomes in Gestational Diabetes Mellitus: Ethnic-Specific Differences Among a Diverse Asian-American Population

Candace Levian[1]; Mariam Naqvi[2]; Alexandra Navarrete[1]; Mona Garcia[1]; Tania F. Esakoff[2]

[1]Cedars-Sinai Medical Center, Los Angeles, CA; [2]Cedars Sinai Medical Center, Los Angeles, CA

4:00 PM - 6:00 PM

Objective: The prevalence of gestational diabetes mellitus (GDM) is higher in Asian populations. Comparative data on pregnancy outcomes among specific ethnic groups within Asian cohorts is lacking. Our objective was to study Asian patients with GDM and describe perinatal outcomes by country of origin.

Study Design: Retrospective cohort study of Asian patients with GDM stratified by region of origin (East: China, Korea, Japan, Taiwan; Southeast: Philippines, Thailand, Vietnam; South: India) who delivered at a single institution from 2020-2023. Classification of race/ethnicity was self-reported. Data were obtained through chart abstraction. Comparisons were performed using χ^2 and t-test. Multivariable logistic regression was then performed to adjust for potential confounders.

Results: We identified 667 patients with GDM during the study period, of whom 274 (41%) identified as Asian (36% East, 32% Southeast, 32% South). Specific ethnic groups within each region are shown in the Figure. Southeast and South Asian patients were more likely to be obese compared to those from Eastern regions (27% and 26% vs 11%, $P = 0.01$) (Table). South Asian patients were more likely to require insulin for blood glucose management and to develop poor glycemic control, defined as failure to meet recommended glycemic targets > 50% of the time despite medical therapy. Southeast Asian patients were more likely to require rapid-acting insulin and to develop a hypertensive disorder of pregnancy. Other maternal and neonatal outcomes were similar between groups. After adjustment for obesity, Southeast and South Asian patients remained more likely to require insulin compared to East Asian patients (aOR 3.0, CI 1.5-5.8 and aOR 2.0, CI 1.1-4). Poor glycemic control remained associated with South Asian descent compared to East Asian after adjustment for obesity (aOR 2.5, CI 1.1-5.9).

Conclusion: There are differences in glycemic management between Asian ethnic groups. Though Asian race is a known risk factor for GDM, patients who identify as Asian represent a heterogeneous group with diverse backgrounds and different clinical outcomes.

444 | The Impact of Senate Bill 8 on LARC and Permanent Contraception Trends in Texas

CeCe Cheng[1]; Maria I. Smereka[2]; Belem Suarez[3]; Paula A. Jaimes[3]; Carolina Vivas-Valencia[3]; Alexander Testa[4]; John J. Byrne[5]
[1]University of Washington, Seattle, WA; [2]University of Texas Health Science Center at San Antonio, San Antonio, TX; [3]The University of Texas at San Antonio, San Antonio, TX; [4]School of Public Health, University of Texas Health Science Center at Houston, Houston, TX; [5]University of Texas Health San Antonio, San Antonio, TX

4:00 PM - 6:00 PM

Objective: The goal of this study was to determine the impact of Senate Bill 8 (SB8) on trends in long-acting reversible contraception (LARC) and permanent sterilization (PS) procedures in the state of Texas.

Study Design: We conducted a retrospective cohort study utilizing the Texas Outpatient Public Use Data to characterize the relationship between the Texas "Heartbeat Act" (SB8) and trends in LARC/PS procedures before (1/2021-6/2021) and after (10/2021-3/2022) its passage in 9/2021. We excluded data from 7/2021-9/2021 which included the passage of SB8 and treated it as a washout period. Inclusion criteria were patients aged 15 to 54 who underwent LARC placement or female PS for contraceptive purposes. We excluded patients who underwent procedures for presumably non-contraceptive purposes (ie. ectopic pregnancy requiring salpingectomy). ICD-10 diagnostic and procedure codes were used. We used patients' home zip codes and the Rural and Urban commuting area codes to categorize geographic area.

Results: Of the 26,576 patients who met inclusion criteria during the study period, 14,006 (52.7%) and 12,570 (47.3%) received LARC/PS in the 6 months prior to and after passage of SB8, respectively. A decrease was observed in LARC use after SB8 (12.9 v 11.8%, p = 0.0048), while there was a significant increase in PS procedures (87.1 v 88.2%, p = 0.0027). A significant increase was noted in LARC/PS after SB8 in Hispanic patients compared to other racial/ethnic groups (31.9 v 33.2%, p< 0.0001). There were increases in patients ages < 20 (3.2 v 3.7%, p = 0.021), 30-39 (33.9 v 36.7%, p< 0.0001), and a decrease in those ≥50 (14.4 v 10.0%, p< 0.0001) post-SB8. More patients with Medicaid (20.7 v 21.8%, p = 0.03) and commercial insurance (40.6 v 42.4%, p = 0.003) received LARC/PS after SB8. The rate of rural LARC/PS users increased after SB8 (15.2 v 17.9%, p≤ 0.0001) compared to urban dwellers (84.6 v 82.1%, p≤ 0.0001).

Conclusion: The significant increase in PS use compared to LARC after SB8 may indicate the desire for more reliable forms of contraception in areas where access to reproductive healthcare is at risk.

Table. LARC and Permanent Contraception Utilization before and after passage of SB8

445 | Regional Differences in LARC and Permanent Contraception procedures in Texas after the Dobbs Decision

CeCe Cheng[1]; Maria I. Smereka[2]; Belem Suarez[3]; Paula A. Jaimes[3]; Carolina Vivas-Valencia[3]; Alexander Testa[4]; John J. Byrne[5]

[1]University of Washington, Seattle, WA; [2]University of Texas Health Science Center at San Antonio, San Antonio, TX; [3]The University of Texas at San Antonio, San Antonio, TX; [4]School of Public Health, University of Texas Health Science Center at Houston, Houston, TX; [5]University of Texas Health San Antonio, San Antonio, TX

4:00 PM - 6:00 PM

Objective: The aim of this study is to determine if there are differences in long-acting reversible contraception (LARC) and permanent contraception (PS) procedures in Texas before and after the Dobbs v Jackson Women's Health Organization (Dobbs) decision.

Study Design: We conducted a retrospective cohort study utilizing the Texas Outpatient Public Use Data to determine rates of LARC/PS procedure before (1/2022 to 6/2022) and after (7/2022 to 12/2022) the Dobbs decision in June of 2021. Inclusion criteria were patients aged 15 to 54 who underwent LARC placement or female PS for contraceptive purposes. We excluded patients who underwent procedures for presumably non-contraceptive purposes(ie. ectopic pregnancy requiring salpingectomy). ICD-10 diagnostic and procedure codes were used. We used patients' home zip codes and the Rural and Urban commuting area codes to categorize geographic setting.

Results: Of the 13,544 patients who met inclusion criteria during the study period, 6675 (49.3%) and 6869 (50.7%) received LARC/PS in the 6 months prior to and after passage of the Dobbs decision, respectively. Although there were no differences in overall rates of LARC/PS placement after passage of Dobbs, we noted a significant increase in LARC/PS procedures in patients from rural areas (17.9 v 20%, p = 0.0017) and a significant decrease in patients from urban areas (82 v 79.9%, p = 0.0013). Apart from a decrease in LARC/PS utilization after passage of Dobbs in the Hispanic population (32.7 v 31%, p = 0.03), there were no significant racial/ethnic differences in LARC/PS utilization after the passage of Dobbs. Similarly, there were no changes in LARC/PS rates across different age groups except for a decrease in the ≥50 age group (14.3 v 11.8%, p< 0.0001). There were no differences in LARC/PS rates based on insurance type.

Conclusion: The slight decline in LARC/PS procedures for patients living in urban areas and of Hispanic ethnicity in Texas following the Dobbs decision may indicate emerging healthcare disparities related to changes in reproductive health policy.

446 | Strict Blood Pressure Control and Risk of Postpartum Readmission

Celeste A. Green; Brooklynn Earls; Haleh Sangi-Haghpeykar; Dominique Williams; April D. Adams
Baylor College of Medicine, Houston, TX

4:00 PM - 6:00 PM

Objective: Hypertensive disorders of pregnancy (HDP) comprise approximately 10% of postpartum readmissions. Strict discharge criteria for the delivery encounter are a suggested practice for reduction in HDP-related readmission. We evaluated whether implementation of discharge criteria requiring BP < 150/100 for at least 24 hours reduced the likelihood of postpartum readmission for HDP.

Study Design: Analysis included live- and stillbirths >/ = 20 weeks' at a single site from 2019-2022. Readmissions included inpatient stays with any hypertension-related primary diagnosis code 1-42 days after discharge. Patients discharged pre-implementation of strict BP discharge criteria, (1/1/19-1/31/22) were compared to those discharged post-implementation (2/1/22-12/31/22). Race and ethnicity were excluded from regression models to avoid conflating the social construct of race with biological contributors to a clinical outcome.

Results: We reviewed 23,734 deliveries and 358 readmissions. HDP-related readmission rates were 1.4% (N = 259) pre-implementation of strict BP discharge criteria, and 2.1% (N = 99) post-implementation, p< .0003. Our delivery cohort was racially and ethnically more diverse than the United States' population, though EMR-reported Black patients were readmitted disproportionately more than others (Tables). The most common readmission diagnosis was severe preeclampsia. Post-implementation of strict BP discharge criteria, a higher proportion of patients (N = 307, 6.4%) also presented to triage for HDP issues than pre-implementation (N = 1068, 5.7%), p = .0003. The odds ratio (OR) for HDP readmission post-2/1/22 was 1.53 (CI 1.2-1.9, p = .0004). After adjusting for confounders, the OR was 1.48 (CI 1.13-1.92, p = .004).

Conclusion: HDP readmission risk was higher after implementing strict BP discharge criteria. This may represent more severe disease exacerbations, and strict BP discharge criteria may mitigate risk of unnecessary readmissions. Close outpatient follow-up, remote BP monitoring, and patient education on HDP exacerbation may encourage appropriate presentations to care and prevent out-of-hospital mortality.

447 | Timing of Delivery of Preterm Membrane Rupture at 34 Weeks and Beyond: a Cost-Effectiveness Analysis

Celine Huynh[1]; Sarah K. Dzubay[2]; Megha Arora[2]; Jacqueline M. Powell[3]; Aaron B. Caughey[2]
[1]Oregon Health and Science University, Portland, OR; [2]Oregon Health & Science University, Portland, OR; [3]University of Wisconsin School of Medicine and Public Health, Madison, WI

4:00 PM - 6:00 PM

Objective: To examine outcomes and the cost-effectiveness of immediate delivery at 34 weeks' gestation versus expectant management to 35, 36, and 37 weeks in the setting of preterm premature rupture of membranes (PPROM).

Study Design: A decision-analytic model was built using TreeAge software to compare outcomes of immediate delivery versus expectant management to 35, 36, and 37 weeks in a theoretical cohort of 35,913 pregnant people with PPROM at 34 weeks. Clinical outcomes included stillbirth, neonatal death, neurodevelopmental disorder, maternal mortality, healthy neonate, maternal sepsis leading to ICU admission, neonatal sepsis, NICU admission, costs and quality adjusted life years (QALYs). Probabilities, costs, and utilities were derived from literature.

Results: In our cohort, expectant management resulted in fewer neonatal deaths, neurodevelopmental disorders, and NICU admissions, in addition to increasing the number of healthy neonates delivered across all expectant management weeks (Table 1). Conversely, expectant management was found to increase the number of cases of stillbirth, maternal mortality, maternal sepsis, and neonatal sepsis. Each increasing week of expectant management yielded additional QALYs but was associated with increased costs. In this comparison, the optimal outcome and most cost-effective was expectant management to 37 weeks. One-way sensitivity analysis for the cost of antepartum care revealed that when the cost of antepartum admission exceeded $54,267 then management up to 36 weeks became cost-effective as compared to waiting until 37 weeks. One-way sensitivity analysis for the cost of NICU stay demonstrated that at 16 times the NICU cost, expectant management to 36 weeks becomes dominated by 37 weeks.

Conclusion: Management of PPROM at 34-36 weeks' gestation remains controversial, with guidelines incorporating both immediate delivery and expectant management. The current model suggests that ongoing expectant management to 37 weeks may improve outcomes and be a cost-effective strategy.

Figure 1. One-way sensitivity analysis of antepartum stay demonstrating the incremental cost-effectiveness ratios (ICER) for delivery at 34 weeks and expectant management to 35, 36, and 37 weeks.

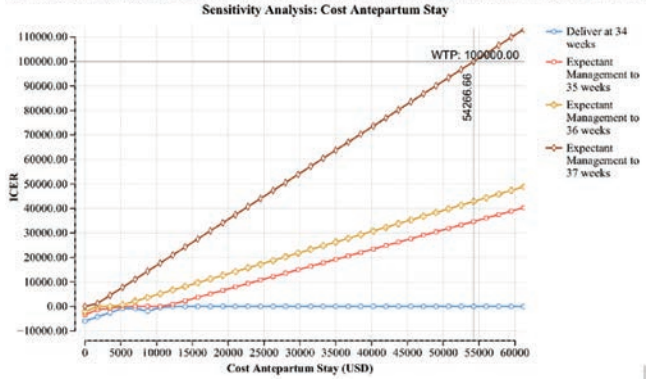

Table 1. Outcomes associated with delivery at 34 weeks, expectant management to 35 weeks, expectant management to 36 weeks, and expectant management to 37 weeks in a theoretical cohort of 35,913 women with PPROM at 34 weeks.

Outcome	Deliver at 34 weeks	Expectant management to 35 weeks	Expectant management to 36 weeks	Expectant management to 37 weeks
Cost (USD)	$1,222,700,202	$1,372,952,843	$1,689,642,023	$2,041,820,315
Effectiveness (QALYs)	1,881,061	1,920,673	1,953,104	1,965,813
Stillbirth	0	6	11	17
Neonatal death	151	111	96	74

Neonatal sepsis	0	130	255	384
NICU	32,884	22,782	14,473	11,191
Incremental cost-effectiveness ratio (ICER)		34 versus 35 weeks	35 versus 36 weeks	36 versus 37 weeks
		$3,793.16	$9,764.91	$27,710.86

448 | Safe Reduction of NTSV Cesarean Delivery Rates using Multidisciplinary Quality Improvement Efforts

Chandler M. McGee[1]; Celeste A. Green[1]; Lauren Shubert[2]; Adewunmi Babalola[2]; Audra Timmins[2]; Stephanie Gonzales-Hughes[2]; Sharon Burks[2]; Khanh Nguyen[2]; Erin Gonzales[2]; Sheena Glover[2]; Tara Barrick[2]; Courtney Thompson[2]; Grace Achim[2]; Matt Carroll[2]; Christina Davidson[2]
[1]Baylor College of Medicine, Houston, TX; [2]Texas Children's Pavilion for Women, Houston, TX

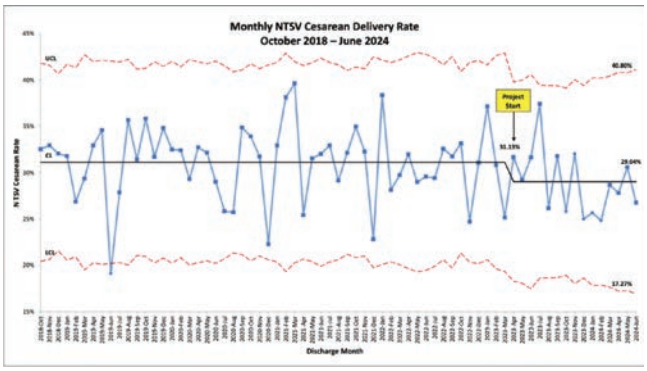
4:00 PM - 6:00 PM

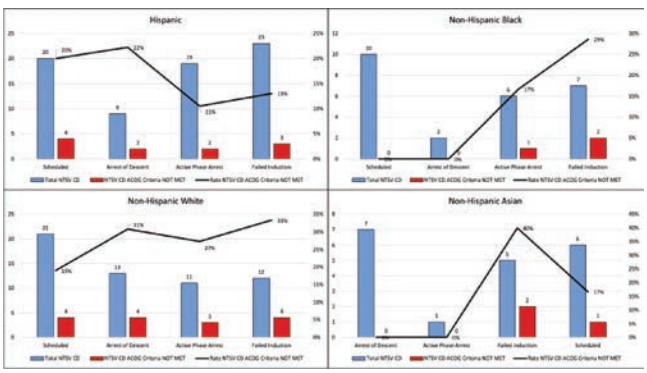
Objective: The rate of cesarean deliveries (CD) in nulliparous, term, singleton, vertex (NTSV) patients at our hospital has been ~30% since we began tracking this measure in 2016. Our aim was to evaluate the impact of quality improvement (QI) initiatives on this metric.

Study Design: Our level IV urban academic center formed a multidisciplinary workgroup in 4/2023. We reviewed CD rates stratified by indication, physician practice, race and ethnicity, which were regularly presented to the department and practice leaders. Nurses audited oxytocin management for adherence to hospital protocol and introduced non-pharmacologic options to help patients cope with labor pain. Retrospective chart review of all NTSV CD from 5-10/2023 determined if the indication for CD met ACOG criteria for failed induction of labor (FIOL), active phase arrest (APA), second stage arrest (SSA), and prelabor CD. Results were presented at departmental meetings and each physician was sent a scorecard with their total NTSV CD and adherence to ACOG criteria.

Results: The NTSV CD rate decreased in concordance with hospital QI efforts, to a nadir of 27.2% in the 2024 calendar year to date (Fig 1). Severe newborn complications (SNC) rate was similar before and after QI efforts (0.44% vs 0.61%, $p = 0.13$). Among all 298 NTSV CD, 13.8% did not meet ACOG criteria. FIOL was the most common indication (23%) that did not meet criteria across all racial and ethnic groups. Prelabor CD not meeting ACOG criteria were highest for White and Hispanic patients, driven by CD for estimated fetal weight lower than ACOG thresholds.

Conclusion: Our hospital NTSV CD rate decreased without an increase in SNC rates. Our chart audit allowed us to identify an opportunity to target FIOL and prelabor CD as future interventions. Sharing disaggregated data coupled with detailed chart review to identify hospital-specific drivers of non-medically indicated CD may be strategies to safely reduce NTSV CD rate and drive quality improvement initiatives.





449 | is Severity of Congenital Cardiac Disease Associated with Increased Perinatal Mood Symptoms

Christina Paidas Teefey[1]; Juliana S. Gebb[2]; Alexandria Budney[3]; Nahla Khalek[1]; Shelly Soni[1]; Desiree Fiorentino[1]; Joanna C.M. Cole[3]; Julie S. Moldenhauer[1]; Jack Rychik[3]
[1]Richard D. Wood Jr. Center for Fetal Diagnosis and Treatment at CHOP, Philadelphia, PA; [2]Richard D. Wood, Jr Center for Fetal Diagnosis and Treatment, Children's Hospital of Philadelphia, Philadelphia, PA; [3]Children's Hospital of Philadelphia, Philadelphia, PA

4:00 PM - 6:00 PM

Objective: To assess whether fetal cardiovascular disease severity is associated with perinatal mood symptoms in mothers with prenatal diagnosis of congenital heart disease (CHD).

Study Design: Expectant mothers completed validated screens for depressive, anxiety and traumatic symptoms following diagnosis of CHD (Time 1) and immediately postpartum (Time 2). Postpartum Depression Screening Scale (PDSS) was used to identify symptoms of depressive risk (≥ 60 and ≥ 21) and Impact of Events Scale (IES-R) was administered to determine traumatic risk (≥ 33) in a cohort of patients at a single fetal therapy center from December 1, 2012 through July 1, 2017. A fetal cardiologist reviewed echocardiographic imaging blinded to clinical course and assigned a Fetal Cardiovascular Disease Severity Score (FCDSS score severity range:1, lowest thru 7, highest) based on previously validated scale (Davey et al., 2014). Demographics were collected including mental health history confirmed by a licensed perinatal psychologist. Statistical analysis was performed using Fisher's exact test and chi squared test for categorical variables and Mann-Whitney U test for continuous variables.

Results: Depressive risk was 47% (n = 177/380) during pregnancy and 34% (n = 129/380) postpartum. Anxiety and traumatic stress risk was 14% (n = 52/380) during pregnancy and 4.7% (n = 18/380) postpartum. Increasing FCDSS did not corelate with clinical depressive, anxiety or traumatic stress risk during pregnancy or postpartum (Table 1). While FCDSS was not associated with increased risk for mood symptoms, patients with a FCDSS ≥ 5 (n = 197), received more psychosocial support during pregnancy (Table 2). History of maternal mental health diagnosis strongly correlated with increased depressive risk in pregnancy (67% vs 43%, p = 0.001) and postpartum (50% vs 31%, p = 0.009).

Conclusion: Severity of fetal cardiovascular disease is not associated with additional depressive, anxiety and traumatic risk. Pre-existing maternal mental health diagnosis is strongly associated with perinatal mood symptoms emphasizing the importance of perinatal psychosocial support.

Table 1: Positive Depressive (PDSS) and anxiety/traumatic (IES-R) Risk in Mothers based on assigned cardiac severity score

450 | Refractory Hypotension with Combined Spinal Epidural and Prophylactic Phenylephrine Infusion During Scheduled Cesarean Delivery

Kristina Fin[1]; Christine E. Henricks[1]; Elise A. Rosenthal[2]; Jessica E. Pruszynski[3]; Jacqueline Galvan[1]; David B. Nelson[1]; Elaine L. Duryea[1]
[1]University of Texas Southwestern Medical Center, Dallas, TX; [2]NYU Langone Health, Brooklyn, NY; [3]University of Texas Southwestern, Dallas, TX

4:00 PM - 6:00 PM

Objective: Prophylactic phenylephrine infusion is commonly used to manage regional anesthetic-induced hypotension during cesarean deliveries, aiming to stabilize maternal blood pressure and maintain uteroplacental perfusion to prevent fetal and maternal effects. This study evaluates the incidence of refractory hypotension with combined spinal epidural (CSE) despite the use of prophylactic phenylephrine infusion.

Study Design: This retrospective cohort study included all scheduled cesarean deliveries (CD) at term from August 2023 to September 2023, excluding patients with acute indications for CD. All patients received CSE for neuraxial anesthesia. Hypotension was defined as a systolic BP < 90 mmHg or a diastolic BP < 60 mmHg with a 20% decrease from baseline BP. Patients with hypotension post-CSE were compared to those without hypotension. Data on additional vasopressor requirements and neonatal outcomes were collected. Statistical analyses performed included chi-squared, Fisher's exact, and Kruskal-Wallis tests.

Results: Among 170 patients undergoing scheduled cesarean delivery with CSE, 60% experienced hypotension despite prophylactic phenylephrine. Fetal heart rate deceleration occurred in 13.7% of hypotensive patients versus 5.9% of non-hypotensive patients (p = 0.09). Median umbilical cord pH was 7.29 [7.25, 7.31] in hypotensive patients and 7.3 [7.27, 7.33] in non-hypotensive patients (p = 0.03). Neonatal ICU admission rates were similar between groups. Rescue vasopressors were used in 75.5% of hypotensive cases and 32% of non-hypotensive cases (p< 0.01).

Conclusion: The study highlights that while prophylactic phenylephrine infusion is used to prevent hypotension during cesarean deliveries, 60% of patients still experience significant hypotension, requiring additional interventions. Further research is necessary to understand risk factors and interventions for refractory hypotension during combined spinal epidural anesthesia in scheduled cesarean deliveries to optimize maternal and neonatal outcomes.

451 | Effectiveness of Intravenous Ferric Carboxymaltose for Severe Anemia in the Late Third Trimester

Christine E. Henricks; Rachel C. Schell; Catherine Y. Spong; Elaine L. Duryea
University of Texas Southwestern Medical Center, Dallas, TX

4:00 PM - 6:00 PM

Objective: Iron deficiency anemia is associated with adverse pregnancy outcomes. Prior studies have shown reduced morbidity with intravenous (IV) iron therapy, but the optimal timing of administration is unknown. The objective of this study was to evaluate whether administration timing of IV ferric carboxymaltose in the late third trimester impacts maternal hematologic indices and outcomes.

Study Design: A retrospective cohort study was conducted from October 2020 to May 2024 of IV ferric carboxymaltose for the treatment of severe anemia in the third trimester, defined by a hemoglobin < 8 g/dL or hematocrit < 25%, plus iron < 40 mcg/dL or ferritin < 15 ng/mL. Eligible patients received two infusions one week apart, regardless of gestational age at diagnosis. Patients beginning treatment early, defined as < 36 weeks gestation (WGA), were compared to those with late treatment starting ≥ 36 WGA. Mann-Whitney U and Chi-squared tests were used for statistical analysis.

Results: Of 129 patients, 101 received IV iron < 36 weeks (early) and 28 ≥ 36 weeks (late). Hemoglobin at diagnosis of severe anemia was not different, median 7.3 [7.0,7.7] g/dL in early cohort and 7.6 [7,7.8] g/dL in the late cohort (p = 0.121). The median rise in hemoglobin between diagnosis and delivery was 3.8 [2.7, 5.2] g/dL for the entire population. There was no difference in gestational age at delivery between the cohorts. Importantly, hemoglobin levels at delivery were not different between the early (11.2 [10.5,12.0] g/dL) and late (10.6 [9.6,11.2] g/dL) cohorts (p = 0.251). The incidence of peripartum transfusion was not different, 5.0% in the early cohort and 3.6% in the late cohort (p = 0.759).

Conclusion: Patients receiving IV ferric carboxymaltose for severe anemia ≥36 WGA demonstrated similar improvements in hemoglobin levels compared to those receiving treatment earlier in gestation and were no more likely to require transfusion at delivery. IV ferric carboxymaltose should not be withheld in the late third trimester based on perceived futility with advancing gestational age.

Obstetric Characteristics	Early Cohort (<36 wk) N = 101	Late Cohort (≥ 36 wk) N = 28	p-value

452 | Accuracy of Ultrasound-Derived Estimated Fetal Weight in Peri-Viable Births

Colleen P. Judge-Golden[1]; Sally Kuehn[2]; Sarah Ellestad[1]; Sarah K. Dotters-Katz[2]; Amanda M. Craig[1]
[1]Duke University Hospital, Durham, NC; [2]Duke University School of Medicine, Durham, NC

4:00 PM - 6:00 PM

Objective: As neonatal resuscitation is offered at increasing extremes of prematurity, ultrasound-derived estimated fetal weight (EFW) is a crucial data point in patient counseling. We aimed to evaluate accuracy of EFW compared to neonatal birthweight (BW) in peri-viable births and identify factors associated with accuracy.

Study Design: Medical records were abstracted for all liveborn, non-anomalous neonates born at 22w0d-24w6d at a single tertiary institution between 1/2013-5/2024, with ultrasound-derived EFW within 7 days of delivery. Primary outcome was absolute percent difference (accuracy) between EFW (Hadlock) and BW. Linear regression and Kruskall-Wallis tests were used to assess associations of accuracy with imaging variables, maternal and pregnancy characteristics. Adjusted linear regression was performed including maternal BMI at EFW (an *a priori* plausible association) and variables associated with accuracy in univariate analyses at p< 0.1.

Results: 141 neonates from 129 pregnancies were included. Median gestational age at delivery was 23w4d, with median BW 560g. Most deliveries (83%) were sequelae of cervical insufficiency, preterm labor, or preterm prelabor rupture of membranes; 17% were iatrogenic for maternal or fetal indications. Median time from EFW to delivery was 2 days. A certified sonographer performed 85% of ultrasounds. EFW was highly correlated with BW (p< 0.001, R^2 = 0.72); 54% of EFWs underestimated BW. Median absolute percent difference was 7.1% [IQR 2.9%,12.2%]. In unadjusted analyses, increasing BW (p = 0.04) and multiple gestations (p = 0.002) were associated with improved accuracy; oligohydramnios was associated with decreased accuracy (p = 0.04). Maternal BMI, sonographer level, fetal presentation and EFW timing were not associated with accuracy. Adjusting for BMI, oligohydramios and multiples, BW remained inversely associated with EFW accuracy (coefficient -0.016, p = 0.013).

Conclusion: Ultrasound-derived EFW was an excellent predictor of BW among peri-viable deliveries at our institution. Accuracy declined with lower BW, which may be considered in antenatal counseling.

Table. Sample Characteristics & Unadjusted Associations with EFW Accuracy

	Median [IQR] or n (%)	Unadjusted Association with Absolute Accuracy*

and Statistics (CRESS), Université Paris Cité, Inserm, Paris, Ile-de-France; [3]INSERM UMR 1153, Obstetrical, Perinatal and Pediatric Epidemiology Research Team (Epopé), Center for Epidemiology and Statistics, FHU PREMA, Université de Paris, Paris, Ile-de-France; [4]Department of Psychiatry, AP-HP, Louis Mourier Hospital, Colombes, Ile-de-France; [5]Université Paris Cité, Inserm, Centre for Research in Epidemiology and StatisticS (CRESS), Obstetrical Perinatal and Pediatric Epidemiology Research Team (EPOPé),, Paris, Ile-de-France

4:00 PM - 6:00 PM

Objective: Postpartum depression(PPD) affects 10-20% of women and previous studies have identified instrumental vaginal birth(VB) as a risk factor. Our study aimed to test this association, in full-term pregnancies with a trial of vaginal delivery, and to explore mediating factors.

Study Design: We used data from the observational nation-wide population-based study ENP 2021, including women who completed the Edinburgh Postnatal Depression Scale(EPDS) at 2-month. Multiple pregnancies, non-cephalic presentations, preterm births and planned cesareans were excluded. An EPDS score ≥ 13 was used as a validated proxy for PPD. Mode of delivery (spontaneous VB/instrumental VB/cesarean), type and indication of the instrument were collected. The association between instrumental VB and PPD was studied using univariate and multivariate analyses and weighted to account for 2-month attrition. Mediation analyses were conducted after identification of intermediate factors: maternal composite criterion (postpartum hemorrhage+/-obstetric anal sphincter injury), episiotomy, neonatal composite criterion (Apgar score ≤ 7+/-neonatal transfer), pain and disrespectful care during delivery. Two sensitivity analyses were performed among women at low psychiatric risk and using an EPDS score ≥ 11.

Results: The study population included 6084 women: 4473(73.5%) had spontaneous VB, 915(15.0%) instrumental VB and 696 (11.5%) cesareans. PPD prevalence was 16.3%[15.3-17.3] reaching 19.3% for instrumental VB (aOR 1.35[1.10-1.66]) compared with 15.6% for spontaneous VB (reference) and 16.7% for cesareans (aOR 1.05[0.83-1.33]). Fetal heart rate abnormalities indication was associated with higher PPD prevalence. The indirect effect mediated by disrespectful care during delivery explained 18% of the association between instrumental VB and PPD (aOR of indirect effect: 1.04[1.01-1.07]). We found no significant mediation effect for other factors. Sensitivity analyses found similar results.

Conclusion: The prevalence of PPD was significantly higher with instrumental VB, an association partly mediated by disrespectful care during delivery.

454 | The Association between Post-Traumatic Stress and Perineal Pain in Patients with Birth Injury

Dana R. Canfield[1]; Emmanuel Elijah[2]; Omar Mesina[3]; Rachel L. Wiley[2]; Aava Saffarnia[2]; Alexandra Nutaitis[2]; Lindsey A. Burnett[4]

[1]UC San Diego Health, San Diego, CA; [2]University of California, San Diego, San Diego, CA; [3]University of California San Diego Health, San Diego, CA; [4]UC San Diego Medical Center, La Jolla, CA

4:00 PM - 6:00 PM

Objective: While the impact of emotional distress on perceived pain has been shown in several studies, few have focused on patients with birth injury. Our goal was to determine whether post-traumatic stress is associated with a higher incidence of reported pain in birth-injured patients.

Study Design: This was a retrospective cohort study of patients seen in a urogynecology clinic specializing in the management of birth injury. Patients completed surveys addressing physical and emotional wellbeing which included a Peritraumatic Stress Inventory (PDI) to assess for childbirth-related trauma symptoms. Demographic and delivery variables were compared between patients who had a PDI score of >14, a cut-off associated with a greater risk of developing post-traumatic stress disorder. Pain was assessed as a binary variable based on response to the question "are you having perineal/vaginal pain?". Demographic

and delivery factors associated with high PDI were added to a multivariable logistic regression model of pain (Table 1). Edinburgh Depression Scale (EPDS) score was excluded given concern for effect mediation.

Results: 48 patients completed the PDI and were included in our analysis. Patients with low PDI were assessed at an average of 11.34 (SD 4.53) weeks postpartum and patients with high PDI at 10.33 weeks (SD 6.24). Incidence of stool and gas incontinence was significantly greater in the high PDI group. While antepartum EPDS scores did not significantly differ, postpartum scores were greater in high PDI group. After adjusting for stool and gas incontinence, patients were more likely to report pain (OR 1.22; 95% CI -0.26, 0.47) but this difference was not statistically significant. However, elevated PDI was associated with leakage of stool in our adjusted model (OR 1.75; 95% CI 1.14, 2.17).

Conclusion: We found that psychologically traumatic birth was positively but insignificantly related to reported pain and significantly associated with increased stool incontinence. While further studies are needed, our results point towards a relationship between an emotionally traumatic birth and physical recovery.

455 | Adverse Childhood Experiences and Perceived Control Over Birth

Dana R. Canfield[1]; Cynthia Gyamfi-Bannerman[2]; Emmanuel Elijah[2]; Karoline Gutierrez[3]; Minhazur R. Sarker[2]; Rachel L. Wiley[2]; Elizabeth Nicole Teal[2]; Marni B. Jacobs[4]

[1]UC San Diego Health, San Diego, CA; [2]University of California, San Diego, San Diego, CA; [3]University of Miami, Miami, FL; [4]University of California, San Diego Health, San Diego, CA

4:00 PM - 6:00 PM

Objective: Adverse childhood experiences (ACEs) have been shown to impact adult health but have not been studied in connection with perceived control over labor, termed labor agentry. We aimed to study the impact of ACEs on labor agentry as recorded on the Labor Agentry Scale (LAS), a 29-item Likert-scale response survey in which higher score corresponds with greater agentry.

Study Design: In this prospective cohort study, patients were enrolled from high-risk obstetric clinics at a single institution from 27-34 weeks gestation. Participants were asked to complete mental health surveys on enrollment including ACE-Q, a 10-item measure to assess adverse experiences prior to age 18. At the time of birth participants completed the LAS. Patients were divided into three conventional ACE categories: low-risk (ACE = 0), moderate-risk (ACE = 1-3), and high-risk (ACE = 4+). LAS was analyzed as a continuous variable. Demographic factors independently associated with ACE scores were included in a multivariable linear regression model of labor agentry score, except history of a mental health condition given concern for effect mediation (Tables 1 and 2).

Results: Of 59 patients that completed the ACE-Q and LAS, 17 (28.8%) were low risk, 29 (49.2%) moderate risk, and 13 (22.0%) high risk. Participants in the high-risk ACE category tended to be younger (Table 1, p = 0.005). Mean labor agentry was 159.9, 166.6, and 162.7 for low, moderate, and high-risk ACE, respectively, and did not differ significantly by ACE group (p = 0.74). Compared to the low-risk ACE group, moderate and high-risk ACE scores were associated with the higher LAS in our adjusted model, but this was not statistically significant.

Conclusion: We did not find significant differences in agentry by ACE score. While additional studies are needed to confirm these findings, is plausible that patients with trauma history are more accustomed to a lack of agentry and this alters their expectations and perceptions during childbirth, attenuating differences that would otherwise be found between groups.

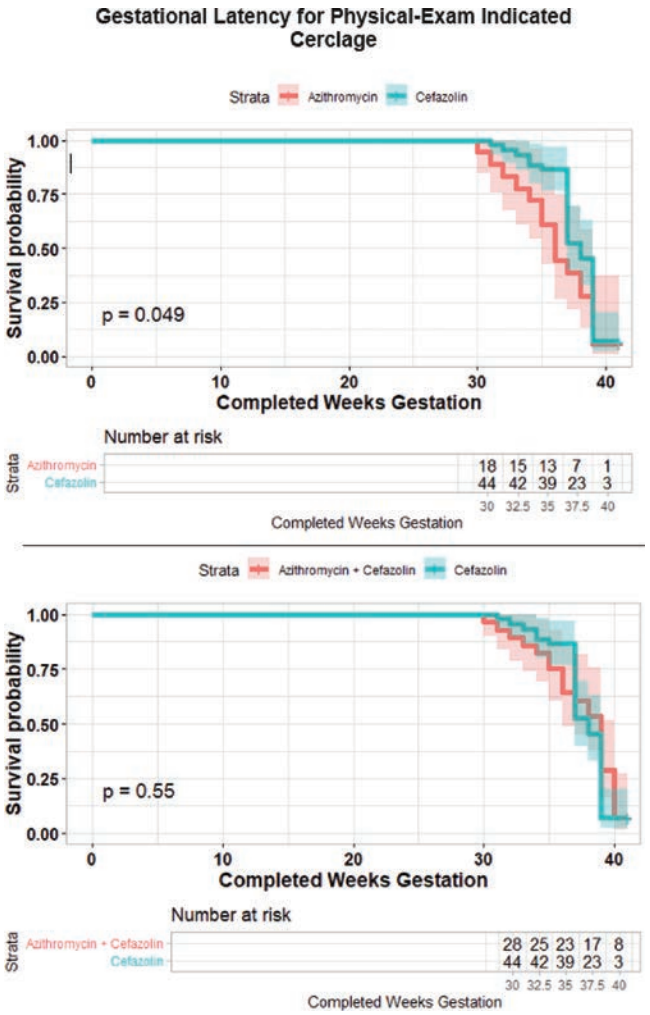
4:00 PM - 6:00 PM

Objective: The effect of prophylactic antibiotics with or without tocolytic medications on gestational latency remains uncertain. This study sought to evaluate the effectiveness of adjunctive antibiotic regimens on increasing gestational latency for pregnancies complicated by cervical insufficiency requiring cervical cerclage.

Study Design: We conducted a multi-center, prospective observational study from 7/2022 to 7/2024 comparing all pregnancies complicated by cervical insufficiency requiring cervical cerclage at a gestational age range of 16 0/7 to 23 6/7 weeks. History-indicated (HC) and physical-exam indicated (PC) cerclages were included. Antibiotic regimens used as covariates included cefazolin and/or azithromycin, and were determined based on physician preference. Each regimen received indomethacin and utilized a vaginal surgical approach. Each regimen was compared to the total patients receiving a different regimen. Patients with multiple gestations, additional tocolytic medication use, or prior vaginal progesterone use, were excluded. The primary outcomes included completed weeks gestation at time of delivery (CW), preterm and term deliveries, as respective, discrete events.

Results: The study included 209 patients with 87 requiring a PC and 112 requiring HC. Demographic factors were not significantly different. In the PC group, 43 (49.4%) received cefazolin, 16 (18.4%) received azithromycin, 28 (32.2%) received both. In the HC group, 78 (70.0%) received cefazolin, 6 (5.4%) received azithromycin, and 28 (25%) received both. Kaplan-Meier survival analysis (Figure 1) noted significantly greater pregnancy latency when comparing cefazolin to azithromycin for PC (p = 0.049). No significant differences in gestational latency or rates of preterm or term delivery were noted in the HC group for any regimen or when comparing other PC regimens.

Conclusion: It is reasonable to administer cefazolin when performing a physical-exam indicated cervical cerclage with a vaginal approach and may offer greater pregnancy latency, with likely no additional benefit when using azithromycin alone or in combination with cefazolin.



457 | Comparison of Antiemetic Regimens for 1st Trimester Pregnancies Complicated by Cannabinoid Hyperemesis Syndrome

Daniel J. Martingano[1]; Amanda F. Francis Oladipo[2]; Marwah Al-Dulaimi[3]; Sandra Kumwong[4]; Andrea Ouyang[5]; Lauren Cue[6]; Ashley Nguyen[3]; Francis X. Martingano[7]; Shailini Singh[8]; Mark Rebolos[3]; Alexander Ulfers[9]; Kristin Cohen[10]; Donald Morrish[3]; Iffath A. Hoskins[11]

4:00 PM - 6:00 PM

Objective: Cannabinoid hyperemesis syndrome (CHS) is characterized by cyclic vomiting in chronic cannabis users. CHS can

both exacerbate and mimic hyperemesis gravidarum (HG) in 1st trimester pregnancies and is often refractory to antiemetic medications use to treat HG alone. This study sought to compare antiemetic regimens in cases of concurrent CHS in first trimester pregnancies.

Study Design: We conducted a multi-center, prospective observational study from 7/2022 to 7/2024 comparing all pregnant patients with concurrent CHS at gestational age range of 8 0/7 to 13 6/7 weeks. CHS was diagnosed by Rome IV criteria for cyclical vomiting syndrome and cannabis use more than 4 times per week on average. The primary outcomes included need to switch medication and patient-reported resolution confirmed by provider assessment, as discrete events. Patients taking overlapping medications or with allergies to any included medications were excluded. Monotherapy oral medications including metoclopramide, odansetron, cyproheptadine, diphenhydramine, and topical capsaicin were included as covariates. All patients endorsed routine hot-water bathing to aid in resolution of symptoms. Medication choice was determined by physician preference.

Results: The study included 537 patients diagnosed with CHS. Baseline demographic factors were not significantly different. Patients who received metoclopramide were less likely to need to switch to an alternative medication (56.2% v. 28.3%, $p = 0.002$) with a 29% decreased risk when adjusted for confounders (RR 0.71, 95% CI 0.43-0.89, p = 0.002). Patients who received topical capsaicin were more likely to report improvement in appetite (51.9% v. 20.2%, p = 0.032), with a 31% increased likelihood when adjusted for confounders (RR 1.31, 95% CI 1.44-1.93, p = 0.001). This same group, however, demonstrated the lowest compliance rate (11.9% v. 45.9%, p = 0.005).

Conclusion: Metoclopramide and topical capsaicin in conjunction with routine hot-bathing are reasonable and efficacious antiemetic regimens for 1st trimester pregnancies complicated by CHS.

458 | Predicting the need for Blood Transfusion Based on CBC at admission in Normal Vaginal Delivery

Daniel Gabbai[1]; Itamar Gilboa[1]; Anat Lavie[2]; Yariv Yogev[3]; Emmanuel Attali[1]

[1]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel-Aviv, Tel Aviv; [2]Tel Aviv Sourasky Medical Center, Tel Aviv Sourasky Medical Center, Tel Aviv; [3]Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv University, Tel Aviv Sourasky Medical Center, Tel Aviv

4:00 PM - 6:00 PM

Objective: The relationship between admission complete blood count (CBC) parameters, specifically the Neutrophil-to-Lymphocyte Ratio (NLR), and the requirement for packed red blood cell (pRBC) transfusion following vaginal delivery remains underexplored. This study aims to investigate the association between various CBC parameters, including NLR, and the need for pRBC transfusion, and to evaluate their predictive value for this outcome.

Study Design: A retrospective cohort study was conducted at a tertiary, university-affiliated medical center with about 12,500 annual deliveries (2012-2023). Women were categorized based on the need for blood transfusion, determined by severe ongoing haemorrhage, symptomatic anemia with Hb levels of 7–8 g/dL, or postpartum Hb levels < 7 g/dL. Maternal demographics, CBC characteristics at admission, and delivery outcomes were analyzed. Multivariate logistic regression identified predictors for pRBC transfusion, and a risk prediction score was developed and evaluated using the ROC curve

Results: During the study period, 145,833 women delivered in our center. The CBC parameters of 37,631 women who delivered vaginally were available. Of them, 957 (2.5%) required pRBC transfusion.

Advanced maternal age, nulliparity, and conception by IVF were associated with increased pRBC transfusion. In contrast, spontaneous onset of delivery (compared to induction) was associated with a lower likelihood of transfusion.

Regarding admission CBC parameters, Hemoglobin < 10.5 g/dL (OR: 6.8, 95% CI: 5.8-8.02, p< 0.001) and Neutrophil to Lymphocyte Ratio (NLR) > 5 (OR: 1.55, 95% CI: 1.3-1.87, p = 0.001) were associated with an increased rate of pRBC transfusion.

A scoring model, using a cutoff of 6 [Table 1], successfully predicted blood cell transfusion with an area under the curve of 0.78 (95% CI: 0.75-0.79, p-value < 0.001), achieving 85% sensitivity and 77% specificity. (Figure 1]

Conclusion: CBC parameters, especially hemoglobin and NLR, along with maternal factors, are valuable predictors for the need of pRBC transfusion in vaginal deliveries.

459 | Risk Factors for Prolonged Hospitalization following Vacuum-Assisted Delivery

Daniel Gabbai[1]; Lee Reicher[2]; Anat Lavie[3]; Yariv Yogev[4]; Emmanuel Attali[1]
[1]Lis Hospital for Women's Health, Tel Aviv Sourasky Medical Center, Tel-Aviv, Tel Aviv; [2]Weizmann Instutute Of Science, Weizmann Institute of Science, HaMerkaz; [3]Tel Aviv Sourasky Medical Center, Tel Aviv Sourasky Medical Center, Tel Aviv; [4]Lis Maternity Hospital, Sourasky Medical Center, Tel Aviv University, Tel Aviv Sourasky Medical Center, Tel Aviv

4:00 PM - 6:00 PM

Objective: We aimed to determine risk factors for prolonged hospitalization following vacuum-assisted delivery (VAD).

Study Design: A retrospective cohort study, in a single, university-affiliated tertiary medical center with approximately 12,500 deliveries annually (2012-2022) was conducted. Standard practice in our department entails a post-vaginal delivery hospital stay of 48 to 72 hours. Length of stay following a VAD was analyzed and parturients who underwent VAD were categorized into two groups by length of hospitalization (more and less than 7 days). Maternal and neonatal characteristics were compared. Risk factors for prolonged hospitalization were examined using univariate and multivariate logistic regression.

Results: (1) Overall, 133,035 deliveries occurred during the study period. Of them, 9,440 (7.1%) were by VAD.

(2) The post-partum hospitalization period was distributed as follows: 9134 (96.76%) women were hospitalized for up to 7 days, and 306 (3.34%) were hospitalized for more than 7 days.

(3) Using multivariate analysis: preterm delivery (delivery prior to 37 weeks) (RR 5.4 95%CI [1.6-17], p = 0.005); preeclampsia (RR 6.0 95%CI [1.9-19], p = 0.002), induction of labor (RR 3.4 95%CI [1.8;6.3], p< 0.001), obstetric anal sphincter injury (RR 3.2 95%CI [1.2-8], p = 0.013), postpartum hemorrhage which required blood transfusion (RR 3.3 95%CI [1.3-8.4], p = 0.012), and Apgar Score under 7 at minute 5 (RR 3.4 95%CI [1.4-39], p = 0.015), were identified as independent risk factors for prolonged hospitalization [Table]

Conclusion: Risk factors associated with prolonged hospitalization following a VAD can be identified, with preterm delivery and Apgar score < 7 at minute 5 being the most prominent.

	aOR (95% CI)	p-value

460 | Diagnostic Value of CFDNA Fetal Fraction in Patients with Prenatally Suspected Placenta Accreta Spectrum Disorder

Danielle L. Chirumbole[1]; Christian M. Parobek[1]; Alex Tai[1]; Haleh Sangi-Haghpeykar[1]; Yamely H. Mendez[1]; Christina C. Reed[2]; Arthur Ladron De Guevara[1]; Keneshia Lane[1]; Claire Hoppenot[1]; Amir A. Shamshirsaz[1]; Michael A. Belfort[3]; Jessian L. Munoz[1]; Hendrik A. Lombaard[4]
[1]Baylor College of Medicine, Houston, TX; [2]Baylor College of Medicine at Texas Children's Pavilion for Women, Houston, TX; [3]Texas Children's Hospital and Baylor College of Medicine, Houston, TX; [4]Texas Children's Hospital, Houston, TX

4:00 PM - 6:00 PM

Objective: The pathophysiology of placenta accreta spectrum (PAS) is unknown but thought to be related to myometrial disruption at the uterine-placental interface. Noninvasive prenatal testing (NIPT) analyzes circulating placental DNA, and it has been postulated that PAS may affect the fetal fraction (FF) of cell-free DNA (cfDNA). The purpose of this study is to investigate the relationship between FF and PAS pathology in patients with prenatally suspected PAS.

Study Design: This was a case-control study utilizing a large database of pregnancies with suspected or proven PAS delivered between 6/2012 and 7/2024 at a single academic institution. Pregnancies were excluded if FF was not reported. Other exclusion criteria were lack of suspicion for PAS on prenatal imaging, twins, fetal demise, abnormal NIPT, fetal structural anomalies, or postnatal diagnosis of a genetic/metabolic disorder. The primary outcome was mean FF in pregnancies with a final clinical diagnosis of no PAS or FIGO1-2 (less complex) versus FIGO3A-C (more complex). A generalized linear mixed model was used and FF was log-transformed to achieve normality. Results were reported as mean FF ± standard error of the mean. Adjusted means were also reported after assessing for confounders.

Results: Of the 468 pregnancies assessed, 165 had NIPT results reporting FF. Of these, 128 met full inclusion criteria. The mean FF in the less complex group did not differ from the more complex group (9.6% ± 0.49, n = 81 vs 10.7% ± 0.64, n = 47; p = 0.22). However, after adjusting for number of prior cesarean deliveries and maternal BMI, the mean FF in the less complex group was significantly lower than the more complex group (9.3% ± 0.48 vs 11.1% ± 0 .64, p = 0.03). Other factors including maternal age, maternal medical comorbidities, gestational age at time of NIPT, and placenta previa were not found to correlate with FF or FIGO grade.

Conclusion: Higher FIGO grade PAS may be associated with a higher FF in pregnancies with prenatal suspicion for PAS. Thus, NIPT may have the potential to assist with delivery preparation and prognostication in this high-risk patient population.

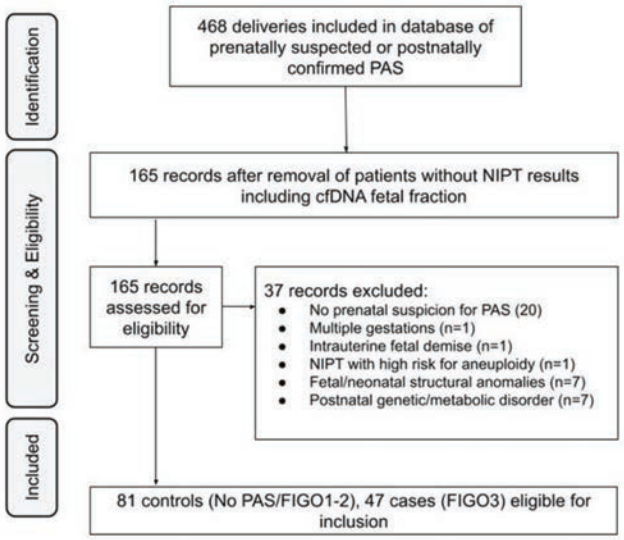

Figure 1: Records from an institutional PAS database were reviewed and eligibility for inclusion determined based on the criteria above.

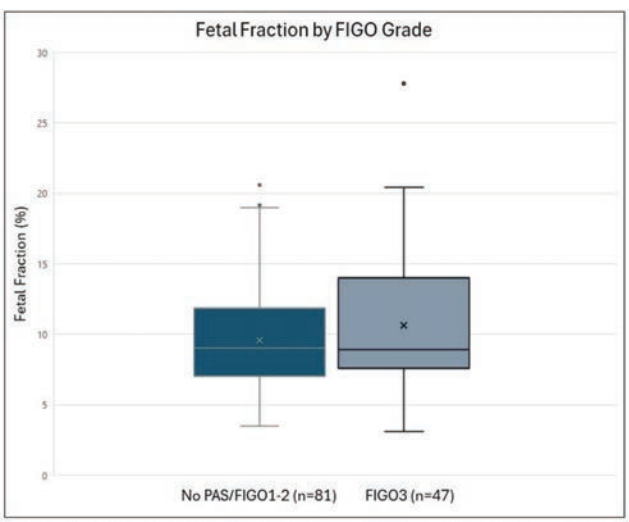

Figure 2: Fetal fraction cfDNA on NIPT in patients with prenatal suspicion for PAS grouped by final clinical diagnosis (less complex vs more complex).

461 | Gestational Diabetic Placental T-Cells Cause Hypertension and Impaired Glucose Utilization in Pregnant GDM Rat Model

Danielle Frieson; Jackson Strong; Baoying Zheng; Jean Vel; Nathan Campbell; Babbette LaMarca; Evangeline Deer
University of Mississippi Medical Center, Jackson, MS

4:00 PM - 6:00 PM

Objective: Gestational diabetes mellitus (GDM) refers to glucose intolerance, insulin sensitivity and beta islet cell dysfunction during pregnancy. GDM pathogenesis is associated with hypertension, impaired placental and renal function, oxidative stress and increased circulating CD4+ T cells. Importantly, there are limited animal models available to study GDM or alternative treatment options. This study sought to determine if a possible mechanism for GDM is placental CD4+ T cell programming in the patient and to test alternative treatment options for GDM.

Study Design: Upon delivery, blood and placental GDM (GDM-CD4+ T cells) and normotensive (NP+NP) placental CD4+ T cells were collected. Purified CD4+T cells were injected into pregnant nude athymic rats on gestational day (GD) 12. On GD 13, a separate cohort rats were treated with Metformin (GDM+Met; 300 mg/kg/day) or MitoTempo (GDM+Mito;1 mg/kg/d). Mean arterial pressure (MAP), circulating glucose, and glucose tolerance tests (GTT) were performed on GD 19. Mitosox Red was used to measure mtROS production in HUVECs incubated with sera from GDM, GDM women treated with Metformin (GDM+Met) or Normotensive women. A one-way ANOVA was used for statistical analysis.

Results: MAP was higher in GDM-CD4+ T cell rats (121±2, n = 8, $p < 0.05$) compared to GDM+MET (95±2, n = 6), GDM+Mito (95±4, n = 7), NP+NP CD4+ T cells (96±4, n = 7), NP+NP MET (99±4, n = 8), and NP nude controls (105±3 mmHg, n = 8) rats. Blood glucose was elevated in GDM-CD4+ T cell rats (227±39 mg/dl, n = 8, $p < 0.05$) compared to GDM+MET (111±11 mg/dl, n = 7), GDM+Mito (97±2 mg/dl, n = 7), NP+NP CD4+ T cells (89±3 mg/dl, n = 7), NP+NP MET (96±2 mg/dl, n = 8), and NP nude controls (82±9 mg/dl, n = 8) rats. GTT was impaired in GDM CD4+ T rats, but was improved with Met and Mito treatment. Mitochondrial ROS was increased in HUVECS treated with GDM patient sera ($p < 0.05$) compared to GDM+Met or Normotensive patient sera.

Conclusion: Our findings indicate that GDM CD4+ T cells cause a diabetic phenotype suggesting a new model to investigate mechanisms and therapies.

462 | Outcomes in Individuals with Expectant Management of Previable PROM in Texas following SB8

Danna Ghafir[1]; Emily Fahl[1]; Nancy Ukoh[1]; Han-Yang M. Chen[1]; Sean C. Blackwell[1]; Julie Gutierrez[2]; Irene A. Stafford[1]
[1]McGovern Medical School at UTHealth Houston, Houston, TX; [2]McGovern Medical School at The University of Texas Health Science Center at Houston (UTHealth), Houston, TX

4:00 PM - 6:00 PM

Objective: We sought to compare outcomes of pregnant individuals diagnosed with previable PROM and expectantly managed at our center before and after implementation of Texas Senate Bill 8 (SB8).

Study Design: This is a retrospective cohort study across three tertiary care hospitals from January 1, 2018-March 31, 2023. ICD-10 codes were used to identify all hospital deliveries of individuals with previable PROM. Trained research staff completed chart review. Patients with singleton or twin gestions and clinical diagnosis of PROM < 22 wks 0 days were studied, excluding those with IUFD and/or active PTL. Expectant management was defined as continuation of pregnancy (no immediate delivery) after admission and delivery for spontaneous PTL, IUFD, or development of a medical indication (infection, bleeding, or other indications). We compared clinical characteristics and outcomes of individuals with expectant management before and after the implementation of SB8 on September 1, 2021. Our primary outcome was composite adverse outcome, which

included ICU admission, transfusion, and/or sepsis. Adjusted relative risk (aRR) with 95% CIs was calculated. Multivariable Poisson regression was used to adjust for confounding factors for the primary outcome.

Results: Over the 5-year study period, 118 individuals met inclusion criteria (49 pre-SB8 vs 69 post-SB8). There were no differences in clinical characteristics pre- vs post-SB8 (Table 1). There was no difference in the rate of the composite adverse outcome (26.5% vs 37.7%, aRR = 1.50, 95% CI = 0.85-2.62), after adjusting for age, race and ethnicity, and gestational age at delivery. Time from rupture to delivery was significantly longer in the post-SB8 cohort (median [IQR]: 3 [1-7] days vs 6 [2-12] day, p = 0.048). The post-SB8 cohort demonstrated a higher rate of sepsis (12.2% vs 31.9%, aRR = 2.69, 95% CI = 1.20-6.03).

Conclusion: After SB8, individuals with PROM < 22 wks had longer latency period and higher rates of sepsis compared to those before SB8. We speculate this may be due to delayed intervention by providers to wait for medical indications that qualify as "medical emergency."

*Sepsis defined as a diagnosis of clinical IAI and two or more of the following: maternal tachycardia > 100, maternal fever 38C/100.4F, respiratory rate > 20 breaths per minute, WBC > 15,000, evidence of organ dysfunction/failure (including altered mental status, lactic acidosis, SBP <90 or SBP drop ≥40 mm Hg of normal, AKI).

463 | Characteristics of Gestational Surrogate Pregnancy in a Large Integrated Healthcare Setting

Darios Getahun[1]; Fagen Xie[1]; Theresa M. Im[1]; Daniella Park[1]; Vicki Y. Chiu[1]; Yinka Oyelese[2]; Morgan R. Peltier[3]; Michael J. Fassett[4]

[1]Kaiser Permanente Southern California, Department of Research & Evaluation, Kaiser Permanente Southern California/Pasadena, CA; [2]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA; [3]Jersey Shore University Medical Center, Department of Psychiatry and Behavioral Health, Jersey Shore University Medical Center/Neptune City, NJ; [4]Kaiser Permanente West Los Angeles Medical Center, Department of Obstetrics & Gynecology, Kaiser Permanente West Los Angeles Medical Center/Los Angeles, CA

4:00 PM - 6:00 PM

Objective: To describe maternal and infant characteristics of gestational surrogate (GS) pregnancies in an integrated healthcare system with a large, diverse pregnant population.

Study Design: An electronic health records (EHR)-based retrospective cohort study of pregnant members delivered at 20-44 weeks' gestation at Kaiser Permanente Southern California from 01/01/2008–12/31/2023 (N = 636,300) was performed. Unstructured data abstracted from EHRs were used to determine GS status via natural language processing (NLP), validated by manual chart review (positive predictive value = 96%). Hospital in- and outpatient physician encounters, and laboratory records were used to ascertain medical and obstetrical histories. Adjusted risk ratios (aRR) and 95% confidence intervals (CI) derived from robust Poisson regression were used to describe the magnitude of associations.

Results: Among pregnant members who delivered during the study period, 1,109 (1.7/1000) were GS pregnancies. Maternal age ≥ 25 years, non-Hispanic white, multiple gestation (aRR: 10.12, 95% CI: 8.6-11.92), and privately funded KP membership (aRR: 2.48, 95% CI: 2.12-2.89) were more likely to be associated with gestational surrogacy. GS patients were more likely to be overweight (aRR: 1.93, 95% CI: 1.56-2.14) and obese (aRR: 2.15, 95% CI: 1.80-2.56). Patients with a GS pregnancy were less likely to smoke (aRR: 0.34, 95% CI: 0.17-0.69) or drink alcohol (aRR: 0.54, 95% CI: 0.47-0.63) during pregnancy. Children of GS were more likely to be born preterm (20-33 weeks [aRR: 2.32, 95% CI: 1.73-3.10], 34-36 [aRR: 2.50, 95% CI: 2.08-3.01] weeks of gestation), and at a birthweight < 2500g (aRR: 1.57, 95% CI: 1.26-1.95), whereas no difference in child's sex was observed.

Conclusion: The findings suggest that gestational surrogates tended to be older, non-Hispanic white, overweight or obese, and seldom smoked or consumed alcohol during pregnancy. They tended to have multiple gestation, preterm and low birthweight children, and privately funded KP membership.

464 | Evaluation of Maternal and Neonatal Outcomes Based on Indication for Cerclage

David M. Esterquest[1]; Rachel K. Harrison[2]; Calla Holmgren[2]

[1]Advocate Lutheran General Hospital, Advocate Lutheran General Hospital, IL; [2]Advocate Health Care, Advocate Health Care, IL

4:00 PM - 6:00 PM

Objective: Comparison of pregnancy outcomes in those undergoing ultrasound, history, and exam-indicated cerclage placement in a large US hospital system.

Study Design: Retrospective cohort study of singleton pregnancies requiring cerclage at multiple hospitals in a large hospital system between 2020-2023. Subjects were included if they had a cerclage placed during pregnancy and available maternal and neonatal outcomes. They were excluded if maternal and neonatal outcomes were not available. Patients were then separated into three groups based on cerclage indication: history (HI), ultrasound (US) and exam indicated (EI). Our primary outcome was delivery < 37 weeks. Maternal and neonatal outcomes were then compared between groups using Chi-squared analysis, ANOVA, as well as logistic and linear regression, with a p-value < 0.05 being considered statistically significant.

Results: 405 singleton pregnancies were analyzed (201 history-indicated, 132 ultrasound-indicated, 72 exam-indicated). Groups were similar in terms of BMI, race, ethnicity, marital status and insurance type, but exhibited a statistical difference in maternal age and nulliparity. Patients in the EI cohort delivered earlier than HI and US groups at an average gestational age of 33.7 w (p = 0.004) . Delivery at < 32 w was most common in EI and US cohorts compared to HI (30.6% vs 18.9% and 12.9%, p = 0.004). Delivery < 32w and < 28w were associated with EI and US groups compared to HI after controlling for confounders . Incidence of neonatal Grade III or IV IVH, sepsis and NICU admission were higher in the EI and US groups compared to HI group. Duration of NICU stay (in days) and incidence of fetal or neonatal demise were greater in the EI cohort compared to the HI group, and these findings persisted in the adjusted analysis (aLRC 37.63, 95%CI 2.82-72.43 and aOR 9.01, 95% CI 1.25-64.87, respectively).

Conclusion: Exam-indicated cerclage is associated with delivery at earlier gestation, greater risk of delivery at < 32 w and < 28 w, longer NICU admission, and increased risk of fetal or neonatal demise compared with history-indicated cerclage.

465 | Evaluation of Prophylactic Antibiotic use in Ultrasound-Indicated Cerclage Placement in a Large Us Hospital System

David M. Esterquest[1]; Rachel K. Harrison[2]; Calla Holmgren[2]
[1]Advocate Lutheran General Hospital, Advocate Lutheran General Hospital, IL; [2]Advocate Health Care, Advocate Health Care, IL

4:00 PM - 6:00 PM

Objective: Compare pregnancy outcomes in patients that did and did not receive antibiotic prophylaxis for ultrasound-indicated cerclage placement

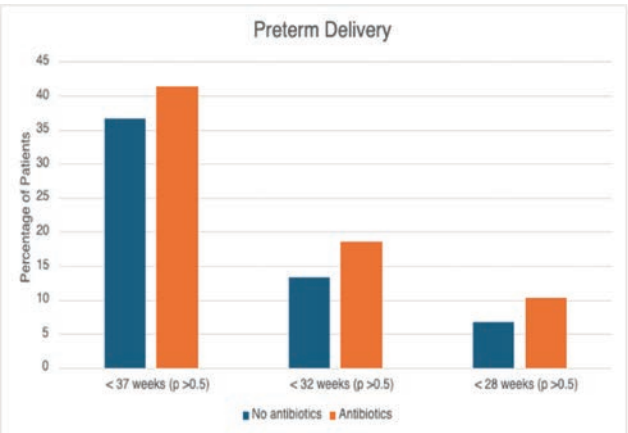
Study Design: Retrospective cohort study of singleton pregnancies undergoing ultrasound-indicated (US) cerclage at multiple hospitals within a large US hospital system between 2020-2023. Subjects were included if they met criteria for US-indicated cerclage. They were excluded if they did not have detailed operative notes and pre- and post-op documentation, or if the maternal and neonatal outcomes were not available. Patients were separated into two groups: those who received antibiotics at the time of cerclage placement and those that did not. Patient demographics, socio-economic factors, and medical co-morbidities were compared as well as operative findings and use of indomethacin. The primary outcome was gestational age at delivery. Secondary outcomes included rates of cesarean section and preterm delivery at < 37 weeks (w), < 32 w, and < 28 w. Student's t-test, chi-squared, and logistic and linear regression were used for statistical analysis, and p-value < 0.05 was considered statistically significant.

Results: 127 singleton pregnancies were analyzed, with 97 receiving antibiotics. Patients across both cohorts were similar in terms of age, parity, BMI, race, ethnicity, marital status, and type of insurance. Additionally, patients did not differ significantly regarding their medical co-morbidities. Those who received antibiotics were more likely to have a dilated cervix at the time of cerclage placement (53.6% vs 26.7%, p = 0.010) as well as prolapsed

membranes (17.5% vs 0%, p = 0.014). Indomethacin use did not vary significantly between groups. Gestational age at delivery as well as incidence of delivery at < 37 w, < 32 w, and < 28 w did not vary significantly between the two groups, even when adjusting for confounding factors (table). There was no difference in rate of cesarean between the groups.

Conclusion: Antibiotic use at the time of ultrasound-indicated cerclage is not associated with a decreased risk for preterm delivery.

	OR/LRC (95% CI)	aOR/aLRC (95% CI)
Gestational age at delivery	-0.06 (-2.46 to 1.24)	-0.06 (-2.57 to 1.36)
Preterm delivery <37 weeks	1.26 (0.54-2.94)	1.01 (0.40-2.53)
Preterm delivery <32 weeks	1.48 (0.46-4.77)	1.47 (0.41-5.32)
Preterm delivery <28 weeks	1.61 (0.33-7.79)	2.65 (0.44-15.81)
Cesarean delivery	1.92 (0.78-4.77)	1.97 (0.74-5.23)



467 | Maternal Morbidity Disparities Amongst Native Hawaiian and Pacific Islander Populations Following Implementation of Safety Bundles

Deepraj K. Pawar[1]; Mary Tschann[2]; Julie Kathman[3]; Rebecca Delafield[4]; Pai-Jong Stacy Tsai[2]

[1]University of Hawaii, Honolulu, HI; [2]University of Hawaii, John Burns School of Medicine, Honolulu, HI; [3]Health Association of Hawaii, Honolulu, HI; [4]University of Hawaii, Manoa, Honolulu, HI

4:00 PM - 6:00 PM

Objective: The Alliance for Innovation on Maternal Health (AIM) has developed evidence-based patient safety bundles (PSB) to decrease severe maternal morbidity (SMM) for several obstetric outcomes including hemorrhage, severe hypertension, and sepsis. Ten of 12 hospitals with birthing facilities in Hawaii adopted AIM PSB in 2021. With evidence of racial disparity among SMM, there is limited data on Native Hawaiian and Pacific Islander people. Our goal was to examine racial and ethnic differences in SMM among OB hemorrhage cases since the implementation of AIM PSB in Hawaii.

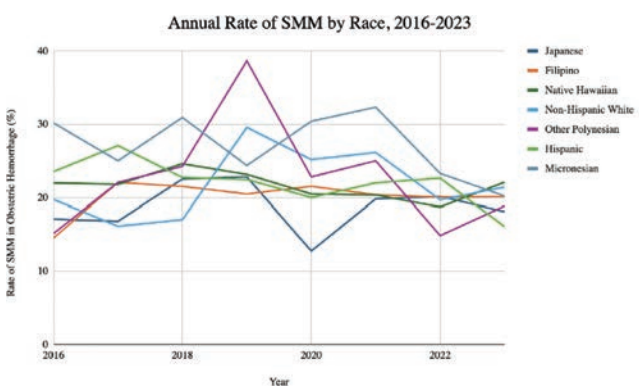
Study Design: We abstracted AIM SBP data from the AIM Data Center, and stratified SMM among OB hemorrhage (excluding ectopic pregnancy and spontaneous abortion) by patient race and year. The groups reported were those with 5 or more incidence of hemorrhage in any given year: Japanese, Filipino, Native Hawaiian, Micronesian, Other Polynesian, Non-Hispanic White, and Hispanic.

Results: From 2016 to 2023, 9545 deliveries were included. Micronesian patients had the highest average SMM rates among OB hemorrhage (27.1%, Table 1), then Other Polynesian (22.7%) and Hispanic (22.1 %) patients. Japanese patients had the lowest rate (18.7%). By year, Micronesian patients had a 30.4% and 32.3% SMM rate in 2020 and 2021, respectively, to 20.2% by 2023 (Graph 1) . Similarly, patients identifying as Other Polynesian had a 38.6%, 22.8%, and 25% SMM rate from 2019-2021, to 14.9% and 18.9% in 2022 and 2023. Native Hawaiian patients had a SMM rate of 20.4% in 2021, 18.7% in 2022, and 22.1% in 2023.

Conclusion: Micronesian and Polynesian patients experienced clinically significant reduction in SMM among OB hemorrhage after the implementation of AIM PSB in 2021. Native Hawaiian patients did not experience a similar decrease. Native Hawaiian and Pacific Islanders are overrepresented in Hawai'i's birthing population compared to the general population, but experience worse outcomes relative to other racial groups. Further studies are warranted to investigate why select populations may benefit from these interventions and how we might provide more equitable care.

Average Rate of SMM by Race/Ethnicity for combined years 2016 – 2023

Race/Ethnicity	Average SMM rate
Japanese	18.76
Filipino	20.09
Native Hawaiian	21.65
Non-Hispanic White	21.86
Other Polynesian	22.70
Hispanic	22.06
Micronesian	27.08



468 | Timing of Delivery in Pregnancies Complicated by Small for Gestational Age with Concurrent Chronic Hypertension

Deirdre Buckley[1]; Kavisha Khanuja[1]; Moti Gulersen[2]; Huda B. Al-Kouatly[3]; Rodney A. McLaren, Jr., Jr.[3]

[1]Sidney Kimmel Medical College at Thomas Jefferson University, Philadelphia, PA; [2]Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA; [3]Thomas Jefferson University Hospital, Philadelphia, PA

4:00 PM - 6:00 PM

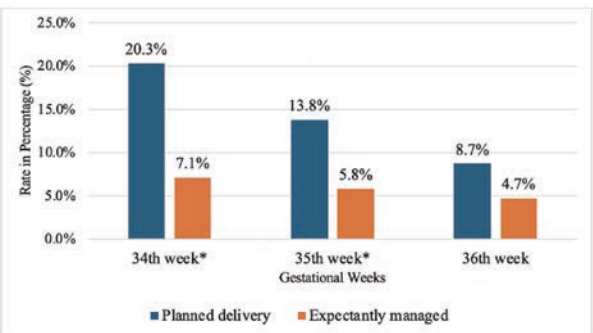
Objective: The American College of Obstetricians and Gynecologists recommends delivery at 34 0/7 - 37 6/7 weeks for pregnancies complicated with fetal growth restriction and concurrent maternal conditions, such as chronic hypertension (CHTN), based on limited evidence. Our objective was to assess neonatal morbidity at birth for each week of gestation in births complicated with small for gestational age (SGA) and CHTN to assess optimal timing of delivery between 34 0/7 - 37 6/7 weeks.

Study Design: This was a population-based cohort study of non-anomalous, singleton, live births complicated by CHTN and SGA between 34 and 37 completed weeks using data from the U.S. Natality Vital Statistics Database from 2015 to 2022. Planned deliveries were births at each completed week from 34 to 37 weeks that had a labor induction or cesarean delivery without labor, excluding spontaneous labor. Expectant management group included all births that delivered on or after the following week (i.e., planned birth at 34 0/7-34 6/7 compared to all births ≥ 35 0/7 weeks). The primary outcome was a neonatal adverse composite, which was compared between both groups at each week using multivariable analyses.

Results: There were 157,985 births that met inclusion criteria. After adjusting for the differences between both groups, planned delivery prior to 36 weeks was associated with greater odds of neonatal morbidity than those expectantly managed (planned 34 weeks birth: 20.3% vs expectant births > 35 weeks: 7.1%, aOR 3.83, 95% CI 3.12-4.70; planned 35 weeks birth: 13.8% vs expectant births > 36 weeks: 5.8%, aOR 2.18, 95% CI 1.74-2.75). Planned delivery ≥ 36 0/7 had similar odds of composite neonatal morbidity than those expectantly managed (Figure 1).

Conclusion: In births complicated by SGA and concurrent CHTN, planned delivery prior to 36 weeks was associated with greater odds of neonatal morbidity compared to expectant management. This data suggests that optimal delivery timing is ≥ 36 weeks. A randomized trial is needed to confirm these findings.

Figure 1. Neonatal composite between planned deliveries and expectant management



Composite neonatal morbidity consists of APGAR score at 5 minutes <5, assisted ventilation use > 6 hours, neonatal seizures, not living at time of report
*significant difference noted on multivariable analyses

469 | Change in Late Preterm PROM Guidelines Result in Increased Expectant Management

Derek Lee[1]; Helena Randle[2]; Tara A. Lynch[1]
[1]Albany Medical Center, Albany, NY; [2]University of Maryland Medical Center, Baltimore, MD

4:00 PM - 6:00 PM

Objective: To investigate the rates of expectant management of preterm prelabor rupture of membranes (PPROM) past 34w0d before and after practice guideline changes in March 2020 at a tertiary level medical center and the corresponding maternal and neonatal outcomes.

Study Design: This is a retrospective cohort study of 299 gravid, singleton patients who underwent PPROM prior to 36w6d and delivered at 34w0d to 36w6d between June 2015 and June 2022. The primary outcome is NICU admission rate, and secondary outcomes include PPROM latency, corticosteroid administration, composite neonatal morbidity (5-minute Apgar < 7, umbilical artery pH < 7.10, assisted ventilation, respiratory distress syndrome, hypoxic ischemic encephalopathy, antibiotic administration >72 hours, intraventricular hemorrhage, seizures, death) and composite maternal morbidity (chorioamnionitis, placental abruption, maternal sepsis, maternal transfusion).

Results: 176 patients (58.9%) before and 123 patients (41.1%) after March 2020 were included. No patients before 2020 and 6 patients (4.8%) after 2020 experienced PPROM before 34w0d and delivered in the late preterm period. There was no difference in PPROM and delivery gestational ages (Table 1). PPROM latency was longer after 2020 (1.01±0.32 vs. 0.52±0.11 days, p = 0.001). More patients underwent expectant management (26.8% vs. 11.9%, p< 0.001) and received corticosteroids (78.0% vs. 60.2%, p = 0.001) after 2020. There was no difference in NICU admission rates and composite neonatal and maternal morbidities (Table 1). In the patients who underwent expectant management, PPROM occurred at a higher gestational age prior to March 2020 (Table 2, p = 0.04). There was no difference in delivery gestational age, latency, NICU admission rates, and composite neonatal and maternal morbidities in patients who underwent expectant management (Table 2).

Conclusion: Significantly more patients underwent expectant management of PPROM past 34w0d after March 2020, but there was no difference in NICU admission rates and composite maternal and neonatal morbidities, even in those who underwent expectant management.

Table 1. PPROM Outcomes Before and After March 2020

	Before March 2020 (n=176)	After March 2020 (n=123)	P-value
PPROM gestational age	35 weeks and 2.8±0.9 days	35 weeks and 2.7±1.2 days	0.98
Delivery gestational age	35 weeks and 3.4±0.9 days	35 weeks and 3.6±1.1 days	0.76
PPROM latency (days)	0.52±0.11	1.01±0.32	**0.001**
Expectant management (n, %)	21 (11.9)	33 (26.8)	**<0.001**
Antenatal corticosteroids (n, %)	106 (60.2)	96 (78.0)	**0.001**
NICU admission (n, %)	94 (53.4)	53 (43.1)	0.08
Composite neonatal morbidity (n, %)	61 (34.7)	42 (34.1)	0.69
Composite maternal morbidity (n, %)	18 (10.2)	12 (9.8)	0.89

Table 2. PPROM Outcomes in Patients who Underwent Expectant Management

	Before March 2020 (n=21)	After March 2020 (n=33)	P-value
PPROM gestational age	35 weeks and 3.5±2.8 days	34 weeks and 6.5±2.4 days	**0.04**
Delivery gestational age	35 weeks and 4.0±2.7 days	35 weeks and 1.6±2.2 days	0.16
PPROM latency (days)	0.64±0.25	1.71±1.05	0.11
Antenatal corticosteroids (n, %)	9 (42.9)	30 (90.9)	**<0.001**
NICU admission (n, %)	10 (47.6)	11 (33.3)	0.29
Composite neonatal morbidity (n, %)	6 (28.6)	9 (27.3)	0.92
Composite maternal morbidity (n, %)	4 (19.0)	4 (12.1)	0.48

470 | Comparison of Weight Gain versus BMI During Pregnancy on Perinatal Outcomes in Singleton Term Pregnancies

Devangi Dave Mahtani; Eleanor R. Germano; Irene A. Stafford; Han-Yang M. Chen
McGovern Medical School at UTHealth Houston, Houston, TX

4:00 PM - 6:00 PM

Objective: Excessive gestational weight gain (GWG) and obesity have significant adverse perinatal risks. Our study compares the impact of excessive GWG on maternal and neonatal outcomes in pregnancies with normal pre-pregnancy BMI (18.5–24.9) to those who had pre-pregnancy BMI ≥ 25 with recommended weight gain.

Study Design: We performed a retrospective cohort study using the National Vital Statistics Database and included singleton, non-anomalous live births who delivered at term from 2016-2022. We excluded patients with multifetal gestations, chronic hypertension and pre-gestational diabetes. We compared three groups: Group 1 (normal pre-pregnancy BMI with excessive GWG), Group 2 (overweight pre-pregnancy BMI (25.0–29.9) with recommended GWG) and Group 3 (obese pre-pregnancy BMI (≥ 30) with recommended GWG). Recommended GWG was defined according to AIUM standards across BMI strata. Multivariate Poisson regression models with robust error variance were used to examine the association. Adjusted relative risk (aRR) with 95% confidence intervals were calculated.

Results: Our study included 6,352,304 patients. Compared to Group 1, overweight and obese patients had a higher risk of composite adverse maternal outcome, mostly due to increased risk of gestational diabetes and cesarean birth. Those with recommended GWG despite being overweight or obese were less likely to have hypertensive disorders (Group 2 aRR 0.92, 95% CI 0.91-0.92) and operative vaginal birth (Group 2 aRR 0.93, 95% CI 0.92-0.94; Group 3 aRR 0.73, 95% CI 0.72-0.74). Compared to Group 1, Group 2 had a reduced risk of the composite neonatal adverse outcome (aRR 0.74, 95% CI 0.74-0.74), mostly due to a reduced risk of large for gestational age fetuses (aRR 0.64, 95% CI 0.64-0.64) and NICU admission (aRR 0.98, 95% CI 0.98-0.99).

Conclusion: While pre-pregnancy BMI is a crucial predictor of these outcomes, recommended weight gain during pregnancy mitigates these risks by improving maternal and neonatal outcomes. Additional studies are needed to quantify the risk of excessive GWG in those with other high-risk conditions.

Table 1. Composite and Individual Maternal Adverse Outcomes

Outcomes	Groups	Total live births	n	%	Crude RR (95% CI)	aRR (95% CI)
Composite maternal adverse outcome	Total	6,348,546	2,632,256	41.5

RR = relative risk; aRR = adjusted relative risk; CI = confidence interval
aRR is adjusted for maternal age, race and ethnicity, education, insurance, prenatal care, nulliparity, prior preterm birth, prior cesarean section, smoking during pregnancy, gestational age at delivery, intra-amniotic infection, gestational diabetes, hypertensive disorders, cesarean birth, infant sex, year

471 | The Impact of Maternal Comorbidities on Neonatal Outcomes in Growth Restricted Fetuses

Dhara Kadakia[1]; Olivia Grubman[2]; Hajer Naveed[3]; Mia A. Heiligenstein[4]; Thomas Owens[1]; Guillaume Stoffels[3]; Nathan S. Fox[5]; Zainab Al-Ibraheemi[1]; Lois Brustman[1]
[1]Icahn School of Medicine at Mount Sinai West, New York, NY; [2]Westchester Medical Center, Westchester, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Mount Sinai West, Astoria, NY; [5]Icahn School of Medicine at Mount Sinai Hospital, New York, NY

4:00 PM - 6:00 PM

Objective: To determine the impact on neonatal outcomes in fetal growth restricted fetuses (FGR) in patients with and without medical comorbidities.

Study Design: A retrospective cohort study performed on singleton gestations from 2018-2022.Patients included had FGR at the last scan prior to delivery. A composite of maternal comorbidities included: chronic hypertension(cHTN), pregestational diabetes(DM), connective tissue disease(CT), IVF, IBD, thrombophilia and maternal age >40. A sub-group of comorbidities with a vascular component (DM, cHTN, CT) was reviewed. FGR was divided into 3 groups: Mild(mFGR): EFW >10% with AC< 10%, Moderate (MFGR):EFW 3rd-10%, Severe (sFGR):EFW< 3rd%.The primary outcome was a neonatal composite: NICU Admission, APGAR < 5 at 5 minutes, and hypoglycemia. Logistic regressions were used to examine the relationship between

maternal comorbidities, timing of FGR diagnosis, and neonatal outcomes.

Results: Total patients were 534: 297 mFGR, 184 MFGR, and 53 with sFGR. Of 534 patients, 105(19.7%) had comorbidities (of these 48 had vascular comorbidities); 429 had no comorbidities. 127(23.8%) of 534 had an adverse neonatal outcome. Adverse outcomes increased significantly with severity of FGR:15.8% in mFGR; 26.6% in MFGR;58.5% in sFGR. In a univariable analysis, cHTN, AMA, early FGR diagnosis, and FGR severity were significantly associated with an increased risk of adverse outcomes (Table 1).The odds of an adverse outcome were 2.17 times more in those with any comorbidity compared to those without comorbidities(OR 2.17, 95% CI 1.37-3.4).When a vascular comorbidity was present, an adverse outcome was 4.50 times more likely compared to those with no comorbidities(OR 4.5, 95% CI 2.45-8.28).The presence of a vascular comorbidity < 32wks had a significant association with an adverse neonatal outcome in all severities of FGR (Table 2).

Conclusion: In the setting of FGR, the presence of maternal medical comorbidities, particularly vascular, had significantly increased risk of adverse neonatal outcomes.These findings could help us better counsel patients in regards to antepartum testing and patients' expectations.

Table 1: Association of maternal comorbidities with adverse neonatal outcomes

Characteristic	All (n=534)	No adverse outcome¶ (n=407)	Adverse outcome¶ (n=127)	Odds ratio§ (95% CI)	P value§
Pre-gestational diabetes – no. (%)	7 (1.3)	3 (0.7)	4 (3.1)	4.38 (0.97, 19.83)	0.06
CHTN – no. (%)	37 (6.9)	15 (3.7)	22 (17.3)	5.47 (2.74, 10.92)	<0.0001
Connective tissue disease – no. (%)	8 (1.5)	4 (1.0)	4 (3.1)	3.28 (0.81, 13.29)	0.10
IVF – no. (%)	27 (5.1)	22 (5.4)	5 (3.9)	0.72 (0.27, 1.93)	0.51
IBD – no. (%)	22 (4.1)	18 (4.4)	4 (3.1)	0.70 (0.23, 2.12)	0.53
Thrombophilia – no. (%)	2 (0.4)	1 (0.2)	1 (0.8)	3.22 (0.20, 51.89)	0.41
Maternal age > 40 years	26 (4.9)	14 (3.4)	12 (9.4)	2.93 (1.32, 6.51)	0.008
FGR diagnosis prior 32 weeks – no. (%)	142 (26.6)	70 (17.2)	72 (56.7)	6.30 (4.08, 9.74)	<0.0001
Comorbidity with vascular component† – no. (%)	48 (9.0)	22 (5.4)	26 (20.5)	4.50 (2.45, 8.28)	<0.0001
Any comorbidity‡ – no. (%)	105 (19.7)	67 (16.5)	38 (29.9)	2.17 (1.37, 3.44)	0.0008
FGR group – no. (%)					<0.0001
sFGR (EFW < 3rd percentile)	53 (9.9)	22 (5.4)	31 (24.4)	7.49 (4.00, 14.06)	<0.0001
MFGR (EFW 3 – 10th percentile)	184 (34.5)	135 (33.2)	49 (38.6)	1.93 (1.23, 3.03)	0.004
mFGR (EFW > 10th percentile & AC < 10th percentile)	297 (55.6)	250 (61.4)	47 (37.0)	1.00 (ref)	--

¶ Neonatal adverse outcome included NICU admission, APGAR score < 5 at 5 minutes and neonatal hypoglycemia.
† Comorbidity with vascular component included pre-gestational diabetes, CHTN and connective tissue disease.
‡ Any comorbidity included pre-gestational diabetes, CHTN, connective tissue disease, IVF, IBD/IBS, thrombophilia, and maternal age > 40 years.
§ Univariable logistic regression models were used.

Table 2: Comorbidities with vascular component and adverse neonatal outcomes based on severity of FGR

Severity of FGR	Characteristic	No adverse outcome¶ N = 250	Adverse outcome¶ N = 47	Unadjusted Odds ratio§ (95% CI)	Unadjusted P value§	Adjusted for early diagnosis Odds ratio§ (95% CI)	Adjusted for early diagnosis P value§

¶ Neonatal adverse outcome included NICU admission, APGAR score < 5 at 5 minutes and neonatal hypoglycemia.
† Comorbidity with vascular component included pre-gestational diabetes, CHTN and connective tissue disease.
§ Univariable and multivariable logistic regression models were used.

472 | Determining the Role of Pregnancy-Induced Alterations to B Cells in Decreasing Risk for Breast Cancer

Dhivyaa Anandan[1]; Marygrace Trousdell[2]; Amritha Varshini Hanasoge Somasundara[2]; Camila dos Santos[2]
[1]Stony Brook Medicine, Stony Brook, NY; [2]Cold Spring Harbor Laboratory, Cold Spring Harbor, NY

4:00 PM - 6:00 PM

Objective: An early age of first pregnancy (< 25 years) decreases the lifelong risk of developing breast cancer (BC). This study characterizes how B cells that infiltrate the gland during pregnancy and lactation may play a role in preventing BC.

Study Design: Wildtype female mice and a mouse model of Brca1 loss ($Krt5^{CRE\text{-}ERT2}Brca1^{fl/fl}p53^{+/-}$) were used in this study. Single-cell RNA-seq (scRNA-seq) datasets were generated from mammary tissue of nulliparous and parous mice with Brca1 loss without tumors. B cell receptor (BCR)-seq datasets were generated from nulliparous and parous wildtype mice. Differential gene expression and clustering analyses were performed using the R pipeline Seurat. Clonotype analysis and extraction of BCR sequences were performed using Loupe V(D)J Browser by 10X Genomics. Recombinant post-pregnancy mammary IgG antibodies were synthesized by the CSHL Antibody & Phage Display Core Facility and tested by immunofluorescent (IF) staining.

Results: scRNA-seq analysis showed that parous mice with Brca1 loss have an expansion of antibody-secreting B cells in their mammary glands (MGs), suggesting that B cells that infiltrate the MG during pregnancy remain there and may secrete antibodies that inhibit mammary tumor formation. To analyze these B cells on a clonal level, we analyzed BCR-seq data to identify the most abundant IgG clones unique to the parous MG. We extracted the sequences of these clones and used them to synthesize recombinant IgG antibodies. Using IF staining of mammary tissue from healthy mice (nulliparous, pregnant, and parous) and mice with mammary pre-neoplasia, we found that post-pregnancy IgG antibodies recognize antigens induced by pregnancy and lactation that are also present in mammary pre-neoplastic tissue. We are currently testing these antibodies in our mouse model of Brca1 loss to evaluate their ability to block mammary tumor development.

Conclusion: In addition to their role in secreting antibodies into breastmilk that confer immunity to the nursing infant, our results suggest a role for pregnancy-induced antibody-secreting B cells in long-term breast oncoprotection.

473 | Change in BMI Category: Impact on Maternal and Neonatal Outcomes

Eleanor R. Germano; Devangi Dave Mahtani; Irene A. Stafford
McGovern Medical School at UTHealth Houston, Houston, TX

4:00 PM - 6:00 PM

Objective: Pre-pregnancy BMI is a risk factor for the development of hypertensive disorders of pregnancy (PIH). However, the association between weight gain during pregnancy and the development of hypertensive disorders is understudied. The objective was to determine if change in BMI category change (eg overweight to class I obesity) was associated with development of PIH. Secondary outcomes were maternal composite outcome and fetal composite outcome.

Study Design: This was a retrospective cohort study performed using data from the National Vital Statistics Database of individuals with singleton, non-anomalous neonates from 2016-2020. Pregnancies with multiple gestations, anomalous neonates, pre-gestational diabetes, or chronic hypertension were excluded. Demographic and obstetrical variables were recorded. Groups were determined as no change in BMI (Group 1) or change in BMI (Group 2) from pre-pregnancy to delivery. Differences between groups were examined using chi-square or Fisher's exact test. Multivariate regression models were used to calculate adjusted relative risk (aRR) with 95% confidence intervals (CI).

Results: A total of 19,718,555 pregnancies met inclusion criteria and 15,426,805 (78%) pregnancies were noted to have a change in BMI category. The overall rate of PIH was 6.6%. After multivariable adjustment, there was a significant difference in the rate of PIH. Compared to individuals in Group 1, individuals with a Group 2 were more likely to develop PIH (aRR of 1.39 (95% CI [1.38-1.39], p< 0.001). In the secondary outcome analysis, Group 2 compared to Group 1 had higher rates of maternal composite outcome (aRR 1.11, CI [1.11-1.11, p< 0.001]) and fetal composite outcome (aRR 1.37, CI [1.37-1.38], p< 0.001).

Conclusion: There was a significant association between change to a higher BMI category and development of PIH along with an increase in composite adverse maternal and fetal outcomes. Future studies are required to further delineate risks for patients whose delivery BMI changes to class III obesity as well as stratified risks for women with pre-pregnancy class IV obesity and above.

Table 1: Primary outcomes

	N	Case Number	%	Crude RR (95% CI)	Adjusted RR* (95% CI)
Pregnancy-induced hypertension					
Group 1: No change	4,291,750	223,209	5.2%	1.35 (1.34-1.35)	1.38 (1.38-1.39)
Group 2: BMI change	15,426,805	1,080,499	7%		

*Adjusted for maternal age, ethnicity, education, insurance, prenatal care, nulliparity, preterm delivery, cesarean section, smoking status, gestational age, fetal sex.

Table 1: Secondary outcomes

	N	Case Number	%	Crude RR (95% CI)	Adjusted RR* (95% CI)
Maternal composite[a]					
Group 1: No change	4,288,389	1,274,776	29.7%	1.16 (1.16-1.17)	1.11 (1.11-1.11)
Group 2: BMI change	15,416,639	5,340,067	34.6%		
Fetal composite[b]					
Group 1: No change	4,285,124	430,765	10.1%	1.43 (1.43-1.44)	1.37 (1.37-1.38)
Group 2: BMI change	15,406,905	2,215,533	14.4%		

*Adjusted for maternal age, ethnicity, education, insurance, prenatal care, nulliparity, preterm delivery, cesarean section, smoking status, gestational age, fetal sex.
a Maternal composite: chorioamnionitis, cesarean section, operative delivery, perineal laceration, blood transfusion, ruptured uterus, unplanned hysterectomy, admission to ICU
b Fetal composite: 5-minute APGAR <5, assisted ventilation >6 hours, neonatal seizure, large for gestational age, NICU admission, neonatal death, infant death

474 | The Impact of Watching an Informative-Video on Possible Obstetric Emergencies Before Labor-A Randomized Controlled Trial

Eliel Kedar Sade[1]; Ilia Kleiner[2]; Shir Lev[2]; Shiran Rona[2]; Daniel Tairy[3]; Hadas Miremberg[2]; Jacob Bar[2]; Eran Weiner[1]; Noa Gonen[4]
[1]Wolfson Medical Center, Wolfson Medical Center, Tel Aviv; [2]Wolfson Medical Center, Wolfson Medical Center, HaMerkaz; [3]Edith Wolfson Medical Center, Holon, HaMerkaz; [4]Sheba Medical Center, Ramat gan, HaMerkaz

4:00 PM - 6:00 PM

Objective: In most obstetric departments women (especially nulliparous) are rarely counseled in detail regarding possible obstetric emergencies that might occur during labor. This randomized controlled trial aimed to evaluate the effect of an informative video regarding possible obstetric emergencies during labor on maternal anxiety, childbirth experience, and peripartum satisfaction among nulliparous women anticipating vaginal delivery.

Study Design: Participants (≥37 weeks gestation) were randomly assigned to an intervention group or a control group. The intervention group watched a 5-minute video planned and produced by our department on the management of delivery and "what to expect" during common obstetric emergencies, including fetal bradycardia, assisted delivery, emergency cesarean delivery, and postpartum hemorrhage. The control group received standard obstetric care. Anxiety levels were assessed at three points using the State-Trait Anxiety Inventory (STAI): at recruitment prior to video exposure (STAI 1), upon admission to the delivery room (STAI 2), and postpartum (STAI 3). Both groups also completed an 11-item Childbirth Experience Questionnaire (CEQ). The study was powered to detect a 5 points difference in the primary outcome (STAI 2).

Results: A total of 161 participants were approached, and 127 were included in the final analysis after completing all study questionnaires. Of these, 63 were in the exposure group, and 64 in the control group (figure). There were no significant demographic differences between the groups, and baseline anxiety levels were comparable (STAI 1). Upon admission to the delivery room, anxiety levels remained similar between the control and exposure groups (STAI 2: 41 [33-48] vs. 42 [34-48], respectively; p = 0.84). Notably, immediate postpartum anxiety levels were significantly lower in the exposure group (STAI 3: 30 [24-38] vs. 28 [21-33]; p = 0.03). There were no differences in the CEQ between the groups (table).

Conclusion: Watching the pre-delivery informative video about possible obstetric complications was associated with lower anxiety levels immediately postpartum.

475 | Differences in Intimate Partner Violence Screening During Pregnancy for Us-Born Versus Immigrant Birthing People

Elizabeth L. Mirsky[1]; Ashley Boerrigter[1]; Gregory Hawk[1]; Emily A. DeFranco[2]
[1]*University of Kentucky, Lexington, KY;* [2]*Department of Obstetrics and Gynecology, University of Kentucky, Lexington, KY*

4:00 PM - 6:00 PM

Objective: Investigate whether socioeconomic and language barriers to healthcare unique to immigrant birthing people in the US are reflected in differences in frequency of screening for intimate partner violence (IPV) in the preconception, pregnancy, and postpartum periods.

Study Design: Cross-sectional study using Pregnancy Risk Assessment Monitoring System (PRAMS) data from 2020 to 2021. PRAMS collected data on screening for physical and emotional IPV before, during and after pregnancy, as well as experience of IPV before and during pregnancy. The prevalence of screening was compared between immigrant versus US-born status, and relative risks calculated. Weighted analyses of PRAMS data were employed to be reflective of representative state populations using predefined methods.

Results: There were 63,761 respondents in the study period, representative of an estimated population of 3,039,459 from participating US states. Sociodemographic characteristics differed between US-born and immigrant status (Table 1). Approximately 3 out of 4 respondents reported being screened for IPV during pregnancy, with screening rates lower for IPV before and after pregnancy. Immigrant respondents were overall less likely to be screened for IPV before pregnancy than US-born, but more likely to be screened during and after pregnancy (Table 2). US-born respondents were more likely to experience IPV before and during pregnancy than immigrant respondents; however, there was no significant association between being screened for IPV and foreign-born status among those reporting having experienced IPV.

Conclusion: Approximately 1 in 4 patients reported not been screened for IPV. Among those who reported experiencing IPV, over one-third were not screened. While multiple barriers to IPV screening exist, immigrant-born status was not associated with lower rates of IPV screening during or after pregnancy. This highlights the importance of IPV screening among all pregnancies, regardless of perceived risk status.

476 | Prenatal Fentanyl Exposure and Replication of a Novel Neonatal Syndrome Study at a Single Institution

Elizabeth L. Mirsky; Cynthia Cockerham; Wendy Whitley; Gregory Hawk; Asmita Shrestha; John O'Brien; Barbara V. Parilla
University of Kentucky, Lexington, KY

4:00 PM - 6:00 PM

Objective: To determine if findings from a previous study on a novel neonatal syndrome associated with prenatal fentanyl exposure (Wadman et al., 2023) can be identified at our institution.

Study Design: Potential cases of this novel syndrome were identified from a prospectively collected database of obstetric patients with substance use disorder (SUD) enrolled in a multispecialty treatment program from 2014 to 2024. The database was screened for neonatal findings consistent with this novel syndrome in cases with prenatal fentanyl exposure resembling Smith-Lemli-Opitz (SLO) syndrome including microcephaly, cleft palate, clubfoot, rocker bottom feet, toe syndactyly, single palmar crease, hypoplastic corpus callosum, and hypospadias.

Results: 639 patients were enrolled in a perinatal substance use treatment program and study. Of the 103 patients found to have neonates with a small head size (head circumference < 10%), 34 individuals self-reported fentanyl use in the 30 days prior to enrollment in the program, with an additional 17 reporting use within the last year. Six of these individuals had confirmatory drug screening for fentanyl. Of the 6 cases with confirmed fentanyl use on drug screening, all patients screened positive in the first trimester. Four neonates displayed characteristic anomalies consistent with a SLO-like syndrome (Table 1). All cases shared lagging head growth, while additional anomalies identified included cleft palate, short nasal tip, thin upper lip, micrognathia, and hypospadias. Of the cases with anomalies, all individuals had polysubstance use. Genetic screening/diagnostic testing varied but an assessment of cholesterol metabolism was not performed.

Conclusion: This study suggests the potential association of prenatal fentanyl exposure with a novel syndrome. As the opiate crisis continues, fueled by rising fentanyl use, more data is needed to confirm and delineate this association and determine the possible long-term developmental effects of such a syndrome.

477 | Asymmetrical vs. Symmetrical Large for Gestational Age Infants in Pregestational Diabetics: Differences in Neonatal Morbidity

Ellen M. Murrin[1]; Barak Rosenn[2]; Shelley Ehrlich[3]; Jane Khoury[3]; Francis Mimouni[4]; Menachem Miodovnik[5]
[1]Inova Fairfax Medical Campus, Falls Church, VA; [2]Jersey City Medical Center, Jersey City, NJ; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [4]Sackler School of Medicine Tel Aviv University, Tel Aviv, Tel Aviv; [5]Inova Fairfax Medical Campus, Fairfax, VA

4:00 PM - 6:00 PM

Objective: Research has highlighted the importance of distinguishing between asymmetrical large for gestational age (aLGA) and symmetrical large for gestational age (sLGA) infants, with the former being associated with higher risk of neonatal complications. We hypothesized that the prevalence and complications of aLGA is higher in infants born to mothers with type 1 diabetes (T1D) compared to type 2 diabetes (T2D).

Study Design: Women with insulin-treated pregestational diabetes (PGDM) were recruited and managed prospectively. Singleton pregnancies recruited before 14 weeks were included in this analysis. Patients were seen every 1-2 weeks and glycemic control was strictly managed using standardized protocols. Infants were weighed and measured immediately after birth and monitored for hyperbilirubinemia, hypoglycemia, and acidosis. LGA (birthweight > 90^{th}%ile) was categorized as aLGA if ponderal index (PI = weight/length^3) was > 90^{th}%ile for gestational age, and sLGA if the PI was ≤ 90^{th}%ile. Outcomes were compared between infants with sLGA and aLGA and between infants born to mothers with T1D and T2D. Characteristics are reported as n (%), mean +/- standard deviation, or median and 25^{th} and 75^{th}

percentiles. Statistical analyses included t-test, Wilcoxon rank sum, chi-square and logistic regression, as appropriate.

Results: The study included 132 LGA infants born to 321 women with T1D (41%) and 26 LGA infants born to 55 women with T2D (47%). The incidences of aLGA and sLGA in both groups and patient characteristics are presented in Table 1. In T2D, aLGA was associated with higher 2nd and 3rd trimester HbA1 compared to sLGA. There was a trend for a similar association in T1D. Most infant outcomes did not differ between groups nor did overall composite outcomes (Table 2).

Conclusion: There is a high rate of LGA, and particularly aLGA, among infants of mothers with both T1D and T2D. However, we identified few differences in infant outcomes between the groups, suggesting the need for further study into the clinical significance of aLGA as compared to sLGA.

478 | Early Indicators and Clinical Characteristics of Preeclampsia in Pregnant Women with Insulin-Treated Pregestational Diabetes

Ellen M. Murrin[1]; Barak Rosenn[2]; Shelley Ehrlich[3]; Jane Khoury[3]; Francis Mimouni[4]; Menachem Miodovnik[5]
[1]Inova Fairfax Medical Campus, Falls Church, VA; [2]Jersey City Medical Center, Jersey City, NJ; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [4]Sackler School of Medicine Tel Aviv University, Tel Aviv, Tel Aviv; [5]Inova Fairfax Medical Campus, Fairfax, VA

4:00 PM - 6:00 PM

Objective: Pregestational diabetes (PDM) is a known risk factor for preeclampsia (PE); however, various co-existing factors can affect the risk of developing PE in this high-risk population. The purpose of this study was to identify early indicators predictive of PE in pregnant women with insulin-treated PDM.

Study Design: Pregnant women with PDM from a prospectively managed cohort were classified as with or without PE based on current ACOG criteria. Patients were seen every 1-2 weeks during pregnancy and were managed by a dedicated team utilizing pre-specified protocols. Individual clinical characteristics, diabetes-related complications, blood pressure measurements, indices of glycemic control, and pregnancy outcomes were compared between patients who did and did not develop PE using t-test, Wilcoxon rank sum test, or chi-square, as appropriate.

Results: Patient characteristics are presented in Table 1 as n (%), mean ± standard deviation, or median and 25th and 75th percentiles. Of the 424 pregnancies, 87 (20.5%) developed PE. Duration of diabetes, microvascular complications, early pregnancy (8-20 weeks) mean arterial blood pressure (MAP), and urine protein levels at 16 weeks were associated with an increased risk of developing PE. Weekly odds ratios for PE based on diastolic blood pressure were highest at 8-10 weeks gestation. There was a trend towards higher Glycohemoglobin A1 (HgbA1) levels in the PE group during the first 20 weeks of pregnancy. PE was associated with earlier gestational age at delivery, lower birth weight, lower placental weight, and cesarean delivery. Live birth and neonatal death rates were similar in both groups (98% vs. 97% and 1% vs. 2% in the PE and non-PE groups, respectively).

Conclusion: In PDM pregnancies, several factors may serve as early predictors for the risk of developing PE, including blood pressure and glycemic control early in pregnancy. These two modifiable risk factors suggest that there may be an opportunity to intervene early in pregnancy and possibly modify the risk of ultimately developing PE.

Table 1: Characteristics of Study Cohort by Preeclampsia (PE) Group

Characteristic	PE n=87 (20.6%)	No PE n=337 (79.5%)	p-value
Age at LMP (years)	26.7 (4.87)	26.0 (5.43)	0.33

HgbA1 reported as standard deviation according to the laboratory units, as two different assays were used over the course of the study.

479 | Inequities in Postpartum Opioid Prescribing by Race-Ethnicity and Insurance Status Across Statewide Quality Collaborative

Ellery G. Sarosi[1]; Joshua S. George[2]; Kyle Latack[1]; Steven Ater[3]; Michelle Moniz[2]; Lisa Kane Low[2]; Molly J. Stout[4]; Jourdan E. Triebwasser[2]; Jennifer Waljee[2]; Vidhya Gunaseelan[2]; Mark Bicket[2]; Courtney Townsel[5]; Alex Peahl[6]
[1]University of Michigan Medical Center, Department of Obstetrics and Gynecology, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]Central Michigan University, Central Michigan University, MI; [4]University of Michigan Medical Center, Ann Arbor, MI; [5]University of Maryland Department of Obstetrics, Gynecology and Reproductive Sciences, Baltimore, MD; [6]Michigan Medicine, Ann Arbor, MI

4:00 PM - 6:00 PM

Objective: To describe differences in discharge opioid prescribing following vaginal (VB) and cesarean births (CB) across historically marginalized groups.

Study Design: Retrospective cohort study of nulliparous, term, singleton, vertex births from 1/1/2023-10/13/2023 in a clinical registry from 71 hospitals participating in a quality improvement collaborative supported by Blue Cross Blue Shield of Michigan. Eligible patients had a VB or CB, were ≥ 18 years, and did not have a history of opioid use, postpartum length of stay ≥ 7 days, maternal transfer to another hospital, and invalid or incomplete opioid prescription data. Patients who underwent repair of a 3rd or 4th degree laceration, hysterectomy, or dilation and curettage were also excluded. We report adjusted opioid prescribing rates by race-ethnicity and insurance status, stratified by mode of delivery.

Results: Of 14,690 VB, 87.4% (n = 12,837) had a spontaneous VB without additional procedures, of whom 1.1% (n = 146) received an opioid prescription. There was no significant difference in receipt of an opioid prescription based on race-ethnicity or insurance after VB. Of 5,957 CB, 99.7% (n = 5,938) had a CB without additional procedures, of whom 89.2% (n = 5,298) received an opioid prescription. Following CB, NHB patients were more likely to receive an opioid prescription compared to NHW patients (Table 1; NHB: OR 1.57, 95% CI 1.16-2.12). Patients with Medicaid were more likely and patients without insurance or self-pay patients were less likely to receive an opioid prescription compared to privately insured patients (Table 1; Medicaid: OR 1.30, 95% CI 1.05-1.62; Self-pay/None: OR 0.43, 95% CI 0.20-0.93).

Conclusion: Discharge opioid prescribing after VB without additional procedures was rare, and without inequities. In contrast, discharge opioid prescribing following CB was common, and higher among historically marginalized groups.

[1]Johns Hopkins University, Baltimore, MD; [2]Nnamdi Azikiwe University Teaching Hospital, Nnewi, Anambra; [3]Chukwuemeka Odumegwu Ojukwu University Teaching Hospital, Amaku, Anambra; [4]Vizient Center for Advanced Analytics, Chicago, IL; [5]Vanderbilt University, Nashville, TN; [6]Johns Hopkins University School of Medicine, Baltimore, MD

4:00 PM - 6:00 PM

Objective: Pregnant patients with HIV require effective antiretroviral therapy (ART) during pregnancy to prevent perinatal transmission and manage their own health, but the choice of regimen can impact pregnancy outcomes. Limited data are available comparing the safety and efficacy of second-generation protease-inhibitors (Atazanavir and Darunavir-based ART) in pregnancy despite their associated risks of hyperbilirubinemia and cholestasis. Therefore, we compared the maternal and neonatal outcomes in pregnant patients living with HIV managed with Atazanavir versus Darunavir-based ART.

Study Design: This multi-center observational cohort study used data from 192 hospitals in 38 US states, sourced from the Vizient Clinical Database. We included pregnant patients with HIV on Atazanavir or Darunavir-based ART, who delivered between January 2021- April 2024. The primary outcome was intrahepatic cholestasis of pregnancy (ICP), with secondary outcomes including hypertensive disorders, preterm birth, and neonatal outcomes. We computed adjusted odds ratios (aOR) using multivariable logistic regression to adjust for potential confounders (maternal age, gestational age, diabetes mellitus, hypertension, baseline viral load and CD4 cell count).

Results: There were 251 patients in the Atazanavir and 218 patients in the Darunavir group. In the overall cohort at study entry, the median (interquartile range, IQR) maternal age was 31 (IQR 27-36) years with most patients identifying as Black (63.4%) . The frequency of ICP was similar in both groups (2.0% vs 2.8%; P = .59) - *Table 1*. The adjusted odds ratios (aOR) of ICP (aOR 1.83; 95% CI 0.51, 6.58), preterm birth (aOR 0.93; 95% CI 0.41, 2.12), gestational hypertension (aOR 0.82; 95% CI 0.44, 1.54), pre-eclampsia (aOR 1.07, 95% CI 0.58, 1.96), placental abruption (aOR 2.71; 95% CI 0.25, 28.93) and stillbirth (aOR 0.66; 95% CI 0.18, 2.25) were similar between both groups (*Table 2*).

Conclusion: Atazanavir and Darunavir-based ART were safe for use during pregnancy and had similar pregnancy and neonatal outcomes.

Table 1: Pregnancy outcomes according to ART use in pregnancy in patients living with HIV

Variable	Atazanavir-Based ART (n = 251)	Darunavir-Based ART (n = 218)	P-value
GA at delivery in weeks (mean, SD)	37.1 (3.31)	37.3 (3.69)	0.67
Preterm birth, n (%)	16 (6.4)	12 (5.5)	0.69
Pre-eclampsia, n (%)	26 (10.4)	27 (12.4)	0.48
Pregnancy induced hypertension, n (%)	26(10.4)	20 (9.2)	0.67
Eclampsia, n (%)	0 (0)	1 (0.5)	0.28
Cholestasis of pregnancy, n (%)	5 (2.0)	6(2.8)	0.59
Oligohydramnios, n, (%)	5 (1.9)	4 (1.8)	0.90
Polyhydramnios, n (%)	10 (3.9)	7 (3.2)	0.66
Placenta abruption, n (%)	1 (0.4)	3 (1.4)	0.25
CD4 (median, Q1, Q3)	478 (251, 710)	386.5 (195, 687)	0.26
CD8 (median, Q1, Q3)	521 (323, 817)	583.5 (319, 886)	0.66
Viral load <50 copies/mL (median, Q1, Q3)	238 (94.8)	210 (96.3)	0.43
AST (median, Q1, Q3)	24.0 (18.5, 31.0)	23.0 (18.0, 29.0)	0.81
ALT (median, Q1, Q3)	22.0 (16.0, 33.0)	22.9 (15.0, 33.0)	0.86
Serum creatinine (median, Q1, Q3)	0.90 (0.70, 1.1)	0.86 (0.68, 1.03)	0.009
Mode of delivery, n (%) - Vaginal delivery - Cesarean delivery	 136 (54.1) 115 (45.9)	 123 (56.4) 95 (43.6)	0.63
Stillbirth, n (%)	6 (2.4)	6 (2.8)	0.68

Table 2: Univariable and multivariable logistic regression models

	Univariable logistic regression			Multivariable logistic regression		
	Odds Ratio (OR)	95% confidence interval	P value	Adjusted Odds Ratio (aOR)	95% confidence interval	P value
Intrahepatic cholestasis	1.39	0.42, 4.63	0.54	1.83	0.51, 6.58	0.35
Preterm birth	0.86	0.40 1.85	0.69	0.93	0.41, 2.12	0.87
Gestational HTN	0.87	0.47, 1.61	0.67	0.82	0.44, 1.54	0.54
Pre-eclampsia	1.22	0.69, 2.17	0.49	1.07	0.58, 1.96	0.83
Placental abruption	3.49	0.36, 33.78	0.28	2.71	0.25, 28.93	0.41
Stillbirth	0.76	0.21, 2.74	0.68	0.66	0.18, 2.25	0.53

Models were adjusted for maternal age, gestational age at study entry, obesity, baseline viral load and CD4 count, history of pre-gestational diabetes, and chronic hypertension.

481 | Postpartum Hemorrhage Requiring Transfusion Increases Short-Term Risk of Readmission for Cardiovascular Disease

Emily E. Daggett[1]; Rachel Lee[2]; Ruby Lin[2]; Morgan C. Dunn[3]; Julia Knypinski[2]; Cande V. Ananth[2]
[1]Rutgers Robert Wood Johnson Medical School, Edison, NJ; [2]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; [3]Rutgers Robert Wood Johnson, New Brunswick, NJ

4:00 PM - 6:00 PM

Objective: Postpartum hemorrhage (PPH) is a common obstetric complication that, in severe cases, may necessitate blood transfusion. We hypothesized that severe PPH constitutes a cardiovascular insult that confers risk beyond the immediate postpartum period and that necessitating blood transfusion serves as a marker of the severity of PPH. Severe PPH may plausibly be linked to cardiovascular disease (CVD) by large-volume acute blood loss causing hypoperfusion and ischemia, leading to impaired cardiac function.

Study Design: We performed a retrospective cohort study of discharges from delivery hospitalizations in the United States, 2010-2020, using the Healthcare Cost and Utilization Project's Nationwide Readmissions Database. ICD 9 and 10 coding were used to identify deliveries complicated by PPH with and without blood transfusion. Associations between PPH and non-fatal CVD readmissions within the calendar year following delivery were derived from Cox proportional hazard models expressed in confounder-adjusted hazard ratios (HR) with 95% confidence intervals (CI).

Results: Of 18,600,829 delivery admissions, 3.9% (n = 752,891) were complicated by PPH. Of these, 13.7% (n = 103,040) received a blood transfusion. The risk of CVD readmission was 170, 197, and 476 per 100,000 hospital deliveries for patients without PPH, PPH without transfusion, and PPH with transfusion, respectively. Compared to those without PPH, patients with PPH and no transfusion had an increased risk of CVD readmission (HR 1.19, CI 1.11-1.28), with more than a doubling of risk among patients with PPH with transfusion (HR 2.20, CI 1.97-2.47). The risks were highest after PPH with transfusion for atherosclerotic heart disease (HR 4.42, CI 3.04-6.42), ischemic heart disease (HR 2.79, CI 2.09-3.71), and acute myocardial infarction (HR 2.39, CI 1.58-3.63)(Figure 1).

Conclusion: PPH, particularly when requiring blood transfusion, is associated with an increased risk of non-fatal CVD readmission within the year following delivery. These findings underscore the burden of CVD risk with PPH and the need for active management to reduce CVD morbidity.

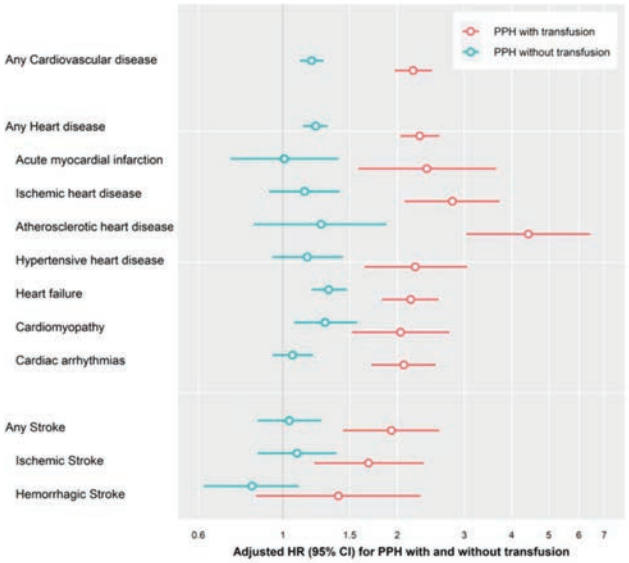

Figure 1. Associations between PPH without and with transfusion and non-fatal cardiovascular disease readmissions within the year following delivery

482 | Postpartum Hemorrhage Requiring Transfusion Increases Short-Term Risk of Cardiovascular Disease Mortality

4:00 PM - 6:00 PM

Objective: Postpartum hemorrhage (PPH) is a common obstetric complication that, in severe cases, may necessitate blood transfusion. We hypothesized that severe PPH constitutes a cardiovascular insult that confers risk beyond the immediate postpartum period and that necessitating blood transfusion can serve as a marker of the severity of PPH. Severe PPH may plausibly be linked to cardiovascular disease (CVD) by large-volume acute blood loss causing hypoperfusion and ischemia, leading to impaired cardiac function.

Study Design: Using the Healthcare Cost and Utilization Project's Nationwide Readmissions Database, we designed a retrospective cohort study of discharges from delivery hospitalizations in the United States, 2010-2020. ICD 9 and 10 coding were used to identify deliveries complicated by PPH with and without blood transfusion. Associations between PPH and CVD-related mortality within the calendar year following delivery were derived from Cox proportional hazard models expressed in confounder-adjusted hazard ratios (HR) with 95% confidence intervals (CI).

Results: Of 18,600,829 delivery admissions, 3.9% (n = 752,891) were complicated by PPH. Of these, 13.7% (n = 103,040) received a blood transfusion. The risk of CVD mortality was 3.3, 4.0, and 13.6 per 100,000 deliveries for patients without PPH, PPH without transfusion, and PPH with transfusion, respectively. Compared to those without PPH, patients with PPH and no transfusion had a similar risk of CVD mortality (HR 1.07, CI 0.71-1.60). However, there was a three-fold increased mortality risk among patients

with PPH with transfusion (HR 2.98, CI 1.65-5.40), including heart disease mortality (HR 2.93, CI 1.53-5.63)(Table 1).

Conclusion: While PPH without transfusion does not appear to increase the risk of CVD mortality in the year following delivery, PPH with transfusion (suggestive of disease severity) has a substantially higher risk of heart disease and stroke mortality. These findings underscore the significance of CVD risk with severe PPH and the need for active management to reduce CVD mortality.

Table 1. Cardiovascular disease mortality within the year of delivery amongst patients with and without postpartum hemorrhage and transfusion in the United States, 2010-2020

	No PPH	PPH without Transfusion	PPH with Transfusion
	Rate per 100,000 deliveries (adjusted hazard ratio, 95% confidence interval)		
All-cause mortality	5.7 (1.00, Reference)	13.4 (2.26, 1.80-2.83)	87.4 (11.85, 8.88-15.81)
Cardiovascular disease mortality	3.3 (1.00, Reference)	4.0 (1.07, 0.71-1.60)	13.6 (2.98, 1.65-5.40)
Heart Disease mortality	2.8 (1.00, Reference)	3.5 (1.11, 0.71-1.72)	11.6 (2.93, 1.53-5.63)
Stroke mortality	0.9 (1.00, Reference)	—*	—*

* Fewer than 10 cases suppressed as specified in the HCUP data-use agreement

483 | Postpartum Hemorrhage is Associated with Reduced Rates of Breastfeeding in a Low-Risk Nulliparous Population

Emma Trawick Roberts[1]; Sarah Heerboth[1]; Tracy A. Manuck[1]; Alison M. Stuebe[2]
[1]University of North Carolina, Chapel Hill, NC; [2]UNC School of Medicine, Chapel Hill, NC

4:00 PM - 6:00 PM

Objective: To examine the association of postpartum hemorrhage (PPH) with reduced rates of breastfeeding at 4-8 weeks postpartum.

Study Design: Secondary analysis of a multicenter randomized controlled trial of elective induction of labor at 39 weeks' gestation vs. expectant management in low-risk nulliparous women from 2014-2017 (MFMU ARRIVE trial). Participants with singleton, non-anomalous pregnancies with no medical or obstetric indication for induction (as assessed at 38 weeks' gestation/enrollment) were included. Those requiring ≥2 uterotonics in addition to oxytocin, transfusion, or surgical interventions to control bleeding (including peripartum hysterectomy) were considered to have PPH. At 4-8 weeks postpartum, participants self-reported infant feeding, categorized as exclusive breast (EBF), breast feeding in combination with formula (CF), or exclusive formula feeding (EFF). The primary outcome was any breastfeeding (EBF of CF) at 4-8 weeks postpartum. Multivariable logistic regression was used to model the relationship between PPH and breastfeeding.

Results: Of 5454 participants that met inclusion criteria, 251 (5%) had a PPH, and 90/251 (36%) required blood transfusion. Clinical cohort characteristics are shown in table 1. At 4-8 weeks postpartum, 33% were EBF, 31% were CF, and 35% were EFF. Of those with a PPH, 72 (28.7%) were EBF, 84 (33.5%) were CF, and 95 (37.9%) were EFF ($p > 0.05$). In regression models, PPH was associated with a non-statistically significant reduced odds of EBF or breastfeeding at all (Table 2). In regression models limited to those with PPH requiring blood transfusion, however, there was a significantly reduced odds of EBF or breastfeeding at all compared to those EFF (Table 2).

Conclusion: In a low-risk nulliparous population, PPH requiring blood transfusion was associated with reduced odds of breastfeeding at 4-8 weeks postpartum. Women who have a PPH, especially if they require transfusion, may benefit from targeted breastfeeding support.

Table 1. Clinical characteristics of cohort. Data are n (row %) or mean (standard deviation) unless noted.

Characteristic	Exclusive breastfeeding n=1807	Breastfeeding in combination with formula n=1694	Exclusive formula feeding n=1953
Maternal age (years)	26.2 (4.8)	24.8 (5.1)	22.9 (4.6)

Bolded if significant.

484 | First-Trimester Virtual Placental Biopsy to Estimate Vascularization and Risk of Preeclampsia: a Prospective Study

Marie-Laurence Côté[1]; Anne-Sophie Lafortune[1]; Mario Girard[2]; Genevieve Marcoux[3]; Louise Ghesquiere[4]; Emmanuel Bujold[1]
[1]Université Laval, PQ; [2]CHU de Québec - Research Center, CHU de Québec, PQ; [3]CHU de Québec, CHU de Québec, PQ; [4]Université de Lille, Lille, Nord-Pas-de-Calais

4:00 PM - 6:00 PM

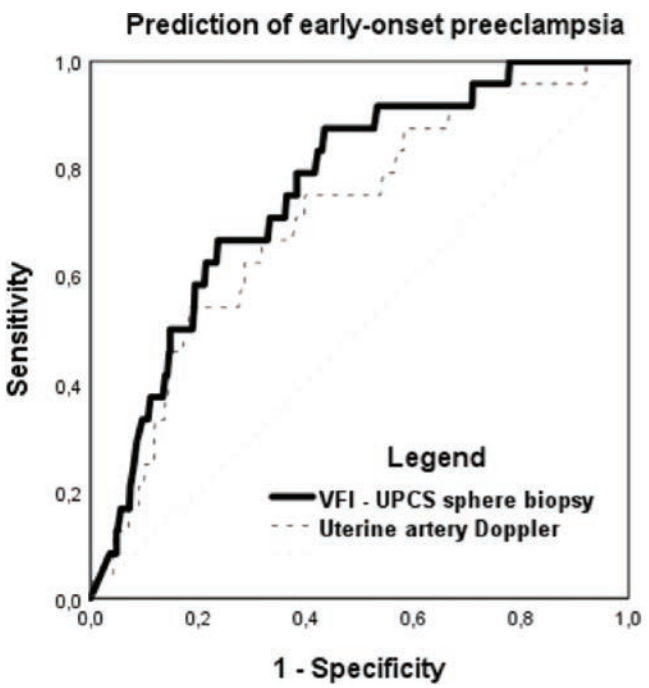
Objective: While preliminary studies have suggested its effectiveness (Dar et al. AJOG 2010), we aimed to assess whether 3-dimensional power Doppler (3DPD) of the uteroplacental circulation space (UPCS) or of the whole placenta, measured in the first trimester was able to predict preeclampsia.

Study Design: A prospective observational study of singleton pregnancies between 11 and 14 weeks. The 3DPD indices, vascularization index (VI), flow index (FI), and vascularization flow

index (VFI), were determined on a UPSC sphere biopsy with the virtual organ computer-aided analysis (VOCAL) program. We also studied the vascularization of the entire placenta and the Doppler of the uterine arteries. Non-parametric and ROC curve analyses were performed.

Results: Among 12,424 women recruited, 498 (4%) had preeclampsia, including 33 (0.3%) with early-onset preeclampsia (< 34 weeks). We were able to determine that all vascularization indices, but particularly the VI and the VFI of the whole placenta and UPCS were largely decreased in early-onset preeclampsia (all with p< 0.01). Taken alone, biopsy sphere VFI is faster to measure than uterine artery Doppler and has a sensitivity of 50% for early preeclampsia with a false-positive rate of 15% (p< 0.001).

Conclusion: First-trimester vascularization indices are decreased among women who will develop early-osnet preeclampsia. Rapid assessment of placental vascularity by virtual UPCS biopsy, as proposed by Dar et al., is feasible on large populations, and is effective in predicting early-onset preeclampsia.



485 | Anticoagulation Preventive Therapy Versus no Therapy and the Risk for Venous Thromboembolism During the Postpartum

Enav Yefet[1]; Sally Hosari Mahamed[2]; Yael Skinez[2]; Zohar Nachum[3]

[1]Tzafon Medical Center, Poriya, HaZafon; [2]Emek medical center, Afula, HaZafon; [3]Emak Medical Center, Afula, HaZafon

4:00 PM - 6:00 PM

Objective: Until 2011, enoxaparin was given for postpartum venous thromboembolism (VTE) prophylaxis in women with thrombophilia or previous VTE (pre-protocol). Since 2012, VTE prophylaxis protocol was implemented and enoxaparin was given also to women with risk factors according to the RCOG. We aimed to compare the efficacy and safety of enoxaparin treatment postpartum before and after protocol implementation.

Study Design: Retrospective cohort study was conducted at Emek medical center in Israel. One delivery per woman was chosen randomly. The study included two periods; the pre-protocol period between 2003 and 2011 (N = 19,783), and the protocol period from 2012 to 2020 (N = 20520). Enoxaparin was administered for 6 weeks in case of thrombophilia or past VTE and 7-10 days in case of other risk factors. The primary outcome was the rate of VTE. Secondary outcomes were bleeding complications. Assuming that the protocol will reduce the rate for VTE from 1:1000 to 1:4000, 34,860 women were required (5% 2-sided alpha, 80% power).

Results: Patients' characteristics and outcomes are presented in the table. In the pre-protocol period, 531 women (2.7%) were treated with enoxaparin in the postpartum period. After protocol implementation, 964 (4.7%) women were treated due to known thrombophilia or past VTE event (P< 0.0001). Another 6.5% of the women received enoxaparin due to risk factors. The rate of VTE events in the postpartum period was 3 (0.02%) and 4 (0.02%) cases before and after the protocol implementation, respectively, (P = 1). Postpartum bleeding complications were comparable between the before and after protocol implementation groups, including postpartum hemorrhage (16 (0.08%) vs. 24 (0.12%), respectively, P = 0.25) or the need for blood transfusions (2 (0.01%) vs. 5 (0.02%), respectively, P = 0.45).

Conclusion: Protocol for postpartum VTE prophylaxis according to risk factors with enoxaparin treatment did not lower the rate of VTE events, which are rare to begin with. The guidelines for postpartum VTE prophylaxis should be re-evaluated.

Table 1: Maternal medical history, pregnancy characteristics and study outcomes

486 | Implementation of a Standardized Fetal Surveillance Protocol for Stillbirth Risk-Reduction

Erik G. Holder[1]; Patrick S. Ramsey[2]; Camille B. Marquez[3]; John J. Byrne[4]
[1]University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]University of Texas Health Science Center San Antonio, San Antonio, TX; [3]University Health System, San Antonio, TX; [4]University of Texas Health San Antonio, San Antonio, TX

4:00 PM - 6:00 PM

Objective: Antenatal surveillance is recommended by the American College of Obstetricians despite the lack of published data proving a direct reduction in fetal mortality. We sought to evaluate the impact of a standardized antenatal fetal surveillance protocol on stillbirth rates at our level IV maternal care, safety-net hospital.
Study Design: Our institution implemented an updated, heightened antepartum surveillance protocol based on the ACOG Committee Opinion #828 in March of 2023. A retrospective cohort study was performed reviewing stillbirths one year pre- and one year post-implementation of the protocol. Cases involving known, life-limiting or lethal fetal anomalies, multi-fetal gestations, and complete absence of prenatal care in the hospital system were excluded from the analysis. Stillbirth was defined as fetal death occurring between 20 0/7 weeks gestation until delivery. Secondary outcomes evaluated neonatal intensive care unit (NICU) admission rates, APGAR scores, and induction rates. Inductions were stratified into late preterm, early term, term, and late-term groups. Chi-square and Fisher's exact test were used for comparisons as appropriate to compare rates between cohorts.
Results: A total of 4078 deliveries occurred pre-implementation (3/10/2022–3/10/2023) with 18 stillbirths identified (0.4%). A total of 4985 deliveries occurred post-implementation (06/10/2023–06/10/2024), with 19 stillbirths identified (0.4%). Overall stillbirth rates did not change despite protocol implementation ($p = 0.74$), nor when evaluated by gestational age time epoch ($p > 0.05$). Rates of induction, however, were significantly decreased for early term and term pregnancies ($p = 0.02$, $p = 0.02$, respectively) in the post-implementation period. NICU admission rates and APGAR scores were not noted to have significant difference across groups.
Conclusion: Our data suggests that increased surveillance does not significantly impact stillbirth rates at our institution but does decrease incidence of early term and term inductions without adverse impact on NICU admission rates or APGAR scores.

Gestational Epoch	Pre-protocol			Post-protocol			
	Stillbirth	Deliveries	Rate	Stillbirth	Deliveries	Rate	P-value
Early preterm (20 0/7 - 33 6/7)	12	238		15	277		
			5.04%			5.42%	p = 1.0
Late preterm (34 0/7 - 36 6/7)	4	412		1	447		
			0.97%			0.22%	p = 0.2
Early term (37 0/7 - 38 6/7)	2	1274		3	1477

4:00 PM - 6:00 PM

Objective: To investigate non-invasive prenatal testing (NIPT) diagnostic accuracy in identifying fetal red blood cell (RBC) antigen genotypes.
Study Design: A systematic search was conducted into four databases up to May 2024. We included studies implementing NIPT for fetal RBC antigen detection in pregnancies at risk of alloimmunization. We calculated sensitivity, specificity, diagnostic odds ratios, and area under the curve. Analysis was conducted per laboratory technique including polymerase chain reaction (PCR) and next-generation sequencing (NGS) and subgroup analyses were performed per fetal antigen into RhC, Rhc, RhD, RhE, Kell, and Duffy (Fya) antigens.
Results: A total of 52 studies of which 48 (37228 maternal samples) used PCR and 4 (170 maternal samples) used NGS were included in the analysis. The diagnostic accuracy for the six antigens (RhC, Rhc, RhD, RhE, Kell, and Fya) in order are i) using PCR technique, the pooled sensitivity is 100% (95% C 99-100), 98% (95% CI 95-100), 100% (95% CI 99-100), 100% (95% CI 98-100), and 98% (95% CI 94-100), respectively and the pooled specificity is 99% (95% CI 99-100), 100% (95% CI 97-100), 100%(95% CI 91-100), 99% (95% CI 98-99), 100% (95% CI 99-100), and 100% (95% CI 97-100), respectively, and ii) using NGS technique, the pooled sensitivity is 100% (95% CI 75-100), 100% (95% CI 92-100), 100% (95% CI 89-100), 100% (95% CI 95-100), 100% (95% CI 93-100), 100% (95% CI 70-100), respectively and the pooled specificity is 100% (95% CI 79-100), 100% (95% CI 78-100), 100% (895% CI 6-100), 100% (95% CI 93-100), 100% (95% CI 96-100), 100% (95% CI 80-100), respectively.
Conclusion: NIPT can accurately detect six fetal blood group antigens of which antibodies are associated with fetal anemia. Clinical adoption of NIPT for the detection of fetal antigens for both alloimmunized and RhD-negative non-alloimmunized

pregnant individuals may streamline care and reduce unnecessary treatment, monitoring, and patient anxiety.

Table 1. Diagnostic Accuracy of non-invasive prenatal test for fetal red blood cell antigen testing

Technique	Antigen type	Number of studies	Number of samples for each antigen	Sensitivity% (95% CI)	Specificity% (95% CI)	DOR (95% CI)	AUC
PCR	All antigens	48	37205	99 (99-100)	99 (99-100)	5121 (2428-10799)	0.989
	RhC	4	183	100 (99-100)	100 (97-100)	1287 (175 – 9475)	0.988
	Rhc	5	183	98 (96-100)	100 (93-100)	442 (83 – 2355)	0.977
	RhD	44	35654	100 (99-100)	99 (98-99)	5096 (2306 – 11262)	0.989

4:00 PM - 6:00 PM

Objective: A recent meta-analysis (4 trials) concluded that aspirin dose of 150-162 mg vs 75-81 mg initiated < 16 weeks gestational age (GA) decreased rates of preterm preeclampsia and preeclampsia with severe features (sPE). However, 3 of the 4 trials included were of low quality, and primary outcome was preeclampsia in only 1 of the trials. We conducted a secondary analysis of an RCT with primary outcome of sPE, and compared rates of sPE and preterm sPE between 162 vs 81 mg aspirin when initiated at < 16 weeks GA.

Study Design: Secondary analysis of a RCT in high-risk obese gravidas comparing aspirin 162 (ASA 2) vs aspirin 81 mg (ASA 1) for preeclampsia prevention (ASPREO). Inclusion criteria were BMI $\geq$30 kg/m^2 and $\geq$ 1 high risk factor: PE in prior pregnancy, at least stage I hypertension in the index pregnancy, diabetes. Exclusion criteria were: delivery < 20 weeks GA or delivery outcome data not available. For this analysis we focused on those enrolled < 16 weeks GA. The primary outcome was: sPE. Secondary outcomes were: preterm sPE, total PE, abruption, postpartum hemorrhage, severe maternal morbidity. Relative risks with 95% CIs were reported.

Results: A total of 107/209 (51%) were enrolled prior to 16 weeks GA (54 on ASA 2, 53 on ASA 1). Baseline characteristics were similar between groups (Table 1). There was no statistical difference in rates of sPE (28% vs 40%, RR: 0.7 (0.41-1.21)), or preterm sPE (13% vs 24%, 0.53 (0.23-1.22)) in those receiving ASA 2 vs ASA 1. Also, no differences were found in any of the analyzed secondary outcomes (Table 2).

Conclusion: When comparing aspirin 162 mg vs 81 mg started prior to 16 weeks, we found a trend towards reduced rates of preeclampsia with severe features and preterm preeclampsia with severe features in those receiving the 162 mg dose, although this was not statistically significant. A large RCT is needed to address the optimal dose and timing of initiation of aspirin for preeclampsia prevention.

Table 1. Baseline Characteristics in those enrolled < 16 weeks GA on Aspirin 162 mg vs Aspirin 81 mg

Characteristic	Aspirin 162 mg N = 54[1]	Aspirin 81 mg N = 53[1]	P Value

489 | Prediction of Cesarean Delivery Using Maternal Measurements–Secondary Analysis of a Prospective Multicenter Study

Rachel Malone[1]; Patrick Dicker[1]; Naomi Burke[1]; Ronan Daly[1]; Elizabeth Tunney[1]; Rebecca Boughton[1]; Alex Dakin[1]; Fergal D. Malone[2]
[1]*Royal College of Surgeons in Ireland, Dublin, Dublin;* [2]*Royal College of Surgeons in Ireland, Dubiln, Dublin*

4:00 PM - 6:00 PM

Objective: Prediction of intrapartum cesarean delivery (CD) would be of significant benefit in reducing labor-associated morbidity. While different fetal sonographic biometric parameters have been studied to develop individual patient CD risks, they are subject to ultrasound resource limitations, as well as interobserver variability in ultrasound precision. Our objective was to evaluate whether simple, easily repeatable measurements of a pregnant woman's head circumference and her height could provide an easy method of CD risk prediction in routine antenatal clinics.

Study Design: A multi-center prospective study recruited 2,336 nulliparous women with a vertex presentation between 39+0 and 40+6 weeks' gestation at seven hospitals to examine a range of CD predictors. Maternal head circumference (MHC) and maternal height (MH) were recorded at the first antenatal visit, with data entered into a prospective database at study enrolment at 39+0 to 40+6 weeks' gestation. Maternal proportionality of MHC to MH was assessed using the ratio MHC:MH.

Results: From a total enrolled cohort of 2,336 nulliparous patients, 491 (21%) had an unplanned CD. Mean MHC was 56.2cm (SD = 1.8cm, range = 50.0-65.5cm). Mean MH was 165.5cm (SD = 6.3cm, range = 142-188cm). The mean MHC:MH ratio was 0.346 (SD = 0.015), and this was used to standardize the MHC:MH ratio (sMHC:MH) for risk calculation. Table 1 shows that the sMHC:MH ratio was more predictive of emergency intrapartum CD than any maternal or fetal measurement individually (OR = 1.65, 95%CI 1.49-1.83, p< 0.001, AUC = 0.64). Table 2 shows delivery outcomes based on quartile of sMHC:MH.

Conclusion: We have demonstrated that a simple ratio of MHC to MH is a useful predictor of CD, showing that the shortest patients with the largest maternal head measurements have a 1 in 3 chance of requiring CD, with CD at full dilation and failure to progress being significantly more likely. In particular when late pregnancy ultrasound resources may be limited, a simple maternal biometry ratio can be a powerful predictor of emergency intrapartum CD, at no cost.

Table 1: Relative performance of maternal and fetal factors for predicting emergency intrapartum CD

Parameter	Odds Ratio	95% CI	Area under curve
Maternal age	1.21	1.07 – 1.31	0.55
Fetal Abdominal Circumference	1.29	1.17 – 1.43	0.57

490 | Cost-effectiveness of External Fetal and Maternal Heart Rate Monitoring vs. External Fetal Heart Rate Alone

Gabriela Hernandez Duran; Megha Arora; Aaron B. Caughey
Oregon Health & Science University, Portland, OR

4:00 PM - 6:00 PM

Objective: Standard observation of a fetus during labor involves the use of external fetal monitoring to track fetal status. Recent evidence suggests that dual monitoring of external fetal heart rate (FHR) with concurrent maternal heart rate (MHR) can reduce the incidence of adverse neonatal outcomes. This study examined the cost-effectiveness of concurrent MHR and FHR monitoring during labor.

Study Design: We constructed a decision-analytic model using TreeAge Pro to compare neonatal outcomes between external FHR monitoring alone and dual external FHR and MHR monitoring. Outcomes examined included cost, neurodevelopmental delay (NDD), encephalopathy, death, NICU admission, and quality-adjusted life years (QALYs). The theoretical cohort was 2,512,945 patients, the estimated annual singleton vaginal births at term. We applied a willingness-to-pay threshold of $100,000 per QALY for the incremental cost-effectiveness ratio (ICER). The model inputs were sourced from literature and the QALYs were calculated using a 3% discount rate.

Results: In our theoretical cohort of 2,512,945 patients, dual MHR and FHR saved $843,454,354 and increased QALYs by 37,644. There would be 223 fewer patients with NDD, 1,131 fewer patients with encephalopathy, 8,325 fewer NICU admissions, and 291 fewer neonatal deaths. The negative ICER of $-22,406/QALY suggests that not only is this strategy more effective, but also cost-saving. Univariate sensitivity analysis of neonatal encephalopathy indicates that the dual monitoring would be cost-saving once the probability of encephalopathy exceeds 0.06% (Figure 1).

Conclusion: In our study, the use of dual external FHR and MHR monitoring during labor is a cost-saving strategy when compared to external FHR monitoring alone. Standardizing labor protocols to include external MHR monitoring may reduce dire neonatal outcomes.

	FHR Alone	FHR+MHR	Difference
Cost (USD)	18,513,090,886	17,669,636,532	843,454,354
Effectiveness (QALY)	141,235,080	141,272,724	-37,644
Neurodevelopmental Delay (NDD)	3,287	3,064	223
Encephalopathy	3,512	2,381	1,131
Neonatal death	493	202	291
NICU Admission	57,802	49,478	8,325
ICER	Dominated	Dominant	

491 | Interpregnancy Interval and Uterine Rupture Risk in Women Undergoing Trial of Labor After Cesarean

Gal Bachar[1]; Naphtali Justman[1]; Ron Beloosesky[2]; Nira Gridish[2]; Dalia Jabarin[2]; Dana Vitner[1]; Zeev Weiner[2]; Yaniv Zipori[1]; Nizar Khatib[2]

[1]Rambam Medical Center, Haifa, Hefa; [2]Rambam Medical Health Center, Haifa, Hefa

4:00 PM - 6:00 PM

Objective: The interpregnancy interval (IPI) is the time between the end of one pregnancy and the start of the next. A short IPI, defined as 18 months or less, linked to negative outcomes like uterine rupture and preterm delivery. This study examines how the length of IPI affects the risk of uterine rupture and other major maternal and neonatal complications in women attempting a trial of labor after cesarean (TOLAC).

Study Design: A retrospective cohort study was conducted at a single tertiary care center between 2010 and 2024. The study population included pregnant women with a history of one previous cesarean delivery (CD) who attempted a TOLAC. Participants were stratified based on interpregnancy interval (IPI) of less than or greater than 18 months. The primary outcome was the incidence of uterine rupture. Secondary outcomes encompassed other maternal and neonatal complications.

Results: A total of 2386 women attempting TOLAC were included in the study, with 2151 (90.1%) in the IPI > 18 months group and 198 (9.9%) in the IPI $\leq$ 18 months group. Baseline characteristics, including indication for previous CD, were comparable between the two groups (Table 1).

When attempting TOLAC, there was no significant difference in the incidence of uterine rupture between the two groups (0.5% vs. 0.8%, p = 0.235; Table 2). Vaginal delivery rate was also similar between group, with failed TOLAC rate was ~38%. Other maternal and neonatal adverse outcomes did not differ significantly between the groups (Table 2).

Conclusion: Our study found no association between short IPI and an increased risk of uterine rupture or other maternal and neonatal complications in women attempting TOLAC. These findings suggest that IPI may not be a strong predictor of adverse maternal or neonatal outcomes in women undergoing TOLAC. However, the small number of women in the short IPI group, limits the strength of these conclusions. Further research with larger sample sizes is needed to confirm these findings and to explore other factors that may influence outcomes in this population.

Table 1: Delivery characteristics

Characteristics	IPI≤18m N=198	IPI>18 N=2151	P-value

492 | Cost Analysis of Permissive Intrapartum Glucose Control for Diabetes: The PERMIT Randomized Controlled Trial

Ghamar Bitar[1]; Elenir B. Avritscher[2]; Kendra Folh[3]; Sarah A. Nazeer[4]; Sean C. Blackwell[1]; Baha M. Sibai[1]; Michal Fishel Bartal[5]

[1]McGovern Medical School at UTHealth Houston, Houston, TX; [2]University of Texas Health Science Center at Houston, Houston, TX; [3]Children's Memorial Hermann Hospital, Houston, TX; [4]The University of Texas Health Science Center at Houston (UTHealth), Houston, TX; [5]UTH Houston & Sheba Medical Center Israel, Houston, TX

4:00 PM - 6:00 PM

Objective: In PERMIT randomized controlled trial (RCT), permissive intrapartum glucose control led to reduced need for maternal insulin drip and equivalent neonatal blood glucose when compared to usual care for patients with diabetes (Bitar, AJOG 2024). We aimed to evaluate its economic impact.

Study Design: This is a pre-planned cost analysis of a multisite RCT of permissive intrapartum glucose control (target maternal blood glucose 70–180mg/dL) or usual care (70–110 mg/dL) in patients with diabetes. Costs were assessed from the hospital perspective and included the facility costs for all the inpatient services provided to all enrolled parturients and their neonates during the delivery and birth admissions, respectively, as recorded in the cost-accounting system of the participating sites. Costs were inflated to 2024 based on the medical Consumer Price Index. We assessed differences in total combined maternal and neonatal costs (primary economic outcome), as well as individual maternal and neonatal costs, using frequentist generalized linear models (GLMs). We assessed the probability of reduction in costs using a Bayesian GLM model with a neutral prior assuming no benefit (rate ratio [RR] = 1.0; 95% credible interval, 0.3–3.3). All frequentist and Bayesian models used gamma distribution with log link and adjusted for the stratifying variables (site and type of diabetes).

Results: Costs were determined for all 96 maternal-infant pairs. In intent-to-treat analysis, the total maternal and neonatal costs for permissive care were similar to those of usual care ($20,135 vs. $20,654; RR = 1.00 [95% CI, 0.77–1.30], p = 0.99; 49% probability of reduction). Costs between permissive care and usual care were similar for both the parturients ($13,480 vs. $14,119; RR = 0.96 (0.78–1.18), p = 0.70; 69% probability of reduction) and the neonates ($6,655 vs. $6,535; 1.04 (0.63–1.73), p = 0.87; 41% probability of reduction).

Conclusion: Permissive care is clinically equivalent and cost-neutral for both total maternal-neonatal costs and individual costs. These findings require validation in additional sites.

Table. Cost Outcomes by Treatment Group

	Permissive Care (N=48)	Usual Care (N=48)	Adjusted Risk Ratio†	*P* Value	Bayesian Probability of Cost Decrease
Hospital costs* mean (95% CI)					
Total combined costs	$20,135 ($16,710–$23,560)	$20,654 ($15,678–$25,631)	1.0 (0.77–1.30)	0.99	49%
Maternal costs	$13,480 ($11,823–$15,138)	$14,119 ($11,217–$17,022)	0.96 (0.78–1.18)	0.70	69%
Neonatal costs	$6,655 ($4,147–$9,163)	$6,535 ($3,693–$9,378)	1.04 (0.63–1.73)	0.87	41%

*Costs are reported in 2024 U.S. dollars.

†Estimates of differences between the two treatment groups were obtained using generalized linear models with gamma distribution and a log link function. The models included the dependent variable (cost), treatment groups (permissive care or usual care) and the stratifying variables (site and type of diabetes) as covariates.

493 | Maternal Cardiac and Perinatal Outcomes Among Pregnant Individuals with Ebstein's Anomaly

Gianna L. Wilkie[1]; Rahi Patel[2]; Lara Kovell[3]; Anna R. Whelan[2]

4:00 PM - 6:00 PM

Objective: Ebstein's anomaly, a congenital cardiac condition, is defined by apical displacement of the tricuspid valve and atrialization of the inlet portion of the right ventricle. Advancement in cardiac intervention over time has led to an increase in people with Ebstein's anomaly surviving into the reproductive years. Due to its historical early lethality, the impacts of this condition are not well known in pregnancy. The objective of this study was to describe the maternal cardiac and perinatal outcomes associated with maternal Ebstein's anomaly in pregnancy through use of a large, contemporary dataset.

Study Design: Utilizing Epic Cosmos, an integrated dataset from over 1500 hospitals across the United States and includes 250 million patients, we identified a cohort of pregnancies among individuals with maternal Ebstein's anomaly. Individuals with simultaneous diagnoses codes for maternal Ebstein's anomaly and pregnancy between July 2021 and July 2024 were identified. Descriptive statistics, including demographics, cardiac and perinatal outcomes were obtained.

Results: During the study period, 487 individuals with a maternal Ebstein's anomaly and pregnancy were identified. Subjects were

a mean age of 32.0 years old (±9 years) and identified as predominately White (78.9%). Approximately 30.8% of patients experienced a cardiac arrhythmia, while 14.8% developed heart failure. The most common arrhythmias were supraventricular tachycardias (SVT) (52%) and atrial fibrillation/flutter (36%). There was complete obstetric outcome data available for 235 individuals (48.2%). The average gestational age at delivery was 35.4 weeks (± 9.1 weeks) with 13.2% experiencing a preterm birth less than 37 weeks. Regarding mode of delivery, 77.0% had a vaginal delivery, while 23.0% had a cesarean delivery.

Conclusion: Ebstein's anomaly is associated with significant cardiac risks in pregnancy, specifically cardiac arrhythmia. Further prospective studies are needed in modern cohorts to guide optimal management of pregnant patients with Ebstein's anomaly and to determine the highest risk time period for cardiac complications.

Table 1. Demographics, Cardiac and Perinatal Outcomes of Perinatal Individuals with Ebstein's Anomaly

Demographics	Patients with Ebstein's anomaly (n=487)
Age (mean ± SD)	32.0 years old ± (9)
Race*	
American Indian/Alaskan Native	<10
Asian	19 (3.9%)
Black	47 (9.7%)
White	384 (78.9%)
Other	89 (18.3%)
Ethnicity	
Hispanic	89 (18.3%)
Non-Hispanic	340 (69.8%)
Unknown	58 (11.9%)
Cardiac Outcomes	(n=487)
Cardiac Arrhythmia	150 (30.8%)
Supraventricular tachycardia (SVT)	78 (52.0%)
Atrial Fibrillation/Atrial Flutter	54 (36.0%)
Other Arrhythmia	18 (12.0%)
Heart Failure	72 (14.8%)
Maternal Death	<10
Perinatal Outcomes†	(n=235)
Gestational Age at Delivery (Mean ± SD)	35.4 weeks (±9.1)
Preterm Delivery (<37 weeks)	31 (13.2%)
Neonatal Birthweight (Mean ± SD)	3002.2 grams (±612.3)
Mode of Delivery	
Vaginal or Assisted Vaginal Delivery	181 (77.0%)
Cesarean Delivery	54 (23.0%)

All data are summarized as n(%) or mean ± standard deviation. Cells with less than 10 subjects are noted as <10 due to the nature of dataset and protection of patient identity.
*Subjects may identify with multiple races.
†Complete perinatal outcomes were only available for a subset of subjects.

494 | Exposure to Maternal Chronic Hypertension (UNRELATED to PREECLAMPSIA) and Offspring Risk for Long-Term Cardiovascular Morbidity

Gil Gutvirtz[1]; Tamar Wainstock[2]; Eyal Sheiner[2]

4:00 PM - 6:00 PM

Objective: Women with chronic hypertension are at an increased risk for adverse perinatal outcomes, such as superimposed preeclampsia and preterm labor. Both complications are associated with the maternal preexisting vascular disease that alters maternal adaptation to pregnancy and may expose the offspring for both short and long-term adverse consequences. However, most studies regarding offspring long-term outcomes included preeclampsia and chronic hypertension together. In this study we investigate the long-term cardiovascular morbidity of children exposed to maternal chronic hypertension, unrelated to preeclampsia.

Study Design: We conducted a population-based retrospective cohort study of singleton deliveries occuring between the years 1991-2021 at a tertiary center. Deliveries of women with chronic hypertension were compared with deliveries of women without chronic hypertension or any other hypertensive disorders of pregnancy. Offspring long-term (up to 18 years) cardiovascular morbidity was compared using diagnoses from hospitalizations of the offspring involving a cardiovascular morbidity. A Kaplan–Meier survival curve was used to compare the cumulative incidence of cardiovascular morbidity and a Cox regression model was constructed to control for confounders.

Results: During the study period, 342,365 singleton deliveries occured, among them 3,097 (0.9%) were in mothers with chronic hypertension. Offspring total cardiovascular morbidity rate was significantly higher in children of mothers with chronic hypertension as compared with children from pregnancies uncomplicated by hypertensive disorders (**Table**). Also, the cumulative incidence of cardiovascular morbidity was higher for children exposed to maternal chronic hypertension (**Figure**). The Cox regression model, controlling for maternal and gestational age, found that maternal chronic hypertension is an independent risk factor for long-term cardiovascular morbidity of the offspring (**Table**).

Conclusion: Maternal chronic hypertension, unrelated to preeclampsia, is an independent risk factor for offspring long-term cardiovascular morbidity.

Figure. Kaplan-Meier survival curve demonstrating the cumulative incidence of cardiovascular morbidity in children exposed and unexposed to maternal chronic hypertension

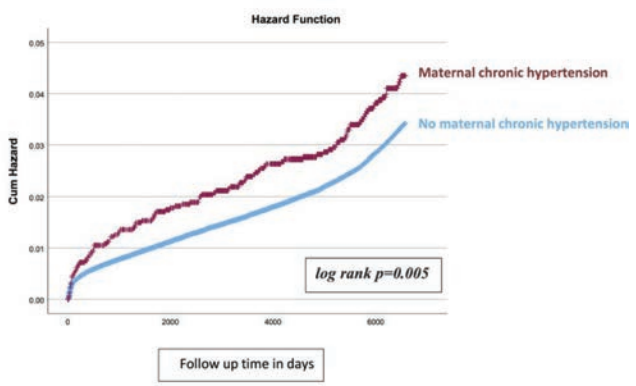

Table. Long-term cardiovascular morbidity of children born to mothers with and without chronic hypertension: crude and adjusted hazards ratio (HR)

	Maternal chronic hypertension (n=3,097)	No maternal chronic hypertension (339,538)	Odds ratio (95%CI)	Adjusted* HR
Total cardiovascular morbidity, n (%)	108 (3.5%)	7,170 (2.1%)	1.67 (1.38 – 2.03)	1.28 (1.06 – 1.55)

* The model adjusted for maternal and gestational age

495 | Fertility Treatments Resulting in Twin Pregnancy and the Risk for Childhood Respiratory Morbidity

Gil Gutvirtz[1]; Tamar Wainstock[2]; Eyal Sheiner[2]
[1]*Soroka University Medical Center, Metar, HaDarom;*

Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel., Beer Sheva, HaDarom

4:00 PM - 6:00 PM

Objective: The increasing use of fertility treatments in the last decades has led to a significant rise in multiple pregnancies. While singletons born using fertility treatment were found to have an increased risk for perinatal and long-term adverse outcomes as compared with spontaneous pregnancies, twin pregnancies achieved using fertility treatments were scarcely investigated. We investigated the long-term respiratory morbidity of twins born following fertility treatments as compared with twins of spontaneous pregnancies

Study Design: A population-based retrospective cohort study of twin deliveries born between the years 1991-2021 at a tertiary center was conducted. Twins born using fertility treatments including ovulation induction (OI) and in-*vitro* fertilization (IVF) were compared with twins of spontaneous pregnancies. Respiratory morbidity was collected from community clinics and hospitalizations of offspring up to the age of 18 years. A Kaplan–Meier survival curve was used to compare the cumulative incidence of respiratory morbidity and a Cox regression model was used to control for confounders

Results: A total of 7790 twins were included: 696 (8.9%) were born after OI and 1380 (17.7%) following IVF. The total respiratory morbidity rate was significantly higher in twins born following fertility treatments and specifically in IVF twins ($p< 0.01$; using the chi-square test for trends), as compared with twins from spontaneous pregnancies (**Table**). Likewise, the cumulative incidence of respiratory morbidity was higher for twins of fertility treatments, with IVF showing the highest cumulative incidence (**Figure**). The Cox model, controlling for maternal and gestational age, hypertensive disorders, diabetes mellitus and ethnicity, found that IVF, but not OI, was an independent risk factor for long-term respiratory morbidity of the twin offspring (adjusted HR (aHR) for IVF = 1.22, 95%CI 1.1-1.3, $p< 0.001$ and aHR for OI = 1.04, 95%CI 0.9-1.1, $p = 0.585$; compared with spontaneous twins)

Conclusion: IVF treatments resulting in twin pregnancies are independently associated with long-term respiratory morbidity of the offspring

Figure. Kaplan-Meier survival curve demonstrating the cumulative incidence of respiratory morbidity among study groups

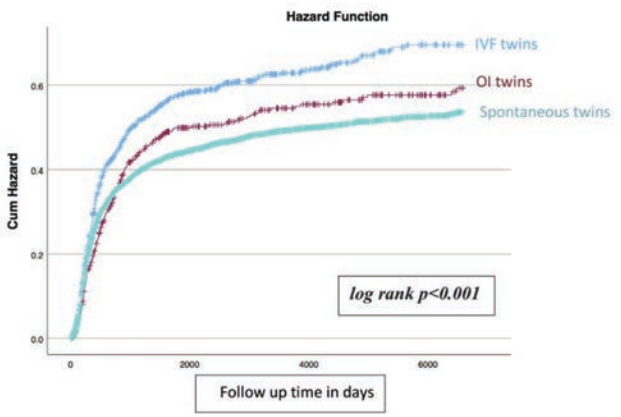

Table. Selected long-term respiratory morbidities of twins born following fertility treatments and after spontaneous twin pregnancies

Respiratory morbidity	IVF twins (n=1,380)	OI twins (n=696)	Spontaneous twins (n=5,714)	P value
Asthma, n (%)	569 (41.2%)	252 (36.2%)	1,883 (33.0%)	<0.001
Obstructive sleep apnea (OSA), n (%)	34 (2.5%)	11 (1.6%)	94 (1.6%)	0.109
Other, n(%)	6 (0.4%)	4 (0.5%)	45 (0.7%)	0.336
